ServiceNow Vault overview

ServiceNow Vault is a set of data security tools that protect sensitive information from unauthorized access, corruption, or theft throughout its entire life cycle. You can use ServiceNow Vault to apply protections like encryption, secrets management, and data privacy for the redaction and auditing of sensitive information.

Note:

ServiceNow Vault is a paid plugin that ServiceNow personnel must activate on your production instance. ServiceNow Vault includes the components listed here.

To purchase a subscription, contact your ServiceNow account manager. When you purchase a subscription, certain plugins are activated automatically. If a paid plugin isn't activated automatically, you can manually activate it from the **All Applications** list in your instance.

ServiceNow Vault benefits

ServiceNow Vault benefits

Benefit	Feature	Users
Get a comprehensive ServiceNow Vault overview and review the metrics related to the discovery, classification, and protection of your data	ServiceNow Vault console dashboard	Platform Admins
Guided setups to easily start using ServiceNow Vault tools with applications	Guided Vault	Platform Admins

What to explore next

To learn more about configuring and using ServiceNow Vault, see:

- ServiceNow Vault console dashboard
- Configuring ServiceNow Vault
- Use guided setup for ServiceNow Vault

ServiceNow Vault tools

Encryption

Key Management and Field Encryption is a suite of highly configurable encryption modules

Code Signing

Help improve security by validating sensitive application configuration data and scripts before they are used.

Data Privacy

Use the Data Privacy plugin to remove personally identifiable information (PII) from user data when it is migrated from a production instance to a non-production instance.

Data Discovery

The Data Discovery plugin enables you to find personally identifiable information (PII) from user data. The data can then be classified for further security measures.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Logs

Improve security, performance, and user experience by importing ServiceNow log data into enterprise log analytics using the log export service.

Zero Trust Access

ServiceNow Session Access enables organizations to dynamically reduce user privilege in a web session

Configuring ServiceNow Vault

Learn how to install and configure ServiceNow Vault

Configuration overview

- Install Vault plugins

  Learn how to install ServiceNow Vault for your instance.

-

  Learn and setup the roles necessary to use ServiceNow Vault

- Install Vault plugins

  Install and verify the plug-ins needed to make the most of ServiceNow Vault.

Using guided setup to implement ServiceNow Vault

Guided setup provides a sequence of tasks that help you configure ServiceNow Vault on your ServiceNow instance. To open guided setup for ServiceNow Vault, navigate to **All** > **Vault** > **Vault console**.

For more information, seeGuided Vault.

Install Vault plugins

Learn how to review and install the necessary plugins for ServiceNow Vault.

Before you begin

Role required: sn_vault_console.vault_console_admin

About this task

ServiceNow Vault is best used with other ServiceNow security products. Install and configure the other plugins to make the most of your tools and metrics.

Procedure

1. Navigate to **All** > **Vault** > **Vault Console**.
2. Review the status of your tools.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Tool statuses

Status	Description
Limited access	Tool has a limited access license. Reported metrics may be affected or unavailable.
Included with platform	Tool is included by default with the platform
Needs license	Tool has no license. Reported metrics may be affected or unavailable.
Premium license	Tool has full access.

3. **Optional:** If a status is either limited or needs a license, review its respective installation page, and then install or activate the tool.

Tool installation

Tool	Installation page
Data Discovery	Activating Data Discovery
Data Classification	Included with the platform
Data anonymization	Activate data privacy **Note:** Data anonymization is installed as part of Data privacy
Cloud Encryption with Key Management	Requesting Cloud Encryption for instances with Now Support Service Catalog [KB1117369] article in the Now Support Knowledge Base
Field Encryption	Activate Field Encryption
○ Zero Trust Access (ZTA) ○ Continuous Authentication (CA)	○ Activate Zero Trust Access ○ Activate Continuous Authentication

Use guided setup for ServiceNow Vault

Use guided setup to begin using an application with ServiceNow Vault easily.

Before you begin

Role required: Elevate to sn_vault_console.vault_console_admin role.

Procedure

1. Navigate to **All** > **Vault** > **Vault console**.
2. In the **Guided vault** section, Select the **Get started** button for your application.
3. In **Select app data** use the table to select the application data to be used with ServiceNow Vault, select **Preview classes** when finished

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Select app data table fields

Label	Description
Table	The table the data is located in.
Column	The column the data is located in
Existing Class	The current classification of the data
Recommended Class	The recommended classification for the data.
Application	The application scope of the data

4. In **Preview data classification** preview your data classification settings, when finished check agree and select the **Apply recommended classes** button.

Preview data classification table fields

Label	Description
Table	The table the data is located in.
Column	The column the data is located in
Final class	The class the data will be assigned
Application	The application scope of the data

5. In **Classification summary** review the results of the data classification, select **Next** when finished.

Trouble?
Use Data Classification to review any data that failed to classify.

6. In **Protect existing data** review the protection policies of the data.

Protect existing data table fields

Label	Description
Table	The table the data is located in.
Column	The column the data is located in
Anonymization	Reports if a data anonymization policy can be, or already is applied to the data.
Field encryption	Reports if a field encryption policy can be, or already is applied to the data.
Zero trust access	Reports if a zero trust access policy can be, or already is applied to the data.

7. **Optional:** You can select **Available** to begin applying that columns respective application data protection policy, review Vault tools and metrics for more information.
8. In **Protect real time data** review your real time data protection policies, select **Mark as complete** when finished.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Protect real time data fields

Label	Description
Name	The name of the ???
Type	The data channel type.
Real time anonymization	Reports if there is a real time anonymization policy available, or already applied to the data.

Note:
Real time data will be protected across the entire instance and all applications,.

Result
The select application now has classified data and protection policies. As well, it will now report relevant metrics to the ServiceNow Vault console dashboard.

ServiceNow Vault console dashboard

Use the ServiceNow Vault console dashboard to track and manage your ServiceNow Vault security tools.

The dashboard provides an easy way to review the security, privacy and compliance of your sensitive data. The dashboard reports on ServiceNow Vault tools and their various metrics, as well as showing guided setups for applications compatible for ServiceNow Vault.

To access the ServiceNow Vault console dashboard, navigate to **All** > **Vault** > **Vault Console**

Guided Vault

The guided vault setup offers a step by step process to assess and protect sensitive data for an application.

Guided vault setup offers an easy way to begin using ServiceNow Vault with your applications. The setup will use the selected applications data. Setup first helps the user review the application data for classification, and then helps implement protection policies on the classified data. You can review how to use the ServiceNow Vault guided setup at Use guided setup for ServiceNow Vault

There are 5 steps in a guided setup:

1. Select app data
2. Preview data classification
3. Classification summary
4. Protect existing data
5. Protect real time data

After a guided vault setup you can review application data metrics in the **Tools** section of the Vault console dashboard. For more information see Vault tools and metrics

Vault tools and metrics

Learn about the tools and metrics ServiceNow Vault uses to protect and discover sensitive data.

ServiceNow Vault integrates with several tools to provide a cohesive overview of your sensitive data security. You can hover over a widget to get further insight on the reported data. Select the **Go to** button on any tool to go to its respective page.

Know your data

ServiceNow Vault uses Data Discovery and Data Classification to help you understand and know your data.

Tools and metrics

Tool	Metric	Description
Discovery Use Data Discovery to run a discovery scan to look for data patterns that might be sensitive data. Once discovered, data can then be reviewed or classified for further protection and management.	Discovered data	Occurrences of sensitive data across tables in your instance, categorized by sensitive data pattern type.
	Discovery status	Current state of all discovered sensitive data patterns, including new findings pending review, classified, or marked as ignored.
	Discovered attachments	Total sensitive data occurrences in attachments across tables in your instance.
Classification Data Classification create data classes and helps organize	Classifiable data	Proportions of classifiable data.
	Classified data	Proportions of classified data.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Tools and metrics (continued)

Tool	Metric	Description
your data into data classes for better management. Classified data can be protected at the class level.		

Protect your data

ServiceNow Vault uses data anonymization, cloud encryption, field encryption, and zero trust access to help secure and protect your data.

Tools and metrics

Tool	Metric	Description
Anonymization Anonymize data by data class with different anonymization techniques to preserve data patterns but remove sensitive data. Useful for sanitizing instances for development or removing specific user data because of rights to be forgotten.	Existing data	All classified data per workflow that is anonymized or not.
	Real time data	The amount of anonymized real time data.
	Anonymization run times	Run times in hours of data anonymized in real time by channel, such as Now Assist or Virtual Agent.
Cloud Encryption with Key Management Securely protect sensitive data in encrypted storage for your data using block encryption, along with enhanced key management.	Active cloud key	Total rotations of the active cloud key. **Note:** To view this data, you need the Key Management Framework admin role (sn_kmf.admin or sn_kmf.cryptographic_manager).
	Key rotation	Time elapsed between each rotation of active keys on your instance. Bar height measures how long a key was used before rotation. **Note:** To view this data, you need the Key Management Framework admin role (sn_kmf.admin or sn_kmf.cryptographic_manager).

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Tools and metrics (continued)

Tool	Metric	Description
Field Encryption Securely protect sensitive data while providing access for authorized users. Useful for increasing protections from bad actors.	Encrypted fields classification status	Classification status of all data protected with Field Encryption.
	Classes protected with Field Encryption	The proportion of classified data protected withField Encryption.
	Active encryption keys	Number of active Field Encryption keys in your instance. Ideally, the number of active keys matches the number of classifications. **Note:** To view this data, you need the Key Management Framework admin role (sn_kmf.admin or sn_kmf.cryptographic_manager) and the security_admin role.
Zero Trust Access (ZTA) Continuous authentication while accessing classified sensitive data in real time.	Continuous Authentication classification status	Number of classifications that are protected due to the continuous authentication policies.
	Classes protected with Continuous authentication	Number of classes protected with continuous authentication, categorized by their class.

All ServiceNow Vault tools

Encryption

Key Management and Field Encryption is a suite of highly configurable encryption modules

Code Signing

Help improve security by validating sensitive application configuration data and scripts before they are used.

Important:

- Not all model providers are available for customers with in-country SKUs, and some Now Assist products/features are currently unavailable for in-country customers. For more information, see the KB1584492 article in the Now Support Knowledge Base. Be sure to check for model provider availability updates in future releases.
- Some Now Assist products/features are currently unavailable for customers in the FedRAMP, NSC DOD IL5, or Australia IRAP-Protected data centers, self-hosted customers, or in other restricted environments. For more information, see the KB0743854 article in the Now Support Knowledge Base . Be sure to check for availability updates in future releases.
- Some Now Assist products/features are currently available only for customers in some regions. Be sure to check for availability updates in future releases.
- Some AI products and skills are not available in Regulated Markets. For more information, see KB2593939: Regulated Markets AI Products/Skills Not Available. Be sure to check for availability updates in future releases.

AI limitations

This application uses artificial intelligence (AI) and machine learning, which are rapidly evolving fields of study that generate predictions based on patterns in data. As a result, this application may not always produce accurate, complete, or appropriate information. Furthermore, there is no guarantee that this application has been fully trained or tested for your use case. To mitigate these issues, it is your responsibility to test and evaluate your use of this application for accuracy, harm, and appropriateness for your use case, employ human oversight of output, and refrain from relying solely on AI-generated outputs for decision-making purposes. This is especially important if you choose to deploy this application in areas with consequential impacts such as healthcare, finance, legal, employment, security, or infrastructure. You agree to abide by ServiceNow's AI Acceptable Use Policy, which may be updated by ServiceNow.

Data processing

This application requires data to be transferred from ServiceNow customers' individual instances to a centralized ServiceNow environment, which may be located in a different data center region from the one where your instance is, and potentially to a third-party cloud provider, such as Microsoft Azure. This data is handled per ServiceNow's internal policies and procedures, including our policies available through our CORE Compliance Portal.

Data collection

ServiceNow collects and uses the inputs, outputs, and edits to outputs of this application to develop and improve ServiceNow technologies including ServiceNow models and AI products. Customers can opt out of future data collection at any time, as described in the Now Assist Opt-Out page.

Exploring Now Assist for Vault

With the Now Assist for Vault application, you can generate custom data patterns from text descriptions to streamline your workload, check role access for an encrypted column to monitor your instance's encryption access posture, and schedule Data Discovery jobs to detect sensitive data.

Ask Now Assist panel in ServiceNow Vault console

The Ask Now Assist panel in ServiceNow Vault console lists skills to accomplish common security tasks. Selecting a skill opens a conversational interface that lets you accomplish a task through prompts. For more information about the Now Assist conversational interface, see Now Assist panel.

Configuring Now Assist for Vault

Install the ServiceNow® Now Assist for Vault application from the ServiceNow® Store to get Now Assist for Vault.

Before you begin

Review the Now Assist for Vault application listing in the ServiceNow Store for information on dependencies, licensing or subscription requirements, and release compatibility. Now Assist for Vault installs the Now Assist for Vault application (sn_vault_gen_ai).

Role required: admin

Procedure

1. From the Now Assist for Vault application page on the ServiceNow Store, select **Buy**.
2. After approval has been granted, on your instance, navigate to **All > System Applications > All Available Applications > All**.
3. Using the search bar, search for the Now Assist for Vault application (sn_vault_gen_ai).
4. Select **Install**.
5. Verify that Now Assist for Vault is installed:
   a. Navigate to **All > Now Assist Admin > Now Assist Skills**.
   b. In the workflow list, select **Vault**.
   c. Verify that the Now Assist for Vault skills are active.

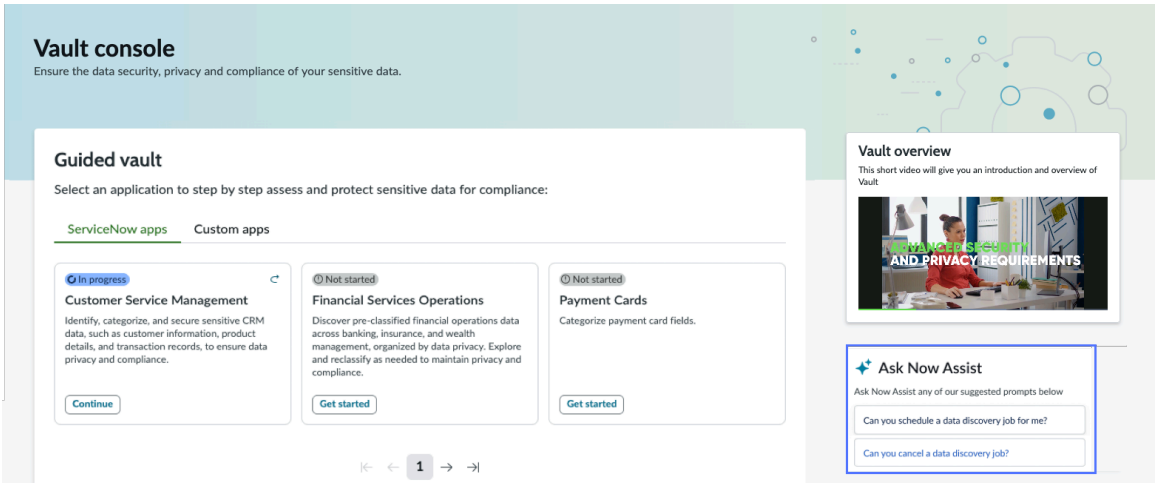
Using Now Assist for Vault

The Now Assist for Vault application includes the generative AI skills and features that enable you to streamline your administrative workload.

After you activate skills, they appear in the Ask Now Assist panel in ServiceNow Vault console.



By default, all skills exist in the global domain. When you use Now Assist in a domain-separated environment, users are only able to access data in their domain. For example, if a user uses the summarization skill, Now Assist only uses material that exists in the user's domain when generating that summary. Additionally, there is no co-mingling of data for domain-separated instances when using generative AI skills. The data resides only on the instance, and the shared services used for generative AI do not persist any requests (prompts) and responses. For more information, see Domain separation in the Now Assist Admin console. (Note that global domain is not the same as global scope. For more information, see Exploring Next Experience pickers.)

Generate a custom data pattern by using Now Assist for Vault

Use the generate custom data pattern skill to create a custom regular expression data pattern from your description and add it as an active data pattern to your instance.

Before you begin

- Install ServiceNow Vault. For more information, see Configuring ServiceNow Vault.
- Ensure that the generate custom data pattern skill is active. For more information, see Activate a Now Assist skill.

Role required: sn_vault_console.vault_console_admin

About this task

This skill improves your efficiency by reducing the time required to understand and write regular expressions.

Procedure

1. Navigate to **All** > **Vault** > **Vault console**.
2. In the Ask Now Assist panel, select **Generate custom data pattern** and specify the details.

Example

Example prompt: `I need help creating a regex to detect sensitive data for a Netherlands drivers license.`

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Check role access for an encrypted column with Now Assist for Vault

Use the check role access for encrypted column skill to identify user roles that have access to encryption and decryption keys in your instance.

Before you begin

- Install ServiceNow Vault. For more information, see Configuring ServiceNow Vault.
- Ensure that the check role access for encrypted column skill is active. For more information, see Activate a Now Assist skill.

Role required: sn_vault_console.vault_console_admin

Procedure

1. Navigate to **All** > **Vault** > **Vault console**.
2. In the Ask Now Assist panel, select **Check role access for encrypted column** and specify the details.

   Example
   Example prompt: `Which roles have decryption key access to an encrypted column? Access includes read access.`

Schedule a Data Discovery job with Now Assist for Vault

Use the schedule data discovery job skill to schedule one-time or recurring Data Discovery jobs with Now Assist. Data Discovery jobs can detect sensitive data such as PII or PHI provided as input to the Now LLM.

Before you begin

- Install ServiceNow Vault. For more information, see Configuring ServiceNow Vault.
- Ensure that the schedule Data Discovery job skill is active. For more information, see Activate a Now Assist skill.

Role required: sn_vault_console.vault_console_admin

Procedure

1. Navigate to **All** > **Vault** > **Vault console**.
2. In the Ask Now Assist panel, select **Schedule data discovery job** and specify the job details.

   Example
   Example prompt: `Configure a data discovery job that scans the tables Task and Knowledge, looking for data patterns like Credit Card-Visa and Phone Number in columns such as Description and Text. Schedule a sample scan to occur on August 15th, 2025, with a time window from 10:00 AM to 5:00 PM. Name the job "Credit Card & Phone Number Scan" and describe it as "Scans for credit card and phone number data in Task and Knowledge tables."`

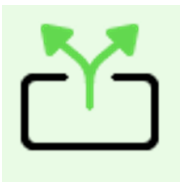
Platform Security

Platform security provides capabilities to secure the instance.

Security Center

Allow admins to continuously maintain the highest level of security posture and easily monitor for insecure events and behaviors.

Log Export Service

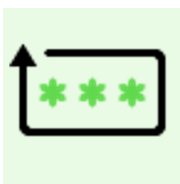


Log Export Service (LES) lets you seamlessly export your instance system and application logs into your enterprise security analytic tools. The service provides a highly scalable and near real-time integration with your analytic tools that is easy to setup and maintain.

Logs

Logs module provides a variety of logs that you can use to troubleshoot and debug transactions and events that take place within the instance.

Secrets Management



Use ServiceNow Secrets Management for granular management of access to your passwords to fit your business needs.

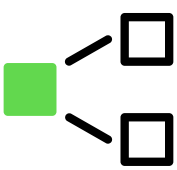
Code Signing

Code Signing creates digital signatures for the data which later are checked to confirm the authenticity and integrity of the data.

Antivirus Scanning Capabilities

Use Antivirus Scanning to help protect your instance against virus infections that can be introduced by file attachments to your system records, such as incidents, problems, and stories.

HTML Sanitizer



Auditing

High Security Settings

Remove unwanted code and protect against security concerns such as cross-site scripting attacks by sanitizing HTML markup in HTML fields and translated HTML fields.	Track record changes on auditing-enabled tables. By default, the system tracks changes to the incident, change, and problem tables, among others.	High Security Settings refer to several security options available in your instance.
Virtual Private Network (VPN) Use a virtual private network (VPN) to integrate your instance with external data sources over the Internet.	**Hardening Settings** Find detailed descriptions and compliance values for Security Center (SSC) hardening settings content	

Security Center

ServiceNow Security Center is an application that consists of a set of tools designed to help your organization maintain the security of your ServiceNow deployments. Using Security Center, you can improve security posture and strengthen compliance levels with a seamless user experience.

Security Center is a free application that administrators can download from the ServiceNow Store. It's installed by default starting with the Vancouver release. It's also made available in the ServiceNow Store every quarter, between family releases, to facilitate faster adoption of new functionality.

Important:

Instance Security Center (ISC) has reached the end of sales as of September 2024, and is no longer supported or available for activation.

Security Center (SSC) is the recommended solution going forward. For more information, see Instance Security Center to ServiceNow Security Center migration.

Security Center landing page

Use the Security Center landing page to find the information and tools you need to secure your instance.

My Security Tasks

The my Security Tasks section displays a list of Security Tasks assigned to you. Open a task by selecting the number to review a tasks details, or select **View all** access the Security Tasks Manager, where all tasks are visible. For more information on Security Tasks, see Security Tasks.

Instance summary

The instance summary displays a high-level overview of the state of your instance's security.

Select the info ( ) icon on any card for details on what each represents. You can also select any card to navigate to the relevant area of Security Center.

Identity and Access Management

Use the tools in the Identity and Access Management (IAM) section verify that your data is only accessible to the users and processes that need it. For details on these tools, see Identity and Access Management.

Security consoles

Select a card within the security consoles section to navigate to any of the three security consoles.

- Security configuration console
- Security monitoring console
- Security posture console

Tools

Use the tools section to navigate to the tools you need to manage your instance security. These tools are organized into three tabs displayed at the top of the section. Select a card to navigate to the selected tool.

Additional resources

Use the additional resources section on the edge of screen to navigate to documentation and videos relevant to learning Security Center as well as information on managing instance security.

Security center has been updated in Zurich to provide guidance to understand what the tool can do how to use it. This redesign is tailored to assist both new and infrequent users of Security Center. New modal windows appear within security center to demonstrate how these tools can help you achieve your security goals.

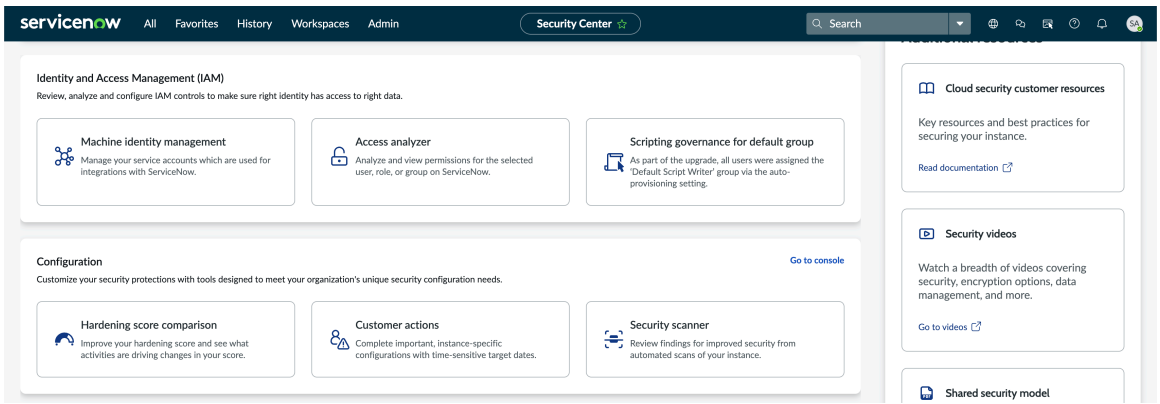
Identity and Access Management

Use the tools in the Identity and Access Management (IAM) section verify that your data is only accessible to the users and processes that need it.



IAM consists of three tools you can use to manage access to the data on your instance.

Machine Identity Management

Machine identities are digital credentials such as certificates, keys, and tokens. Servers, applications, containers, and cloud services use these identities authenticate with each other. Use the **Machine Identity Console** to manage the machine identities used for integrations with ServiceNow.

Access analyzer

Use the **Analyze Access and Permissions** console to view permissions for a selected user, role, group, or compare access between two users.

Scripting Governance for default group

Use the Scripting Governance Tool to configure preferences for the Conditional Script Writer group. Users in this group are assigned the *`snc_required_script_writer_permission`* role, which allows users to access scripts and script-like fields across the platform.

With the settings on this console you can turn auto-assignment of this role on or off, as well manually assign users to the group. You can also see information on who is assigned, and scan your instance to find users who have scripted in a specific time frame.

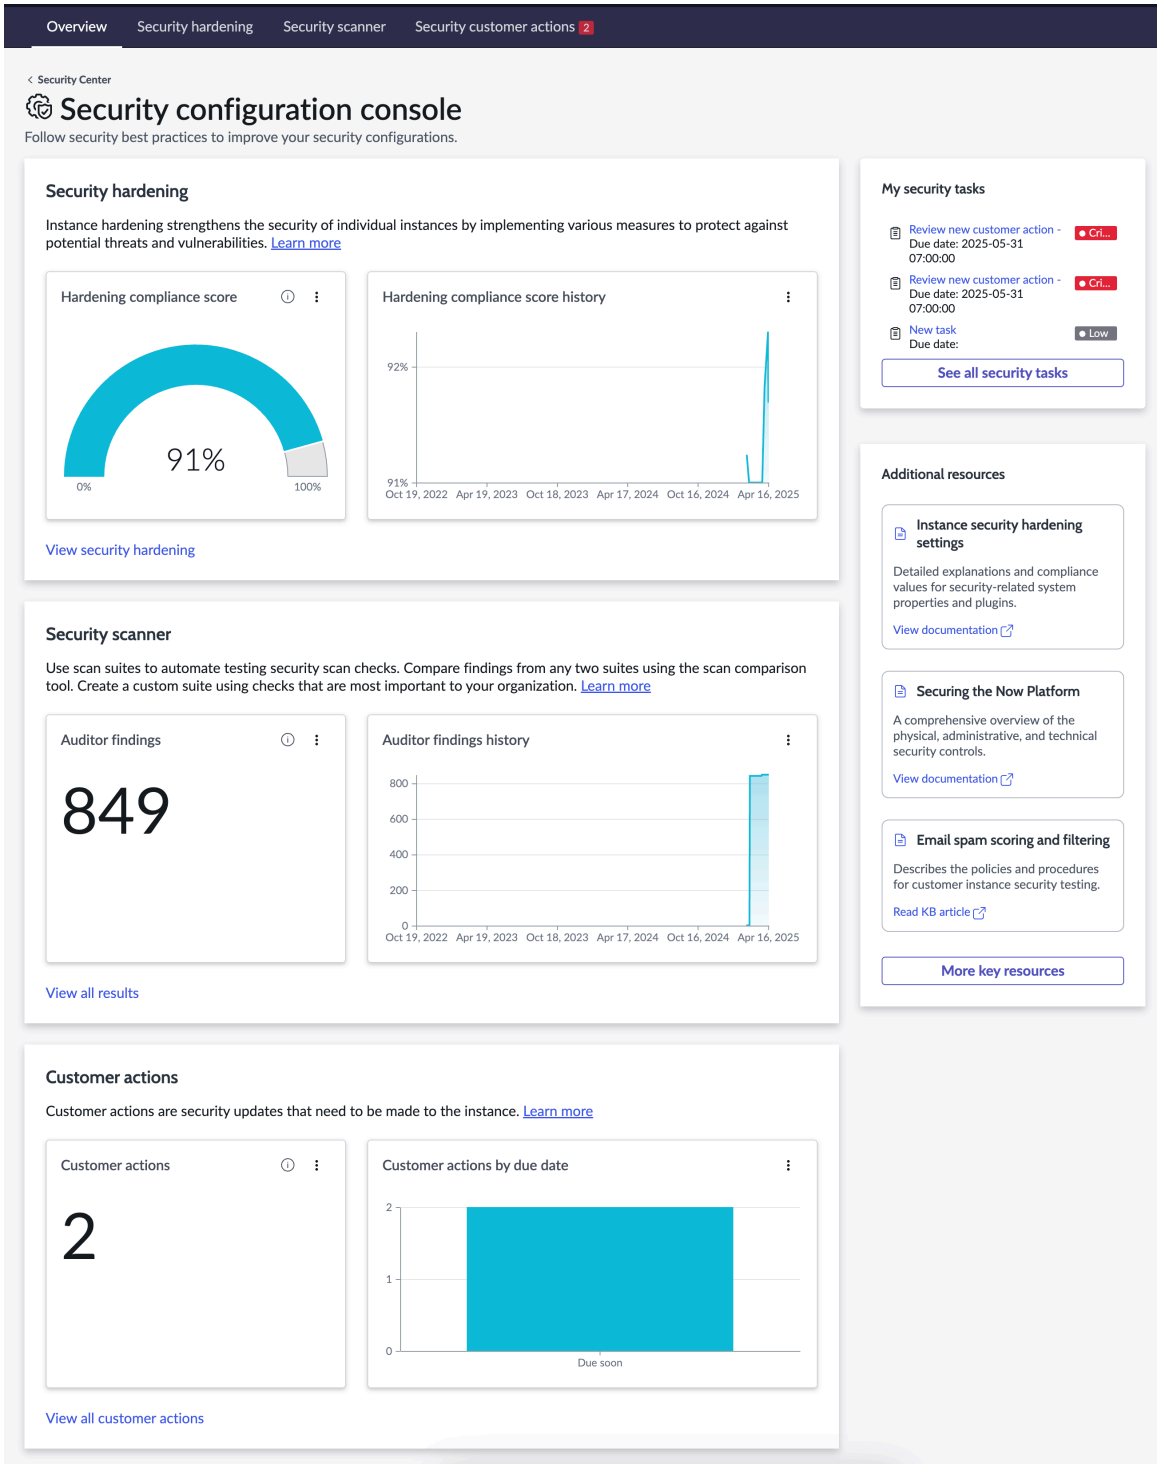
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Security configuration console

Use the security configuration page to get an overview of the security posture of your instance. View your hardening compliance score, discover graphical trends, analyze the top non-compliant hardening settings, and see the results of your security scans.



Navigation bar

Use the bar at the top of the page to navigate between this page and the security hardening, security scanner, or security Customer Actions section of Security Center.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Security hardening

Find details about your hardening compliance in the security hardening section. Select the cards on in this section to navigate to the Security hardening page.

The hardening compliance score is a percentage that shows how closely your security settings align with the recommended settings. The security hardening section shows this percentage, as well as the history of the score on your instance over time.

Security scanner

Review the results of automated security scan checks using the security scanner section. These checks and help you find security vulnerabilities, inefficiencies, and issues with compliance.

Select the cards on in this section to navigate to the security scanner page.

Customer actions

Find security updates that can be made to the instance in the Customer Actions section. This section shows the number of available actions and a chart indicating the due date for these actions. Select the cards on in this section to navigate to the Customer Actions page.

My Security Tasks

View the most urgent Security Tasks assigned to you. Select a task to view its details, or select **See all Security Tasks** to view a complete list of Security Tasks.

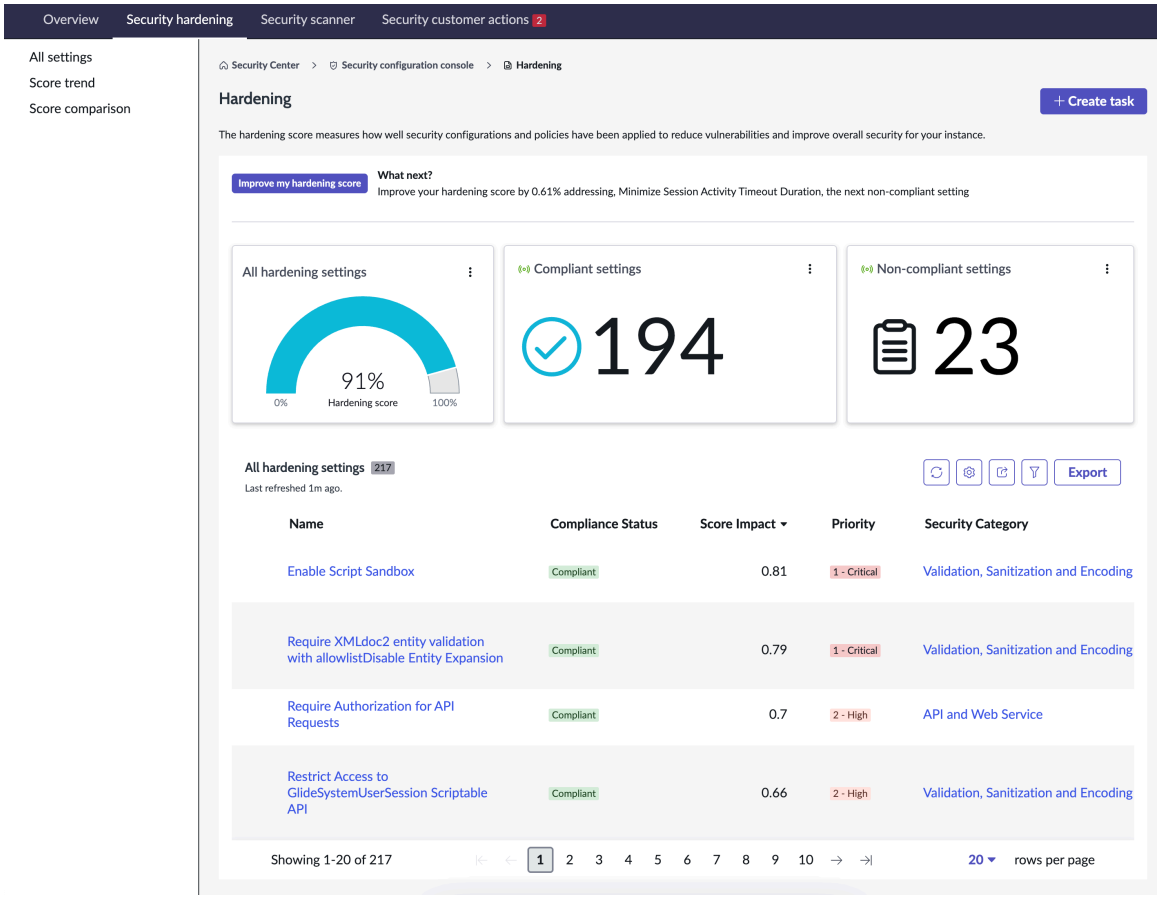
Additional resources

Use the additional resources section on the edge of the screen to navigate to documentation and videos relevant to learning Security Center as well as information on managing instance security.

Security hardening

View your hardening compliance score, compare it with previous scores, and change settings to improve your compliance score and security posture in the security hardening page.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Hardening settings specify recommended values for the security-related properties and plugins in the ServiceNow AI Platform. The hardening tool calculates the hardening setting compliance score as a percentage. This number indicates how compliant your instance is with the Security Center hardening settings.

The formula for calculating the hardening compliance score:

- Each hardening setting has a risk score between 0-10. You can see the values of individual settings in the **All settings** section.
- The score equals the sum of all the compliant risk scores divided by the sum of all risk scores.

For example, the sum of all the compliant risk scores is 25.4, and the total for all risk scores is 34.9. For this sum, the compliance score is (25.4 /34.9) × 100 which equals 72.7. This decimal gets rounded up to the nearest whole number and will therefore be equal to 73.

This calculation is automatically performed on the first of the month, or after an installation or reinstallation of ServiceNow Security Center. You can trigger a recalculation at any time using the **Update score** button on this page.

Security hardening subsections

The security hardening section contains three subsections that you can select on the left edge of the screen.

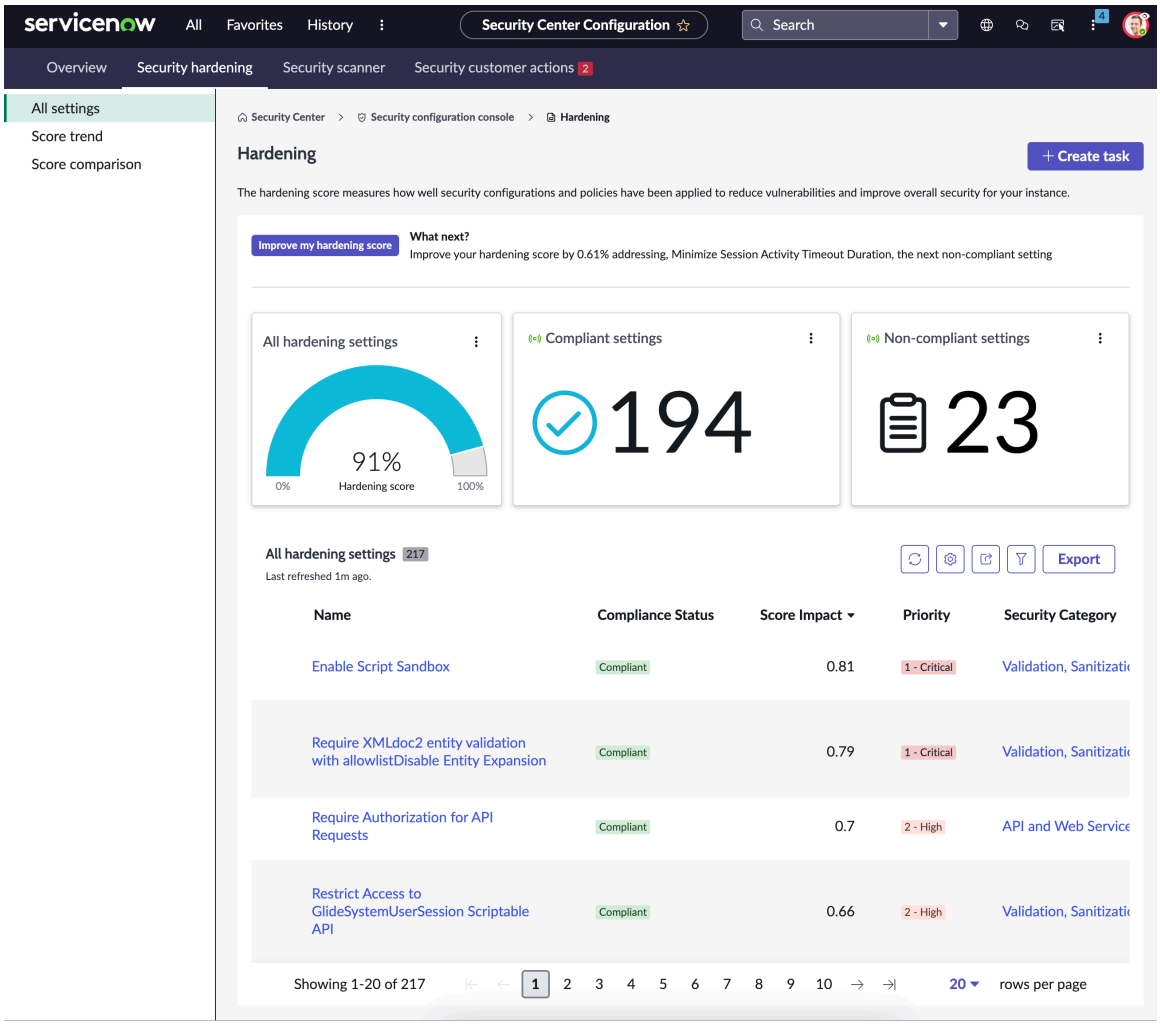
- All settings
- Hardening compliance score trend
- Hardening score comparison

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

All settings

Review all of your instance hardening settings available from a single page.

The **All Settings** page displays information about all instance hardening settings. Use the buttons in the upper right to refresh, filter, and export this information.\



Use the **+Create task** button to create a Security Task to complete a Customer Action. This button appears both in the **All Settings** page as well as the pages for individual hardening settings. For details, see Security Tasks.

The following information about hardening settings can be found on the list.

Name

Name of the hardening setting.

Compliance Status

Whether the setting is properly configured according to the system's recommendation (compliant) or must be configured (non-compliant)

Score Impact

Impact this hardening setting has on your security posture, expressed as a percentage. All score impacts sum to 100%.

Priority

The criticality of the setting: Critical, High, Moderate, and Low. A higher score indicates a greater impact and priority.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Security category

The security category of the property. Select the category to view details.

Resolution Details

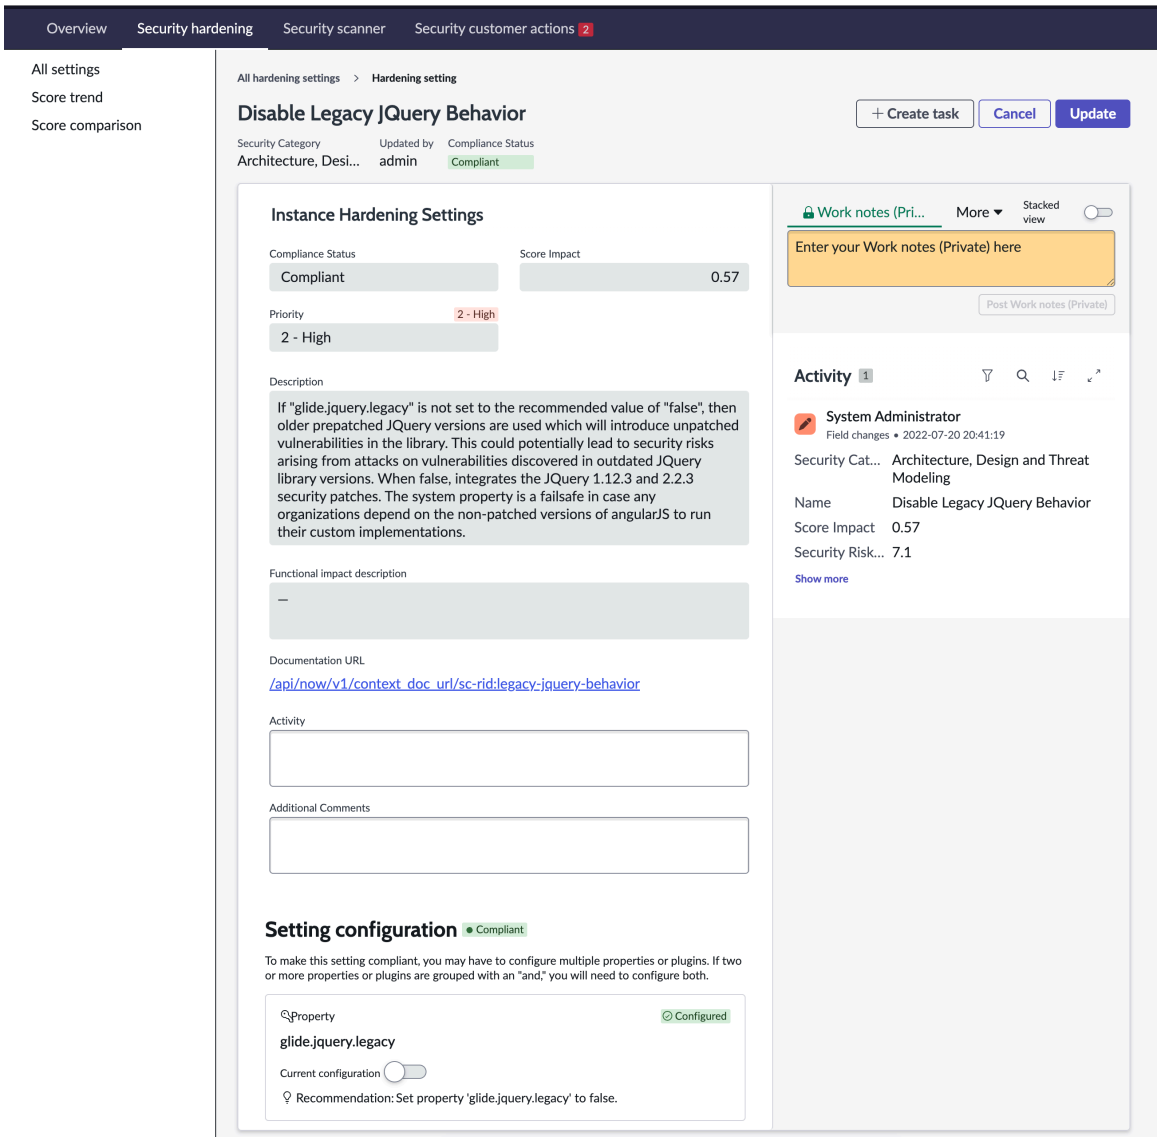
Description of the steps to remediate the security vulnerability of the hardening setting.

To learn how to configure a property hardening setting see Increase hardening compliance score.

Hardening settings details

Analyze the details of a hardening setting by selecting its link within the Security Center app.

Navigate to **Hardening** > **All settings**, and then select a hardening setting to be redirected to a page within the hardening setting tool that displays its security-related information.



Use the **+Create task** button to create a Security Task to complete a Customer Action. For details, see Security Tasks.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Hardening settings configuration details

Configuration attribute	Description
Compliance status	Indicates if the hardening setting is compliant nor not.
Score impact	A percentage that indicates how much this hardening setting impacts your security posture.
Priority	A number within the range of 1-4, with 1 having the most weight that indicates the strength of impact this hardening setting has on your security posture.
Functional impact	The impact this hardening setting has on the operation of your instance.
Description	A general overview about the hardening setting.
Documentation Url	Link to documentation for the hardening setting.
Activity	Notifications of updates related to the hardening setting.
Setting configuration	Details related to the compliance status of your hardening setting along with instructions on how to make them compliant. **Note:** Some hardening settings may require you to configure multiple properties and plugins to make them compliant.

Filter hardening settings

Simplify your hardening review process using filters. These filters can create a working list of hardening settings for review, which restored for later use and shared with other users.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Security** > **Security Center**.
2. In the **Security Consoles** section, select the **Security configuration console**.
3. Select the **Security Hardening** tab.
4. Select **All settings**.
5. Select the **Show filter panel** button ( ).
6. In the **Filter** window, select **Advanced view**.
7. Create a filter showing only the hardening settings you want to review.
8. Once your filter is complete, select **Save Filter**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

9. Enter a name for your filter and select **Save**.

> **Note:**
> You may also make this list available to other users by setting permissions to **Everyone**, or **Group** to share with a specific group. These users must also have permission to use Security Center.

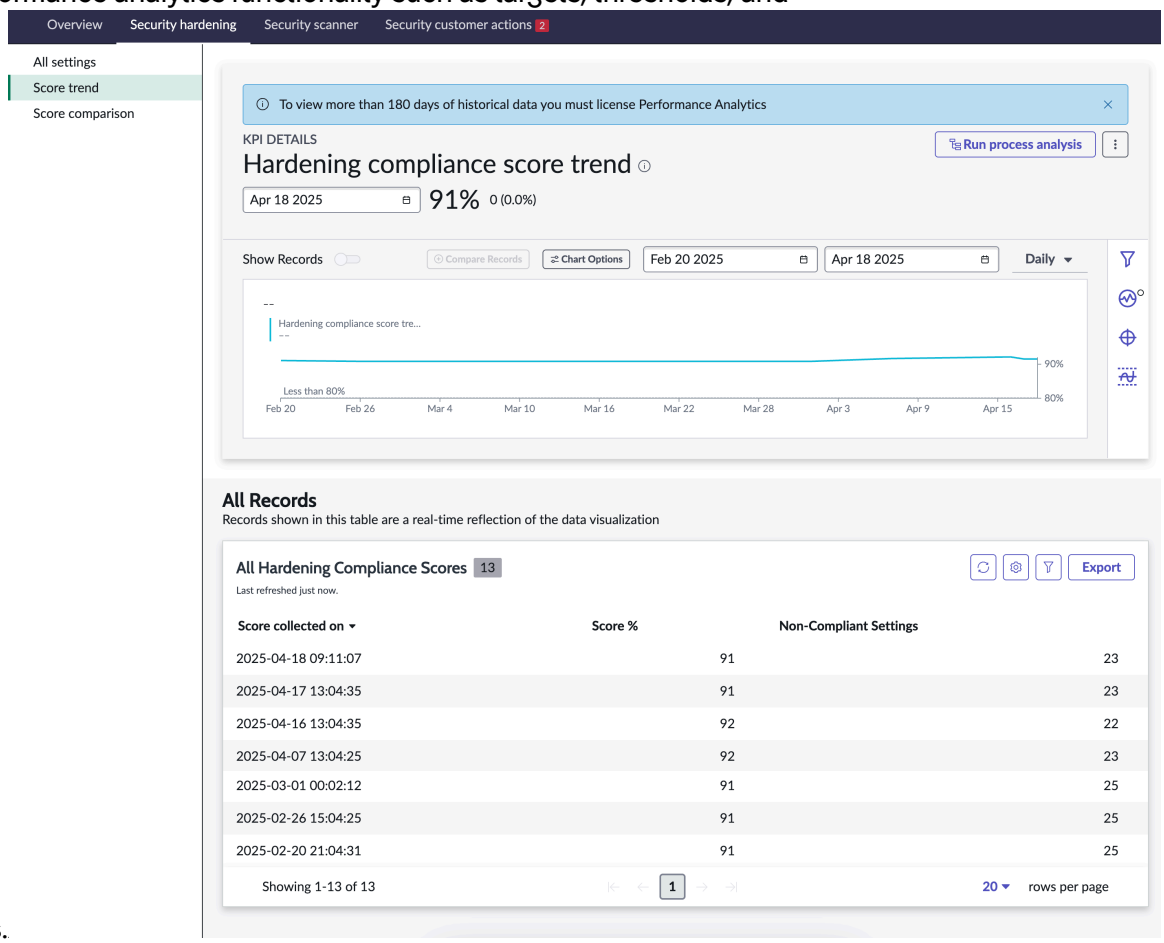
What to do next

After saving a filter you can load it in the **Advanced View** using the **Use existing filter** button.

Hardening compliance score trend

View the trends of your hardening compliance score over time in a chart or table.

See trends in your compliance score over time. Use the date picker to select a time range to analyze to gain insights into the data by applying performance analytics functionality such as targets, thresholds, and KPIs.



Compliance score chart

Use the **Chart options** button to specify what information to analyze and how to present the information.

Analysis

Select from the list of options. Some options may be unavailable depending on the selected chart type.

Target

Goals your organization wants to achieve. See Indicator targets.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Threshold

Defines a normal range of scores for an indicator and alert you when a certain event occurs. See Indicator thresholds.

Forecast

Describes the ability to forecast future scores based on past behavior. See Performance Analytics scores forecasts.

Trend

Shows how the value of one or more items change over time.

Comments

Displays annotations on individual data points.

Labels

Displays scores related to visualizations.

Statistics

Displays statistics related to your compliance score.

Time series

Select which metric to display on the chart.

Score

Score for the Key Performance Indicator (KPI).

Change

Change of score for this indicator.

Change percentage

Change as a percentage of scores.

Chart type

Select a chart type to control how the information your selected is visualized. See Use cases for different time series visualization types.

All Records table

The All Records table displays the date on which the compliance scores were collected, the score percentages, and the number of non-compliant settings. You can use this table as another option to analyze the security posture of your instance over time.

Increase hardening compliance score

Increase your hardening compliance score by ensuring that the hardening settings are compliant with the system's recommendations.

Before you begin

Role required: admin

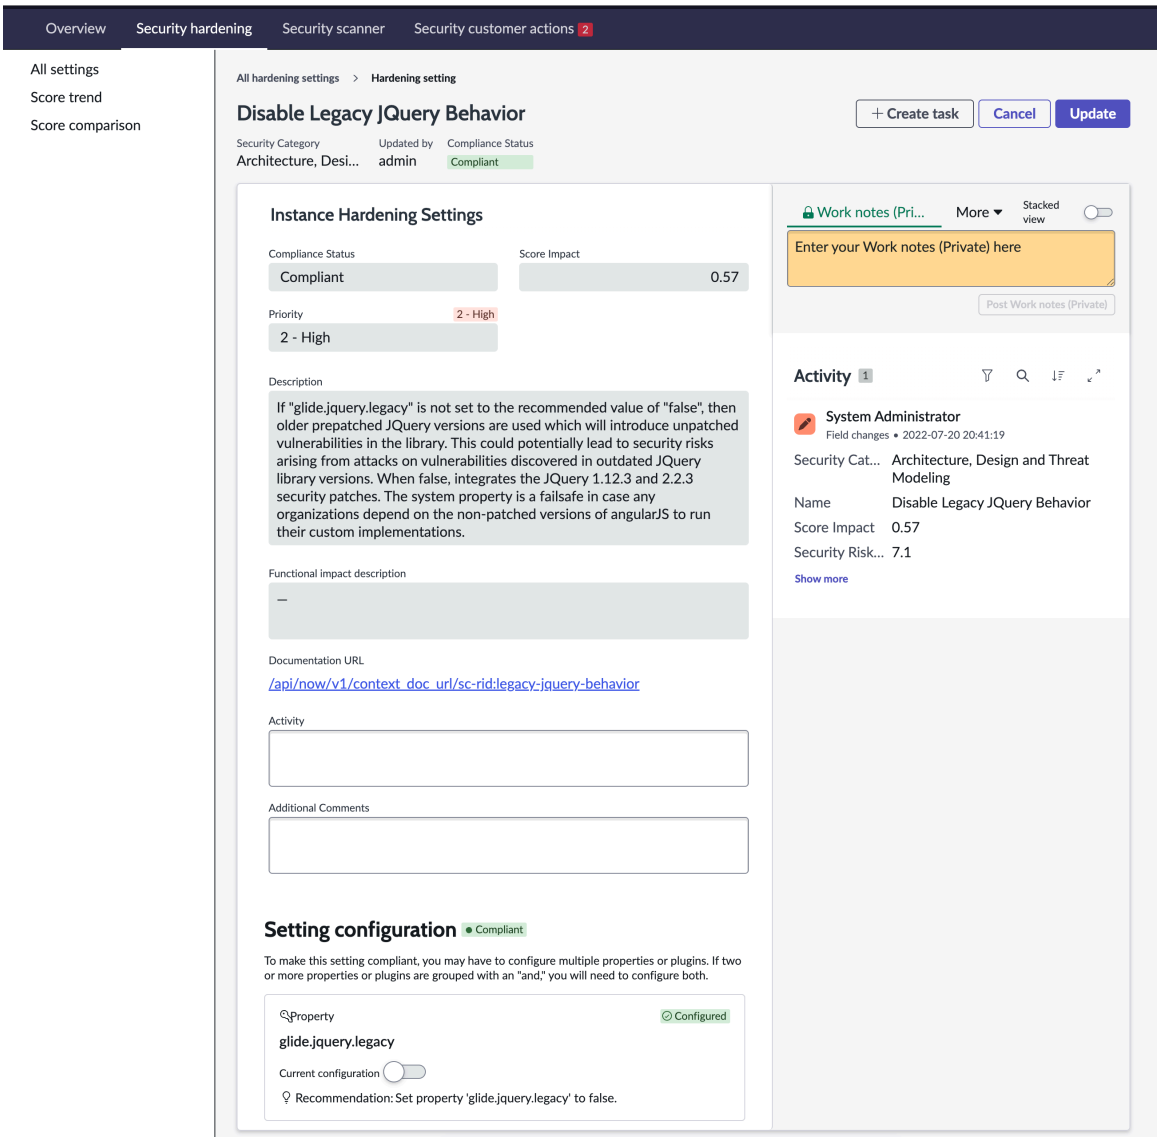
Identify non-compliant hardening settings with the highest score impact on your instance. Review them to see whether you can comply with system recommendations so that you can increase your overall compliance score.

Procedure

1. Navigate to **Hardening** > **All settings**.
2. Filter Compliance Status column to view only non-compliant hardening settings.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. Select **Score Impact** to sort from largest to smallest.
4. Select settings and review the setting details to decide whether you want to comply with recommendations.

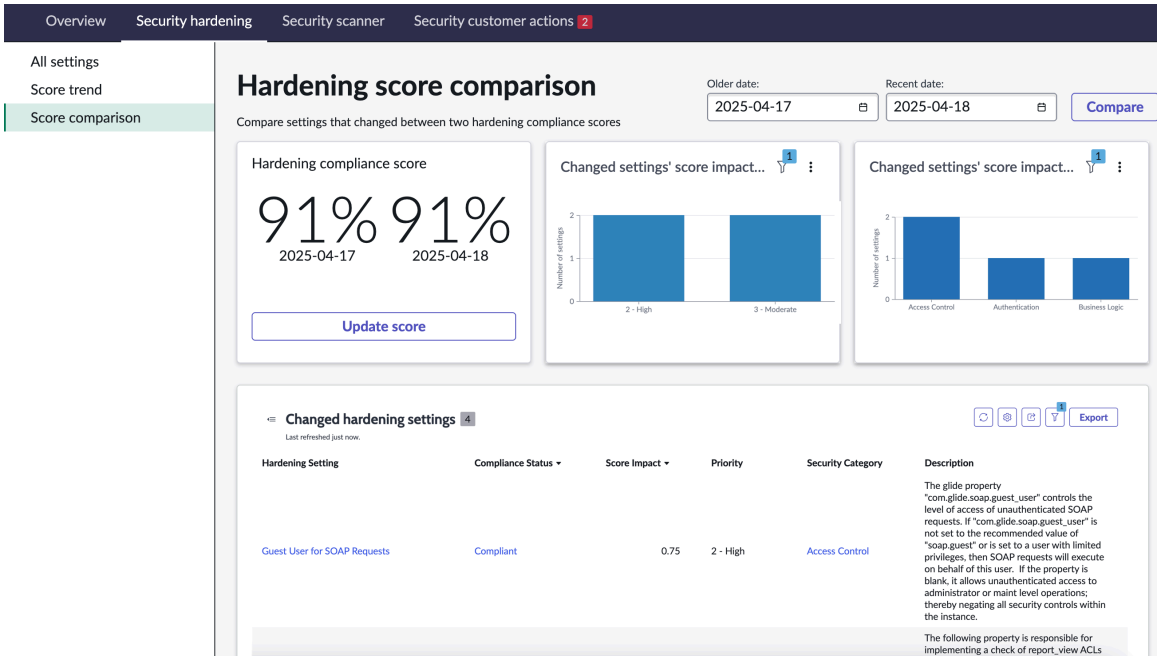


5. Make the hardening setting compliant.
6. If you update a non-compliant hardening score to make it compliant, go to the Homepage and select **Update score** to view the most up-to-date score.
   The hardening score is rounded up. A score of 86.75% will be rounded up to 87.

Hardening score comparison

Gain visibility to the health of your hardening settings and use this data to improve the security posture of your instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



This page displays a summary of your hardening compliance and the changes made to your instance that impact this score.

The hardening score comparison page displays hardening settings with changes in compliance status between the dates selected in the **Older date** and **Recent date** fields. With this information you can see how they've impacted your hardening compliance score.

Hardening compliance score

The card compares the compliance score of your instance on the selected dates as a percentage.

Changed settings' score impact by priority

Displays the number of hardening settings that have changed their compliance status since the last score update, organized by priority value.

Changed settings' score impact by security area

Displays the number of hardening settings that changed compliance status between the two selected dates, organized by security area.

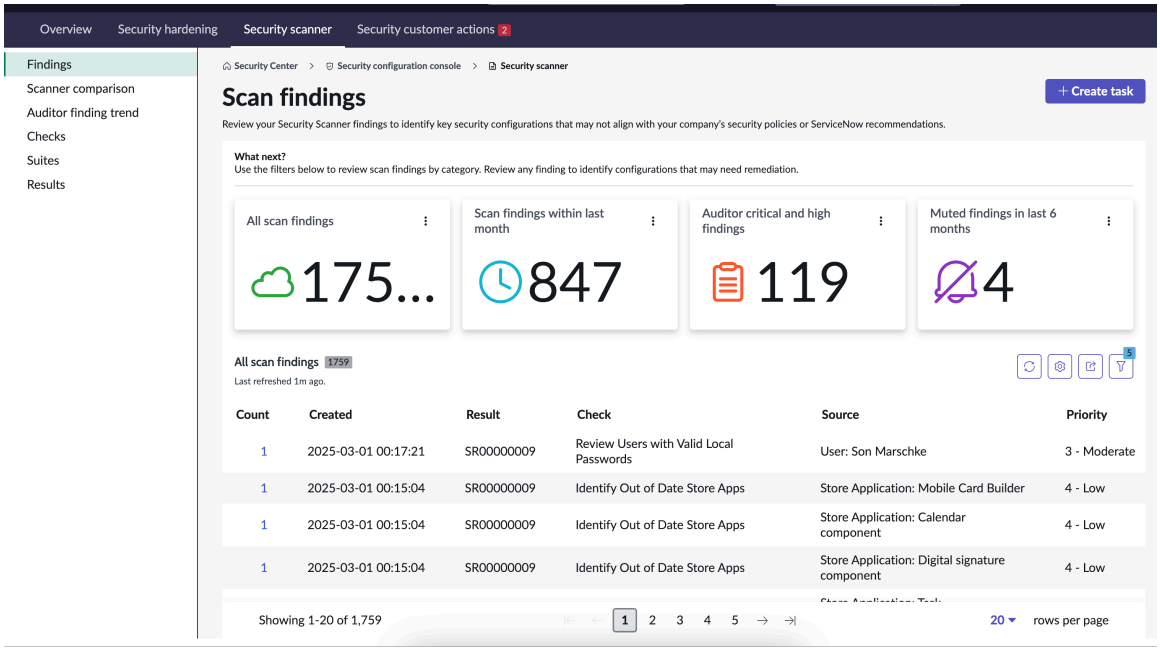
Changed hardening settings

Displays the list of hardening settings that have changed compliance statues between the selected dates. Review settings that became non-compliant and decreased your hardening comparison score for opportunities to make them compliant to increase your score. See Increase hardening compliance score.

Security scanner

Scan your instance against a set of security checks to identify misconfiguration. The scanner tool simplifies the process of creating different suites of checks for different use cases so that you can analyze the results over time.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

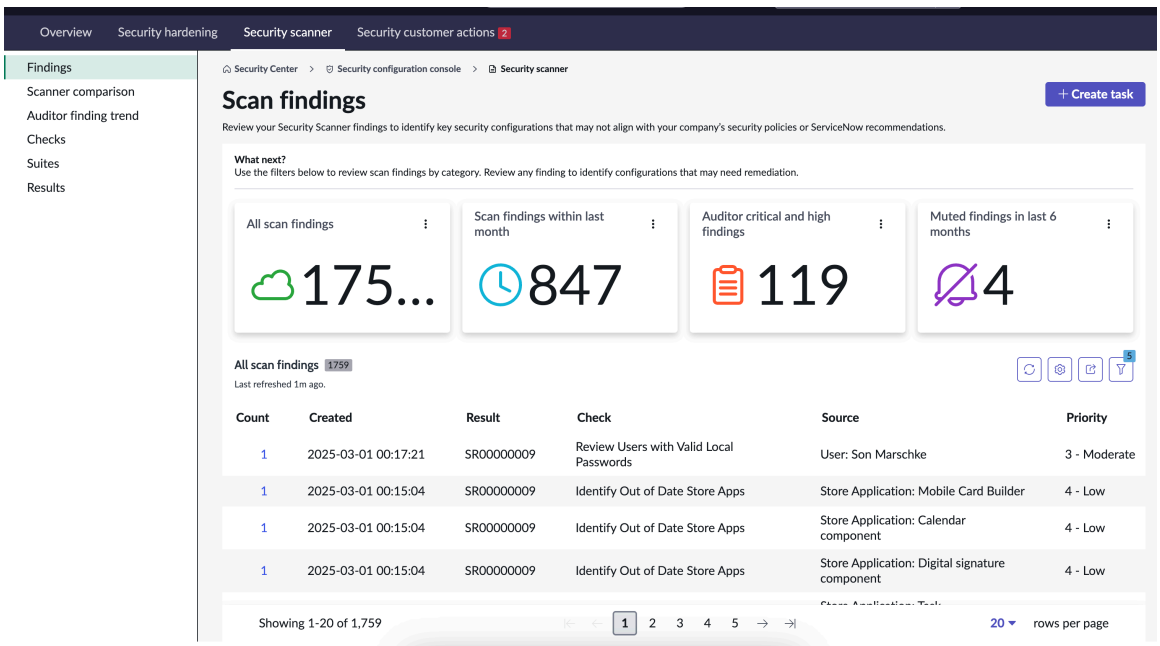


Security scanning is a method to investigate your instance for configurations that indicate security health issues. This method enables you to identify opportunities to implement security recommendations for your organization.

When accessing the scanner tool, there's no comparison available until you select the suite to be compared with at least two scan results of the suite. You can use the default suite and checks, or you can create your own custom checks and suites.

Scan findings

A finding is a reference to a record that has violated a rule from a check on the instance. You can find the source record and the number of times the record triggered the rules of a given check.



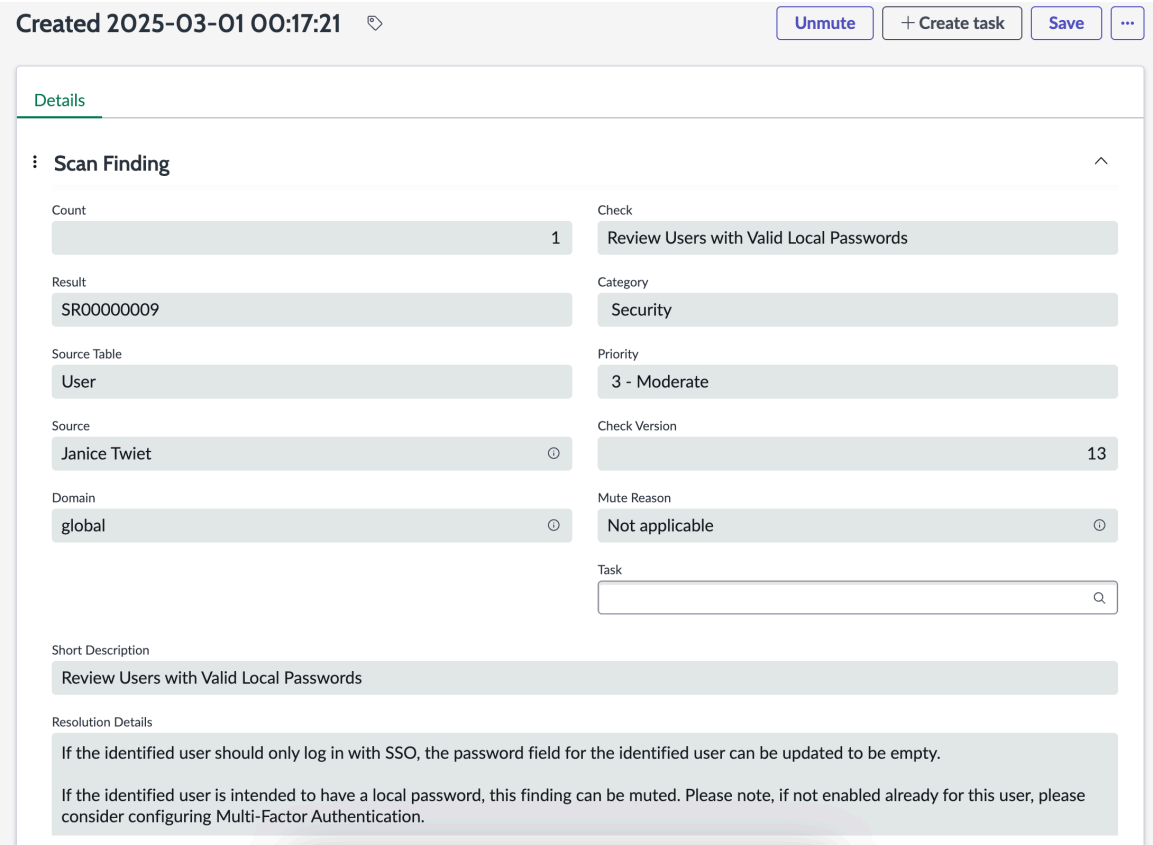
Navigate to the **Findings** tab to view scan findings in a list. The cards above the list provide a count of the findings that match specific criteria listed on the card. Select any of these cards to filter the list to show only those that match the criteria.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Select the **+Create task** button to create a Security Task to resolve a finding. This button appears both on the list and within the finding record. For details on Security Tasks, see Security Tasks.

Scan findings

Select a link under the **Count** column to view a finding record, which displays granular details related to a specific finding.



Check

List of checks associated with the scan.

Category

Security category associated with the scan. For example, access control or malicious code.

Count

Number of times the record violated check rules.

Priority

Severity of the security risk: 1 is highest priority while 4 is lowest.

Result

Status and type of scan.

Check Version

Version of the check.

Source Table

Record that has violated a rule from the check.

Mute Reason

Reason for muting the finding.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Source

Date the finding was created.

Task

Task record associated with the scan. Used to facilitate task assignments from the finding of a record.

Domain

Which domain the scan is applied to.

Short Description

Brief explanation of the scan.

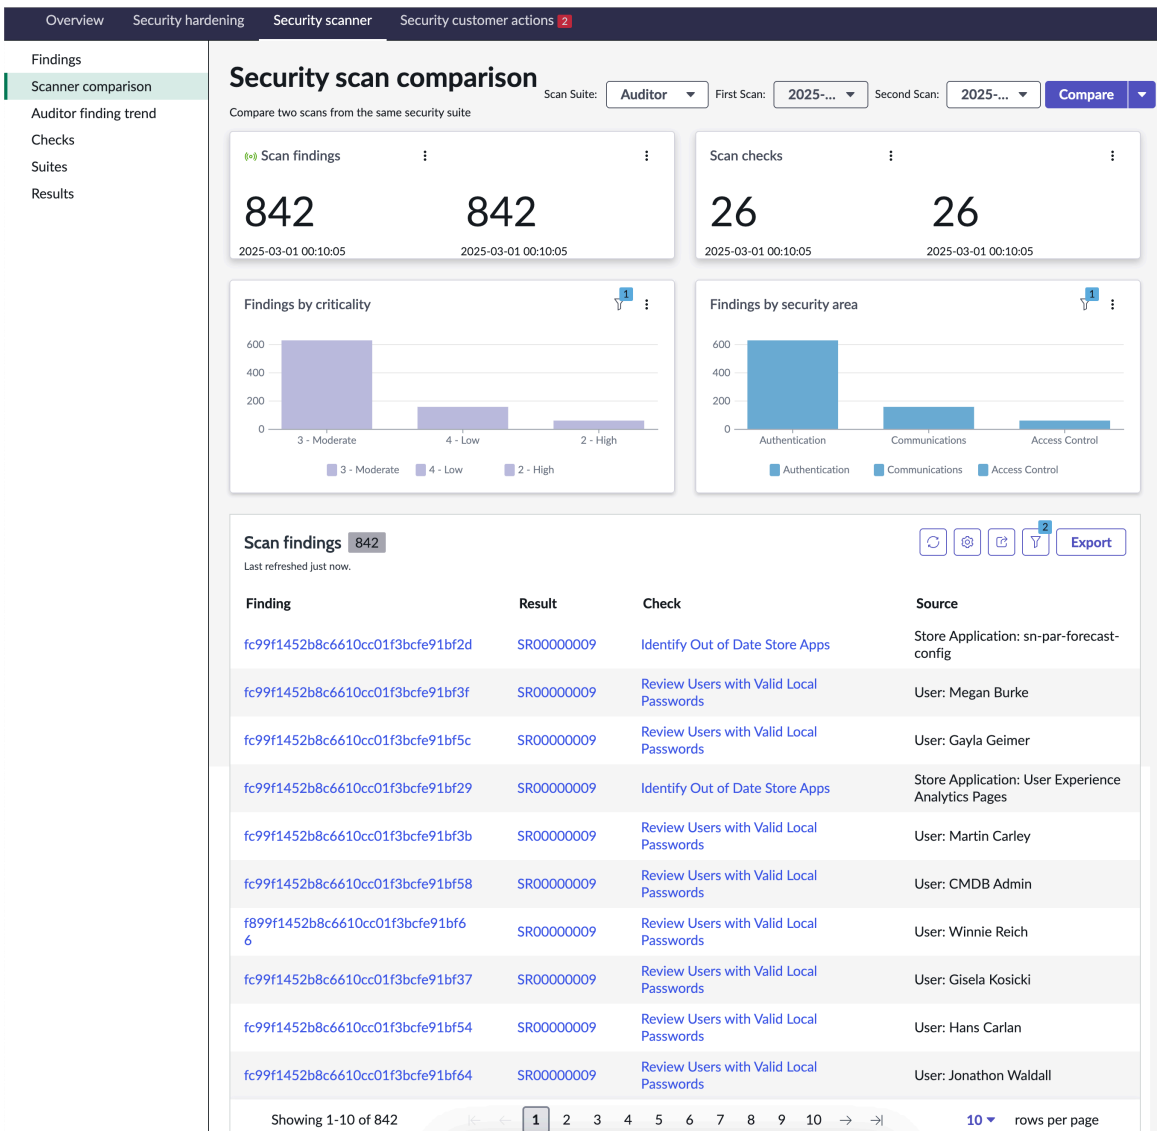
Resolution Details

Instructions on how to resolve issues reported by the scan.

Findings can be muted by selecting the **Mute / Unmute** button. When muting a scan finding, you're prompted a reason for muting the finding. Findings muted in the last six months are available in the muted findings card in the **Scan Findings** page.

Security scan comparison

Compare two scans of the same security suite to gain visibility to the health of your hardening settings and improve the security posture of your instance.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Important:
This page appears empty if you don't have two or more instances of the same scan to compare. Run a scan at least twice to view a comparison on this page.

Select a scan in the **Scan Suite** list, then select a **First Scan** and **Second Scan** to begin a comparison.

The security scan comparison page displays the security changes in your hardening settings between the first and second scans. Below is an explanation of each card:

Scan findings

Number of findings in the selected scan at each selected date.

Scan checks

Number of scan checks performed in the selected scan at each selected date.

Changed findings by criticality

Chart displaying all findings organized by criticality.

Changed findings by security area

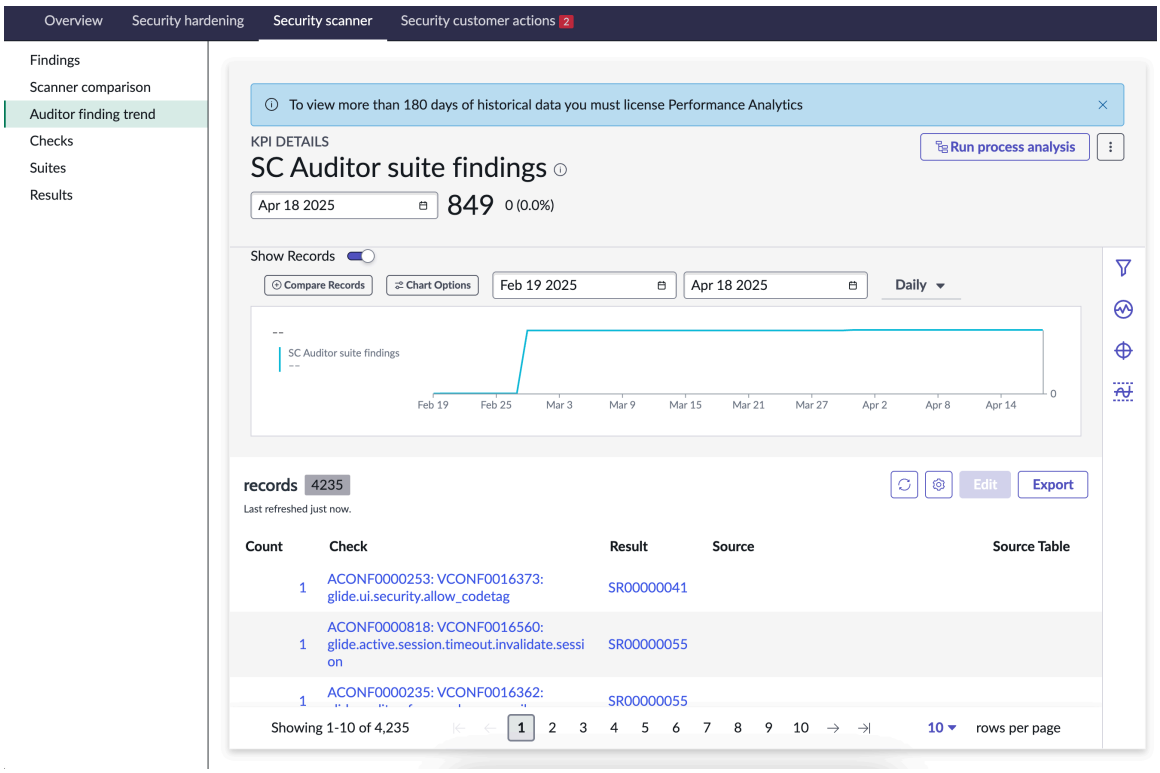
Chart displaying all findings organized security area.

Scan findings

List of all scan findings. Select a finding, scan result, or check to view the associated record and find additional details. Use the bottoms in the upper right to filter, refresh, or export the list.

Auditor suite findings

Review Security Center Auditor suite findings over time.



SC Auditor suite findings chart

The page shows SC Auditor suite findings compared between the two selected dates.Use the **Chart options** button to specify what information to analyze and how to present the information.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Analysis

Select from the list of options. Some options may be unavailable depending on the selected chart type.

Target

Goals your organization wants to achieve. See Indicator targets.

Threshold

Defines a normal range of scores for an indicator and alert you when a certain event occurs. See Indicator thresholds.

Forecast

Describes the ability to forecast future scores based on past behavior. See Performance Analytics scores forecasts.

Trend

Shows how the value of one or more items change over time.

Comments

Displays annotations on individual data points.

Labels

Displays scores related to visualizations.

Statistics

Displays statistics related to your compliance score.

Time series

Select which metric to display on the chart.

Score

Score for the Key Performance Indicator (KPI).

Change

Change of score for this indicator.

Change percentage

Change as a percentage of scores.

Chart type

Select a chart type to control how the information your selected is visualized. See Use cases for different time series visualization types.

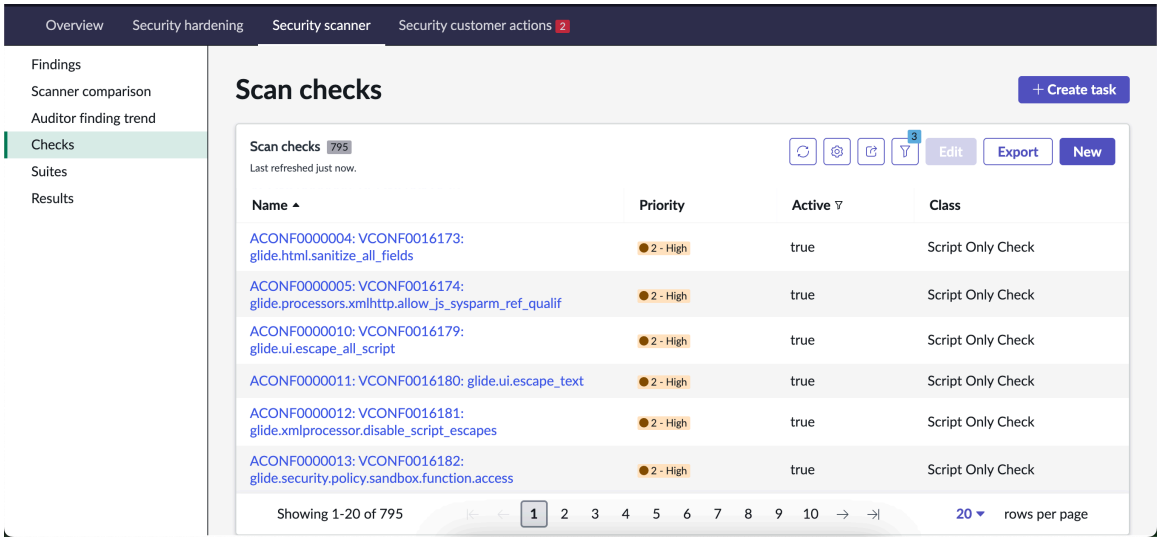
Records list

Lists the checks performed as part of the suite.

Scan checks

Use checks to detect anomalies within an instance, running against tables, records, or metadata.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Checks are rules designed to detect anomalies within an instance. Select a check on the list to view details including what the check evaluates, and possible steps to correct the issue if the check returns any findings.

Select the **+Create task** button to create a Security Task related to a scan check. For details on Security Tasks, see Security Tasks.

Checks are divided into four classes to identify issues and implement security recommendations for your organization: table checks, column type checks, script only checks, and linter checks.

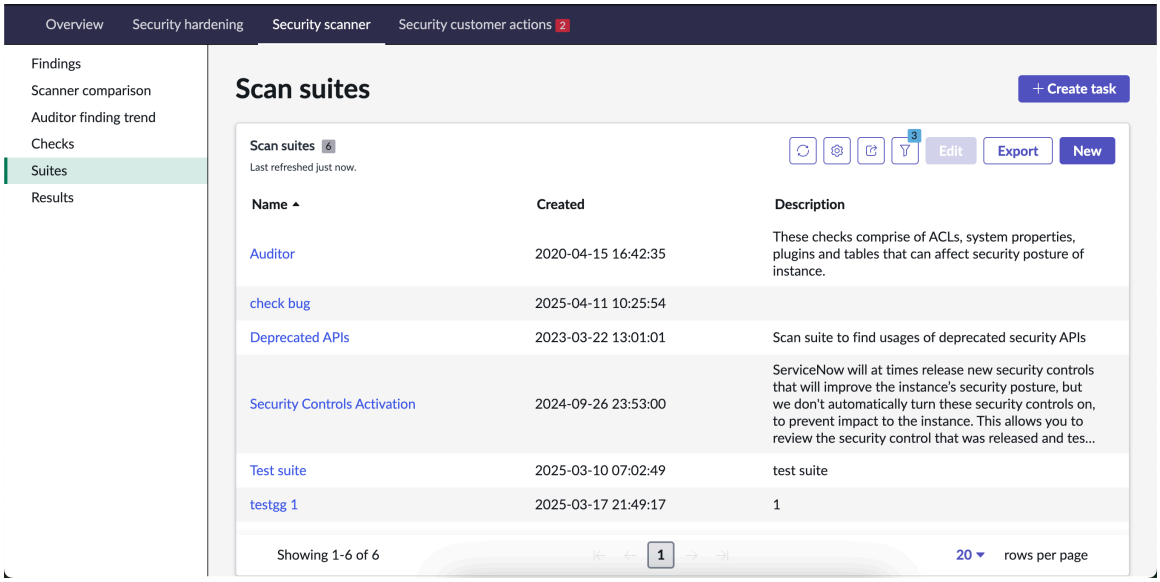
Check classes

Check class	Description
Table checks	Use this check class when you know the specific tables and checks you want to test.
Column checks	Use this check class to implement the rule you created to iterate all records matching the target column field type.
Script checks	Use this check class to verify meta data, configurations, and execute complex checks by writing your own checks.
Linter checks	Use this check class to identify any issues in a script. When a linter check is run on a record, an abstract syntax tree for its code is generated which can be used to analyze issues with the code.

Scan suites

Review details on the scan suites available on your instance.

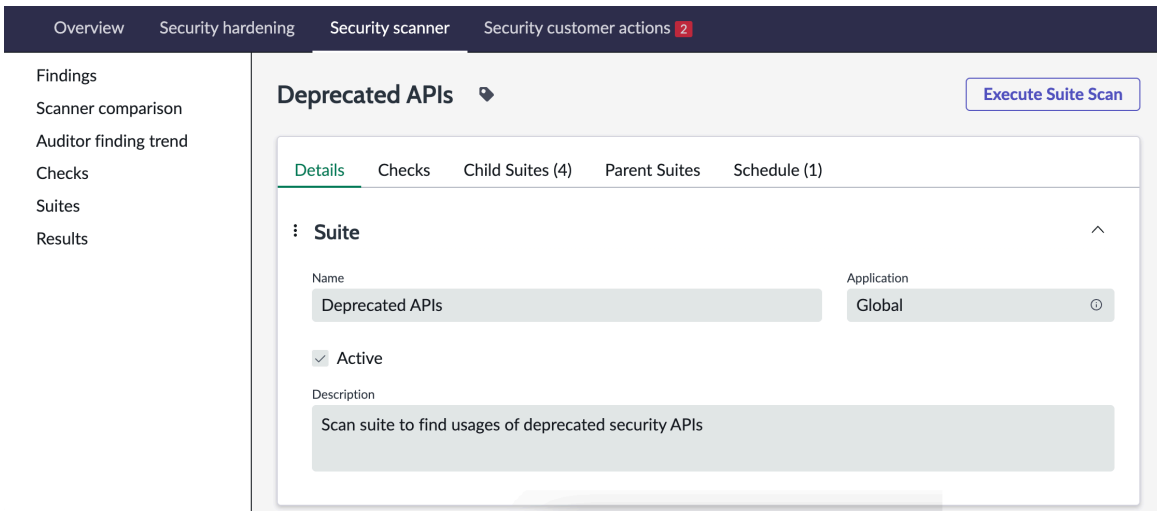
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Scan suites are collections of security center checks that execute together. You can use base system suites or create your own by cloning an existing suite and updating the checks made in the clone. For details, see Create a scan suite.

Select the **+Create task** button to create a Security Task related to a scan suite. For details on Security Tasks, see Security Tasks.

Scan suite details



Select the **Name** field of a suite to view the suite details. This page provides details on the scan suites in a tabbed interface. In the tabbed page, you can find this information:

Details

Details on the suite include its name, application, and description.

Checks

List of the checks included in this suite. Details on individual checks are the same as are found in Scan checks.

Child Suites

List of child suites associated with this suite. When you execute this suite, all child suites also execute.

Parent Suites

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

List of suites in which this suite is a child suite. When you execute a parent suite, this suite is also executed.

Schedule

Details of the scheduled execution of this suite.

Access Controls Auditor checks

Learn about the checks available in the default Access Controls Auditor Suites, what criteria they evaluate, and how they can be used to improve the security of your instance.

Access Control List rules (ACLs) restrict access to data by requiring users to pass a set of requirements before they can interact with it. Access Controls Auditor checks evaluate your instance according to the eight criteria listed in the following table. Use the findings on these checks to improve the security of your instance.

Access Controls Auditor checks

Check Name	Check Criteria	Description
All Processors of type - SCRIPT must be protected with CSRF Token	Checks for Processors with the **SCRIPT** type that aren't protected with a CSRF token.	All Processors with the **SCRIPT** type should be protected with a Cross-site Request Forgery (CSRF) token. These processors should have the CSRF option checked, which prohibits the processor from running unless the instance uses a CSRF token.
Can Contribute / Cannot Contribute user criteria to be defined on each knowledge	Checks for knowledge base records that don't have **Can Contribute** or **Cannot Contribute** user criteria defined.	Each knowledge base should have either **Can Contribute** or **Cannot Contribute** user criteria defined. Otherwise, any user can contribute content to a knowledge base with no Contribute criteria defined.
Empty ACLs	Checks for Access Control List (ACL) records that have no security attribute, no role, or the **public** role.	Leaving ACLs empty or using the **public** role may provide open access to any content protected by this ACL.
Access Controls on Client callable Script Includes	Checks for client-callable script includes that aren't secured by ACLs.	All client callable script includes should be secured with an ACL using required roles.
Access controls on UI Pages	Checks for UI Pages that aren't secured by ACLs	Without an ACL securing access to a UI Page, that UI Page is accessible to all logged-in internal users. Without any restrictions logged-in users can potentially make unauthorized changes.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Access Controls Auditor checks (continued)

Check Name	Check Criteria	Description
Access controls on Tables	Checks for tables without ACLs	Tables should be secured with ACLs. Access to data stored in tables should be limited only to users that need it.
User Account shouldn't have both Internal and External roles	Checks for user records with both **Internal** and **External** roles assigned	Internal user roles are intended for users within your company. External user roles are intended for external personnel, such as customers and partners.
Publicly accessible knowledge base and articles	Checks for publicly accessible knowledge bases and knowledge base articles	Publicly accessible knowledge bases and articles are visible to all users in the instance. Increase security by limiting knowledge bases and articles to the specific audience that needs them.

Auditor checks

Use the Auditor suite to SecureCheck to detect misconfiguration that can impact the security posture of your instance.

Check information

Access Controls Auditor checks

Check Name	Description	Scan finding type
Identify out of date store apps	Identifies apps activated on your instance that have updated versions available. Verify you're running to the most up-to-date versions of store applications, which can include fixes to potential security issues.	Resolution Recommended
Insecure GlideRecord calls	Identifies scripts that are directly invokable by end users (such as Client-Callable Script Includes, Widgets, Processors, REST Endpoints) These scripts should respect ACLs and use GlideRecordSecure or GlideRecord with canRead, canWrite, canCreate, canDelete.	Resolution Recommended
Review allowed JavaScript libraries	Identifies scripts where JavaScript Content Access Control is used to allow or deny specific third-party JavaScript libraries.	Resolution Recommended

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Access Controls Auditor checks (continued)

Check Name	Description	Scan finding type
	Review instance customizations to verify that libraries aren't in use before blocking access. The JavaScript Content provider Access Tracking [sys_js_content_provider_access_tracking] table can be reviewed to see the last date that the library was accessed. **Note:** This check can be ignored in instances initially provisioned on Tokyo or later. Records on the associated table have deny rules set by default. In instances initially provisioned prior to Tokyo, there may be allow rules in the JavaScript Access Control tables.	
Review client callable script includes with no corresponding ACL	Identifies client callable script includes that don't have a corresponding ACL. These scripts use the default ("*") client callable script include ACL. For these scripts, create ACLs that defines the appropriate criteria for access to verify that only expected users can interact with the functionality provided.	Resolution Recommended
Review custom tables with record producers and no business rule	Identifies record producers that don't have additional server-side validation. This check identifies custom tables with a Record Producer but without an associated business rule. These may enable users to submit unexpected data into the associated table.	Resolution Recommended
Review empty ACLs	Identifies ACL records which have no script, condition, security attribute, or role, or ACLs with the **public** role. Leaving ACLs empty or using the **public** role provides open access to any content protected by this ACL.	Resolution Recommended
Review fields with HTML Sanitization disabled	Identifies HTML fields where HTML Sanitization is inactive. HTML sanitization removes or replaces potentially harmful elements and attributes within HTML code. Review HTML fields where	Resolution Recommended

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Access Controls Auditor checks (continued)

Check Name	Description	Scan finding type
	sanitization is inactive to confirm whether this configuration is necessary.	
Review inactive security feature plugins	Identifies plugins that aren't activated that provide additional, configurable security controls. The findings produced by this check are provided for informational purposes. Before enabling one of the identified plugins, verify that the plugin meets your use cases or requirements. You can mute these findings if you don't have a use case for the identified.	Inform
Review large allowed IP address ranges	Identifies IP Address Access Control Ranges that contain a large number of IP Addresses. **Note:** If you're seeing a large number of false positives, consider adjusting the largestExpectedCIDRBlock variable for your specific business needs. Classless Inter-Domain Routing (CIDR) blocks contain a larger amount of IP addresses as the number decreases. For example, the CIDR block size 8 is larger (contains more IP addresses) than the CIDR block size 16. Review and confirm that the current configuration aligns with your business needs.	Review and Decide
Review public GraphQL schemas	Identifies public GraphQL schemas in the GraphQL API [sys_graphql_schema] table. These schemas can be configured to be available without authentication. Depending on the endpoint's functionality, this may allow unauthenticated users to perform unexpected actions or interact with unexpected data.	Review and Decide
Review public knowledge base articles	Identifies knowledge bases and knowledge base Articles configured to enable access to unauthenticated users. Review and confirm that the current configuration aligns with your business needs.	Review and Decide

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Access Controls Auditor checks (continued)

Check Name	Description	Scan finding type
Review public REST API endpoints	Identifies Rest API Endpoints in the Scripted REST Resource [sys_ws_operation] table that are configured to be available without authentication. Depending on the endpoint's functionality, this may allow unauthenticated users to perform unexpected actions or interact with unexpected data.	Review and Decide
Review public Service Portal pages	Identifies Service Portal pages that are made public. Service Portal pages are made available to unauthenticated users by setting the "public" field to "true." Review and confirm that the current configuration aligns with your business needs.	Review and Decide
Review public UI Pages	Identifies UI Pages that are made public. UI Pages can be made available to unauthenticated users using the [sys_public] page. Review and confirm that the current configuration aligns with your business needs.	Review and Decide
Review roles that contain the 'admin' role	Identifies any roles (Roles [sys_user_role] table) that contains the **admin** role. The **admin** role grants users administrative privileges and should be used only when necessary. Review and confirm that the current configuration aligns with your business needs. If this is an intentional configuration, this check can be muted.	Review and Decide
Review UI Pages without corresponding ACLs	Identifies UI Pages that don’t have an ACL for that UI Page. UI Pages that don’t have a specific ACL default to a generic UI Page ACL, which may grant access to unintended users.	Resolution Recommended
Review users with valid local passwords	Identifies users with locally set passwords. Users with local passwords may interact with the instance via APIs using the local credentials, even if local logins are disallowed.	Review and Decide

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Access Controls Auditor checks (continued)

Check Name	Description	Scan finding type
	This password configuration is needed for integration user accounts to function correctly. Review these user accounts to verify that only intended users (such as integration accounts) can authenticate with local authentication.	
Rotate passwords stored with outdated hashing algorithms	Identifies user accounts with passwords created in previous versions of the ServiceNow AI Platform, which may have used what is now considered a legacy or outdated hashing algorithm. Accounts created on old platform versions that haven't rotated their passwords may still have passwords stored with a legacy hashing algorithm. Review the identified accounts created consider password resets.	Resolution Recommended
Securing record producers	Identifies insecure record producers. If not assigned to appropriate roles unauthorized users can access them, potentially revealing sensitive information. Assign appropriate roles to record producers to verify that they're accessible only to users that need them.	Resolution Recommended
UI action visibility	Identifies UI actions that can be accessed by a user with no roles who doesn't have read access to the table. These users may be able to alter data on a table they don't have access to via these UI actions. Verify that UI actions are only available to users with access to the table they affect.	Resolution Recommended

Create a scan suite

Create and schedule a custom suite so that you can analyze the security of your instance for your organization.

Before you begin

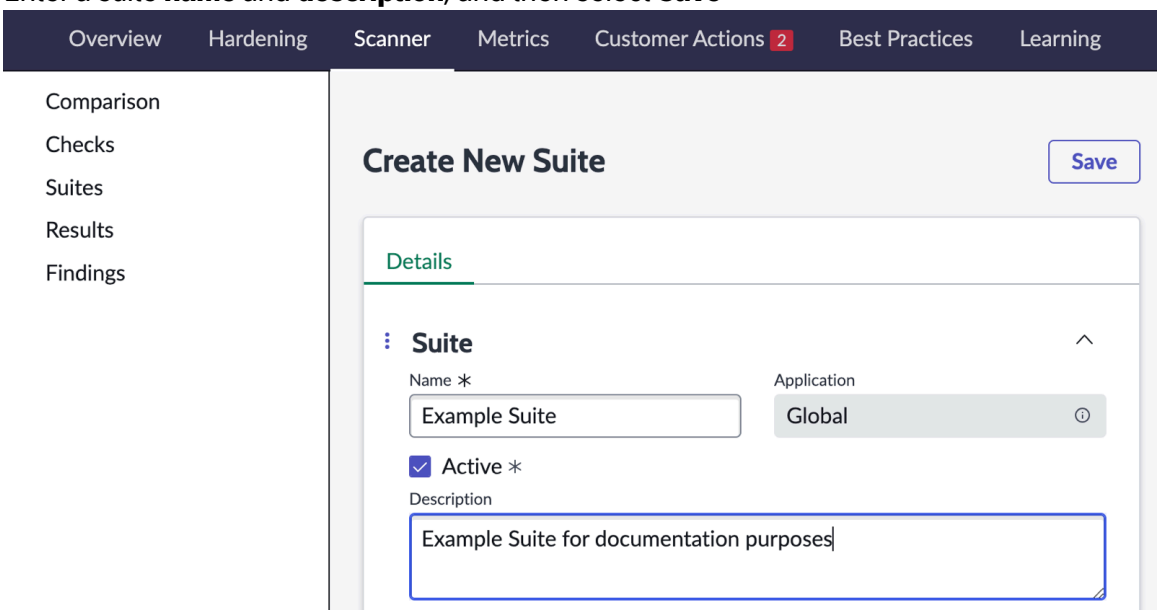
Role required: admin or sn_vsc.security_center_viewer.

A suite is a collection of checks that can be used for a scan. View a list of scan suites organized in a table by navigating to **Scanner** > **Suites**. Create your own suites or to use the default suite, Auditor. Auditor is a default base system suite that contains checks for security best practices. These checks consist of system properties, plugins, and tables that can affect the security posture of your instance. The following steps show how to create a suite along with the several options available for configuring them.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. In Security Center, select the **Scanner** tab, then select **Suites** in the panel on the left side of the screen.
2. In the **Scan Suites** page, select the **New** button.
3. Enter a suite **name** and **description**, and then select **Save**



After selecting **Save**, configuration options for the suite display in a tabbed interface.

4. Select the **Checks** tab.
   Use this tab to add checks to your suite.
   a. Select **Edit**.
   b. Select the checks that you want to add, and then select Add (**>**) to place it in your suite.
   c. **Save**.
5. Select the **Child Suites** tab.
   Use this tab to add child suites. Suites added as child suites are also executed.when this suite is used in a scan.
   a. Select **Edit**.
   b. Select the child suites that you want to add, and then select the Add (**>**) to place it in your child suite.
   c. **Save**.
6. Select the **Parent Suites** tab.
   Use this tab to add parent suites. Parent suites that are executed in a scan will also execute this suite.
   a. Select **Edit**.
   b. Select the child suites that you want to add, and then select Add (**>**) to place it in your parent suite.
   c. **Save**.
7. Select the **Schedule** tab.
   Use this tab to set a time for your suite to execute.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

a. Select **New**.

b. Enter details of the scheduled scan.
The time fields are in the format: hour:minutes:seconds.

c. **Save**.

Clone the access controls auditor suite

Clone and customize the default access controls auditor suite in your instance to create a new suite tailored to your organization's security practices.

Before you begin

Role required: admin

About this task

The default access controls auditor suite provided with your instance can't be modified. However, if you want to add, remove, or edit checks to align with your organization's security practices, you can duplicate the access controls auditor suites. Copying the access controls auditor suites enables you to customize it and create a new suite based on the default one. The access controls auditor suites includes checks related to security best practices, covering system properties, plugins, and tables that impact the instance's security posture. The following steps demonstrate how to duplicate the default access controls auditor suites to tailor it to your organization's requirements.

Procedure

1. Navigate to **All** > **Instance Scan** > **Suites**.
2. Select **New** and enter a name for your suite, along with an optional description.
3. Right-click the form header and select **Save**.
4. Add the checks needed for your scan.

   a. In the **Checks** tab, select **edit**.

   b. Add the conditions.
   For example, to add scan checks apply the following fields, operators, values, and conditions:

   [Category][is][Security] AND [Application][is][Global]

   For example, it should look like the following: `Category is Security And Application is Global`.

5. Select **run filter**.
6. Select the scan checks that you want to add from the collection list to the check list, and then select the add (>) button.
7. Select **save**.
   The suite with your custom checks added have been created.
8. Select **Execute Suite Scan**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

View the Access Controls Auditor Suite

View the checks available in the default Access Controls Auditor Suites to understand which checks are executed when this suite runs.

Before you begin

Role required: admin

About this task

The steps you need to complete to access the default access controls auditor suites within your ServiceNow instance.

Procedure

1. In Security Center, select the **Scanner** tab, then select **Suites** from the panel on the left.
2. In the **Scan Suites** page, select **Auditor** from the list.
3. To review the suite checks, select the **Checks** tab.
   You should see the list of 8 checks available for the suite.
4. Select the name of a check you want to analyze.
5. Analyze the fields associated with the check.

Name	Description
Name	Name of the check.
Application	The application to which the check belongs (Security Center).
Category	Category associated with the check.
Priority	The level of urgency.
Version	Version number of the check.
Active	The status of the check, for example, active or inactive.
Short Description	A brief summary of the check.
Description	A more comprehensive summary of the check.
Resolution Details	Mitigated potential security incidents.
Documentation URL	Links to related documentation in the product documentation or Knowledge Base (KB) articles.
Run Condition	Conditions that trigger the start of the checks.
Table	The table to which the check belongs.
Conditions	Conditional logic applied to the checks.
Advanced	Advanced configuration options.

Reschedule a scan suite

Change the schedule of your scan suites to suit your needs.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin

Role required: admin, sn_vsc.security_center_viewer

Procedure

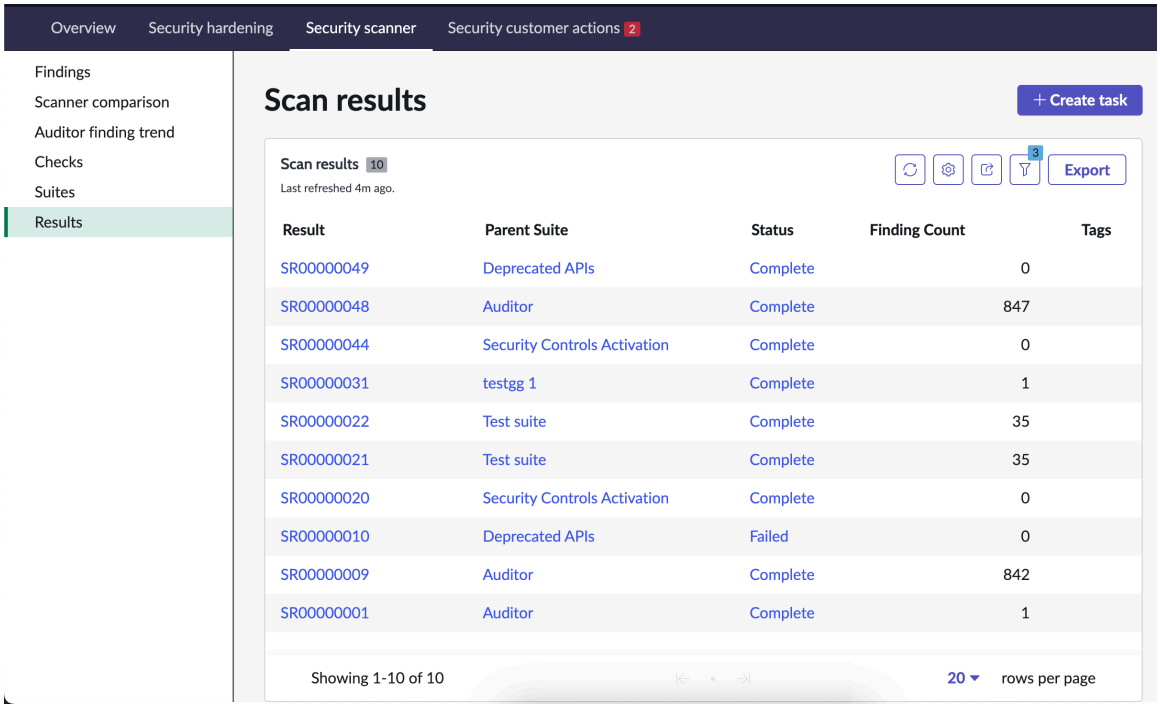
1. Navigate to **All** > **System Security** > **Security Center**.
2. In the **Tools** section, select **Security scanner**.
3. Select **Suites** in the menu on the left edge of the screen.
4. Open the suite you want to reschedule.
5. Select the **Schedule** tab.
6. Select an existing schedule, or select **New** to create a new schedule.
7. In the **Scheduled Scan** form, fill in the fields as needed.

Field	Description
Name	Name of the scan schedule
Run	Select the how often your suite will run. **Note:** Additional fields will appear to help define your schedule. These fields vary depending on your selection.
Active	Whether the schedule is active. Inactive schedules are never executed.
Conditional	Select to enable the **Condition** field, where you can define a scripted condition for your schedule.
Condition	A scripted condition for your schedule. The suite will only run when the script evaluates to `true`.
Run as tz	Which timezone the schedule uses when determining when to run.

Scan results

View data related to your scan results from a single view.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



A scan result reports the status and type of the scan. You can also see all the checks that ran as part of the scan and all other information related to the scan such as errors and scan logs.

You can find your scan results dashboard by selecting the **Scanner** tab in Security Center, then selecting **Results** in the left panel. The scan results are listed under the **Scan results** list. Select a result to drill in and view the details, which are separated into tabbed sections.

Details

Overview of the scan results including the status, type, and execution time in seconds.

Scan Findings

Findings encountered during the execution of the checks.

Suites

Displays the suites that ran as part of this scan.

Checks

Displays the checks that ran as part of this scan.

Failures

Displays the checks that failed during the scan and the reason of its failure in the form of an error message.

Scan Log

Displays messages output during the scan.

Scan Statistics

Displays statistics related to the scan.

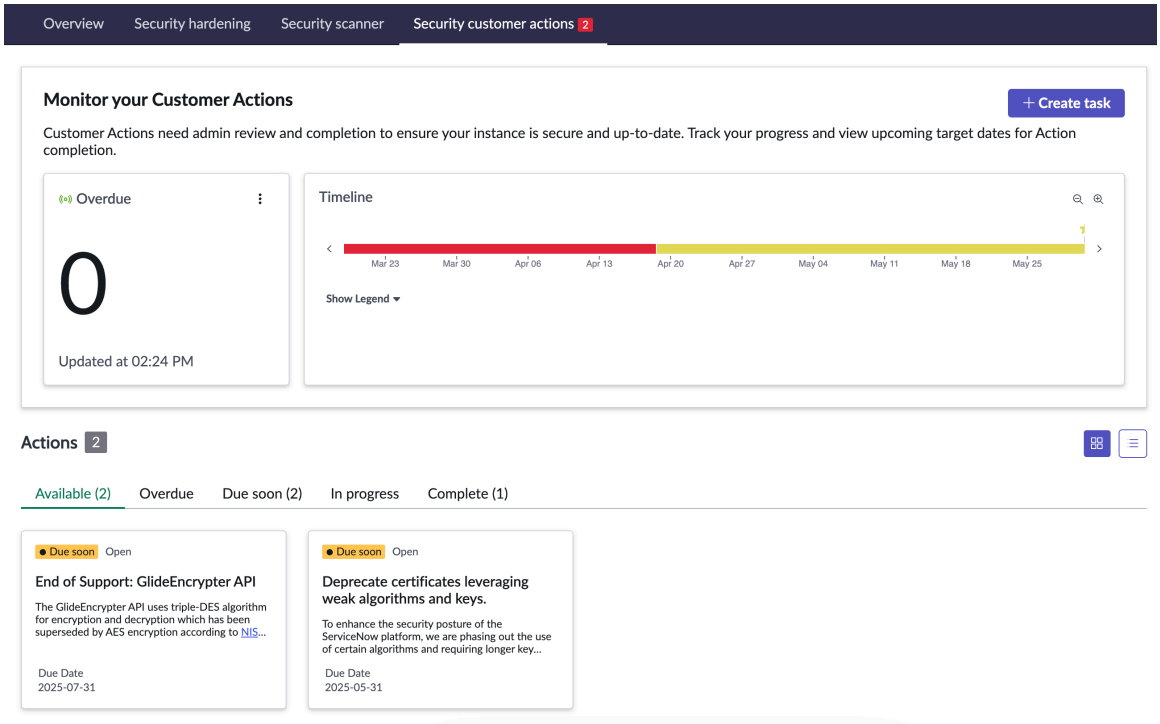
Targets

Displays all the targets against which the checks have executed.

Customer Actions

Use the Customer Actions tool to implement important security updates based on your instance and the configuration of plugins.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



ServiceNow updates your instance with family releases and patches to keep base system platform code and functionality current and secure. However can be additional actions you can take to secure your instance that are unique to your custom instance configuration. These recommended updates are found in the Customer Actions tool.

Customer Actions vs. Family releases and patches

Feature	Customer Actions	Family releases and patches
Definition	Manual, guided tasks for admins to implement important security changes.	System-driven updates applied automatically during family releases or patches.
Purpose	Address security risks that can't be resolved by ServiceNow upgrades alone. Designed to avoid disrupting custom configurations.	Keep platform code and functionality current and secure.
Examples	Deprecating weak certificates, enforcing multi-factor authentication (MFA), disabling insecure protocols.	Platform version upgrades, patch-level fixes, backend security enhancements.

Access this tool by navigating to **Customer Actions** within Security Center.

Elements of the Customer Actions tool

Create Task button

Use the **+Create task** button to create a Security Task to complete a Customer Action. For details, see Security Tasks.

Overdue actions

A count of the number of Customer Actions that are part their due date. Select the overdue actions card to see a list of past due Customer Actions.

Customer Actions timeline

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

A timeline of Customer Actions so that you can prioritize when to implement the steps. The timeline in the preceding image shows the Customer Actions that are overdue, and the ones that are due soon.

Actions tabs

A tabbed interface showing Customer Actions by category:

- Available
- Overdue
- Due soon
- In progress
- Complete

Select a tab to view a list of actions in each category.

For details on how to review individual Customer Actions, see View Customer Actions.

For information on how to apply the changes recommended by Customer Actions, see Implement Customer Actions.

Implement Customer Actions

Learn how to implement Customer Actions on your instance to increase its security posture.

Before you begin

Role required: admin

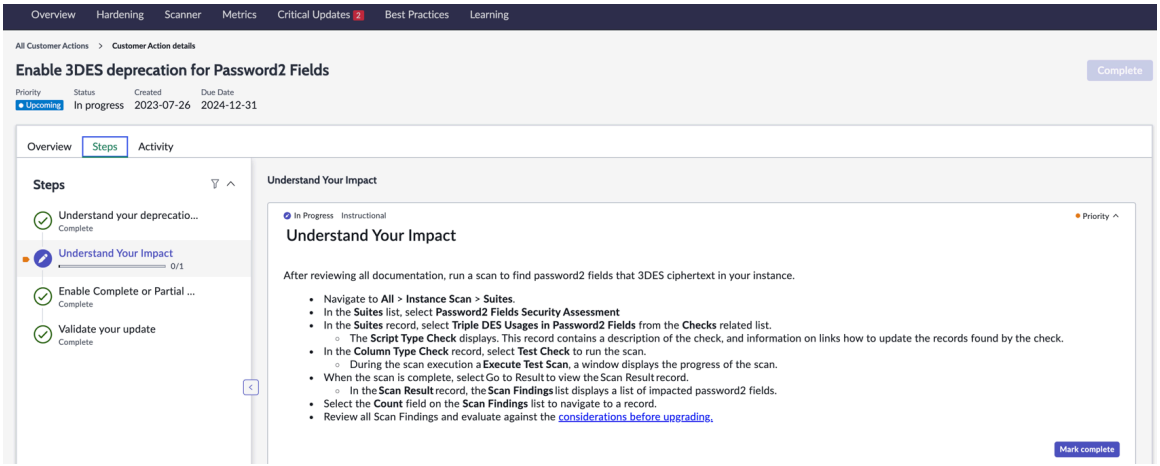
About this task

Customer Actions provides you step by step instructions for how to implement the changes on your instance to increase your security posture. Customer Actions pulls relevant content from the product documentation to guide you through each step of the implementation process. Follow the steps below to learn how to implement a Customer Action.

Procedure

1. Navigate to the **Customer Actions** app.
2. Select a Customer Action to implement.
   Under the **Updates** section, the Available tab lists all the Customer Actions on your instance. Click on a Customer Action under this tab to view the instructions.
3. Read the overview to learn why the Customer Action is needed, and to prepare for implementing the steps.
   Click on **Go to next step** to progress to the implementation details.
4. Implement the update steps.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



a. Read each group of instructions and implement them within your instance.

b. Click **Mark complete** when you are done with a set of instructions.

c. Repeat steps a-b until you have completed all of the update steps.

d. Click **Complete**.
The Customer Action should appear in the **Complete** tab.

View Customer Actions

See details of all of the activity related to your Customer Actions.

Before you begin

Role required: admin

About this task

The activities will be listed from newest to oldest so that you can analyze the most recent activity first. Each update to an activity is timestamped, and you can use search and filter to query for specific information.

Procedure

1. Navigate to the **Customer Actions** app within Security Center.

2. Navigate to the **Updates** label of Customer Actions.

3. Click a state, and then select a Customer Action from that state.

In the example below, the **Complete** state is selected and then the Customer Action for **End of Support: GlideEncrypter API** is selected.

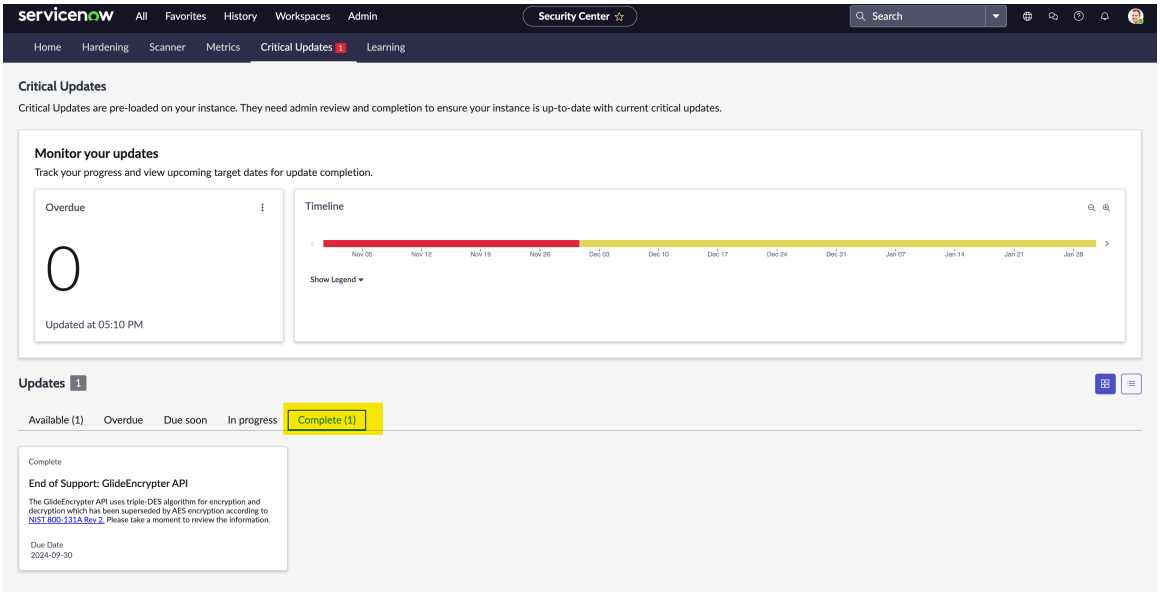
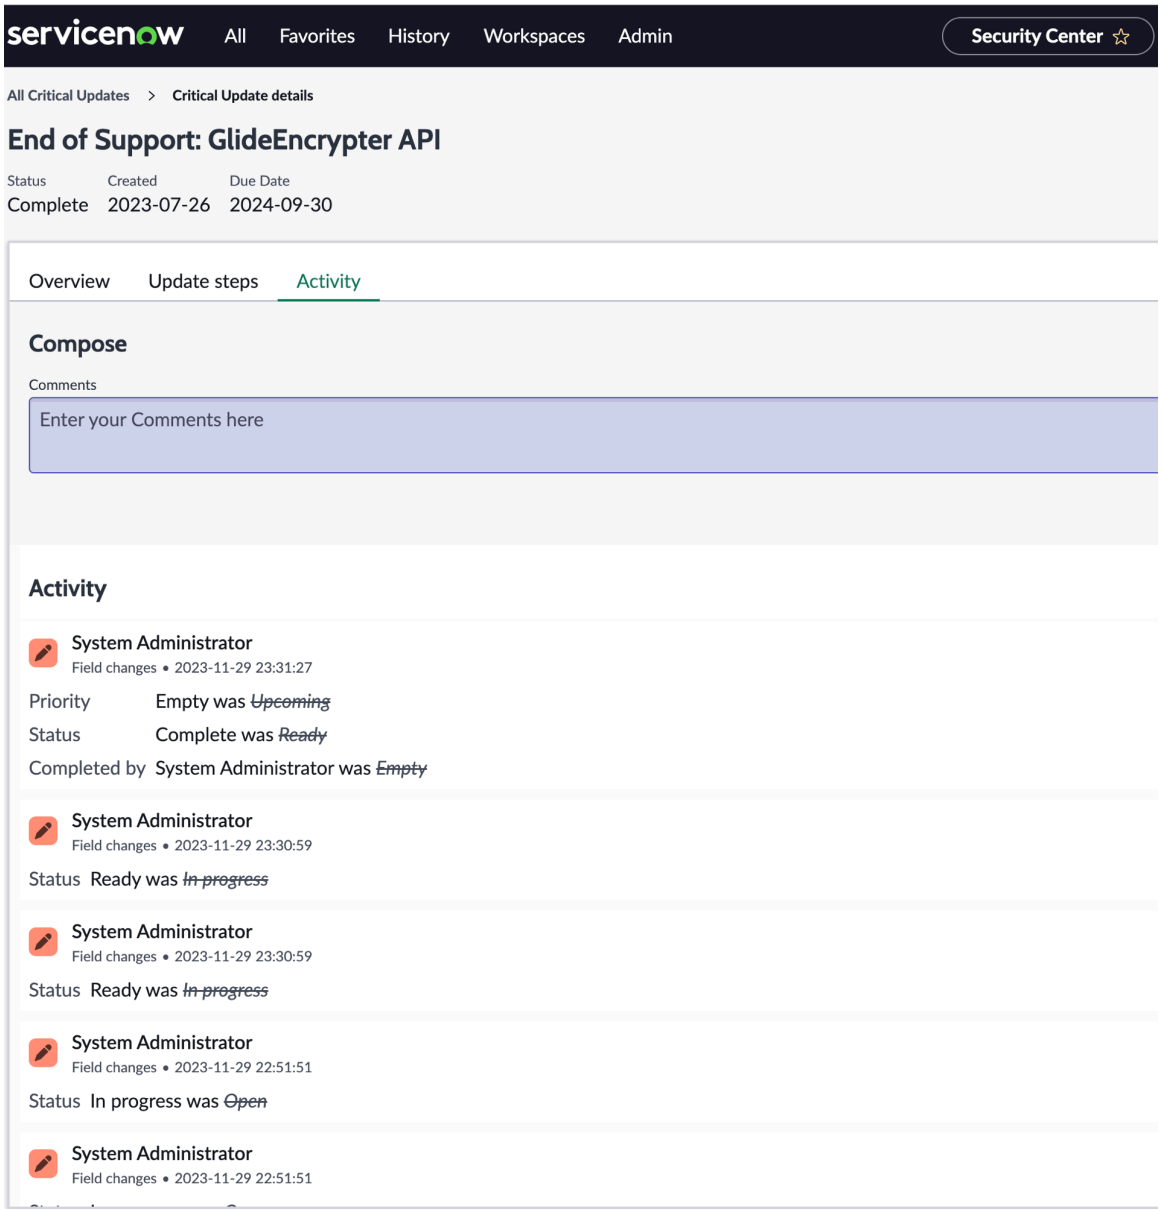
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



4. View the activity of your Customer Action.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

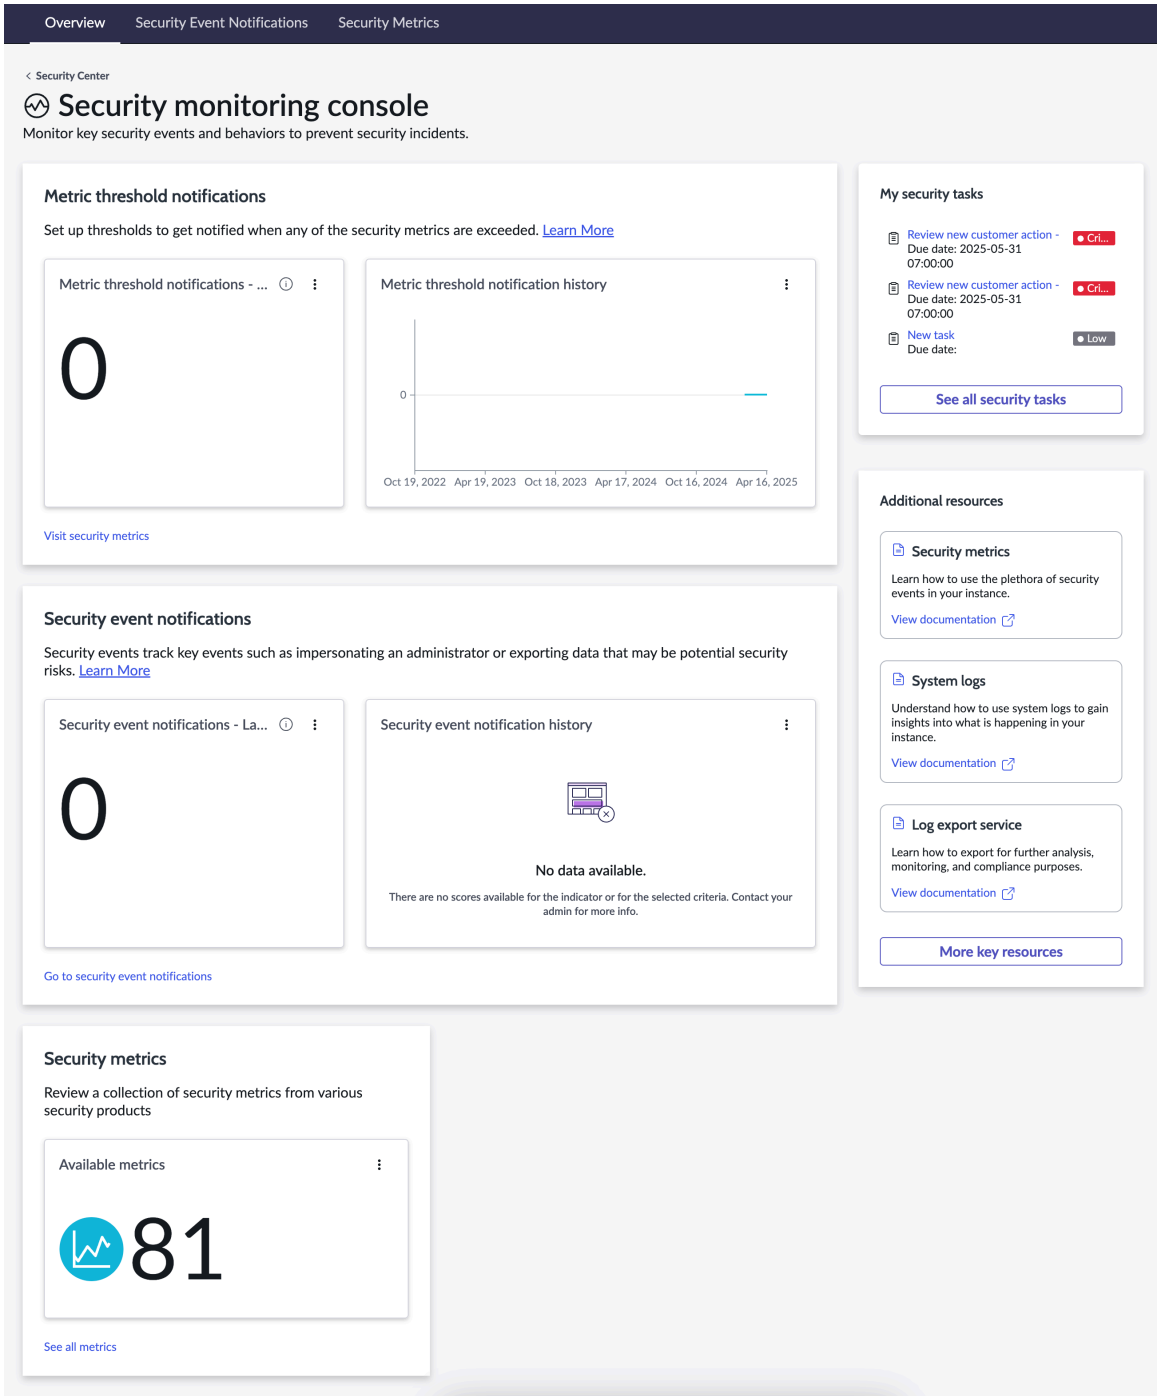


All of the activity related to a Customer Action is automatically recorded. In addition, you have the ability to add additional comments to activities.

Security monitoring console

Supervise security notifications and metrics to stay informed about potential security risks on your instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



The Security monitoring console is organized into sections, each with cards containing information on a specific aspect of security monitoring. Select the info (ⓘ) icon on any card for details on what each represents.

Navigation bar

Use the bar at the top of the page to navigate between the **Overview**, **Security Event Notifications**, and **Security Metrics** sections.

Metric threshold notifications

Learn about the metric threshold notifications on your instance in the Metric threshold notifications panel. Thresholds define a normal range of scores for an indicator and alert you

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

when certain events occur, like when a score reaches an all-time high. This panel displays the count of threshold notifications in the last seven days, and a chart showing the threshold count over time.

Select either card to open the Security metrics tab to see more detail on these notifications.

Security event notifications

Track security events such as impersonation or data exports in the Security event notifications section. This panel displays the count of security events in the last seven days, and a chart showing the count over time.

Select either card to open the Security metrics tab to see more detail on these notifications.

Security metrics

This section displays a count of available Security Metrics on your instance. Review a collection of Security Metrics from various security products.

My Security Tasks

View the most urgent Security Tasks assigned to you. Select a task to view its details, or select **See all Security Tasks** to view a complete list of Security Tasks. For details on Security Tasks, see Security Tasks.

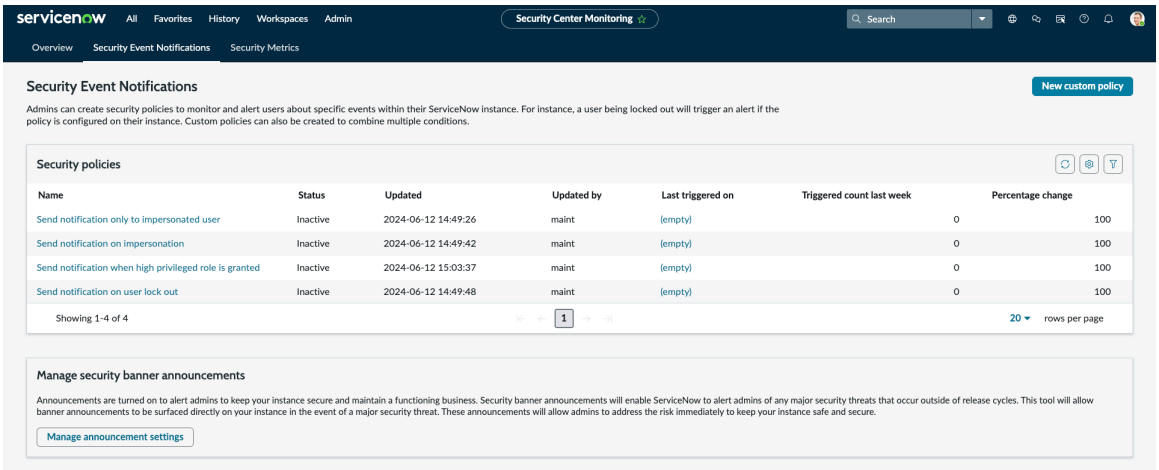
Additional resources

Use the additional resources section on the edge of the screen to navigate to documentation and videos relevant to learning Security Center as well as information on managing instance security.

Security Event Notifications

View, manage, and analyze the default security event notification policies on your ServiceNow instance, as well as access the functionality to create custom policies.

Access Security Event Notifications from the Security Center homepage by opening the **Security Monitoring Console** in the **Security Consoles** section, then selecting the **Security Event Notifications** tab.



Customize and create notification policies that trigger email notifications when users perform actions in the ServiceNow AI Platform that might be insecure or require admin monitoring.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Admins can customize the values for the default policies, clone, and edit default policies or create their own custom ones.

Security policies

The Security Event Notifications console displays important information regarding the security policies on your instance. This table includes columns displaying:

Label	Description
Name	The name of the security event notification policy.
Status	The status of a policy can be either active or inactive.
Updated	The date and time of when the policy was last updated.
Updated by	The user that updated a policy.
Last triggered on	The date and time the policy last ran.
Triggered count last week	The number of triggers a policy generated the past 7 days.
Percentage change	The rate of change for weekly triggers, calculated as a percentage. **Note:** For example, if this policy triggers an average of 5 notifications a week and it triggered 10 times last week, that would be a percentage increase of 100%.

Select a policy on the table to view more detail, including an overview, settings, and notification history. Select the **New custom policy** button to create a custom policy tailored to your organization's use cases.

Manage security banner announcements

Select **Manage announcement settings** to control whether admins receive banner notifications on this instance. For information on these announcements, see Security banner announcements.

Create custom security event notification policies

Learn how to create custom security event notifications that are specific to your organization's needs. This enables you to monitor actions taken by users and groups on your instance and generate notifications for potential security risks.

Before you begin

Role required: admin

Procedure

1. Navigate to the Security Center app and select **Notifications**.
2. Select **New custom policy**.
3. Select one of the three event types that will trigger the start of the policy, and select **Create**.
4. Configure the policy.
   See Configure preferences for security event notification policies to learn how to configure your new custom security event notification policy.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Modify security event notification policies

Learn how to modify the settings of your security event notification policies.

Before you begin
Role required: admin

Procedure

1. Navigate to the Security Event **Notification** homepage and select any of the policies you want to modify.

   Note:
   You cannot modify the trigger or condition logic for default policies. To modify these settings, you must first duplicate the policy which can be done by selecting the down arrow next to **Update**, and then selecting **Duplicate**.

2. Select **policy settings** to change the settings.
3. Select **Update** to save your changes.
4. **Optional:** Select **deactivate** until you are ready to start triggering notifications.
5. **Optional:** Start triggering notifications by selecting **Activate**.
   See Configure preferences for security event notification policies to learn how to configure your new custom security event notification policy.

Configure preferences for security event notification policies

Discover how to customize security event notification policies in Security Center to align with your organization's specific needs.

Before you begin
Role required: admin

About this task
The **Policy settings** page is where you can customize the settings for a security event notification policy. Here, you can adjust options related to when the policy runs, the conditional logic, and the notifications that are sent.

Procedure

1. In Security Center, select **Notifications**.
2. Under the Security policies table, select a security event notification policy that you want to configure.
   For example, **Send notification when high privileged role is granted**.
3. Select **Policy settings**.
4. Configure the policy settings.

Policy settings configuration options

Label	What to configure
When to run	**Trigger**: The event that starts the policy.
Conditions	The conditional logic and conditions to apply to your policies.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Label	What to configure
	○ **Condition logic**: two options ▪ **All conditions must be met to trigger this policy**: all conditions need to be valid for the policy to send notifications. ▪ **Any of the conditions must be met to trigger this policy**: notifications will be sent if any one of the conditions is valid. ○ **Add Condition**: Select Add Condition and provide the appropriate values for it. You can remove a condition by selecting **Remove condition**.
Notifications	The email body and email recipients: ○ **Notification**: Select one of the predefined notification templates. See Create a custom email for security event notifications for more information. ○ **Add Notification**: Select Add Notification. ○ **Groups**: Select the group who should receive the notification. ○ **Users**: Select the users who should receive the notification. You can remove a notification by selecting **Remove notification**.

Note:
If you want to make a policy inactive, select **Deactivate**. If you want to replicate a policy, select the down arrow next to the **Update** ( ) button.

5. Select **Update** to save your settings.

Create a custom email for security event notifications

Learn how for creating a custom email for security event notifications by configuring new notifications, setting triggers, defining recipients, and crafting email content with dynamic event fields.

Before you begin
Role required: admin

Procedure
1. Select **system notifications** > **notification**.
2. Select **new**.
3. Enter a **name** for the notification field.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Select the field next to **table** and enter security policy notification (*sn_vsc_security_policy*).
5. Configure the new record.
   There are three tabs within the record that must be configured: **When to send**, **Who will receive**, and **What it will contain**.

Tab	Description
When to send	Select the field next to **Send when** label and select **Triggered**.
Who will receive	○ Select the local icon next to **Users/Groups in fields**, and select both **Users** and **Groups**. Select the **Add Item** (>) icon to move the fields into the **Selected** text field. ○ Right click on the record header banner and select **Save**.)
What it will contain	Create an email template. See Create an email template for more information. Enter fields of the event into **Message HTML**. This can be done by using the `${event_id.FIELD_NAME}`. Here's an example: `Role: ${event_id.role.URI_REF} Granted to: ${event_id.granted_to.URI_REF} Granted by: ${event_id.user.URI_REF} Logged at: ${event_id.sys_created_on} Security Center Notification: ${execution.policy.name}`

6. Select **Submit**.
7. Add a custom notification to email template in security event notifications.
   a. In Security Center, select **Notifications** > **Policy settings**.
   b. Navigate to the **Notifications** label.
   c. Enter the name of the custom notification you created in the **Notification** field.

Security Event Notifications history

Explore the complete history of security event notifications on your instance.

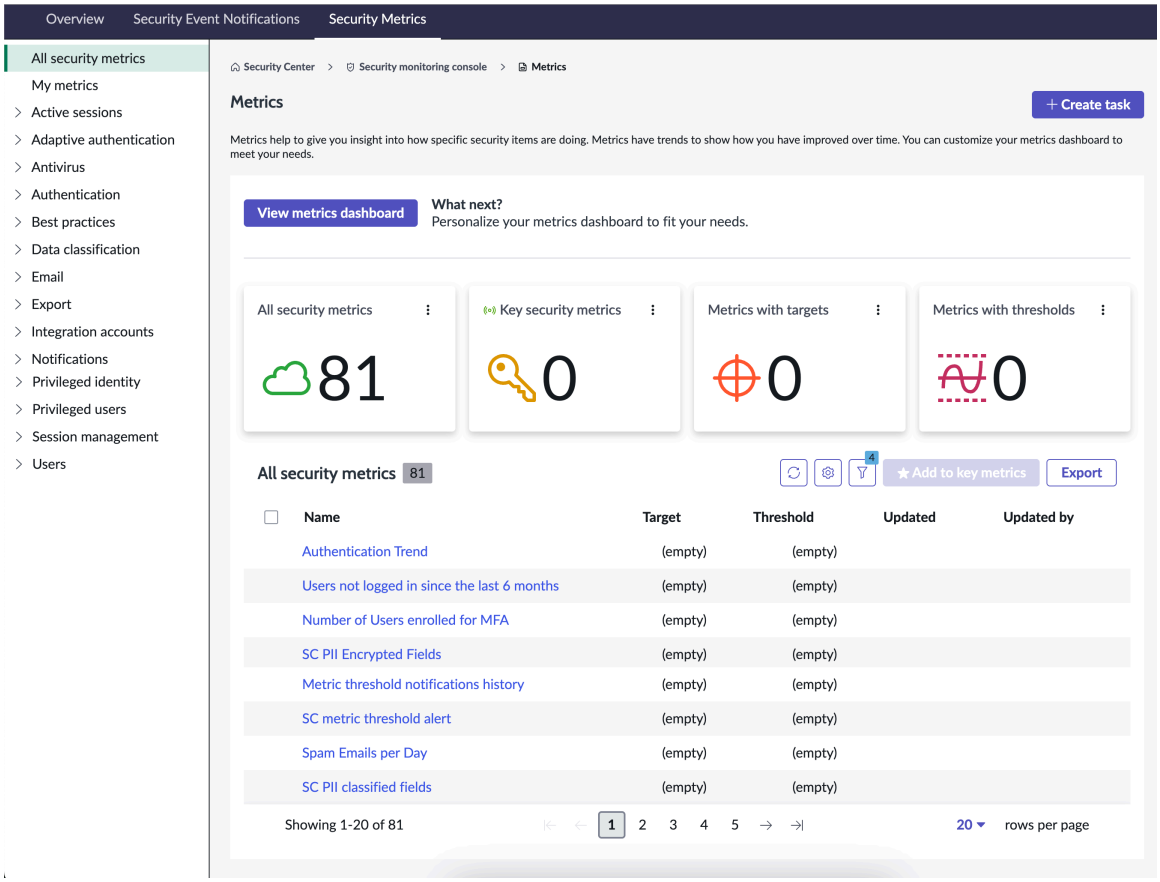
The **Notifications** page provides an overview of the notification history for all security event notification policies on your instance. You can view the data in charts, presenting it graphically and applying performance analytics functionalities like targets, thresholds, and KPI

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

signals. Alternatively, you can view the data in a table format, enabling you to utilize standard functionalities such as search, sort, filter, and querying.

Security metrics

Monitor over 50 different Security Metrics to identify potential security threats or insecure behaviors. Set thresholds for email notifications, visualize, and analyze the data in multiple ways. Export the data, or create dashboards with the metrics that are most important to your organization.



Access Security Metrics within Security Center by selecting **Security Monitoring** in the tools section. Then, select the **Security metrics** card.

All Security Metrics dashboard

View metrics such as failed logins, exports, impersonations, and more using this dashboard. The cards above the list provide a count of the metrics that match specific criteria listed on the card. Select any of these cards to filter the list to show only those metrics that match the criteria.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

My metrics dashboard

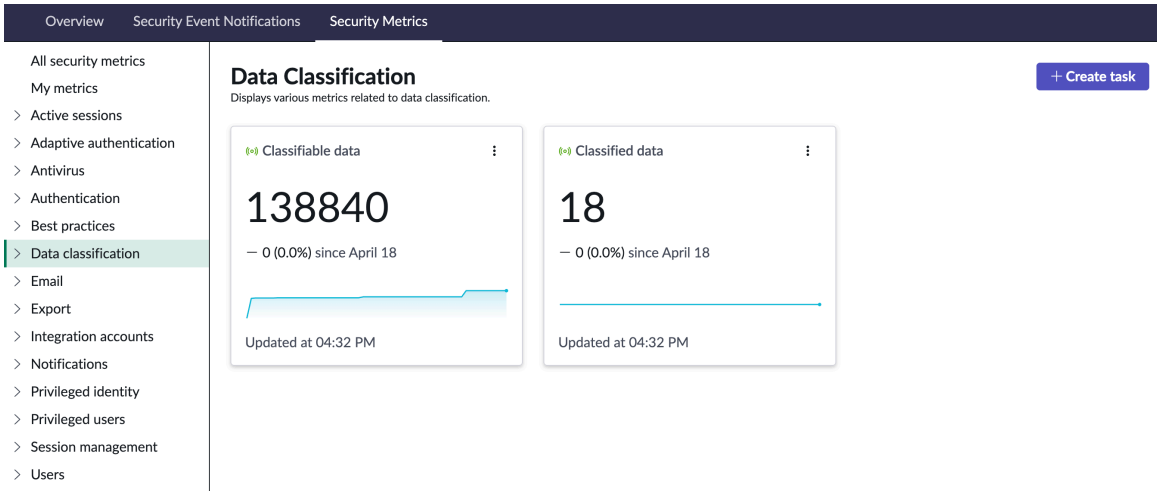
This is a customizable dashboard that displays information about metrics you care about most. Select **Edit** to customize your dashboard by adding visualizations, filters, headings, images, rich text, and lists. To learn about the various ways you can customize your dashboard, see Dashboards in Platform Analytics.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Metrics navigation pane

The navigation pane on the edge of the screen displays your instance metrics. Select **All Security Metrics** to view all metrics in a single list. Select any of the items under **All Security Metrics** the entry to browse the metrics organized by category.

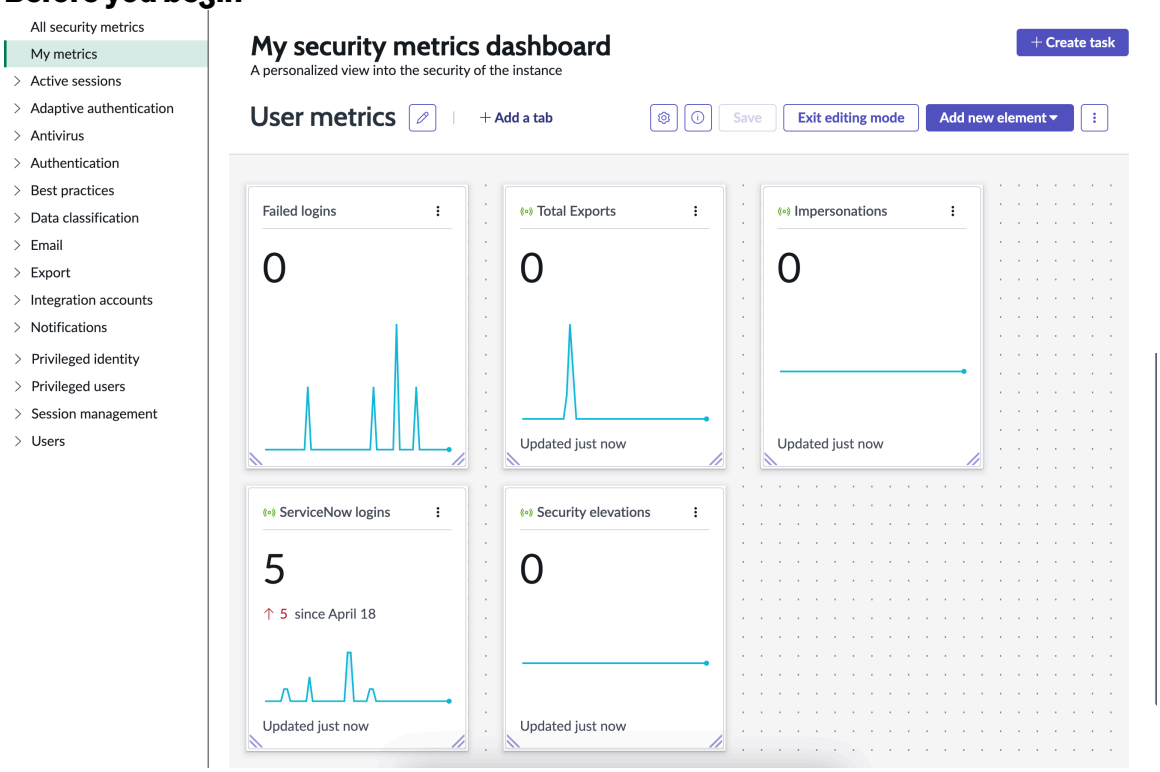
Each category displays a dashboard similar to the security **My metrics dashboard**, with cards for the metrics in that category.



Customize the My security metrics dashboard

Discover the flexibility of the My security metrics dashboard, which can be customized with metrics from various sources like graphs and charts. Tailor the dashboard to suit your organization's specific requirements.

Before you begin



To customize the Security Metrics dashboard, confirm you are within the Security Center application scope. To switch to this scope, select **application picker** > **Application scope**, and type security center.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Role required: admin

About this task

Implement and customize My security metrics dashboard. Add metrics and content to your dashboard from a variety of sources, such as graphs and charts generated from a report. Learn the steps required to add a tab to your dashboard so that you can customize it to meet your organization's needs.

Procedure

1. Access Security Metrics within Security Center by selecting **Security Monitoring** in the tools section, and selecting the **Security metrics** card.
2. Enter edit mode by selecting **Edit**.
3. Create a tab by selecting **+Add a tab**.

   Note:
   You can also add a new tab by selecting the **plus (+)** icon next to an existing tab.

4. Edit the title of your newly created tab by selecting the pencil icon and entering a name.
5. Add an element to your tab by selecting **Add a new element**.
6. Select **Save**.
7. **Optional:** To share the dashboard with users, groups, and roles in your organization, select **More actions menu** > **Share**.
   a. Enter the name of a user to grant access to.
   b. Select **Confirm**.

Configure Security Metrics to send email when thresholds are triggered

Learn how to configure Security Metrics so that your instance generates an email notification when a threshold is triggered.

Before you begin

Role required: admin

Procedure

1. In the Security Center, navigate to **metrics**.
2. Select a metric that you want to set a threshold for in your organization.

   Example
   To manage failed logins, you can set a threshold. When the number of failed logins reach this threshold, admins or security experts in your organization are notified. The appropriate Security Metric to target in this case is **users** > **failed logins**.
3. Select the **Thresholds** icon.
4. Select the **plus (+)** icon on the thresholds panel to configure the form.
   The options available are to set the visibility, threshold type, and threshold value.

   a. For visibility, select **for everyone** if you want everyone to receive the notification, or **for me** if you only want to receive a notification.

   b. In **threshold type**, select **all time high**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

This field triggers the threshold notification.

> **Note:**
> A threshold value must only be entered when the **Threshold Type** is set to **Less than** or **More than**.

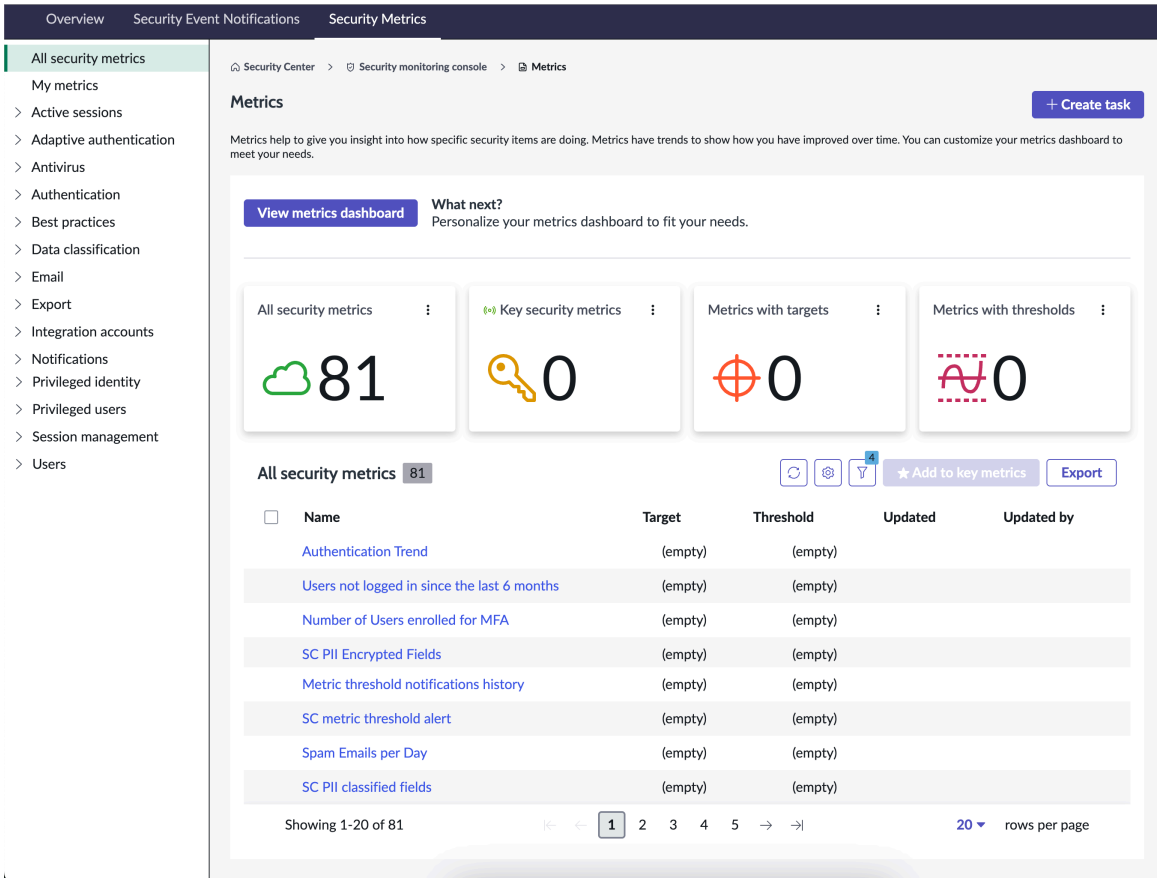
5. Select **save** to create the threshold.
   Next, the notification must be set up.
6. Select **all**, and enter **system notification**.
7. Navigate to **email** > **notifications**.
8. In the **name** column, enter `*pa thre`.
   The threshold notifications are event-based, and they're set up in the PA Thresholds Notification table.
9. Select **PA Thresholds Notification**.
   There are three tabs in the results:
   - When to send: Specifies what must occur to send the email notification. In this example, once the threshold you previously set is reached, the email is triggered.
   - Who will receive: Specifies which users receive the notification. You can add users and groups.
   - What it will contain: Specifies the script action that a user can modify to customize the message that users and the group will receive. To learn more about creating script actions, see Script actions.

All Security Metrics

Navigate to **All Security Metrics** to view a table with the data related to the Security Metrics of your instance.

Access the list of all Security Metrics on a filterable list by accessing the Security Metrics Dashboard, and selecting the **All Security Metrics** option on from the list on the left.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Select any item on the list to view details on each metric.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Active Sessions

View the trend line of the active users on the ServiceNow AI Platform.

This page displays cards with information on metrics related to active sessions. Each card displays a trend line for the following metrics:

- User sessions: Metrics related to active user sessions on your instance.
- Privileged user sessions: Metrics related to privileged users or those who have been assigned additional roles.

Select the cards to view the individual metrics page with additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Adaptive authentication Security Metrics

Use authentication policies to evaluate authentication requests and deny or allow access to your instance based on the specified policy conditions.

Adaptive authentication metrics enable you to monitor how adaptive authentication is being used on your instance. View a summary of all of your metrics on Adaptive authentication, individual metrics such as policy result rates or denied IP addresses. This page requires the Adaptive Authentication (*com.snc.adaptive_authentication*) plugin for adaptive authentication to be available in your instance. You must enable Authentication Policy to see the

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

metrics. See Activate adaptive authentication and Configure adaptive authentication properties for more details.

Note:
This feature was released with version 1.2.

- Policy result rates: All the successful and failed adaptive authentication events.
- Event failure distribution: All the failed events for each event type.
- Event success distribution: The successful events associated with every event type.
- Denied IP addresses: The number of IP addresses blocked by the instance, along with their associated data.
- Authenticated user logins: The number of events counted for each event type, excluding the pre-login event.
- API user logins: The number of events associated with API Authentication policies for each event type.
- Authentication trend: The total number of events recorded.
- Authenticated users: The number of users counted for each event type, excluding the pre-login event.

Select the cards to view the individual metrics page with additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Antivirus

Displays the trend of when events occur on potentially infected files. See when they are discovered, placed into quarantine, restored, or deleted.

This page displays cards with information on metrics related to antivirus activity on your instance. Each card displays a trend line for the following metrics:

- Quarantined files: The number of files that potentially contain malware.
- Downloaded files: The number of downloaded files.
- Restored files: The number of files that have been restored.
- Deleted files: The number of deleted files.

Select the cards to view the individual metrics page with additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Authentication

View trends for metrics related to authentication schemes, such as Multi-Factor Authentication(MFA) use, web service accounts, and biometric scanner usage.

This page displays cards with information on metrics related to authentication. Each card displays a trend line for the following metrics:

- Users enrolled for MFA
- Users using MFA
- High privileged non-MFA users
- Active MFA users

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Locked out MFA users
- Web service account only
- X509 certificates expiring in 30 days
- Biometric scanner/hardware key users
- REST API's Without Access Policy
- Integration Accounts without Web Service Access Only Flag enabled

Select the cards to view the individual metrics page with additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Data Classification

Access the Security Metrics for data classification on your ServiceNow instance.

Data classification enables you to apply data classification labels to existing dictionary entries in any table. These labels help to provide visibility into the types of data hosted in your instances. Use these classifications to comply with privacy laws, and meet industry regulation requirements.

See data classification for more information.

- **Classifiable data**: Tables or columns that can be classified.
- **Classified data**: Dictionary entries, tables, or columns that are classified.

The data is graphically displayed in a customizable chart that provides detailed analysis such as setting targets, thresholds, trends, statistics, or forecasts. The data is also organized as records in a table. See Analytics Hub for more information.

Select the cards to view the individual metrics page with additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Authentication metrics

View metrics related to authentication on your instance from a dashboard.

This page displays cards with information on metrics related to authentication. Each card displays a trend line for the following metrics:

- Users enrolled for MFA: Total count of users enrolled to use MFA.
- Users using MFA bypass: Total count of users who are circumventing multi factor authentication.
- High privileged non-MFA user: Total count of high-privileged users that are not using MFA.
- Active MFA users: Total count of MFA users that are active on your instance.
- Locked out MFA users: Total count of MFA users who are locked out on your instance.
- Web service account user: Total count of users with web service account only.
- X509 certificates expiring: Total count of X509 certificates that are expiring in the next 30 days.
- Biometric scanner/Hardware key users: Total count of users login with biometric scanner or Hardware key.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- REST API's Without Access Policy: Total count of users login without REST API's Access Policy.
- Integration Accounts without Web Service Access Only Flag enabled: Total count of users login without Integration Accounts Web Service Access Only Flag enabled.

Select the cards to view the individual metrics page with additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Email

Displays data related to spam emails that are being received externally.

The page displays a card displays a trend line for the spam emails, representing the number of junk mail received per day.

Select the card to view additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Export

Discover the data that is commonly exported, and which users do the exporting.

This page displays cards with information on metrics related to export. Each card displays a trend line for the following metrics:

- Total exports: Total count of table records exported by user.
- Classified exports: Total count of table records exported, summarized by the data classification assigned to them.

Select the cards to view the individual metrics page with additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Integration Accounts

View the trends about the integration accounts that are created on the ServiceNow AI Platform.

This page displays cards with information on metrics related to integration accounts that are created on the ServiceNow AI Platform. Each card displays a trend line for the following metrics:

- Total integration accounts: Trends related to integration accounts on your instance.
- Active integration accounts: Trends related to active integration accounts on your instance.
- Inactive integration accounts: Trends for the total count of integration accounts that are inactive on your instance.

Select the cards to view the individual metrics page with additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Privileged Identity

Analyze data related to metrics for users with privileged identity.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

This page displays cards with information on metrics related to privileged identity users and their activity on your instance. Each card displays a trend line for the following metrics:

- Admin logins: Total count of logins with users of the admin role.
- Impersonation: Total count of impersonations performed by users with the impersonator role.
- Elevation: Total count of security elevations performed by users with the security_admin role.
- ServiceNow logins: Total count of logins by ServiceNow employees.
- Admin users added: Total number of users given the admin role.

Select the cards to view the individual metrics page with additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Privileged Users

View the trend line for the privileged users (active and inactive) and their activity on the ServiceNow AI Platform.

The Privileged users overview section displays the trend line for the privileged users (active and inactive) and their activity on the ServiceNow AI Platform. Privileged users are users who have been assigned additional roles by admins to access the features like High Security Settings, Import, and Portal users.

Below is an explanation of the privileged users:

- Total users: Total count of users on your instance.
- Active users: Total number of users who initiated sessions on your instance.
- Inactive users: Users who have not recently logged into your instance.
- Inactive users who are not locked out: Users who have not recently logged in but still have access to their account.
- Locked out users: Users who are not permitted to authenticate into their account.
- New users: Users who have recently been added to your instance.
- Successful logins: Users that have successfully logged in.
- Failed logins: Unsuccessful login attempts.
- Local logins not protected by MFA: Users that logged in without MFA.
- Users never logged in: Users that have never logged into your instance.
- Users not logged in since last month: Users that have not logged in the last 30 days.
- Users not logged in since the last 6 months: Users that have not logged in the last 6 months.
- Users not logged in since the last 1 year: Users that have not logged in the past year.
- Need to reset password: Users that need to reset their password.
- Password reset failures of the users: Number of password failures per user.

Select the cards to view the individual metrics page with additional details.

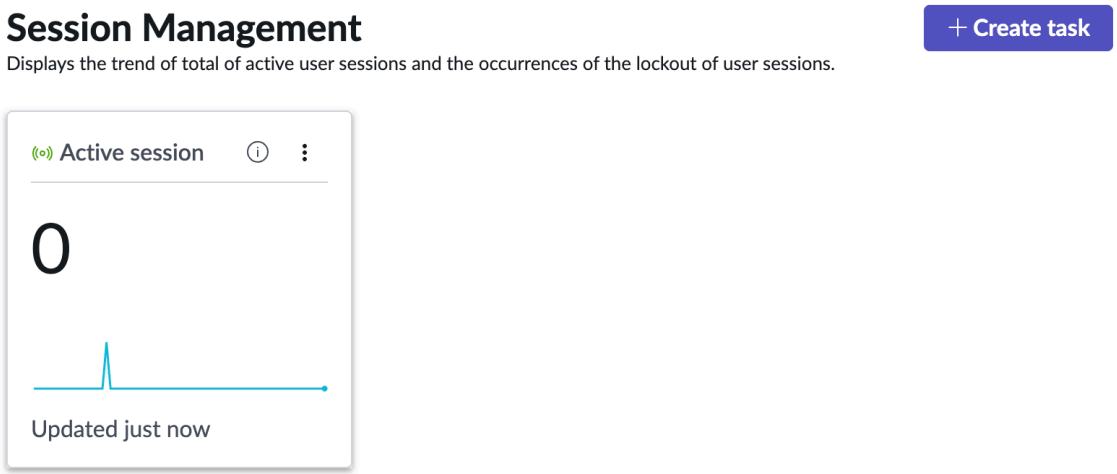
Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Session management

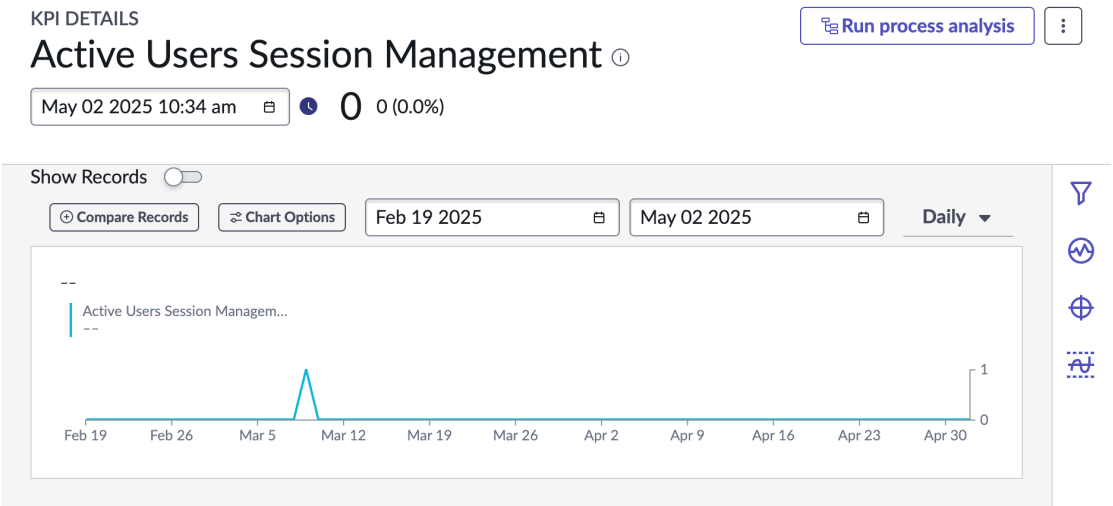
View metrics related to user sessions and the frequency of lockouts of the sessions.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The page displays a card displays a trend line for active sessions, representing the number of active sessions on your instance.



Select the card to view additional details.



From the details page, you can use the buttons on the edge of the screen to configure filters, KPI signals, targets, and thresholds.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Users

View the trend line for total users (active and inactive) and their activity on the ServiceNow AI Platform.

The Users overview section displays the trend line for total users (active and inactive) and their activity on the ServiceNow AI Platform.

Below is an explanation of the type of users:

- Total users: Total count of users on your instance.
- Active users: Total number of users who initiated sessions on your instance.
- Inactive users: Users who have not recently logged into your instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Inactive users who are not locked out: Users who have not recently logged in but still have access to their account.
- New users: Users who have recently been added to your instance.
- Successful logins: Users that have successfully logged in.
- Failed logins: Unsuccessful login attempts.
- External logins: Authentications that uses a 3rd party.
- Local logins not protected by MFA: Logins that do not use MFA.
- Users not logged in since last month: Users that have not logged in the last 30 days.
- Users not logged in since the last 6 months: Users that have not logged in the last 6 months.
- Users not logged in since the last 1 year: Users that have not logged in the past year.
- Need to reset password: Users that need to reset their password.
- Password reset failures of the users: Number of password failures per user.

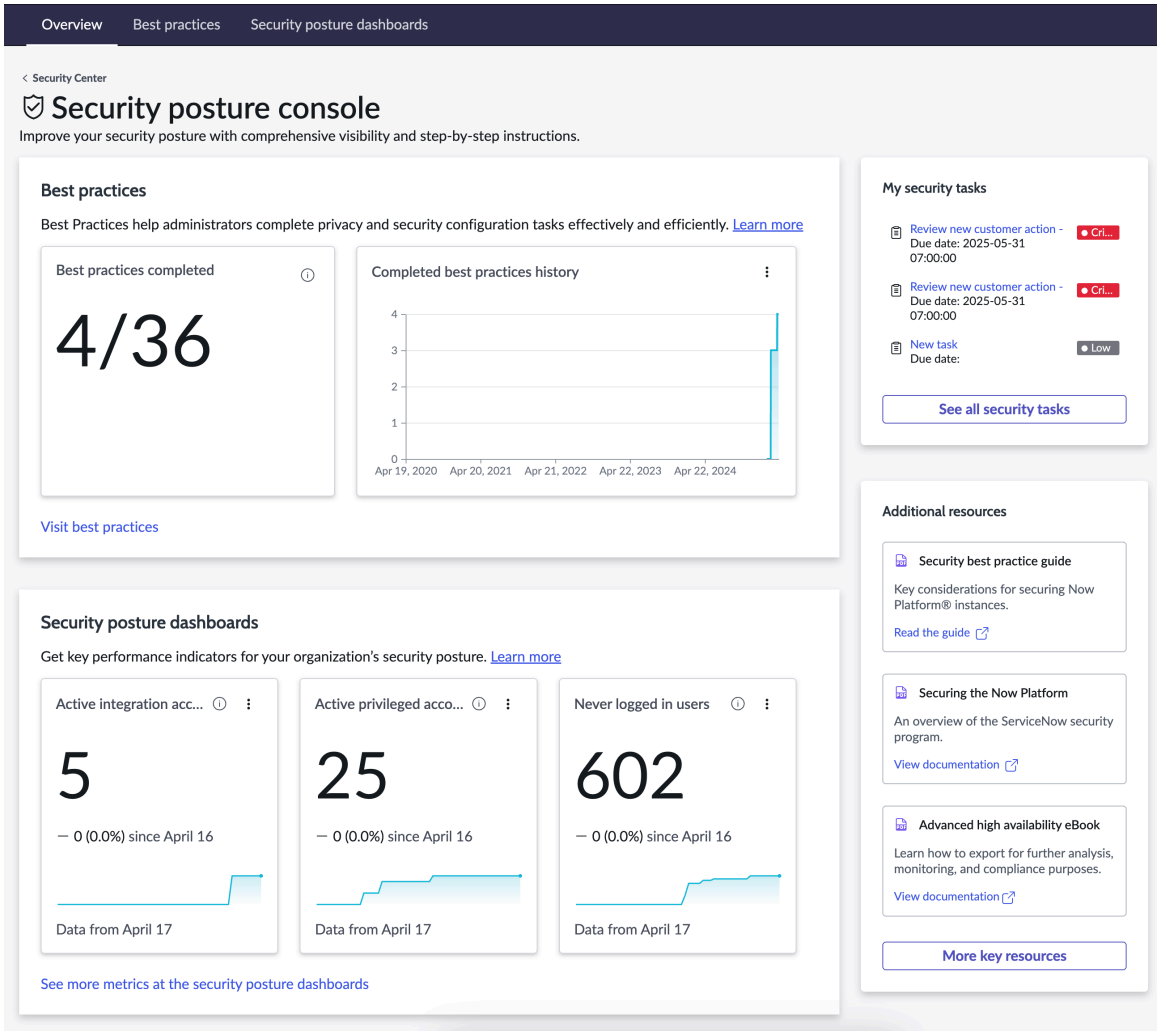
Select the card to view additional details.

Select the **+Create task** button to create a Security Task related to a metric. For details on Security Tasks, see Security Tasks.

Security posture console

Improve your ability to identify, respond to, and recover from security threats with comprehensive visibility and step-by-step instructions.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



The security posture console is divided into sections to provide information about best practices and security posture dashboards. Find additional details by selecting any of the cards in these sections. You can also use the bar at the top of the page to navigate between this page and the best practices and security posture dashboards section of Security Center.

Best Practices

This section displays the count of best practices, and how many you have applied to your instance. You can see a chart showing your completed best practices over time.

Security posture dashboards

This section displays the number of active integration accounts, active privileged accounts, and users that have never logged in.

Active integration accounts

Integration accounts are user accounts that manage integrations between your instance and third party applications.

Active privileged accounts

Privileged users are users who have been assigned additional roles by admins to access the features like High Security Settings, Import, and Portal users.

Never logged-in users

User accounts that have never logged in to your instance.

My Security Tasks

View the most urgent Security Tasks assigned to you. Select a task to view its details, or select **See all Security Tasks** to view a complete list of Security Tasks.

Additional resources

Use the additional resources section on the edge of the screen to navigate to documentation and videos relevant to learning Security Center as well as information on managing instance security.

Security Best Practices

Use Security Best Practices to implement privacy and security configuration tasks on your ServiceNow instance.

Identify best practices to improve your security posture, and follow step-by-step instructions on how to implement them. Security Best Practices provide the following:

- The home page shows an overview of your progress on implementing security best practices. You can also organize and manage lists of security best practices according to your organization's goals.
- The overview page provides details of each security best practice, the steps to implement them, and a record of all activities and comments.
- The task steps page provides you with instructions on how to implement security best practices.
- The activity page tracks the history of the user and system actions related to your security best practices.

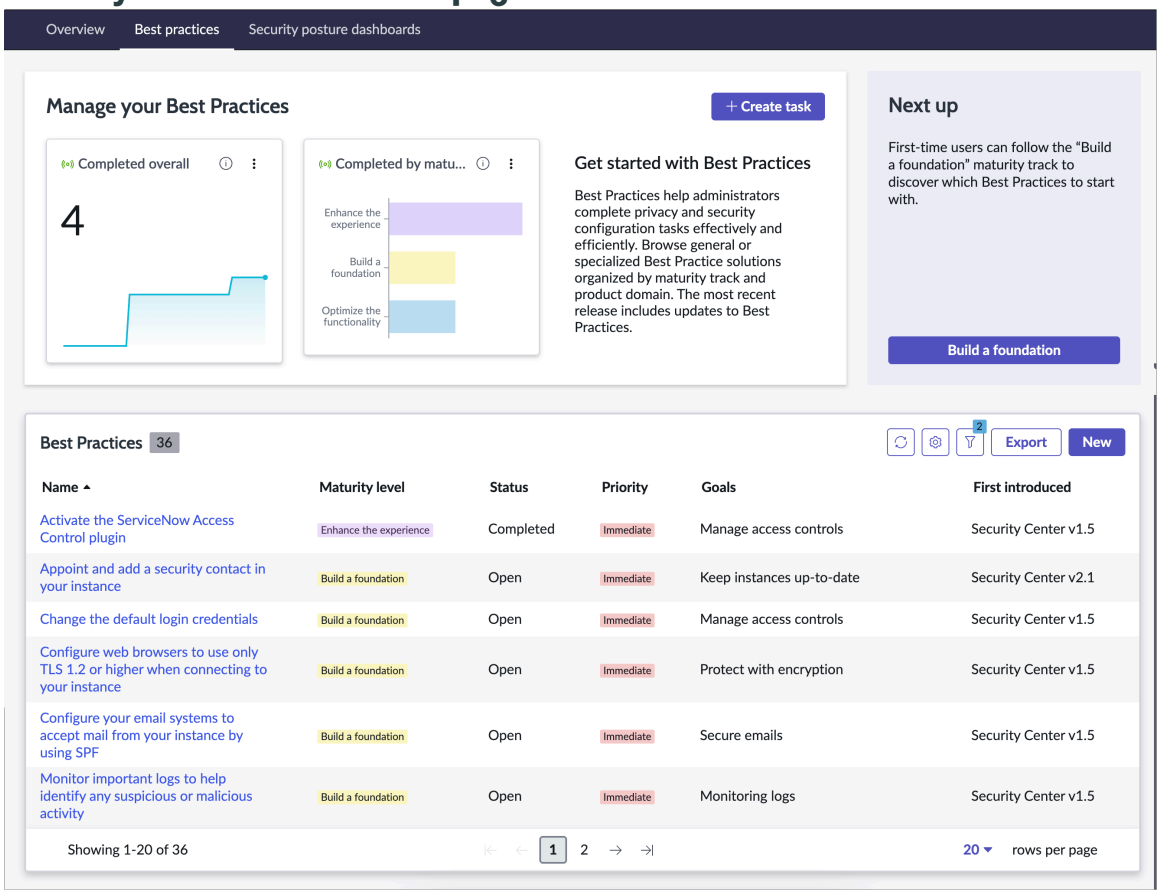
Security Best Practices home page



The home page displays a **Manage your best practices** section, which includes graphs provide an overview of your progress.

Completed overall

Displays a count and trend line of best practices you have completed. Select the card to view the **Completed Overall** metric page in Security metrics.

Completed by maturity level

Displays a chart of completed best practices organized by maturity level (see a description of maturity levels in the proceeding table). Select the card to view the **Completed by Maturity Level** metric page in Security metrics.

Build a foundation

Select the **Build a foundation** button to filter the table on this page to display only best practices in the **Build a foundation** maturity level. These are lower impact changes you can make to start improving instance security.

Create a task

Use the **+Create task** button to create a Security Task to track or delegate best practice work. For details on Security Tasks, see Security Tasks.

The table enables you to apply filters so that you can sort and save filtered lists, which you can use as work lists for different use cases or roles. See save a filtered list for more information.

The following are explanations of the fields related to the security best practices table.

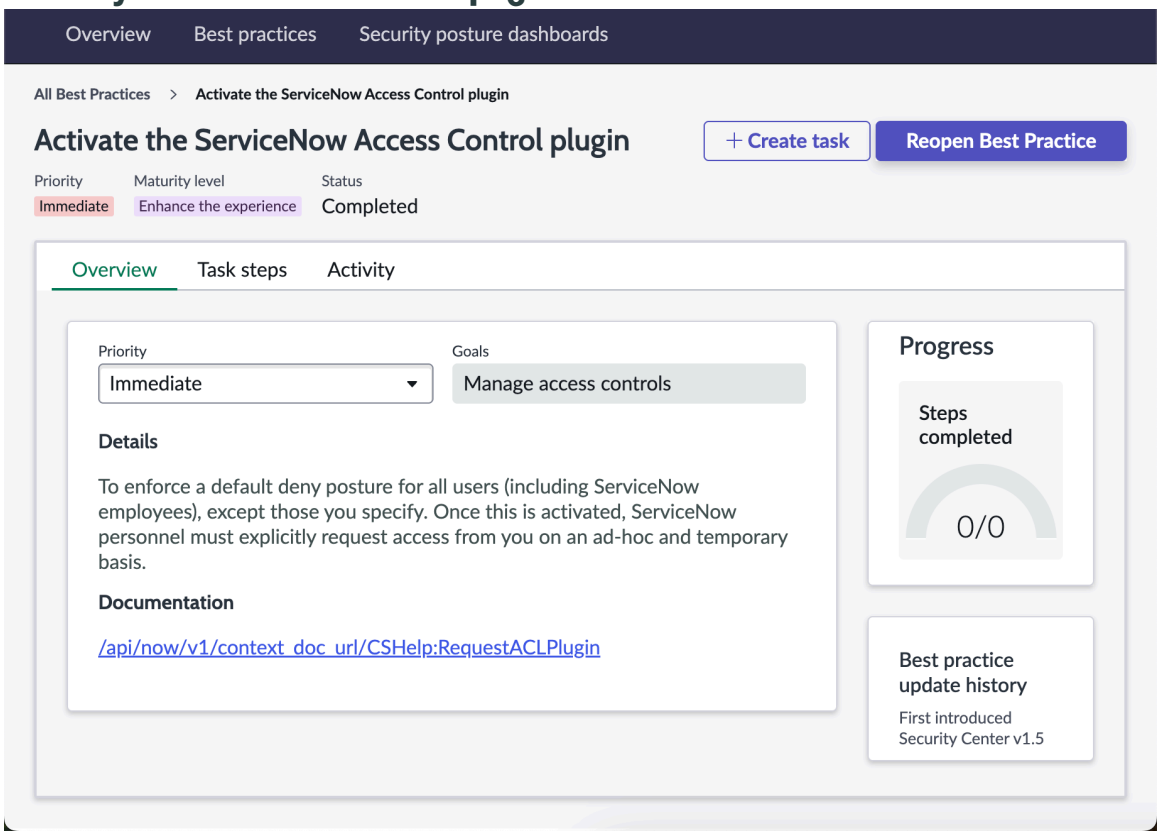
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Summary of fields used in the security best practices table

Name	Description
Name	Word used to identify a security best practice.
Maturity level	Applications and features that have been arranged by the order of impact to provide you measurable results. The values for maturity levels are: • Build a foundation • Enhance the experience • Optimize the functionality • Add advanced features These can also be thought of as crawl, walk, run, and fly phases.
Status	Current state of a best practice: • Open • In progress • Completed
Priority	Order of importance for implementing a best practice in your organization: • Immediate • Later • Not applicable
Goals	Security category that a best practice addresses: • Address initial security configurations • Secure emails • Monitoring logs • Manage access controls • Protect with encryption • Keep instances up to date
First introduced	Which Security Center version the best practice was introduced.
Changed	Which Security Center version the best practice was changed.
Removed	Which Security Center version the best practice was removed.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Security Best Practices details page



Select a best practice from the table to view its page. At the top of the details page, you can view general information about the security best practice including priority, maturity level, and status. Use **Complete Best Practice** button to mark a the practice as complete, or **Reopen Best Practice** button to mark the practice complete. Use the **+Create Task** to create a Security Task to track and delegate this task. For details on Security Tasks, see Security Tasks.

This page provides more information on the best practice, divided into tabs:

Overview

This tab contains the **Priority** drop-down menu, which enables you to specify the security best practices that are important to you at this time and which are not applicable.

The details section provides content about the features associated with the security best practice, and the documentation section provides one or more links where you can find additional information.

The **Progress** card on the right shows the number of steps completed versus the total number of steps included. Select **go to next step** to navigate to the next incomplete step.

The **best practice update history** card provides a snapshot of the release information for the best practice. You can track which ServiceNow Security Center version the security best practice was released in, and which versions it was subsequently last updated in.

Task Steps

This tab provides step-by-step instructions for how to implement this security best practice. See complete a security best practice for more information.

Activity

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

This tabe displays timestamped activities listed from newest to oldest. Use search and filter to query for information. See apply filters to the security best practices table for more information.

Complete a security best practice

Learn how to complete a security best practice on your ServiceNow instance.

Before you begin

Role required: admin

About this task

Complete the following steps to implement security best practices on your ServiceNow instance.

Procedure

1. Access Security Best Practices by selecting **All** on your ServiceNow instance and then entering **best practice**.
2. Apply a filter to view security best practices to implement.
   a. Navigate to the **Best Practices** table in the UI.
   b. Select the kebab menu, or the item with three vertical dots (⋮) in the **Status** column.
   c. Select the **Open** and **In progress** options, and then select **apply**.
3. Select the name of a security best practice to implement.
4. Select **Go to next step**.
5. Select a task step from the **task steps** list.
6. Select the caret down (v) icon to view the implementation instructions for that step.
7. Read the instructions and then implement them on your ServiceNow instance.
8. Select **Mark step complete** when you're done with the task.

   Note:
   You can skip the task if you want to come back to it later, or if it doesn't apply to your organization's goals. In addition, you can reopen a completed task step by selecting the task step, and then selecting **Restart step**.

9. Select **Complete Best Practice**.

   You can complete a security best practice at any time. You don't have to complete all the steps and it's ok if you skip them. However, consider inserting a comment in the Activity subtab when completing a security best practice when you have not completed all the steps for an audit reference.

View activity of a best practice

Track the chronological and timestamped history related to a security best practice that you're completing on your ServiceNow instance, along with the user that initiated the activity.

Before you begin

Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Access Security Best Practices Manager by selecting **All** on your ServiceNow instance and then enter best practice.
2. On the Best Practices table, select a security best practice you want to view the activity for in the **Name** column.
3. Select the **Activity** tab.

   Examples of activity that you can view includes field changes such as if the status of a security best practice has changed from Open to Complete, or when a task step is completed or skipped. In addition, you can enter additional information related to an activity by entering in a comment in the text box.

View data of completed best practices

See visual representations of the total amount of best practices completed, or segmented by maturity level.

Before you begin
Role required: admin

About this task
Complete the actions to see charts that provide visual trends of security best practices that were completed overall, and by maturity level.

Procedure

1. Access the Security Center app and navigate to the **Best Practices** tab.
2. Under the **Manage your Best Practices** card select the **Completed overall** chart.
3. View the chart to see trends regarding security best practices configurations that were completed.
4. Select **Completed by maturity level** to see a chart, which displays trends of best practices completed by maturity level.

Filters the security best practices table

Apply filters to return more relevant results for your security best practices.

Before you begin
Role required: admin

Procedure

1. Access Security Best Practices Manager by selecting **All** on your ServiceNow instance and entering best practice.
2. Navigate to the **Best Practices** table and select a field you want to apply a filter to by selecting its kebab menu, or the one with three vertical dots (⋮).

Save a filter for future use

Discover the steps for saving filters in your security best practices for later reuse.

Before you begin
Role required: none

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

About this task
After you create filters in the security best practices table, you can save them for use the next time you authenticate into your instance. If you want more flexibility on the type of filters you can create, you can apply an advanced filter.

Procedure

1. Select the Show filter ( ) panel icon.
2. In the **Filter** dialog panel, scroll down and select **Advanced view**.
3. Build a filter by adding conditions that contain a field, operator, and values.
4. Select **Save filter**
5. Enter the Filter name.
6. Select a permission.
7. Select **Save**.
8. Select **Update** to apply the saved filter to the security best practices table.

Use a saved filter

Discover the steps for using the filters that you saved for your security best practices.

Before you begin
Role required: none

About this task
After you log out of your instance your filters are reset to the default settings. The following steps show how to retrieve a saved filter so that you can reapply it on the security best practices table.

Procedure

1. Select the Show filter panel ( ) icon.
2. In the Filter dialog box, scroll down and select **Advanced view**.
3. Select **Use existing filter**, and then select a saved filter from the dropdown list.
4. Select **Update** to apply the saved filter.

Best Practices

Learn details about the Best Practices in the Security Posture Console.

Best Practice	Description
Activate the ServiceNow Access Control plugin	Use the ServiceNow Access Control plugin to control which employees can access your instance, and when. Enforcing a default deny posture for all users except those users you specify. This can include ServiceNow employees. Using this plugin helps prevent unwanted access to your instance. **Note:** After ServiceNow Access Control is activated, personnel must explicitly request access from you on an ad-hoc and temporary basis.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Best Practice	Description
	For details on this plugin, see ServiceNow access control.
Appoint and add a security contact in your instance	Select an information security contact within your organization who receives security-related information from the Security Team. This contact is in addition to your admin, who also receives these updates. This information could be security issues, security alerts, or details about important software updates. For details on adding a security contact, see KB0621516.
Change the default login credentials	Change the passwords on your instance's built-in user accounts, such as admin, ITIL, and employee. These accounts are provisioned with default passwords, unique to your instance, but should be changed as soon as possible. For details on how to change the passwords for user accounts on your instance, see Configure password for a user.
Configure web browsers to use only TLS 1.2 or higher when connecting to your instance	Verify that browsers that connect to your instance are using the more secure Transport Layer Security (TLS) 1.2. This change can be made on the browser or enforced by your web proxy or other gateway. Consult the documentation for your browser, web proxy, or gateway for steps on how to configure those products to use only TLS 1.2.
Configure your email systems to accept mail from your instance by using SPF	If your organization uses Sender Policy Framework (SPF) to control inbound email with anti-spam technology, you must configure it to accept email originating from your instance. Configure SPF to query the SPF records dynamically. If SPF isn't an option, another approach is to add the mail server IP addresses to your allow list. This configuration must be monitored as the addresses could be subject to change. For steps and additional details on these solutions, see KB0535456
Consider limiting file attachments, uploads, and downloads	Restrict attachment uploads by role, file extension, MIME type, or size to help prevent potentially malicious files being stored and then delivered from your instance. You can also control which file types can be downloaded, including by MIME type, and prevent image access by unauthenticated users. These attachment restrictions are controlled by system properties on your instance. For details on their configuration, see Configure attachment system properties.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Best Practice	Description
Disable browser SQL messages	Prevent SQL error messages from being presented in the web browser. Though useful to users and developers, these messages can be used by attackers to learn information about your system or to help guide their attempts to access your data. These messages can be turned off using a system property. For details on this system property, see Disable SQL Error Messages [Updated in Security Center 1.3 and 1.5].
Disable password-less authentication	Help ensure strong authentication by disabling password-less authentication when possible. Without disabling password-less authentication, potential attackers could gain access to your instance by correctly guessing a user name (such as firstname.lastname or a role title). You can disable password-less authentication on your instance using a system property. For details on this property see Disable password-less authentication.
Enable table auditing for important or sensitive data	Track changes to your data using table auditing. Auditing tracks the creation, update, and deletion of all records in the table where it's enabled, enabling admins to track changes to important or sensitive data. Admins can also choose to select specific fields in a table for auditing to see more targeted results or to reduce performance impact. For details on auditing on instances, see Auditing. For specific instructions on enabling auditing on a table, see Configuring auditing for a table.
Encrypt data at rest within the instance	Encrypt your data to maintain its confidentiality and integrity. Data on your instance can be within the database. You can also elect to subscribe to functionality to encrypt the data volume transparently on the backend. The physical disks on which the instance runs can also be encrypted in their entirety to guard data in case of their loss or theft. You can use different methods of encryption simultaneously for data stored in your instance, depending on your use case and the risks you wish to mitigate. For example, you can choose to transparently encrypt your data at rest using database encryption on most tables, cloud encryption on the entire data volume. You could also use full disk hardware encryption, which also requires a dedicated environment to protect against drive or server theft. Review the encryption options available with in Key Management Framework.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Best Practice	Description
Enforce the use of strong passphrases	Use password policies to enforce the length, complexity, expiration, uniqueness, lockout, and more for native and local accounts on your instance. Use these policies to maximize security, encourage the adoption of long passphrases and help to eliminate the use of simple passwords. You can retain your existing policies for any external authentication services you have integrated, such as LDAP or SAML. For details on password policy configuration, see Configure your password policy.
Ensure automatic account creation	Use this feature to create user accounts by email dynamically. Activate this feature only if necessary for your business needs, only after you have defined a list of trusted domains from which accounts can be created. You can also control how passwords are assigned to new accounts created this way. For details on automatic user creation, see Enable automatic user creation.
Ensure Secure Access to knowledge bases	Manage access to knowledge bases and articles to help ensure secure and efficient information sharing. You can determine whether certain users or categories of users can access knowledge bases and knowledge articles by controlling contribute and read access. The specific configuration depends on your business needs. Learn about your options for configuring knowledge access at Managing access to knowledge bases and knowledge articles.
Ensure that the High Security plugin is installed and activated	Use the High Security plugin (HSP) to enhance security management and applying appropriate settings. High Security Settings provides a central location for security settings, creates a distinct security administrator role, a default deny property, and other important security features. HSP is installed and enabled by default on all new instances. You can request HSP activation for older instances, including instances that have had upgrades from an older version. Enabling HSP should be done only after careful testing in a non-production environment, as activation changes some fundamental properties and behaviors. For more details on the High Security plugin, see Enable High Security Plugin [Updated in Security Center 1.3].
Familiarize yourself with NOW security resources	Security information constantly evolves, so it's crucial to stay updated with security resources to keep your information security strong.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Best Practice	Description
	Use the following resources to stay informed about security resources: • CORE Directory: ServiceNow CORE Compliance Portal • Securing the ServiceNow AI Platform: How ServiceNow protects customer data • Secure your instance
Harden your Instance	Use the Security Center Hardening tool to reduce risk by limiting weaknesses that could be exploited, and implement recommended settings to secure your instance further. Learn more about Security Center at Security Center. Review the available hardening settings at Hardening settings.
Install patches as soon as possible	Install patches and platform updates as soon as possible help ensure the highest levels of security for both your instance and those of other customers. Keeping current with updates also enables you to maintain continuous support by conforming to the EOL policy. Use Upgrade Center to help manage the process. Security fixes are routinely released for the Now Platform via the patches and hot fixes that accompany product feature updates. Upgrading when new patches and hot fixes are available helps reduce the risk of potential vulnerabilities. Information about Now Platform releases, patches, and hot fixes can be found in the Release Notes section of the product documentation. For more information, see Phase 1 - .
Integrate with MFA	Integrate third-party multi-factor authentication (MFA) with your existing SAML IdP to provide additional login security. MFA provides a high level of security because authentication requires multiple authentication factors. Something the user knows (the password) as well as something they own (a one-time code, mobile phone, or biometric attributes, such as a fingerprint). Learn more about MFA integration at Multi-factor authentication.
Limit accepted email sender domains	Control which domains and users your instance can communicate with via email by using system address filters. These filters can be customized to your requirements. Learn how to configure trusted domains at Designate email domains as untrusted or trusted.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Best Practice	Description
Monitor important logs to help identify any suspicious or malicious activity	The system logs module provides a variety of logs that you can use to troubleshoot and debug transactions and events that take place within the instance. **Event logs** Event logs reveal much about system activity, including login events (successful or otherwise), and privilege escalation. **System logs** System logs contain extensive information about general activity, including configuration changes, system errors, workflows, and inbound / outbound data connections. **Note:** The Event and System logs can also be used to provide an audit trail of any activity by personnel. **Transaction logs** Transaction logs record all web browser-related activity for an instance and can provide details of every request made. Transaction logs can be useful for identifying unusual or malicious activity. **Table auditing and record history** Enable auditing for database tables. Record history is perpetual and enables you to track and view details of any changes made to the data since its creation. By default, only the incident, problem, and change tables are tracked. For other tables, auditing must be enabled manually. **Import logs** You can view detailed information related to data import activity into your instance by checking the import logs. These logs include information about source and status, time, and so on **Outbound web services logs** These show REST and SOAP request activity and can help you to track the volume and destination of connections to external services. Learn more about system logs in System logs.
Monitor login failure rates and create alerts	Monitor for unusual activity such as high numbers of failed logins, especially within short time frames. You can create alerts to send emails when a threshold you define is exceeded. Learn how to configure these thresholds at Indicator thresholds.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Best Practice	Description
Monitor security events	Review the **My security metrics dashboard** to see the available security metrics for your instance, and set thresholds to generate email notifications for notable activity. Examples of notable activity can include: **Privilege escalation** Unexpected modifications made to privileged roles, such as Admin, ITIL_Admin, or any other roles with higher privileges could indicate suspicious actions. **Failed logins** Unusual numbers or patterns of failed logins can reveal potential brute force attempts or password spray attacks. **Admins and high privilege users added** New admin account creation should be checked for validity to help to prevent attempts at unauthorized privileged access.
Monitor your instance's Hardening Compliance level	Ensure that your instances are in compliance with the latest security hardening metrics using the Hardening tool in Security Center. Access this tool in a non-production instance assess impact to your environment. Ideally, the score should be as close to 100% as possible with a minimum score of 83%, without affecting product functionality. Learn more about Security Center's hardening settings tool at Hardening settings.
Refer your developers to the Secure Coding Guide	Help to ensure that your instance is secure and resistant to unauthorized access as possible using secure coding practices. The ServiceNow Secure Coding guide for Instance developers provides an overview of application security-related GlideScriptable classes and methods offered by ServiceNow. This guide is designed to assist and educate developers while creating and modifying the code on the target Instance. Review the guide at ServiceNow Secure Coding guide for Instance developers.
Remove the 'Remember Me' check box	Help prevent unwanted access to your instance by deactivating the **Remember Me** feature. When active, this feature stores a cookie is on the user's computer, which automatically authenticates the user on subsequent visits. This can present security issues if users access your instance from an insecure endpoint, such as a shared computer. Learn more about this feature, and how to deactivate it in Remember me.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Best Practice	Description
Restrict access to your instance from unknown IP addresses	Help prevent unauthorized access to your instance by restricting access from IP addresses unrelated to your organization. Anyone trying to access the instance from an unauthorized IP address are denied. If using this approach, consider allowing only your gateway or web proxy external addresses, as well as addresses from which your users access the instance from, including remote users. You can restrict both outbound and inbound access by IP address. Learn how to restrict access to your instance by IP address in Restrict access to specific IP ranges plugin [Updated in Security Center 1.3].
Review ServiceNow's guidance on password spray attacks	Protect your instance against password spray attacks. These attacks attempt to gain access by testing a commonly used password against multiple accounts in succession. Learn more about spray attacks, and how to protect your instances from them in Password Spray Attack Mitigating Strategies.
Review the Shared Security Model	Understand your shared role as a customer in maintaining the security of your instances by reviewing the Shared Responsibility Model. The Shared Responsibility Model defines the partnership between and the customer, both with specific responsibilities. Learn more at ServiceNow Shared Responsibility Model.
Transfer log data from the instance for archival and reference	Archive your log data to retain it beyond the default 21-day log rotation period. This archival can be achieved using web services requests, the data export feature, the MID Server, or the Log Export Service from the Vault package. Use the following resources to learn more about these methods: • Web services • Exploring Log Export Service (LES)
Use encryption modules with RBAC to further enhance data access control	Learn how to use the Key Management Framework (KMF) to protect the data on your instance using Role-Based Access Control (RBAC). KMF uses cryptographic modules, which enable you to define what data on your instance is encrypted, and what method of encryption to use. Using multiple modules, you can encrypt different areas of your instance with different specifications. Learn how KMF and its components are used to encrypt your data at Exploring the Key Management Framework.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Best Practice	Description
	Learn about cryptographic modules in Cryptographic module overview.
Use of certificate-based authentication with integration providers	Configure traffic to your integration providers using REST/SOAP connections to use certificate-based authentication. Secure Socket Layer (SSL) certificate authentication encrypts data in transit, helping to prevent it from being read as it is sent. Learn more about this configuration in Configure mutual authentication.
Use SAML authentication	Integrate third-party multi-factor authentication (MFA) with your existing SAML IdP to provide additional login security. MFA provides a high level of security because authentication requires multiple authentication factors. Something the user knows (the password) as well as something they own (a one-time code produced by an MFA token or mobile phone, or biometric attributes, such as a fingerprint). ServiceNow supports direct MFA integration with local accounts, LDAP, SSO with SAML, OIDC, or Digest. Adaptive Authentication is a prerequisite for SSO with MFA. MFA can be enabled for specified users and specified roles, and configured for ease of use. For example you can exempt recognized devices for a number of hours. You can view metrics for MFA use in the Security Center. Learn more about SAML authentication using these resources: • SAML 2.0 concepts • SAML 2.0 configuration using Multi-Provider SSO
Use the email filters feature set to deal with suspect inbound messages	Create email filters to filter out messages marked as suspicious by ServiceNow Antivirus Protection. In addition to virus protection, Antivirus Protection analyzes email for malware and SPAM, scoring and the results adding this information to the message in x-headers. You can use these headers as criteria for the Email Filters Plugin to act on if desired. Learn more about ServiceNow's antivirus feature at Antivirus Scanning. Learn how to configure email filters on your instance at Email filters.
Use the Syslog Probe to send logs to your SIEM	Use the ServiceNow syslog probe to send log messages from your instance to a Security Information and Event Manager (SIEM). An SIEM is third-party software or service that can be used for activity monitoring and identifying security events.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Best Practice	Description
	Learn more about ServiceNow syslog probe configuration at Syslog probe.
Use your own mature email security environment	Consider using your own (or third-party) infrastructure to send and receive instance-related email and benefit from more precise perimeter email control. By using your own SMTP, POP3, or IMAP servers, you can control how mail is filtered and received before being sent to your instance. **Note:** Configuration of your own email infrastructure is considered an advanced email configuration, and can optionally use a third-party email infrastructure via OAuth 2.0 email authentication. See your own email vendor documentation and instructions for details.
Validate access using Access Analyzer	Use the ServiceNow Access Analyzer tool to help you compare and analyze permissions for selected users, roles, or groups. You can use this information to troubleshoot access issues, identify who has access to your sensitive data, and determine the correct level of access for users on your instance. Learn more about the benefits of Access Analyzer at Explore Access analyzer.

Security posture dashboards

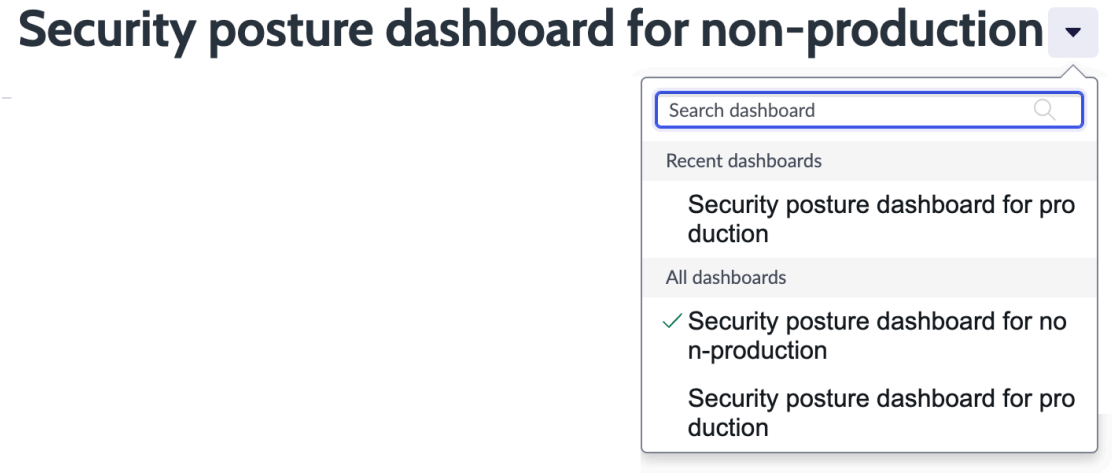
Use the customizable single and multi-instance security posture dashboards to monitor your security KPIs. These dashboards consolidate the important information regarding the security of your instances in a single location and include a number of base system dashboard widgets.

Accessing the Security posture dashboards

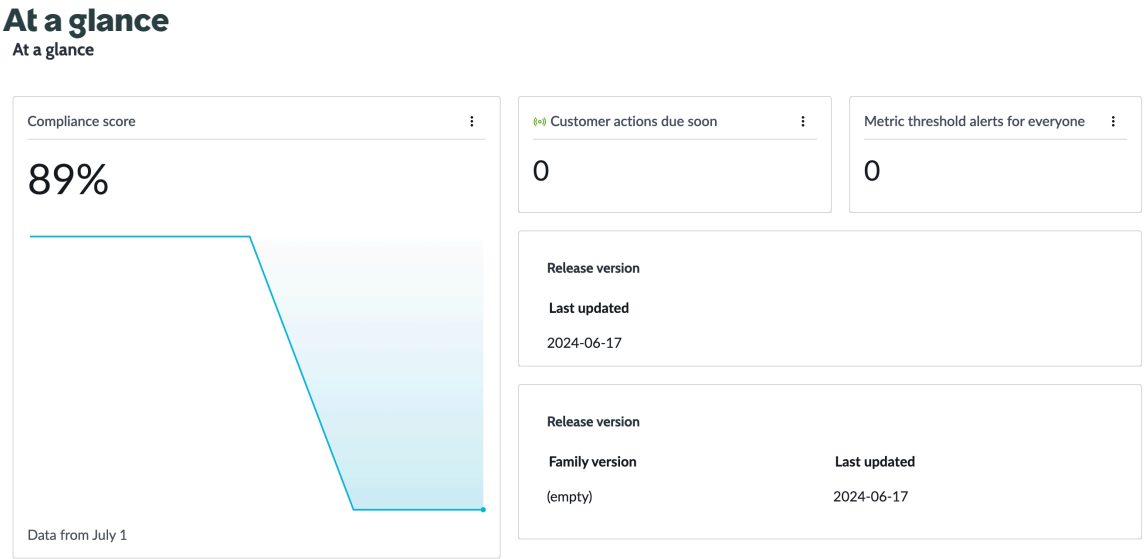
To access the Security posture dashboard, open Security Center by navigating to **All** > **Security Center**. Select **Security posture console** in the **Security consoles** section. On the **Security posture console** page, select **Security posture dashboards** at the top.

Use the down arrow next to **Security posture dashboard** to switch between instance dashboards.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



The dashboard is divided into multiple sections containing widgets related to an aspect of instance security. Select any widget on the dashboard to view more detail on this aspect of your instance's security.



The **At a glance** section displays an overview of security on an instance, such as a compliance score, Customer Actions due, and release information for the instance.

Compliance score

Displays your instance compliance score percentage over time, beginning with the date sown at the bottom of the widget. Select this widget to navigate to the Hardening compliance score trend.

Metric threshold alerts for me

Displays a count of Metric threshold event [n_vsc_metric_threshold_event] records assigned to the current user. Select this widget to navigate to a list of these records.

Metric threshold alerts for everyone.

Displays a count of unassigned Metric threshold event [n_vsc_metric_threshold_event] records. Select this widget to navigate to a list of these records.

Customer actions due soon

Displays a count of customer actions due soon. Select this widget to navigate to Customer Actions.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

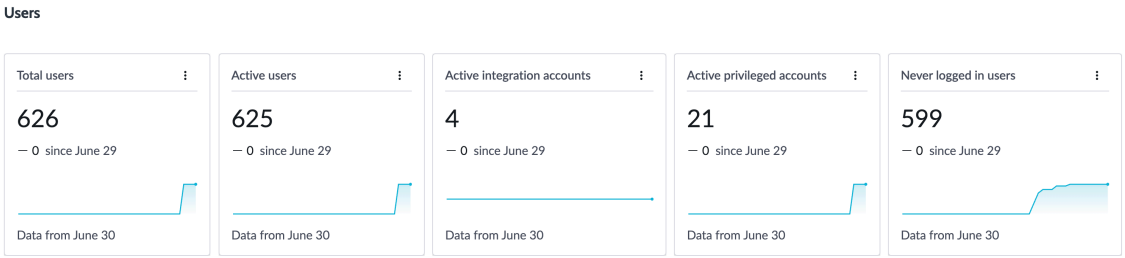
Antivirus downloaded files

Displays a count of files uploaded to your instance that have been quarantined. Select this widget to view these quarantined files in the Antivirus section of Security metrics.

Release version

Displays the family version of the instance and the date of the last instance update.

Users



The **Users** section provides information on the users in your instance. The widgets on this section show user information, and a line graph showing changes to this information over time. Select a widget to view more detail.

Total users

Displays a count of users on your Users [sys_user] table. Select this widget to see details on these records in the Active Sessions section of Security metrics.

Active users

Displays a count of active users on your Users [sys_user] table. Active users are user records where the **Active** field is selected. Select this widget to see details on these records in the Active Sessions section of Security metrics.

Active integration accounts

Displays a count of integration accounts on your Users [sys_user] table. Integration accounts are user records where the **Web service access only** field is selected. Select this widget to see details on these records in the Active Sessions section of Security metrics.

Active privileged accounts

Displays a count of active privileged users on your Users [sys_user] table. Privileged users are user records where the **Active** field is true, the **Internal Integration User** is false, and **Internal Integration User** is inactive. Select this widget to see details on these records in the Active Sessions section of Security metrics.

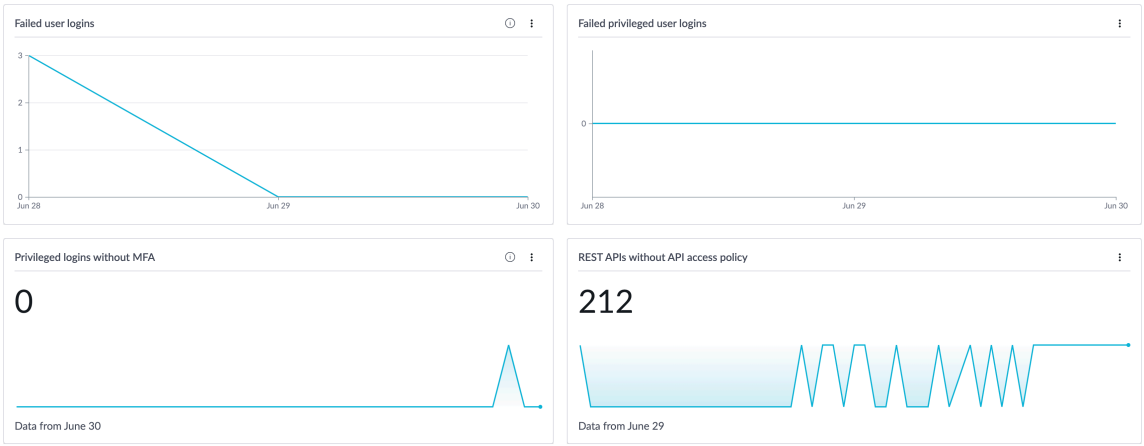
Never logged-in users

Displays a count of users on your Users [sys_user] table created in the last 60 days, and have no value in the **Last login time** field. Select this widget to see details on these records in the Active Sessions section of Security metrics.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Login protection

Login protection



The **Login protection** section includes information on failed logins, including failed login attempts for privileged users. These widgets include a line graph showing changes to this information over time. Select a widget to view more detail.

Failed user logins

Displays a count of failed user login attempts. Select this widget to navigate to see details on failed logins in Security metrics.

Failed privileged user logins

Displays a count of failed user login attempts from privileged accounts. Privileged users are user records where the **Active** field is true, the **Internal Integration User** is false, and **Internal Integration User** is inactive. Select this widget to navigate to see details on failed logins in Security metrics.

Privileged logins without MFA

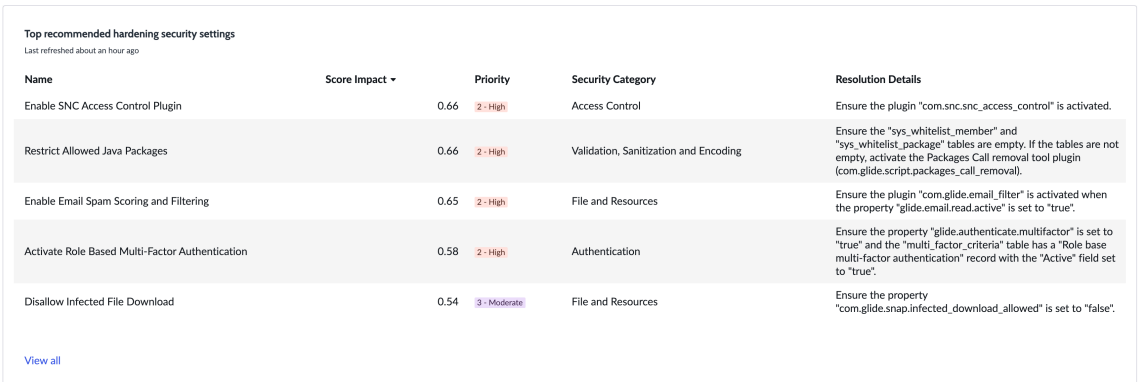
Displays a count of privileged accounts that aren't configured for multi-factor authentication (MFA). Select this widget to navigate to see a list these accounts in Security metrics.

REST APIs without API access policy

Displays a list of REST APIs that aren't restricted with an API access policy. Select this widget to navigate to see a list these REST APIs in Security metrics.

Instance hardening

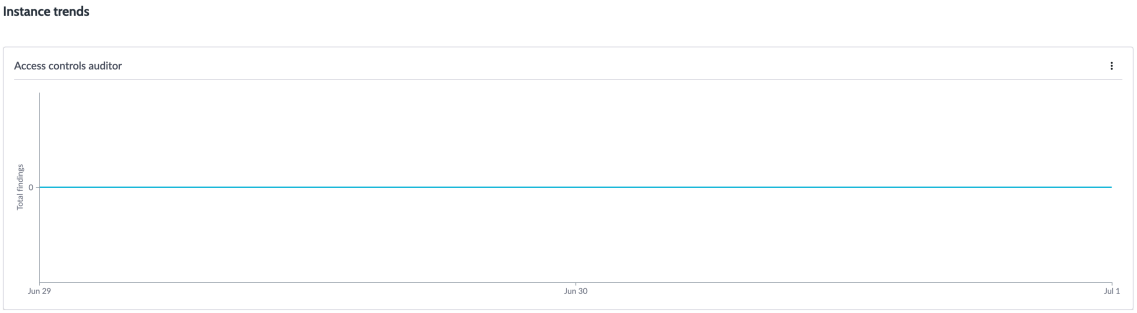
Instance hardening



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

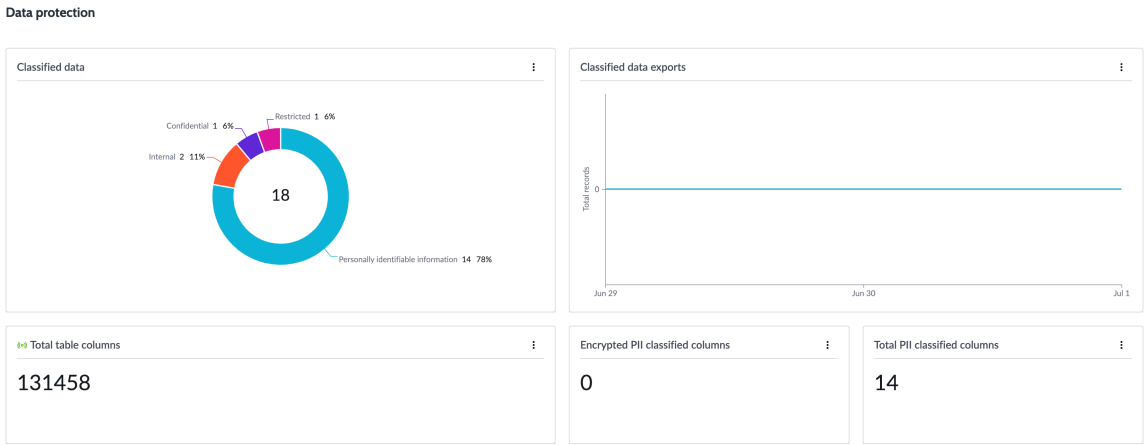
The **Instance hardening** section contains recommended hardening security settings that you can change to improve instance security. Use this section to see the priority and potential impact of these changes.

Instance trends



The **Instance trends** dashboard displays the results of the access controls auditor scan suite.

Data protection



Use the **Data protection** section to see an overview of classified data, such as personally identifiable information (PII). The dashboard also tracks exports of classified data.

Classified data

Displays a pie chart of classified data on your instance, separated by type. Select a section of the chart to view details on these records. For details on data classification, see Data classification.

Classified data exports

Displays a count of classified records that have been exported from your instance. Select this widget to see a list of classified exports in the Export section of Security metrics.

Total table columns

Displays a count of all columns(fields) in tables on your instance. Select this widget to review these columns in the Data Classification section of Security metrics.

Encrypted PII classified columns

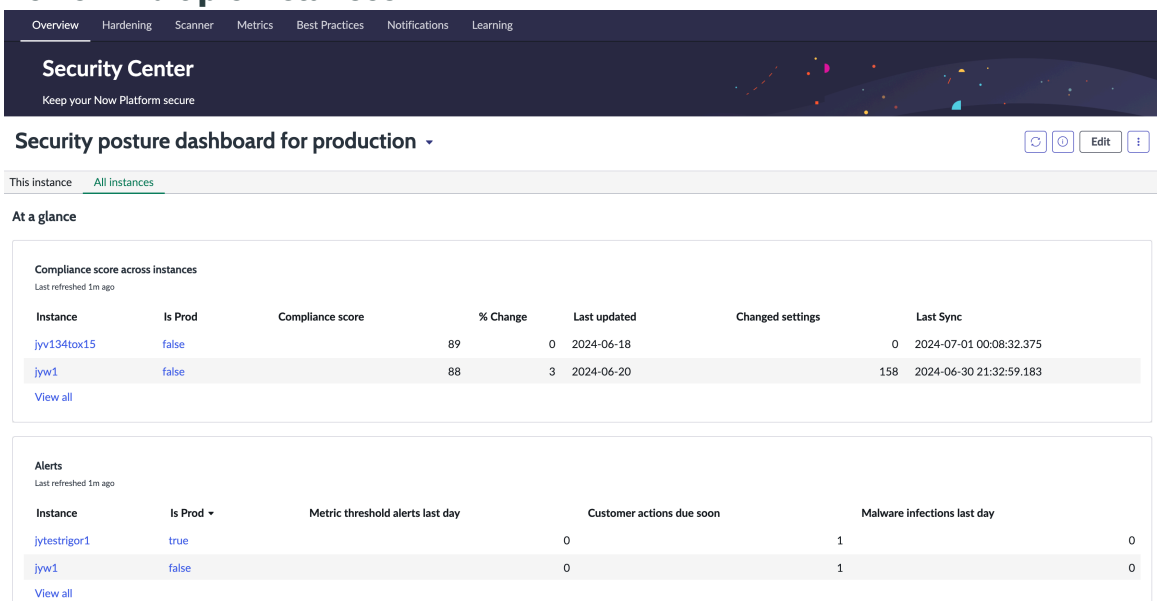
Displays a count of encrypted records classified as Personally Identifiable Information (PII). Select this widget to review these records in the Data Classification section of Security metrics.

Total PII classified columns

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Displays a count of all records classified as Personally Identifiable Information (PII). Select this widget to review these records in the Data Classification section of Security metrics.

Review multiple instances



View the security posture of your non-production instances without leaving your production instance using the **All instances** tab at the top of the dashboard. The **All instances** tab displays a condensed version of the same information as the **This instance** tab, but also includes data from all your non-production instances.

By default, the **All instances** tab displays information on the production instance you're logged in to, and all non-production instances across all your production environments.

You may add or remove instances that appear on this dashboard by modifying your trust configuration. Providing data visibility between instances allows them to appear within your dashboard. For details on this process, see Basic trust configuration for data sync applications.

Dashboard customization

The instance security posture dashboard can't be customized, but you can duplicate the dashboard by selecting the **More Actions** (⋮) icon and selecting **Duplicate**. You can change the duplicate dashboard.

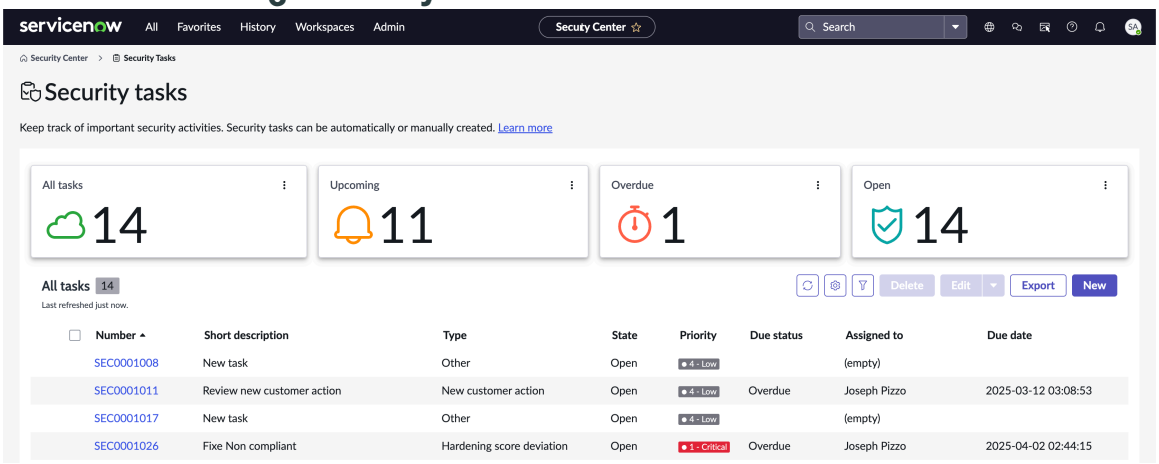
Security Tasks

Use Security Tasks to monitor, prioritize, and assign all your security-related tasks in one place.

Save time tracking and organizing all the tasks needed to improve and maintain your instance security posture using Security Tasks.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Review and manage Security Tasks



Access the Security Tasks by navigating to **All** > **Security Center** > **Security Tasks**. By default, all tasks are displayed in the list. You can easily filter upcoming, overdue, or open tasks by selecting the cards above the list. These cards also display the current count of tasks in each of these categories. You can further refine your filter by using the normal table field filtering options and then selecting the filter button ( ), then selecting the Advanced view button to create and save a custom filters to use later.

User roles

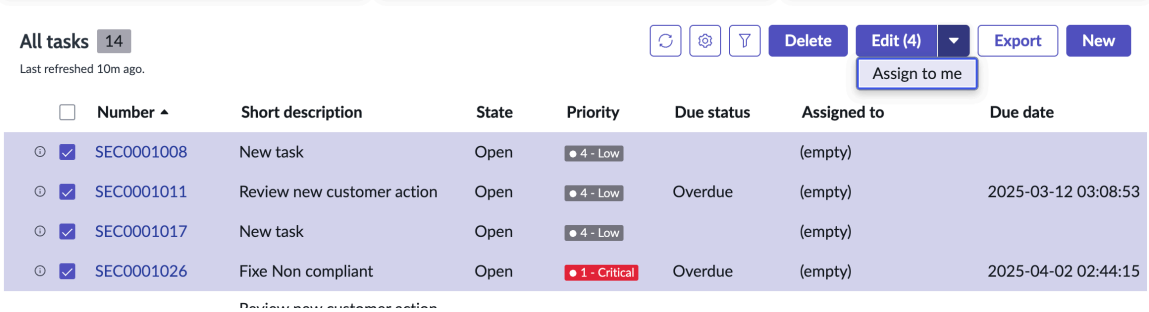
The Security Tasks use the following roles:

User	Required role	Description
System Administrator	admin	System Administrators can view, create, assign, and delete Security Tasks.
Security Center Viewer	sn_vsc_security_center_viewer	Viewers can view, but not create, delete or edit Security Tasks.
Security Task Manager	sn_vsc_task_manager	Security Task Managers can work on assigned tasks, view task manager-related pages, and create and manage tasks within Security center. They can view tasks assigned to other users but can't edit tasks assigned to other users. Task managers can't access non-task manager pages in Security Center.
ITIL	itil	ITIL users can interact with Security Tasks assigned to them, but can't view all tasks as the admin and Security Task manager roles can.

Quickly assign to yourself Security Tasks

Use the check boxes to the left of the items in the list to select multiple items. When one of more tasks is selected, you can use the **Delete** button to delete the selected tasks, or the **Edit** button to assign the selected tasks to yourself.

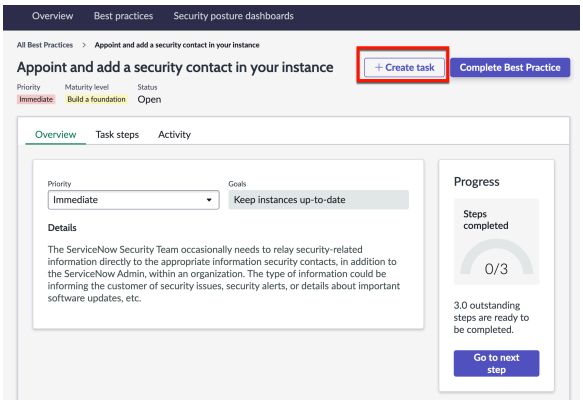
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

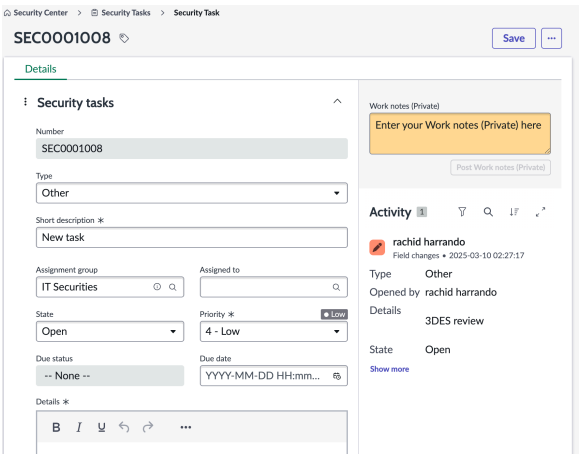


Create Security Tasks

Create a Security Task with the **+Create Task** button, which is available various platform security pages.

For example, in Security Center, on the Best Practices tool details page, the admin can select the **+Create Task** button to create and assign a task to complete this best practice.





Automatically generated tasks

Security Tasks can be automatically generated. Automatic Security Task generation is triggered by an associated event that occurred on the platform. Learn more about generated Security Tasks in Automatic Security Task generation.

Edit and assign Security Tasks

Edit Security Tasks to assign them to users, define due dates, and provide additional details to the users who will complete these tasks. For details, see Edit Security Tasks.

Export tasks

You can export Security Tasks into the format of your choice. For details, see Export Security Tasks.

Automatic Security Task generation

Learn about how and when your instance generates Security Tasks.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Automatically generated Security Tasks

Security Tasks can be automatically generated. Automatic Security Task generation is triggered by an associated event that occurred on the platform. For example:

Metrics threshold breached

A Security Task is generated for a metric when it's threshold is breached. There's only one open task for a metric, even if the same metric has multiple breaches. If a Security Task for a breached metric is closed, a new task is generated is the threshold is breached again.

Event notification

A Security Task is generated when a security event notification triggers (meets conditions of it's policy). As with metrics, there's only one open task for a policy, with a new task being generated if the previous one is closed, and the notification triggers again. For details on security event notifications, see Security Event Notifications.

Hardening score deviation

When the hardening score degrades below the configured threshold value (default 3), a Security Task is generated. For example, if the hardening score is 97, and is 94 the next day, a Security Task is created just after the score of 94 is calculated. Only a single open task is created. The platform will not generate another task if the score lowers again the next day from 94 to 91. For details on your hardening score, see Hardening compliance score trend.

Customer Action

A Security Task is generated whenever a Customer Action is installed. For details on Customer Actions, see Customer Actions.

Banner announcement

A Security Task is generated for each new banner announcement. For details on banner announcements, see Security banner announcements.

Automatically generated security settings

Configuration options for automatically generated Security Tasks are found in the security center properties page. Find these settings by navigating to **All** > **Security Center** > **Security Center Properties**.

Enable/Disable automated Security Tasks

When the **Yes/No** field is selected, automated Security Tasks are enabled on your instance.

Hardening score degradation threshold

The value in the field represents the amount by which the hardening score must degrade (since the last daily score) to generate a Security Task. This value must be a positive integer. The default value is 3.

Edit Security Tasks

Learn how to create, edit, delete, or export Security Tasks in Security Center

Before you begin

Role required: admin or sn_vsc_task_manager

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

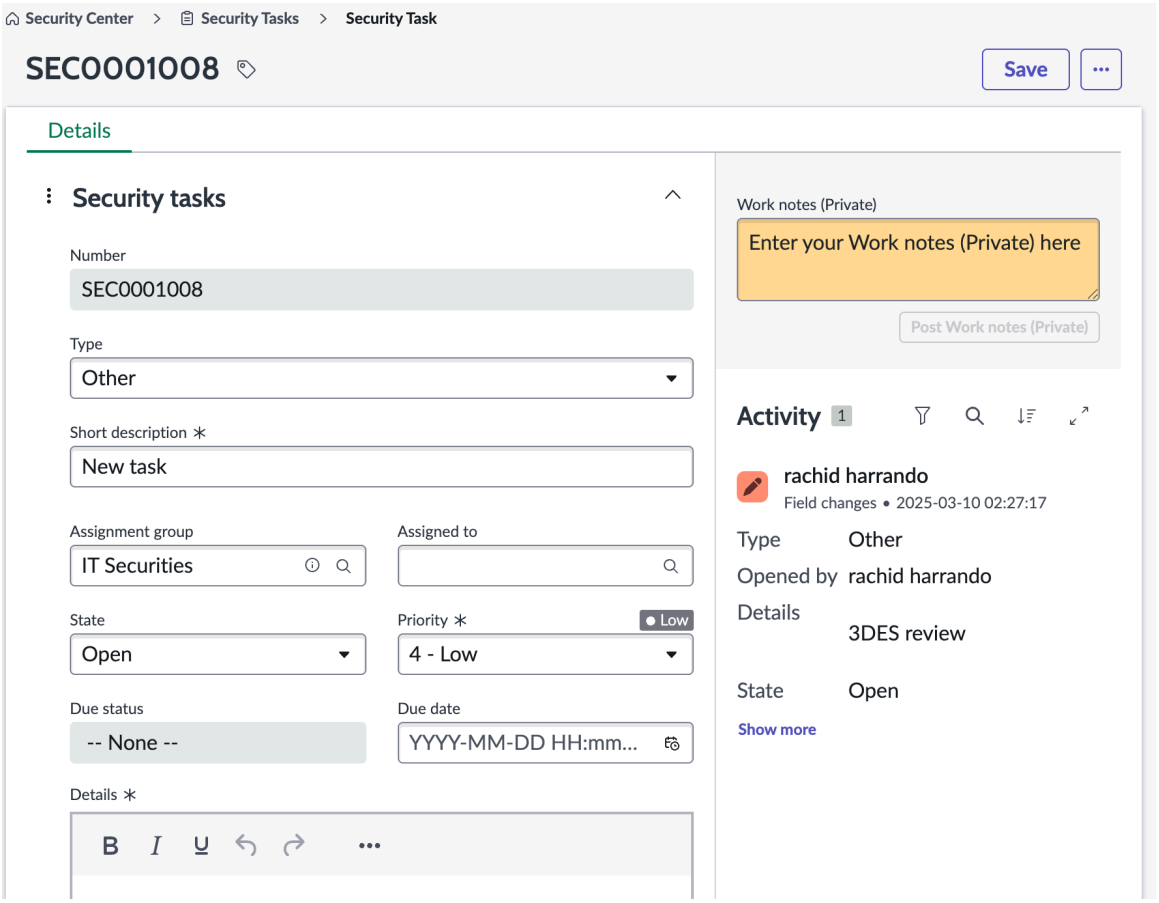
Procedure

1. Access your Security Task list by navigating to **All** > **Security Center** > **Security Tasks**.
2. From the Security Task list, you can edit your Security Tasks in two ways:

Edit in the Security Task form

Select a Security Task number from the list to open the Security Task record and see its details. Here you can edit, assign to another user, and add work notes.

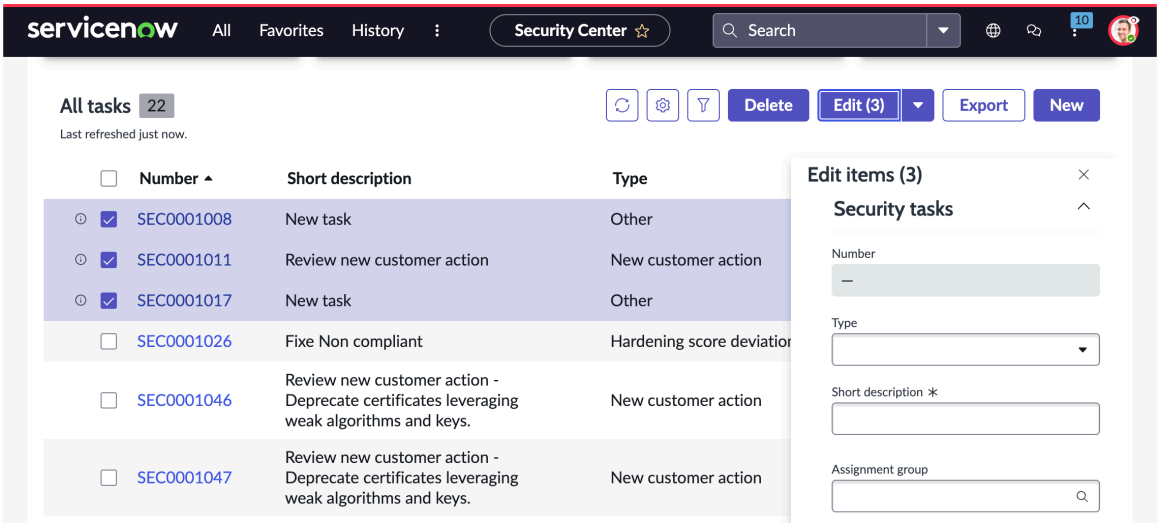
> **Important:**
> Remember that users who are assigned tasks must be admins or have the sn_vsc_task_manager role.



Edit from the Security Task list

Select one or more Security Tasks by selecting on its check box on the left and then select the **Edit** button.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



3. Fill in the fields as needed:

Field	Description
Number	Automatically generated number used to identity the task
Type	Select a task type: ○ Metrics threshold breached ○ New Customer Action ○ Event notification ○ Hardening score deviation ○ New banner announcement
Short description	Brief description of the task
Assignment group	Assignment group for the task
Assigned to	Person assigned to the task. This user must be in the assignment group selected in the **Assignment Group** field, and have the *admin* or *sn_vsc_task_manager* role.
State	State of the task: ○ Pending ○ Open ○ In Progress ○ Closed ○ Canceled
Priority	Priority of the task: ○ 1- Critical ○ 2- High ○ 3- Moderate ○ 4- Low

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Due status	Whether the task is **Upcoming** or **Overdue**, depending on the date in the **Due date** field.
Due date	The date and time by which the task needs to be completed.
Details	Used to provide details, links, or other information users need to know about this task.
Work notes	Notes about this task. Notes entered into this field are timestamped and displayed on the Activity list on the right of the screen.
Work notes (private)	Work notes can be privately added by entering them into this field and selecting the **Post work notes (private)** button.

4. Select **Save** to save the Security Task record, if you are editing a record from the list, select **Update**.
5. **Optional:** If needed, you can delete a task from the list by selecting on its check box on the right, and selecting **Delete**, or in the form by selecting the more icon (...), then selecting **Delete**.

Export Security Tasks

Learn how to export Security Tasks into files you can download and use in other software.

Before you begin

Role required: admin

Procedure

1. Access your Security Task list by navigating to **All** > **Security Center** > **Security Tasks**.
2. Select one or more Security Tasks by selecting on its check box on the left
3. Select the **Export** button.
4. Under **File type**, select the file format you want the Security Tasks exported to. You can select from Excel, CSV, JSON, or PDF formats.
5. Under **Delivery Type**, select either **Download** or **Email**.

   Download

   The export file is downloaded using your browser.

   Email

   The **Email** field displays. Enter a email address in the **Email** field, and the export file is delivered to the specified email address.

Security learning

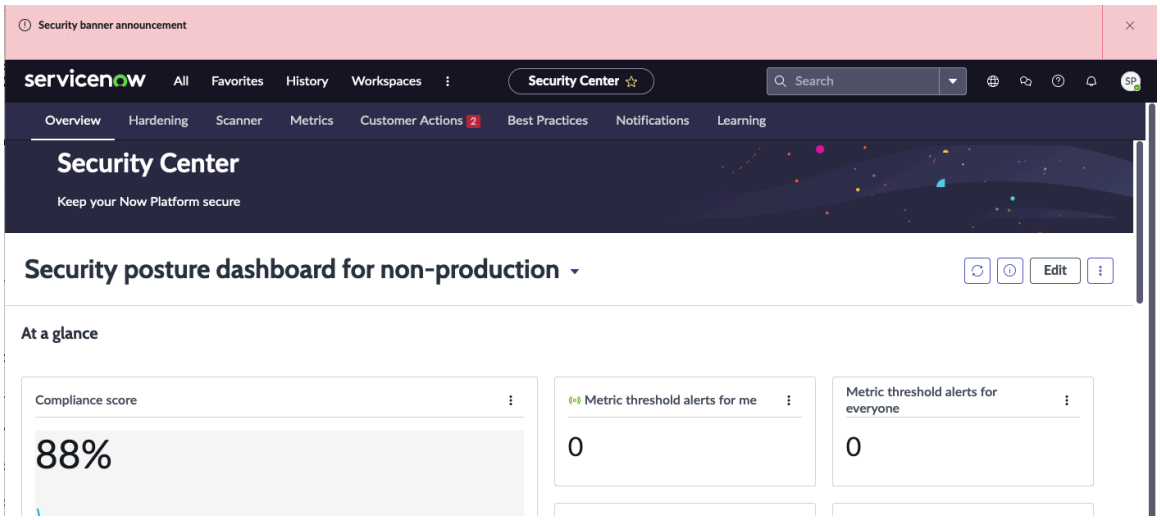
Access security learning materials from a single page.

Read security white papers, ebooks, knowledge base (KB) articles, product documentation, and community discussions from a consolidated view by navigating to **Learning**. The content is organized by headings and descriptive UI cards to make it quick for you to pinpoint the correct resource.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Security banner announcements

Enable security banner announcements to stay informed about urgent and critical security alerts using high visibility banners visible to administrators within the instance UI.

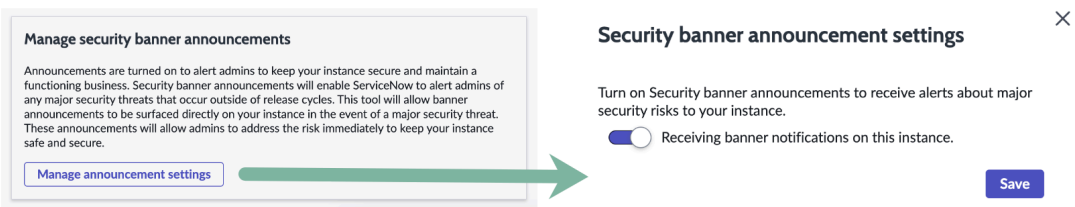


Security banner announcements are announcements displayed to customer administrators, sent by ServiceNow, to keep you informed about fixes for potential security threats that were discovered recently. These alerts contain a summary of the security risk and include a link where you can learn more and act to secure your instance.

Administrators can dismiss banner by selecting the close (x) button, but the banner re-appears with each new session until the banner expiration date is passed. Administrators can disable banner announcements by setting the *`sn_vsc.configure_customer_push_action`* system property value to `false`. The duration for which the banner appears is controlled by **Start** and **End** field values for the banner. These fields are found in banner's record in the Banner Announcement [sys_ux_banner_announcement] table.

Enable or disable security banner announcements

The security banner feature is enabled by default. To enable or disable security banner announcements, navigate to **System Security** > **Security Center** > **Notifications**. From this page, select the **Manage announcement settings** button.



Instance Security Center

Monitor the compliance level of instance security controls, view security event monitoring metrics, and configure and maintain instance security settings all from within the Instance Security Center. The Instance Security Center consolidates several key security components into a single control console that helps you detect, protect, and respond to instance-based security events.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

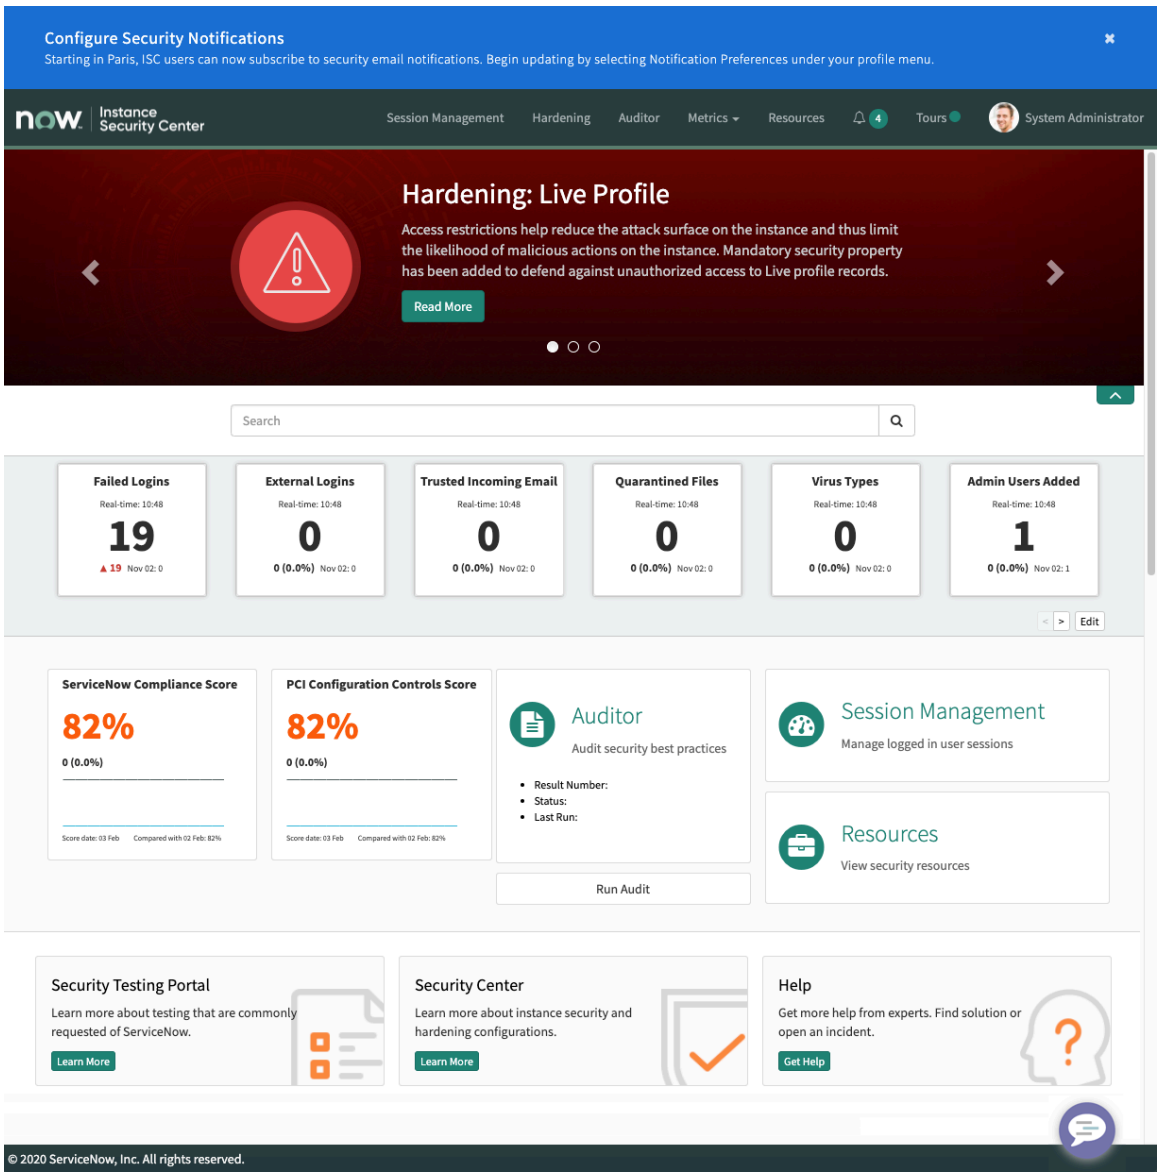
Important:

Instance Security Center (ISC) has reached the end of sales as of September 2024, and is no longer supported or available for new activation.

ServiceNow Security Center (SSC) is the recommended solution going forward. For more information, see Instance Security Center to ServiceNow Security Center migration.

Instance Security Center components

To access the Instance Security Center, navigate to **System Security** > **Instance Security Center** or the System Administration homepage.



The Instance Security Center homepage contains the following security components:

- Administrator messages
- Rotating security banner
- Search
- Security event ribbon
- Daily compliance score

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- PCI Configuration Controls Score
- Session Management
- Hardening
- Auditor
- Metrics (user, email, and antivirus)
- Resources
- Security notifications
- Tours
- Security testing portal
- Security center
- Help
- Virtual Agent access

From the Instance Security Center homepage, you can view the security compliance score for your instance and monitor its overall security health. You can then configure or update system properties that are related to your instance security so that they comply with security requirements.

Note:
The Instance Security Center does not support domain separation.

User roles

To use the Instance Security Center, you must have the admin or security_dashboard_user role.

To learn more about managing per-user subscriptions, see Managing per-user subscriptions in Subscription Management and contact your account representative.

roles

Required role	User	Benefits
admin	This role has access to all system features, functions, and data because administrators can override access control list (ACL) rules and pass all role checks. Avoid assigning this role to your users when more targeted roles are available.	Leverage Security Center tools to improve instance security posture and monitor security related behaviors.
sn_vsc.security_center_viewer	This role allows users who are not Admins to view the information in Security Center but not make changes to the Security Center tools or make instance configurations change leveraging the Security Center tools.	Gain visibility into Security Center tools to monitor instance security posture and monitor security behaviors.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

roles (continued)

Required role	User	Benefits
	For example, platform owners, security operations analysts or compliance stakeholder might want or need to view some of the security KPIs, security insights and security learning material available in Security Center.	

Warning:
To ensure that the Instance Security Center receives up-to-date security information with every upgrade, do not customize this module. If you change any security settings on your instance, make sure that you test them in a non-production environment first.

Administrator messages

Messages and reminders, intended mostly for administrators, appear above the rotating security banner.

For example, a `Configure Security Notifications` message appears to remind administrators to configure preferences for security notifications if they have not done so. It also points them to the proper page to do so.

Note:
The administrator messages banner does not appear for non-admin users, or if there are no actionable items for admin users.

Rotating security banner

To assist you in monitoring the security health of your instance, critical instance security messages appear in the rotating banner.

- Two to three security messages normally rotate at a regular interval.
- The dots at the bottom of the banner show you the total number of current security messages.
- To navigate through them, select the dots, or select the arrows that appear on either side of the messages.

The banner background colors indicate the relative severity of the messages.

Color	Description
Red	Critical security situation requiring a timely response, or a recommendation on how to protect or respond to critical security events.
Dark gray	Non-critical warning message.
Blue	General information message.

To collapse or minimize the text content in the banner, select . To maximize the text content, select it again.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- When you use the Instance Security Center again, the text content appeared as collapsed or expanded, depending on how you used it during your previous session.
- If the text content itself changes, it appears as maximized for all users.

Search

Use the search bar to search the entire Instance Security Center for security resources that assist you with understanding and resolving security issues. You can search the following security-related resources:

- Now Support Knowledge Base articles
- Instance Security Center pages
- External Now Support links
- PA security widgets, such as the Daily Compliance Score and External Incoming Emails
- Banner content

Event ribbon

Use the event ribbon to view key security event monitoring metrics for the current instance.

- To manually scroll through the metrics, select the right or left arrow keys.
- To configure the event ribbon, select **Edit**.

To learn more about the event ribbon and how to configure it, see Monitor security events and Configure the security event ribbon.

Daily compliance score

The Daily Compliance Score section contains the **Daily Compliance Score**, **Session Management**, **Hardening**, **Auditor**, and **Resources** tiles.

You use the Daily Compliance Score to gauge how healthy your instance is from a security standpoint.

The Daily Compliance Score is a percentage score. It is based on how compliant the current settings of your instance security properties are with the compliance values published in the Hardening settings.

- To learn more about Daily Compliance Score calculations, and how hardening settings impact it, see Check the daily compliance score and configure security property settings.
- The **Refresh** button enables an administrator to instantly recalculate the Daily Compliance Score. To learn more, see How Daily Compliance score, trend, and graph data is refreshed.

Hardening

Use this process to adjust the specific security configuration properties that affect the Daily Compliance Score:

1. To access the Hardening Compliance Configurations page and perform instance security hardening, select the **Daily Compliance Score** tile or the **Hardening** link.
2. Specify whether you want to view all or only recommended security controls. Then, select the category you want to work in.
3. Set each security configuration property in the selected category. Click **More Info** to view detailed information for a property.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

To learn more about hardening and optimizing security configuration properties to further increase compliance, see Adjust instance security settings to increase compliance.

To learn more about how trend and graph data is refreshed, see How Daily Compliance score, trend, and graph data is refreshed.

Auditor

Run the Auditor to scan your instance and find incorrect security definitions. It provides findings you can correct to help improve the security posture of your instance.

To access the Auditor page, select the **Auditor** tile or the **Auditor** link. To learn more, see Scan for incorrect security definitions.

Session management

Use Session Management to:

- View and manage user login sessions.
- See the user login session of the current node that you are connected to.
- See detailed information about each session, such as the user name and IP address.
- Isolate and lock out specific user sessions that pose security risks.

To access the Session Management page, select the **Session Management** tile or link.

Field	Description
User	Name of the user associated with this login session. • To locate a specific user session, select the spotlight search icon ( ) to search by user, user agent keyword, or IP address. For example, if you want to find all current logins from a specific type of browser, enter the browser name as a keyword into the **User Agent** field. • Click a user name to access the user profile record. You can modify the user profile only if you have an assigned admin role. **Note:** To learn more about user profiles, see Create a user.
MFA	Check box indicating if Multi-factor Authentication (MFA) is enabled for the logged in user. To learn more about MFA, see Multi-factor authentication.
Active	Check box indicating if the logged in user is active or inactive.
User Agent	Type of browser and the device operating system for the user login session.
IP Address	IP address of the logged in user.
Last Accessed	Date and time this user session last accessed the instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Note: To view detailed information for a particular login session, or to lock out the session itself, select the **User Agent**, **IP Address**, or **Last Accessed** fields.

Metrics

View detail for the following types of metrics:

Type of metric	Description
User	Security metrics that are associated with user activity in the instance. To access the User Metrics page, select the **Metrics** link, and then select **User Metrics**.
Export	Security metrics that are associated with data exported from the instance. To access the Export Metrics page, select the **Metrics** link, and then select **Export Metrics**.
Authentication	Security metrics that are associated with authentication, such as infrequently used IP addresses, failed logins, and types of authentication schemes used by your users. To access the Export Metrics page, select the **Metrics** link, and then select **Authentication Metrics**.
Email	Security metrics associated with anomalous behaviors related to the incoming emails to your instance. To access the Email Metrics page, select the **Metrics** link, and then select **Email Metrics**.
Antivirus	Security metrics that are associated with antivirus event activity in the instance. To access the Antivirus Metrics page, select the **Antivirus** tile or select the **Metrics** link, and then select **Antivirus**.

Note:
To learn more about monitoring each type of metric, see Monitor instance metrics.

Resources

Access Now Support Knowledge Base articles, resources, and blogs that are related to instance security. These resources include security settings, coding, compliance, fixes, and related topics. To access the Resources page:

1. Click the **Resources** tile or link.
2. In the Resources page, select a category:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Category	Description
Recommended Guidelines	Access to recommended security guidelines, including the Hardening settings and Secure Coding Guide [KB0623354] articles.
Security Resources	Access to security-related resources in the Knowledge Base, including: ○ Customer Instance Security Testing ○ Cloud Security, Trust, and Compliance Center KB articles

Security notifications

A notifications bell icon ( ) appears in the Instance Security Center, with a count total of unread security notifications. Notifications persist and are included in this count until you mark them as read.

1. Click the bell icon to view the first five unread security notifications.

   A notification appears when **Admin Login**, **Admin Unlocked**, **Failed Login**, **High Privilege Role**, **Impersonation**, **Security Elevation**, and **Weekly Digest** events take place in your instance. To learn more about these security events, see Monitor security events.

2. To view detailed information for a specific security event, select the notification.

   For example, if you select a High Privilege Role notification, you can view the Roles (sys_user_role) table. Use this table to see which users were assigned privileged roles during the calendar day. Using this history helps you to determine if roles have been properly assigned.

3. If there are more than five unread notifications, select **View All Notifications** to access an All Notifications page with a listing of all unread notifications.
   - To view detailed information for a specific security event, select the notification.
   - To mark all listed notifications as read, select **Mark All as Read**.

Note:
As an administrator, you can also configure preferences for sending specific types of notifications for each type of security event. To learn more, see Set preferences for security event notifications.

Tours

Click the **Tours** link to view a guided visual tour of the Instance Security Center.

- The guided tour includes only the security monitoring functions that are listed on the homepage.
- It does not include the security functions that you access when you select the tiles or links on the homepage.

Security testing portal, security center, and help

The Now Support Service Portal is a central resource that you use to manage instances, tasks, and accounts. You can also access useful resources you can use to diagnose and resolve security and technical issues in your instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

To access these resources, select **Learn More** or **Get Help** in the following tiles:

Tile	Description
Security Testing Portal	Access to the Security Dashboard in the Now Support Security Testing Portal.
Security Center	Access to Security Compliance in the Now Support Security Portal.

Help	Access to the following help resources in the Now Support Security Portal:
	• Ask an expert to find answers to common questions.
	• Report an issue or outage to ServiceNow Global Technical Support by opening a case.
	• Self-Service Support Resources, including:
	  ○ Videos
	  ○ Documentation
	  ○ ServiceNow Community
	  ○ Knowledge Base
	  ○ Known Error Portal
	  ○ Security RFX Database
	• ServiceNow Community questions that are recommended for your use.

Virtual Agent access

The Virtual Agent is a platform for providing user assistance through conversations within a messaging interface.

With the associated plugins installed, administrators can access the Virtual Agent and Natural Language Understanding (NLU) functions by selecting the Virtual Agent icon:

It enables you to perform the following tasks:

- Ask security-related questions, then get quick summary answers and reference links to learn more.
- Get answers related to processes such as:
  - Instance Security Center
  - Platform Security
  - ServiceNow security policies
  - Trust, Governance, and Risk
- Search for security-related resources, such as Knowledge Base topics in the Now Support Security Portal.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
To learn more about how to use and activate the Virtual Agent, see:

- Virtual Agent
- Activate the ISC Virtual Agent interface

Instance Security Center to ServiceNow Security Center migration

Learn the key differences when migrating from Instance Security Center (ISC) to ServiceNow Security Center (SSC).

Important:

Instance Security Center is a legacy product that will reach the end of sales by September 2024. ServiceNow Security Center is the recommended solution for customers to adopt going forward. For more information, see the deprecation process article (KB0867184) in the Now Support knowledge base.

ServiceNow Security Center (SSC) is a security application that consists of a set of purpose-built tools designed to help organizations maintain the security of their ServiceNow deployments. Using SSC, organizations can improve their security posture, strengthen their compliance levels, and do so with a seamless user experience.

Use this document to learn about SSC enhancements in functionality and how to execute tasks in SSC that were previously done in ISC.

Security hardening

Feature enhancements	ISC vs SSC

User interaction updates	• Review latest score by navigating to the Overview or hardening comparison page.
	• Manually update latest score by navigating to Overview and selecting update score.
	• Change setting configuration by selecting a setting name link on any of these pages and then make edits on the **Settings detail** page:
	  ○ Overview
	  ○ **Hardening** > **All settings**
	  ○ **Hardening** > **Comparison**

Set a schedule for to recalculate your compliance score	Using SSC, you can set when the system triggers a refresh of your compliance score. **1.** Navigate to the Scheduled Script Executions [sysauto_script] table. **2.** Find and open the `SC - Calculate Compliance Monthly` record.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Feature enhancements	ISC vs SSC
	3. Use the **Run**, **Day**, **Time zone**, and **Time** fields to set your preferred schedule.  **4.** Select **Update** to save your changes.

Security KPIs and metrics

Feature enhancements	ISC vs SSC
Enhancements to KPIs	Using SSC, you can: • See the trend of the score over time. • Monitor all KPIs and metrics using the same interface and analytical capabilities.
Enhancements to metrics	SSC includes these metrics enhancements: • Over 65 metrics have been added. • Monitor and analyze KPIs and metrics from a single user interface. • Create targets and thresholds for metrics.
User interaction updates	Access Metrics in SSC by navigating to **Overview** > **Metrics**, and then selecting metric from the navigation menu. Alternatively, you can navigate to **All metrics**.

Security scanner

Feature enhancements	ISC vs SSC
New functionality	SSC includes these functions: • Manually execute scans or schedule them to run at specific times. • Create your own scan checks. • Create your own scan suite. • Compare the results of two scans.
Enhanced email functionality	Set up email notifications to stay informed about security events on your instance.
User interaction updates	• Run the Auditor scan by navigating to **Overview** > **Scan** > **Suites** and selecting **Auditor suite** from the list. • See scan results by navigating to **Overview** > **Scan** > **Results**.

© 2026 ServiceNow, Inc. All rights reserved.

Additional security features

Feature enhancements	ISC vs SSC
Monitor sessions functionality	• Visualize session activities using the Analytics Hub. • Monitor session activity by navigating to **Metrics** > **Sessions**.
Find resources	Access all learning resources in a single page at **Overview** > **Learning**.

Opt out of Security Center features

To disable Security Center features on your instance, follow the steps provided in KB1702514: Guidelines to disable Instance Security Center components (while using Security Center).

Monitor security events

Analyze the event metrics in your instance so that you can identify and prevent potential security events.

Important:

Instance Security Center (ISC) has reached the end of sales as of September 2024, and is no longer supported or available for new activation.

ServiceNow Security Center (SSC) is the recommended solution going forward. For more information, see Instance Security Center to ServiceNow Security Center migration.

In the event ribbon, which is on the Instance Security homepage, you can analyze these metrics and accompanying detail to identify potential security events in the instance.

- For each event metric, a real-time single score count appears, indicating how many times that the event occurred during the day in this instance. These single score reports are updated automatically as the corresponding events take place.
- Each event metric also contains compliance trend and graph information over a range of dates. This information updates on a daily basis when you run the performance analytics job. To learn more, see the **Analyzing event trend detail** section.

Event types

You can monitor at least six of the following types of events. For more than six events, use the left or right arrows below the event ribbon to scroll through them. To learn how to configure the event ribbon, see Configure the security event ribbon.

Notification preference	Description
Admin Logins	Number of login attempts in this instance, during the calendar day, by users who have an assigned admin role.
Admin Users Added	Number of users with an admin role that were added in this instance during the calendar day. For example, your instance may have a security issue if the count is 10, but 4 users are known to have an assigned admin role.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Notification preference	Description
External Incoming Email	To learn more, see Email metrics.
External Logins	Number of users with an assigned snc_external role who logged into this instance during the calendar day. These logins typically occur for maintenance, support, consulting, or audit purposes. Monitoring this metric enables you to verify that the external login attempts are legitimate and not potential security issues. To learn more about assigning external user roles, see Explicit Roles.
Failed Logins	Number of attempted logins that failed in this instance during the calendar day. This metric may indicate that attempts are being made to log in and compromise your instance security.
Impersonations	Number of impersonation logins in this instance during the calendar day. To learn about impersonating users, see Impersonate a user.
Quarantined Files	Number of files that were quarantined when you ran Antivirus Scanning in this instance during the calendar day. To learn more about quarantined files and Antivirus Scanning, see Antivirus metrics and Antivirus Scanning.
Security Elevations	Number of times that a security administrator has elevated security for standard users by changing their assigned user role to a high privilege security role during the calendar day. These high privilege security roles include oauth_admin, admin, security_admin, and impersonator. • This metric indicates that someone might have tried to elevate the security of an unauthorized user. Do not use this metric by itself to detect a specific security compromise. Instead, treat this metric as an indication that you should check another metric to see if a security compromise has occurred. • To learn more about elevating user security, see Elevate to a privileged role and Elevated privilege roles.
SNC Logins	Number of Customer Service and Support personnel who logged into this instance using the hi-hopping technique during the

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Notification preference	Description
	calendar day. These logins typically occur for maintenance, support, consulting, or audit purposes. For information on how to control ServiceNow corporate employee access, see ServiceNow access control.
Spam	To learn more, see Email metrics.
Trusted Incoming Email	To learn more, see Email metrics.
Untrusted Incoming Email	To learn more, see Email metrics.
Virus Types	Number of different types of antivirus events that occurred in this instance during the calendar day. To learn more about antivirus event types, see Antivirus metrics.

Analyzing event trend detail

To view trend details for an event metric, click the event count to access the Analytics Hub page. The details that appear for the instance depend on the type of metric.

For example, to view a listing of each failed attempt on the Security Dashboard Event Logs page:

- Select the **Failed Logins** metric.
- In the Analytics Hub page, click **Show Records**.
- Click one of the failed login attempts.
- The detail includes the name of the user who attempted to log in, their IP address, and the table name that they tried to access.

You can set up event threshold triggers in the Core UI Analytics Hub or Platform Analytics KPI Details to provide alerts when a certain event occurs within a range of scores for an indicator. You can also set targets that enable you to visualize the difference between the desired score and the actual score of an event.

For example, you can set a threshold of 10 for the **Failed Logins** metric. When ten or more failed login attempts occur during the day, an alert is sent to specific security personnel. You can also set a similar target that provides a visual highlight in the Analytics Hub when 10 failed logins occur during a day.

Trend data and graphs that appear in Event ribbon tile and the Analytics Hub are updated after the performance analytics job executes at 02:00 local time. To learn more, see How Daily Compliance score, trend, and graph data is refreshed.

Configure the security event ribbon

Configure the security event ribbon on the Instance Security Center homepage to include only those events that are relevant for tracking instance security in your operations. You can also change the order in which the security event tiles appear on the ribbon.

Before you begin

Role required: security_dashboard_user or admin

About this task

The security event ribbon is initially populated with a full set of standard security events. You can customize it by removing the events that are not relevant to your organization.

- For example, if you suspect that security issues are due to the actions of internal personnel, include the Admin Logins, Admin Users added, and Security Elevations event indicators.
- These indicators monitor how many times users with admin roles attempted to log in and, if admin users were added, what attempts were made to elevate security roles.

Note:
To learn about the types of security events that appear in the event ribbon, see Monitor security events.

Procedure

1. Navigate to **All** > **System Security** > **Instance Security Center**.
2. In the event ribbon, click **Edit** (
).
   On the Edit Events form, the **Selected** column contains the events that are already listed.
3. To add security events to the event ribbon, move them from the **Available** column to the **Selected** column.
   To change the order the events appear on the ribbon, select an event, then click the up or down arrow to move it to its correct position.
   - Place the events in the same sequential order they should appear on the Instance Security Center event ribbon.
   - The events you place at the top of the **Available** column appear sequentially, beginning on the left side of the Instance Security Center event ribbon. The events placed towards the bottom of the column appear on to the right on the event ribbon.
4. To remove security events from the event ribbon:
   - In the **Selected** column, select the security events that you want to remove from the event ribbon.
   - Move them from the **Selected** column to the **Available** column.
5. Click **Save**.

Set preferences for security event notifications

Configure preferences for the types of notifications you want to receive for occurrences of specific security events. For each type, you designate whether to receive notifications by email, by push notification in Now Mobile, or in third party messaging applications such as Slack or Microsoft Teams.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin

To enable third party messaging applications to send security event notifications, you must activate the Messaging Notification (com.glide.notification.messaging) plugin. Individual users must configure their own settings. For details, see Notifications in messaging applications.

Role required: admin.

Procedure

1. In the Instance Security Center home page, click the profile menu, then click **Notification Preferences**.

Notification preferences

Notification preference	Description
Admin Login	Send the selected type of notification whenever other users with assigned admin roles log into this instance from a different IP address.
Admin Unlock	Send the selected type of notification whenever an account for a high privilege user has been unlocked.
Failed Login	Send the selected type of notification whenever other users fail to log in into this instance in less than the number of attempts defined in the *glide.user.max_unlock_attempts* property. If you don't configure this property, the default value is 5. To learn more about this property, see Specify lockout for failed login attempts.
HP Role Added	Send the selected type of notification whenever a high privilege security role (including oauth_admin, admin, security_admin, and impersonator roles) is granted to another user. To learn more about elevating user security, see Elevate to a privileged role and Elevated privilege roles.
Impersonation	Send the selected type of notification whenever another user is impersonating you. To learn more about impersonating users, see Impersonate a user.
Security Elevation	Send the selected type of notification whenever other users are elevated to a security admin role in this instance.
Weekly Digest	Send a weekly digest on the selected type of notification. It includes:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Notification preference	Description
	○ A summary all security activities that took place in this instance throughout the week. ○ The current daily compliance score for the instance.

2. For each type of security event, select the appropriate check boxes to designate the type of notifications to send you.
   You can select multiple notification methods for each.

3. Click **Save**.

Check the daily compliance score and configure security property settings

Review the Daily Compliance Score metric and security configuration properties to see if your instance complies with the suggested security requirements. You can affect the daily compliance score by updating non-compliant security properties in the Hardening Compliance Configurations page.

Important:

Instance Security Center (ISC) has reached the end of sales as of September 2024, and is no longer supported or available for new activation.

ServiceNow Security Center (SSC) is the recommended solution going forward. For more information, see Instance Security Center to ServiceNow Security Center migration.

The Daily Compliance Score is a percentage score. It is based on how compliant the current settings of your instance security properties are with the compliance values published in the Hardening settings.

Review the daily compliance score of your instance regularly. Follow these guidelines when you are evaluating your daily compliance score:

- Greater than or equal to 90% indicates that the instance is compliant with critical security controls.
- Greater than or equal to 50% and less than 90% indicates a moderate level of security compliance.
- Less than 50% indicates a low level of security compliance.

Adjust instance security settings to increase compliance

Using the Hardening Compliance Configuration page, harden and optimize non-compliant security properties that affect the daily compliance score of your instance. Its use ensures that your instance complies with the published security hardening standards, while fulfilling your company's security requirements.

Before you begin

Role required: security_dashboard_user or admin.

Refer to the Hardening settings content for detailed descriptions, and compliance values, for the security-related system properties and plugins in the ServiceNow AI Platform.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Consult the Instance Security Hardening Settings whenever you set or update security-related properties, even if some of the compliance values may not be suitable for your instance.
- When you are updating these properties, ensure that the instance continues to behave as expected. Consult with the appropriate internal personnel who have the expertise to determine the security impacts.

Note:
If you have an admin role, you can view and edit security controls. If you have a security_dashboard_user role, you can view security controls, but you cannot edit them.

Procedure

1. Navigate to **All** > **System Security** > **Instance Security Center**.
2. Click the **Daily Compliance Score** tile or the **Hardening** link to access the Hardening Compliance Configuration page.
3. In the Hardening Compliance chart, view the statistics for compliant and non-compliant security configuration properties.

Option	Description
Compliant	Number of security configuration properties that comply with the compliance values in the Instance Security Hardening Settings. **Note:** You cannot change the settings for com pliant security properties in the Harden ing Compliance Configuration. If you want to do so, you must update them in System Properties. To learn more, see
Non-Compliant	Number of security configuration properties that do not comply with the compliance val ues in the Instance Security Hardening Set tings. You can update settings for non-compli ant properties.

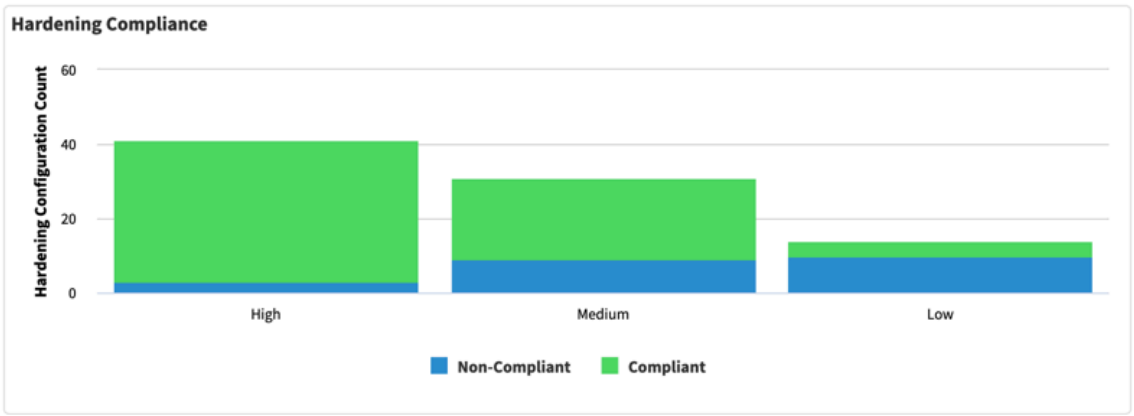
Note:
To view the number of compliant or non-compliant security scores over a range of dates, move the blue dot on the slider below the Daily Compliance Score.

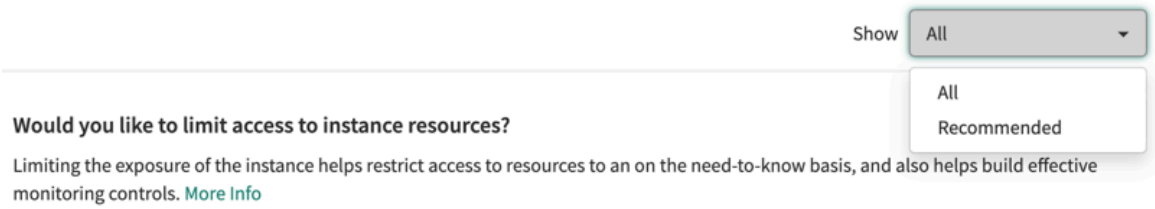
4. In the **Show** list below the chart, specify whether you want to access all security configuration properties, or only recommended ones.

Option	Description
All	(Default) All compliant and non-compliant se curity configuration properties in each select ed category.
Recommended	Only recommended security configuration properties appear in each selected category. These security configuration properties are

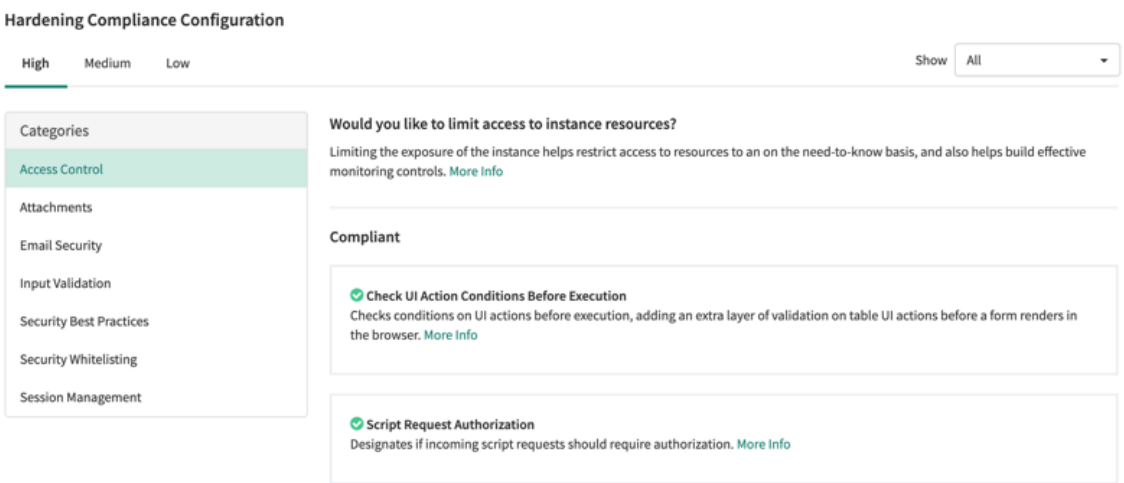
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Option	Description
	a selected subset of the most critical ones used to secure the ServiceNow AI Platform. Consider these security configuration properties to be the bare minimum number of settings you must set to secure the ServiceNow AI Platform. **Note:** To fully secure your instance, use the **All** option. It includes all recommended security configuration properties too.





5. In **Categories**, select the category that contains the security configuration properties you would like to access:



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Option	Description
Access Control	Access controls determine whether to grant or deny user access to a particular resource based on who is permitted to use those re sources. To learn more, see Access control in the Instance Security Hardening Settings.
Attachments	Attachment security controls enable valida tion of incoming attachments to protect your instance against malicious files sent by attack ers. To learn more, see Validate file mime type in AttachmentCreator soap web service [New in Security Center 1.3 and updated in 1.5] in the Instance Security Hardening Settings.
Email Security	Email security encompasses security config uration properties an administrator can con figure to ensure that proper security policies are in place for all inbound emails. To learn more, see Enable email spam scoring and fil tering [Updated in Security Center 1.3] in the Instance Security Hardening Settings.
Input Validation	Input validation includes security-related properties that an administrator can config ure to minimize entry of malformed data, re gardless of source. To learn more, see Vali dation, sanitization, and encoding in the In stance Security Hardening Settings.
Secure communications	Secure communications properties are those that an administrator can configure to secure the transportation of HTTP traffic. To learn more, see Communications in the Instance Security Hardening Settings.
Security Best Practices	Security best practices encompass Security Tasks that an administrator should perform pe riodically, within a certain interval of time, and include related configuration properties. To learn more, see Security Best Practices in the Instance Security Hardening Settings.
Security Inclusion Listing	Security inclusion listing includes security-re lated properties that an administrator can con figure to restrict behavior to known inclusion listings.
Session Management	Session management includes security-relat ed properties that an administrator can con figure to ensure secure session management in the ServiceNow AI Platform. To learn more, see Session management in the Instance Se curity Hardening Settings

6. Configure the non-compliant security properties in the selected category.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Unless otherwise specified, sliding the switch on sets a security property to its recommended setting. For example, you set most controls to true or false, but some require entry of a value, or values, such as a comma-separated value list.
- To access the dedicated Instance Security Hardening Settings topic for the security control, and learn more about it, click **More Info**.

Result
The Daily Compliance score increases or decreases depending on the changes that you make to the non-compliant security control settings.

Instance Security Center

How Daily Compliance score, trend, and graph data is refreshed

Trend and graph data in the Instance Security Center is updated after the performance analytics job executes at 02:00 local time. It appears in the Daily Compliance Score tile, in the Event ribbon tiles, and in the Analytics Hub page detail when you click one of the event tiles.

The [AppSec] Daily Data Management job is a regularly scheduled job that runs nightly and performs the following tasks:

1. Verifies if valid users have been assigned to the [AppSec] Daily Data Management and [PA AppSec] Daily Data Collection jobs when you first schedule them.
   - If you entered a valid user into the **Run As** field, the job continues processing. A valid user is one that is not locked out of the instance and has an assigned admin role.
   - If you entered an invalid user, an error message appears above the rotating security banner in the Instance Security Center.

   Note:
   To learn more about updating the assigned user when running scheduled jobs, see Create or schedule a data collection job.
2. Executes business logic to set the compliance state for the security properties you configure in the Hardening Compliance Configuration page. To learn more, see Check the daily compliance score and configure security property settings.
3. Runs the [PA AppSec] Daily Data Collection performance analytics job to collect compliance data and update the Daily Compliance Score.

Manually refreshing the Daily Compliance Score

Alternately, if you have an assigned admin role, you can refresh and recalculate the Daily Compliance Score at any time by clicking **Refresh**.

Note:
The **Refresh** button does not appear for users with an assigned security_dashboard_user role.

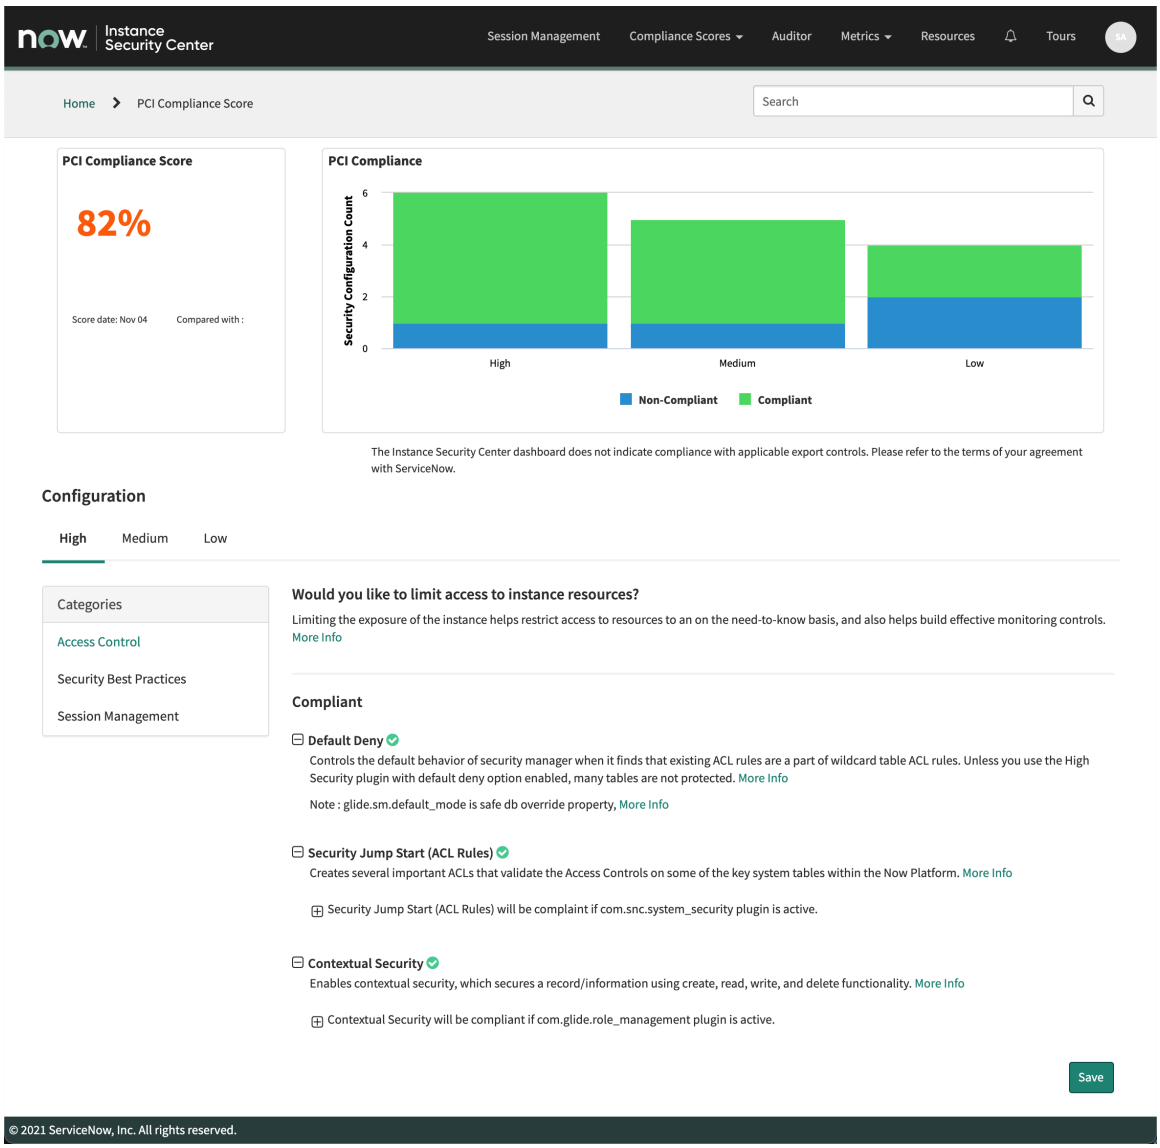
- The Refresh function performs the same tasks as the Daily Data Collection performance analytics job but does it in real time, rather than in a batch process.
- You typically use it when you want to perform updates to the Daily Compliance Score to immediately view the impact of instance security activities.
- There may be a slight delay before the updated score appears.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
When you perform an upgrade (for example, from London to Zurich), the Instance Security Center (ISC) plugin is automatically activated. A supplied fix script automatically assigns a custom user without any assigned roles.

PCI compliance score dashboard

The PCI compliance score dashboard shows how your instance conforms to payment card industry (PCI) security standards. Use the dashboard to view your compliance score and modify your configuration to improve security.



Required ServiceNow AI Platform roles

security_dashboard_user or admin, needed to view the PCI compliance score dashboard.

Access the PCI compliance score dashboard

To open the dashboard, navigate to **System Security** > **Instance Security Center**. From the instance security center, click **Compliance Scores** in the header, then select **PCI Compliance Score**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Use cases

For examples of how different people in your organization would use this dashboard, see these use cases.

User	Dashboard use
Security dashboard user (security_dashboard_user)	Continually monitor and manage instance security compliance.
Admin (admin)	Continually monitor instance security compliance to detect and respond to security threats.

Indicators

Indicator	Description
PCI Compliance Score	Displays your instance's compliance score as a percentage. This percentage of represents the percentage of security configurations on your instance that meet compliance standards. The indicator also displays the date the compliance score was calculated, and a comparison with the previous calculated score.

Data visualization

Title	Type	Source table	Description
PCI Compliance	 Stacked bar chart	Security Configurations [isc_security_configurations]	Displays compliant and non-compliant security configurations in high, medium, and low categories. Click an area of the report to display the matching security configurations.

PCI configuration controls score dashboard

Use the PCI configuration controls score dashboard to review your PCI configuration and determine which security checks are non-compliant. You can change the configuration of the non-compliant security checks from the instance security center.

Required ServiceNow AI Platform roles

The security_dashboard_user or admin role is required to view the PCI compliance score dashboard.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Access the PCI configuration controls score dashboard

To open the dashboard, navigate to **System Security** > **Instance Security Center**. From the instance security center, click **Compliance Scores** in the header, then select **PCI Configuration Controls Score**.

Use cases

For examples of how different people in your organization would use this dashboard, see these use cases.

User	Dashboard use
Security dashboard user (security_dashboard_user)	Continually monitor and manage PCI configuration controls compliance on your instance. Modify PCI configuration to ensure compliance and improve instance security.
Admin (admin)	Continually monitor PCI configuration controls compliance to detect and respond to potential security threats.

Indicators

PCI Configuration Controls Score

Displays your instance's PCI configuration controls score as a percentage. This percentage of represents the percentage of security PCI control configurations on your instance that meet compliance standards. The indicator also displays the date the compliance score was calculated, and a comparison with the previous calculated score.

Data visualization

Title	Type	Source table	Description
PCI Configuration Controls	 Stacked bar chart	Security Configurations [isc_security_configurations]	Displays compliant and non-compliant PCI control configurations in high, medium, and low categories. Click an area of the report to display the matching security configurations.

Scan for incorrect security definitions

Run the Auditor to scan your instance and find incorrect security definitions. It provides findings you can correct to help improve the security posture of your instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Important:

Instance Security Center (ISC) has reached the end of sales as of September 2024, and is no longer supported or available for new activation.

ServiceNow Security Center (SSC) is the recommended solution going forward. For more information, see Instance Security Center to ServiceNow Security Center migration.

The Auditor performs a "full-body" assessment of your instance health that analyzes your system configuration. For security scans, it compares your current security configuration to best practice definitions, and to security property compliance values.

From an instance security standpoint, it provides insights and recommendations into what you should continue doing, and where you might be able to improve. These insights and recommendations help you answer the following questions:

- Are the appropriate security-related properties set?
- Is the High Security plugin enabled?
- Do the right access control rules exist?

Run the Auditor and analyze scan results

1. To run the Auditor, click **Audit** on the Instance Security Center home page.
2. When it completes, open Scan Results to review and analyze the security findings.
3. To review the detail for a specific scan result, double-click the result number. This information includes its status, scan type, execution time, and error messages.
4. Each of the Auditor findings contains resolution details, and a URL to product content about how to address them. Follow the documented guidelines to resolve the issues in each of the findings.

Enable High Security Plugin [Updated in Security Center 1.3]

Access Control List Rules

Monitor instance metrics

Monitor user, export, authentication, email, and antivirus metrics for your instance. For example, you can monitor your email security by checking metrics for spam, external emails, and inbound emails from untrusted and trusted domains for your instance. Analyze these metrics to look for anomalous security behaviors that are related to activities that take place in your instance.

Important:

Instance Security Center (ISC) has reached the end of sales as of September 2024, and is no longer supported or available for new activation.

ServiceNow Security Center (SSC) is the recommended solution going forward. For more information, see Instance Security Center to ServiceNow Security Center migration.

User metrics

Analyze user metrics to look for anomalous behaviors that are related to specific types of user activity in your instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Not Logged in Last Month / Last Six Months / Last Year

Indicates the number of users who have not logged into the instance within the last month, within the last six months, and within the last calendar year. To view user detail for a specific metric:

- Click the metric to view a listing of users that have not logged in to the instance during the indicated time period.
- Click a user name to view more details about that user.

Users with High Privilege Roles

Indicates the number of users with the following high privilege role types:

User role	Description
admin	Primary administrator role that has access to all system features, functions, and data, regardless of security constraints.
ais_high_security_admin	Elevated privilege role that enables a user to access High Security settings for AI Search. To learn more, see Assign roles to AI Search administrators and users.
password_reset_admin	Administrator role that enables a user to view the status of password reset activities, identify potential security threats, and monitor for compliance with password security policies. To learn more, see Password Reset and Password Change reports and logs.
script_include_admin	Administrator role that also has access to script includes.
security_admin	Elevated privilege role that enables a user to create and change access controls and High Security Settings. To learn more, see Security_admin role
user_admin	Administrator role that can also manage users, roles, user groups, roles, and department assignments.

Note:
To learn more about these administrative role types, see Special administrative roles.

To view user detail for a specific user role metric:

- Click the user count role metric to view a listing of users with that high privilege role type.
- Click a user name to view more details about that user. You can then determine if these security-critical roles are assigned to the proper personnel.

Users Trend

Shows count trend information over a time period for the following types of users:

Count type	Description
Active Users	Number of users who are marked as Active in the instance.
Inactive Users	Number of users who are marked as Inactive in the instance.
Locked Out	Number of users who are locked out of the instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

To view user detail for a specific user count (for example, Locked Out Users):

- Click the **Locked out users** metric.
- In the Analytics Hub page, click **Show Records**.
- Click a user name to view more details about that user. You can then determine if there is a reason this person is locked out and remedy the situation.

Events Trend

Shows count trend information for specific types of events, over a time period:

Event type	Description
Admin login	Number of users with high privilege administrator user roles who logged in on a specific day.
External login	Number of users with an assigned snc_external role who logged into this instance during the calendar day. These logins typically occur for maintenance, support, consulting, or audit purposes. Monitoring this metric enables you to verify that the external login attempts are legitimate and not potential security issues.
Failed login	Number of failed login attempts on a specific day.
Impersonation	Number of users logged in on a specific day who are impersonating other users.
Security elevation	Number of times that a security administrator has elevated security for standard users by changing their assigned user role to a high privilege security role during the calendar day. These high privilege security roles include oauth_admin, admin, security_admin, and impersonator.
SNC login	Number of Customer Service and Support who logged in to this instance using the hi-hopping technique during a specific day.

To view user detail for a specific event count (for example, Impersonation):

- Click the user count metric. The Security Dashboard Event Logs page lists event logs for that type of event.
- Click a user name to view more details about that event.

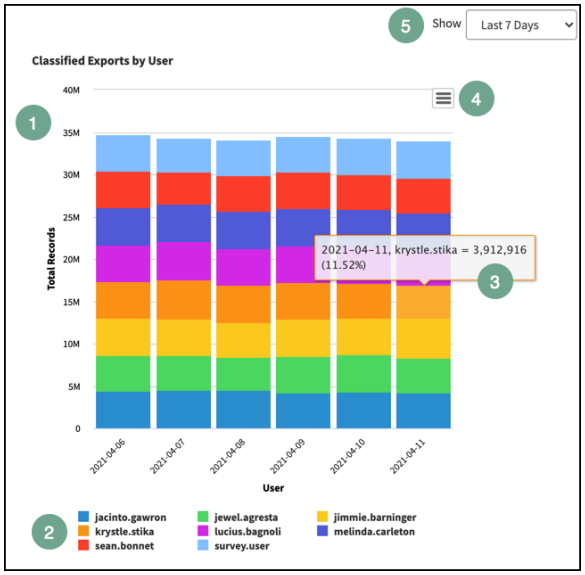
Export metrics

Analyze export metrics to see what data is most commonly exported and which users export the most data.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



1. Export chart

Each report displays the number of export events by date, using a color coded key to indicate which users performed the export. Click a colored section of a column to see the list of **Export Events** [isc_export_event] records matching that entry.

2. Report key

The key at the bottom of the report indicates which colors identify which users or tables.

3. Preview pop-up

Point to an entry in the chart to see a pop-up preview. This preview shows the user or table name, as well as a count of exports and a percentage of the total on that column.

4. Image export

Click the icon to save the report as an image. You can save the report in PNG or JPEG format.

5. Report date range

Use the **Show** list to display exports within the last 24 hours or within the last 7 days.

Export metrics reports

The export metrics page displays four reports.

Exports by user

Use the **Exports by User** report to see which of your users are exporting the most data.

Classified exports by user

Use the **Classified Exports by User** report to see which of your users are exporting the most data matching classifications like confidential, restricted, or personal information. Administrators can define which classifications this report uses in the **Settings** tab.

Exports by table

Use the **Exports by Table** report to see which tables are exported from most frequently.

Classified exports by table

Use the **Classified Exports by Table** report to see which tables are exported from most frequently that match classifications like confidential, restricted, or personal information. Administrators can define which classifications this report uses in the **Settings** tab.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
Export metric reports only track export events. Exports from other sources, such as rest APIs or workflows are not tracked as part of this feature.

Export metrics settings

Use the configuration options in the Settings tab to narrow down reporting results.

Access the settings for your export metrics by selecting the **Settings** tab.

Settings configuration fields

Export metrics configurations

Configuration	Description
Classifications for Metrics	Add or remove classifications to this field to determine which exports are included in the **Classified Exports by User** and **Classified Exports by Table** reports. These reports support the following classifications: • Personally identifiable information • Confidential • Restricted • Internal • Public For more detail on data classifications, see Data classifications
Classifications for Alerts	Add or remove classifications to this field to determine which exports trigger instance security notifications. The classifications supported in the **Classifications for Metrics** field are supported here. For more detail on these alerts, see the security notifications section on the Instance Security Center page. The **Record Threshold** field defines the number of records exported before your instance triggers and alert.
Record Threshold	Number of record a user must export to trigger an alert. To trigger an alert, these records must also match the classifications listed in the **Classifications for Alerts** field.

Save your settings by entering **Control + s** (Windows) or ⌘ **+ s** (macOS).

Authentication Metrics

Analyze authentication metrics to see information related to authentication, such as infrequently used IP addresses, failed logins, and types of authentication schemes used by your users.

Use the **Authentication Metrics** page to view reports relating to your authentication configuration. The following reports are displayed in this tab.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
The authentication metrics page requires the **REST API Access Policy plugin** (com.glide.rest.policy) plugin. For more details about this feature, see REST API access policies.

APIs without authentication policies

Displays a real-time count of all API's without an access policy

Hardening: Account recovery flow

Hardening: Role-based MFA feature related setting

Web service access only accounts

Shows the count of all user records with web service access option enabled in *User* [sys_user] table.

X509 certificates expiring in 30 days

Displays a count of all X.509 certificates from *X.509 Certificates* [sys_certificate] table which are due expire in 30 days.

Adaptive authentication metrics

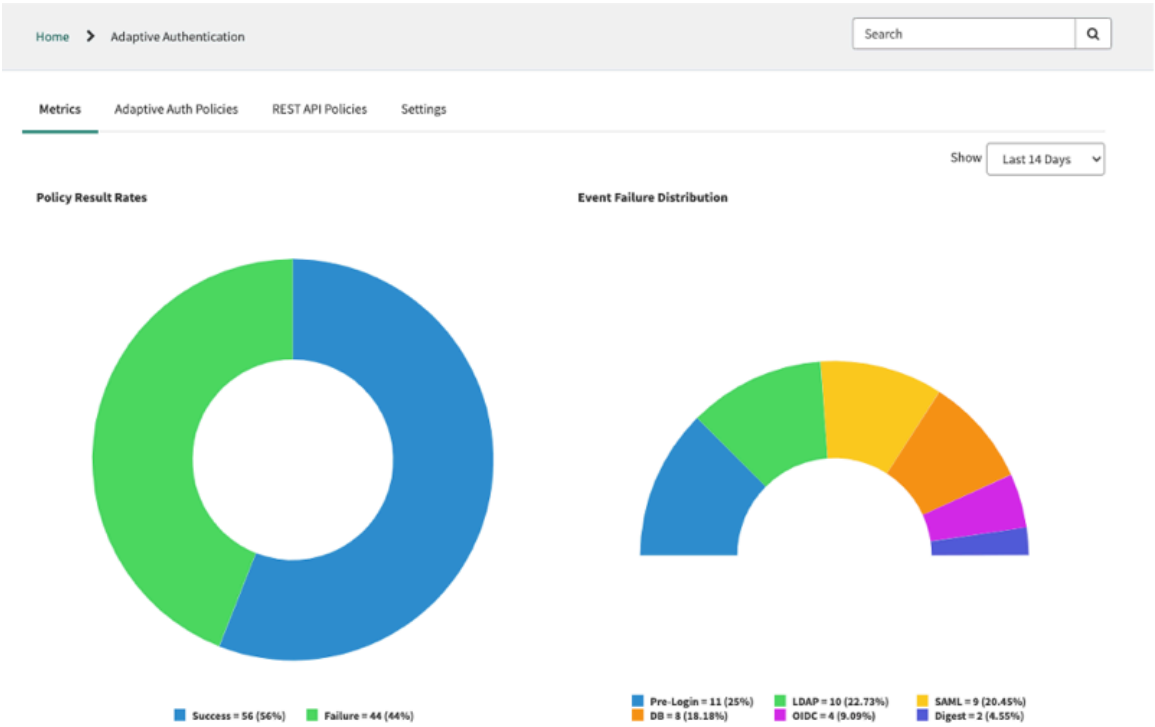
Analyze adaptive authentication metrics to monitor and add insights on how adaptive authentication is being used on your instance.

View reports, settings, and policies associated with adaptive authentication in on place using the adaptive authentication metrics page. Security administrators can use reports to monitor the results of their adaptive authentication policies. Use this data to gain insights and adapt your policies to improve their performance.

Note:
The adaptive authentication metrics page requires the **Adaptive Authentication** (com.snc.adaptive_authentication) plugin. For more details about this feature, see Adaptive authentication.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Metrics



Use the **Metrics** tab to view reports relating to your adaptive authentication configuration. The following reports are displayed in this tab.

- Policy Results Rates
- Event Failure Distribution
- Event Success Distribution
- Denied IP Addresses
- Authentication User Logins
- API User Logins
- Authentication Trend

Use the **Show** list to select a time span for the displayed reports

Adaptive Auth Policies

Use the **Adaptive Auth Policies** tab to view the adaptive authentication policies and policy contexts on your instance. Click on any entry on these lists to view the associated record. For more details on these records, see Adaptive authentication

Settings

Use the settings tab to view and configure adaptive authentication system properties. For more information on these properties, see Configure adaptive authentication properties

Email metrics

Analyze your email metrics to look for anomalous behaviors that are related to the incoming emails to your instance. For example, if the metrics indicate a spike in spam emails from specific domains, you can define inbound actions that prevent their delivery to the instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

For each email metric, a count appears for each type of email that is delivered or sent to the instance during the calendar day.

Notification preference	Description
External Incoming Email	Number of incoming emails for the calendar day that were delivered to the instance from external email domains. **Note:** The external email domains are those domains that are not listed in the *security.list.internal.domains* system property, because this property tracks only your internal email domains. To learn more about this property, see Available system properties.
Spam	Number of incoming emails for the calendar day that were delivered to the instance and marked as spam. A number that is out of line with historical trends may indicate that attempts are being made to compromise your instance security.
Trusted Incoming Email	Number of incoming emails to the instance for the calendar day from email domains designated as trusted.
Untrusted Incoming Email	Number of incoming emails to the instance for the calendar day from email domains designated as untrusted. You can designate untrusted or trusted email domains in the Untrusted And Trusted Domain form so that you can track your inbound emails that are sent from them. To learn how to designate untrusted or trusted email domains, see Designate email domains as untrusted or trusted.

After you click an email metric, you can learn about the possible email security issues in your instance by clicking one of the following:

Command	Description
Chart	Incoming email counts and count trends over time for the selected email type (spam, incoming external, untrusted, or trusted).
Records	Individual email records that compromise the daily count for the selected email type.
More Info	Additional information for the selected email type.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
The email metrics apply only to your incoming emails to the instance. The metrics do not apply to the normal traffic that is processed through your enterprise-wide email servers. To learn about defining inbound actions and how they impact the processing of your inbound emails, see Inbound email actions.

Designate email domains as untrusted or trusted

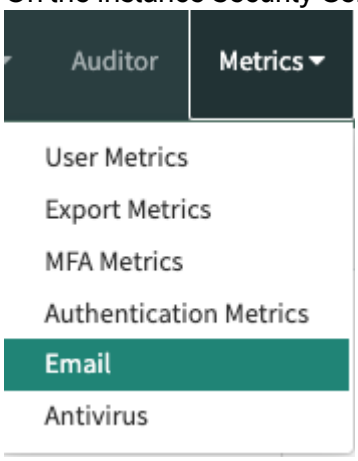
Designate specific email domains as untrusted or trusted so that you can monitor the metrics for incoming emails from these sources in your instance.

Before you begin
Role required: security_dashboard_user or admin

About this task
When untrusted or trusted domains send emails to your instance, their daily counts appear on the **Untrusted Incoming Email** or **Trusted Incoming Email** metrics on the Email page. You can then track email activity from these domains and use email logs to view specific incoming emails. You can also specify a user, usually a manager, or a security analyst, to notify whenever activity occurs from the untrusted or trusted domain.

Note:
Designating an email domain as untrusted is for security tracking purposes only. Administrators can also set up a system address filter to ignore emails from untrusted domains. To learn about filtering emails to block their delivery, see System address filters.

Procedure
1. Navigate to **All** > **System Security** > **Instance Security Center**.
2. On the Instance Security Center homepage, select **Email** from the **Metrics** menu.



3. On the Email page, in the Untrusted And Trusted Domains section, click **New**.
4. On the form, fill in the fields.

Untrusted And Trusted Domain form

Field	Description
Domain	Name of the email domain that you are designating as untrusted or trusted. For example, enter `servicenow.com` to designate ServiceNow employees can send trusted emails to the instance.
Category	Category that indicates if the email domain is untrusted or trusted: **Untrusted**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Designates that the email domain as untrusted. You use it to identify domains that send suspicious or emails that pose a potential security threat to the instance. **Trusted** Designates that the email domain as trusted. You use it to identify domains when your metrics indicate that the incoming emails from it pose no security threats. Designating the domain as trusted enables you to track its inbound email activity over time.
Active	Check box for enabling or disabling the designated untrusted or trusted status for the specified email domain.
Notify	Name of the user to notify by email when activity occurs in the untrusted or trusted domain. Click the spotlight search icon ( ) to search for the name of the user. Leave the **Notify** field blank if you do not want notifications sent.

5. Select **Save**.

Result

Untrusted or trusted email domain information is also added to the **Untrusted And Trusted Domains** listing on the Email page.

Email metrics

Antivirus metrics

If the Antivirus Scanning plugin is activated, Antivirus Scanning runs in your instance to help protect it against virus infections from attachments.

The following metrics appear for the last 60 days of activity, and enable you to assess the effectiveness of the Antivirus Scanning functions.

Antivirus Events

Antivirus Events indicate the number of antivirus events in your instance, by date. To access the antivirus events, navigate to **System Security** > **Instance Security Center** and select the Metrics tab. Color coded graph lines represent the following types of antivirus events:

Color	Description
Blue	Number of files quarantined by Antivirus Scanning in this instance for the indicated date.
Green	Number of infected files downloaded to the instance, and then quarantined for the indicated date. These files are primarily email attachments that contain a virus or rouge code.
Yellow	Number of quarantined files in the instance that were deleted for the indicated date.
Orange	Number of quarantined files in the instance that were restored for the indicated date.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Color	Description
	Note: After Antivirus Scanning runs and finds any false positives, you can restore a quarantined file and make it accessible in the instance.

- To access the Analytics Hub page and view the detailed score card and analytics information for a specific date, click a colored line in the Antivirus Events graph. For example, click the blue graphics line to view analytics information for files quarantined for a specific date.
- To view the following breakdowns in the Analytics Hub page, click , then click:

Breakdown	Description
AppSec - Antivirus Event Source	Source of the antivirus event. ○ **On Upload:** Occurred due to an upload of an infected file, usually an attachment. ○ **From Quarantine:** Occurred due to the quarantine of an infected file, usually an attachment. ○ **On Download:** Occurred due to a download of an infected file, usually an attachment. ○ **From Record:** Occurred due to an infected record in a table.
AppSec - Antivirus Event Type	Type of antivirus event. ○ **Quarantined:** Occurred due to the quarantine of a file, usually an attachment. ○ **Downloaded:** Occurred due to a download of a file, usually an attachment. ○ **Restored:** Occurred due to the restoration of a quarantined file. ○ **Deleted:** Occurred due to the deletion of a quarantined file.
AppSec - Antivirus Uploader	Name of the logged in user who uploaded the files that were the source of virus infections detected by the Antivirus Scanning application.

Quarantined Files

Lists the infected files in the instance quarantined by Antivirus Scanning:

Field	Description
File name	Name of the infected file.
Content type	Type of content that was infected in the file. For example, **application/x-dosexec** is an infected application or DOS executable file, while **text/plain** is an infected .txt file.
Table	Name of the table that contains the infected file. For example, **incident** appears for an incident file record.
Virus	Name of the file quarantined by Antivirus Scanning.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Detected	Date and time the infected file was detected.
Created By	Name of the user who quarantined the infected file.
Created	Date and time the quarantine file record was created.
Table sys ID	Table system identifier assigned to the quarantine file record.

Note:
You can also add **Quarantined Files** and **Virus Types** tiles to the Event ribbon. To learn more, see Monitor security events and Configure the security event ribbon.

MFA metrics dashboard

The MFA metrics dashboard shows information on your instances multi-factor authentication configuration. Use the dashboard to ensure your MFA configuration meets your security standards.

Required ServiceNow AI Platform roles

security_dashboard_user or admin, needed to view the PCI compliance score dashboard.

Access the MFA metrics dashboard

To open the dashboard, navigate to **System Security** > **Instance Security Center**. From the instance security center, click **Metrics** in the header, then select **MFA Metrics**.

Use cases

For examples of how different people in your organization would use this dashboard, see these use cases.

User	Dashboard use
Security dashboard user (security_dashboard_user)	Continually monitor and manage instance security compliance.
Admin (admin)	Continually monitor instance security compliance to detect and respond to security threats.

© 2026 ServiceNow, Inc. All rights reserved.

Activate the ISC Virtual Agent interface

If you have the admin role, you can activate the ISC Virtual Agent Conversations plugin (com.glide.isc_virtualagent). Activating this plugin installs the Virtual Agent and Natural Language Understanding (NLU content packs, providing Virtual Agent access from the Instance Security Center.

Before you begin

Important:

Instance Security Center (ISC) has reached the end of sales as of September 2024, and is no longer supported or available for new activation.

ServiceNow Security Center (SSC) is the recommended solution going forward. For more information, see Instance Security Center to ServiceNow Security Center migration.

The Virtual Agent interface in the Instance Security Center is only available for users with paid Virtual Agent subscriptions, and who have activated the Glide Virtual Agent (com.glide.cs.chatbot) plugin. To learn more, see Activate Virtual Agent.

Role required: admin.

About this task

The ISC Virtual Agent interface enables you to perform the following tasks:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Ask security-related questions, then get quick summary answers and reference links to learn more.
- Get answers related to the Instance Security Center, Platform Security, ServiceNow security policies, trust, governance, risk, and other processes.
- Search for security-related resources, such as Knowledge Base topics in the Now Support Security Portal.

Plugins for ISC Virtual Agent

Plugin	Description
ISC Virtual Agent Conversations [com.glide.isc_virtualagent]	Activates the ISC Virtual Agent Conversations content pack for the Instance Security Center.
ISC NLU Model for Virtual Agent Conversations [com.glide.isc_nlu]	Activates the Natural Language Understanding (NLU) content pack for the Instance Security Center.

Note:
Activating the com.glide.isc_virtualagent plugin automatically activates com.glide.isc_nlu. However, if you activate the com.glide.isc_nlu plugin first, you must manually activate com.glide.isc_virtualagent as well.

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

   Note:
   When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

   You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Hardening settings

The ServiceNow Security Center (SSC) hardening settings content contains detailed descriptions and compliance values for the security-related system properties and plugins in the ServiceNow AI Platform. You can set these properties using the hardening settings app in the Security Center.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Overview and purpose

The Security Center calculates a daily compliance score, expressed as a percentage that is based on how compliant your current instance security settings are with the compliance values in Security Center hardening settings.

You can manage the specific security configuration settings that may affect the score for your instance directly from the Security Center.

The hardening settings configurations are explained with several attributes described in the table.

Hardening settings configuration details

Configuration attribute	Description
Overview	Provides a high level overview of the recommendation.
Configuration name	The property or plugin name.
Configuration type	Describes where the property can be configured outside of the Security Center, such as in system properties (*`sys_properties_list.do`*).
Data type	Describes the type of value required for the configuration. Examples are true/false boolean, installation, plugin, string, etc.
Recommended value	The value that is recommended by the Security Center to enhance security compliance in your instance.
Default value	The value that the configuration is set to in the base system.
Category	The name and link to the category for the hardening setting.
Security risk	**Severity score**: The score indicates the potential security risk to your instance as per the likelihood of the vulnerability to be exploited. The security vulnerability is considered and scored individually using the CVSS (Common Vulnerability Scoring System) score on a scale ranging from **0.0** to **10.0**. See https://nvd.nist.gov/vuln-metrics/cvss/v3-calculator for additional information.
	Severity rating per CVSS score: • Critical: 9.0-10.0 • High: 7.0-8.9 • Medium: 4.0-6.9 • Low: .01-3.9 • None: 0.0
	Security risk details: Describes the importance of the setting configuration and the risk of not utilizing the recommended configuration.
Dependencies and prerequisites	Related settings or configurations that are required before or in conjunction with the hardening configuration.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Hardening settings configuration details (continued)

Configuration attribute	Description
Functional impact	The impact this hardening setting has on the operation of your instance.
References	Links to configuration documentation or other helpful information.

Note:
Some of the configurations can only be completed by Customer Service and Support and will be indicated as such.

To learn more about ensuring your instances meet hardening requirements, see Security hardening.

Other resources

For user reference, the ServiceNow AI Platform maintains extensive configuration capabilities information in the product documentation. You access most of the security content using the links found in Secure your instance. Also, see the following:

- Available system properties
- General security settings properties
- High Security Settings

Hardening settings baseline versions

Explore how baseline versions for hardening settings align with family and store releases.

Security Center works by ingesting a subset of system properties from an instance and displaying its configuration details, along with the security impact of non-compliance within the app. The baseline serves as the reference point for the system properties that are ingested with each release of the Security Center app.

Hardening settings baseline overview

Security Center version	Hardening settings baseline version	Supported families	Store release date	Installed by default with
SSC v1.1	Baseline v1.0	Utah, Vancouver	May 2023	Vancouver family
SSC v1.2	Baseline v1.0	Utah, Vancouver	Aug 2023	Store only
SSC v1.3	Baseline v2.0	Vancouver, Washington DC	Nov 2023	Washington family
SSC v1.5	Baseline v4.0	Washington DC, Xanadu	May 2024	Xanadu
SCC v1.6	Baseline v4.0	Washington DC, Xanadu	August 2024	Store only
SCC v 2.0	Baseline v5.0	Xanadu, Yokohama	November 2024	Yokohama
SCC v 2.2	Baseline v6.0	Xanadu, Yokohama	May 2025	Store Only

New hardening settings

New hardening settings are broken out by baseline release.

New hardening settings for baseline 7.0

New hardening settings have been released with Security Center baseline version 7.0.

- Enable Cross Scope Privilege Checks on Service Portal Form [New in Security Center 7.0]
- Validate query ACLs on Glide DB functions [New in Security Center 7.0]
- Use Document Classification to limit publicly accessible documents [New in Security Center 7.0]
- Restrict write access on system fields to admin users [New in Security Center 7.0]
- Require approval for agent-based Office 365 group membership changes [New in Security Center 7.0]
- Exclude Sensitive Tables and Fields from Data Generation [New in Security Center 7.0]
- Enforce Read Roles for Catalog Variable Search [New in Security Center 7.0]
- Enforce valid query string choice [New in Security Center 7.0]
- Restricted Binding functionality in case Bearer Authorization [New in Security Center 7.0]
- Disable resource owner password credentials (ROPC) in OAuth 2 token grants [New in Security Center 7.0]
- Enforce certificate trust [Updated in Security Center 1.3, removed in 2.0, added in 7.0]
- Prevent usage of 3DES keys [New in Security Center 7.0]
- Allow HTML Links to Trusted Domains in the Description Fields of the Impact Workspace Module [New in Security Center 7.0]
- Ensure Contextual Search Do Not Contain An Unvalidated Redirect [New in Security Center 7.0]
- Sanitize HTML in the Description Fields of the Impact Workspace Module [New in Security Center 7.0]

New hardening settings for baseline version 6.0

New hardening settings have been released with Security Center baseline version 6.0.

- Enforce application specific ACLs only for application data
- Disable legacy JQuery UI usage
- Display recommendations for high risk UI pages
- Enforce current password policy compliance requirements on login
- Prevent Users From Accepting Warning To Bypass CSRF Validation [Updated in Security Center 1.3 and 1.5]
- Set minimal password length [Updated in Security center 2.2]
- Limit session length for high assurance sessions

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Disable deprecated TLS versions
- Disable local login for users with Single Sign-On (SSO) enabled
- Reduce allowed bypasses for multifactor setup
- Prevent impersonating user from viewing application data
- Prevent verbose HTTP request logging
- Enable relay state in SAML requests to prevent replay attacks
- Minimize failed login attempts for high assurance sessions
- Apply continuous authentication policies to mobile sessions
- Disable use of TripleDES/3DES encryption algorithm

New hardening settings for baseline version 5.0

New hardening settings have been released with Security Center baseline version 5.0.

- Enforce ACL on HR Lifecycle Events Data [New in Security Center 2.0]
- Sanitize All Translated HTML Fields [New in Security Center 2.0]
- Configure Service Portal Widgets Allow List [New in Security Center 2.0]
- Enforce ACL on HR Core Data [New in Security Center 2.0]
- Enforce ACL on HR Virtual Agent Data [New in Security Center 2.0]
- Configure Service Portal Widgets Table Allow List [New in Security Center 2.0]
- Enforce Security Scope for Service Application Information [New in Security Center 2.0]
- Prevent Empty ACL Creation [New in Security Center 2.0]
- Prevent Unauthenticated Access to Virtual Agent Embedded Web Client
- Set Automatic Token Cleanup for Token Credentials [New in Security Center 2.0]
- Restrict Global App Development by Role [New in Security Center 2.0]
- Enable ACLs for Encoded Query in Simple List Widget [New in Security Center 2.0]
- Invalidate Session After OAuth Token Expiration [New in Security Center 2.0]
- Set Allowed MIME Child Types [New in Security Center 2.0]
- Restrict Impersonation to Admin [New in Security Center 2.0]

New hardening settings for baseline version 4.0

New hardening settings have been released with Security Center baseline version 4.0.

- Review extraneous explicit role access control conditions [Removed in Security Center 1.5]
- Enable work order management query rules for service organizations [New in Security Center 1.5 and updated in 2.0]
- Restrict flow context read access [New in Security Center 1.5]
- Limit policy based session access mobile refresh token interval [New in Security Center 1.5]
- Enable policy based session access for mobile [New in Security Center 1.5]
- Prevent inactive users from logging in [New in Security Center 1.5]
- Configure event management assignment group admin roles [New in Security Center 1.5]

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Enforce Security Scope for Agent Workspace for HR Case Management [New in Security Center 1.5 and updated in 2.0]
- Enforce security scope license and permit playbook [New in Security Center 1.5 and updated in 2.0]

New hardening settings for baseline version 2.0

New hardening settings have been released with Security Center baseline version 2.0.

- Ensure archive table ACLs are checked [New in Security Center 1.3 and updated in 1.5]
- Enforce application scope restrictions [New in Security Center 1.3 and removed in 1.5]
- Enable the hardened java security manager [New in Security Center 1.3]
- Verify certificate revocation [New in Security Center 1.3]
- Require clearing pasteboard when backgrounding mobile application [New in Security Center 1.3 and updated in 1.5]
- Enable protected tables plugin [New in Security Center 1.3]
- Enforce strict elevate privilege [New in Security Center 1.3]
- Limit integrations' active session life span [New in Security Center 1.3]
- Proactively invalidate inactive sessions [New in Security Center 1.3 and updated in 1.5 and 2.0]
- Enable MID audit log [New in Security Center 1.3 and updated in 1.5]
- Use of secure insert multiple operation within import set API [New in Security Center 1.3]
- Enforce OCSP check on network error [New in Security Center 1.3 and updated in 2.0]
- Enforce security rules to sharing dashboards [New in Security Center 1.3]
- Restrict oauth parameters to POST body [New in Security Center 1.3]
- Limit attachment size in training and prediction flows for GraphQL endpoints [New in Security Center 1.3 and updated in 1.5]
- Disable GlideRecord Scope Fencing Legacy Behavior [New in Security Center 1.3 and updated in 1.5 and 2.0]
-
- Required jms connection factories [New in Security Center 1.3 and updated in 1.5 and 2.0]
- Limit attachment size in training and prediction flows [New in Security Center 1.3 and updated in 1.5]
- Log session audit events [New in Security Center 1.3 and updated in 1.5]
- Require write access to access service catalog add item page [New in Security Center 1.3]
- Define active session timeout exception roles [New in Security Center 1.3]
- Certificate based authentication not enforced [New in Security Center 1.3]
- Enforce scoped ACL access for information request playbooks [New in Security Center 1.3 and updated in 1.5]
- Hide user comments on articles [New in Security Center 1.3]
- Ensure dashboards creation/deletion requires access check [New in Security Center 1.3 and updated in 2.0]
- Enforce device encryption and passcode requirements [New in Security Center 1.3]
- Validate file mime type in AttachmentCreator soap web service [New in Security Center 1.3 and updated in 1.5]

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Verify certificate revocation [New in Security Center 1.3]
- Check impersonation on ACL evaluation in HR App [New in Security Center 1.3 and updated in 1.5]
- Require captcha for guest walk-up experience in customer service application [New in Security Center 1.3 and updated in 1.5]
- Require Authentication on Event Management HTTP Processor [New in Security Center 1.3, Updated in 1.5, and removed in 2.0]
- Limit guest's active session life span [New in Security Center 1.3]
- Disallow target cloning [New in Security Center 1.3]
- Set safe content security policy for svg files [New in Security Center 1.3]
- Anti-CSRF token validation time [New in Security Center 1.3]
- Restrict knowledge bases access [New in Security Center 1.3]
- Enforce scope security for public sector digital services [New in Security Center 1.3]
- Restrict HR case updates from personal emails [New in Security Center 1.3 and updated in 1.5]
- Limit UI active session life span [New in Security Center 1.3]
- Enforce secure referrer policy [New in Security Center 1.3]

Updated hardening settings

Updated hardening settings are broken out for each baseline release.

Updated hardening settings for baseline version 7.0

Some hardening settings have been updated with the release of Security Center baseline version 7.0.

Documentation	Updates

Enable relay state in SAML requests to prevent replay attacks	• Description:
	  ○ (Old) When "glide.authenticate.sso.saml2.enable_relay_state_with_id" is set to "true", the relay state parameter will contain the sys id of a record in the table multisso_request_parameter which the relay state url to redirect to. This relay state protects against SAML Replay attacks which could be possible in some ServiceNow instance versions if the property glide.authenticate.sso.saml2.enable_relay_state_with_id is set to false. Replay attacks allow a well-positioned attacker who has gained access to the SAML request to resubmit a valid request in orger to gain unauthorized access to the platform.
	  ○ (New) Protect against SAML replay attacks using the glide.authenticate.sso.saml2.enable_relay_state_with_id system property. When this property is set to true, the relay state parameter

Documentation	Updates
	multisso_request_parameter which contains relay state url to redirect to. ○ (New) When this property is set to true, the relay state in a SAML request contains the sys_id of a record in the MultiSSO Request Parameters [multisso_request_parameter] table, which contains relay state URL to redirect to.
Disable local login for users with Single Sign-On (SSO) enabled	• Technical Configuration Name ○ (Old) <blank> ○ (New) glide.sso.acr.enabled,glide.authenticate.multisso.enabled • Description ○ (Old) ServiceNow instance owners are responsible for provisioning user accounts for their instance and ensuring that users can access the instance in expected ways. When a user, that is not locked out, has a valid password hash on the "sys_user.user_password" field, that user can perform local database authentication for both interactive and non-interactive access types. If a user is also configured to use SSO authentication, local database authentication can still occur without additional controls in place. That is, SSO users with valid local credentials may access the instance, or parts of the instance, with those local credentials. When SSO authentication is enabled for a user, it is best practice to prevent that user from logging in locally. This reduces the chance that the valid local login credentials are stolen and used to login by a malicious user. ○ (New) Users configured to use SSO authentication may be able to access the instance, or parts of the instance, with local credentials stored in the user_password field of their User [sys_user] record. This access applies to both interactive and non-interactive access for users who aren't locked out.

Disable legacy JQuery UI usage	Fallback Value • (Old) true • (New) false
Enforce application specific ACLs only for application data	• Description ○ (Old) Properties in the format 'glide.enforce_security_scope.' property, such as 'glide.enforce_security_scope.sn_hr_core', control the behavior of application data residing in primary tables outside the application, such as 'sys_attachment' or 'sys_email'. When properties in the format have a value of 'true', only the application specific ACLs are evaluated for access to the application data residing in these tables. When the properties do not have a value of 'true', the ACLs on the primary table will still be evaluated for access, potentially allowing unauthorized or undesired access to application data. Not all applications are designed to work in this configuration or ship a 'sys_properties' record for this purpose. The following application scopes contain this property: ▪ sn_uni_task ▪ sn_uni_req ▪ sn_svc_appl_info ▪ sn_professional

Prevent impersonating user from viewing application data	• Description ○ (Old) Properties in the format '.impersonateCheck', such as 'sn_hr_core.impersonateCheck', control how an impersonating user can access specific application data belonging to another user. When properties in this form are set to 'true', an admin level user impersonating another user will not be able to access the application specific data belonging to that user. Not all applications are designed to work in this configuration or ship a 'sys_properties' record for this purpose. A value of "false" for these properties allows an admin level user to impersonate another user and access application data with the impersonated user's access. This may be undesirable or allow for unauthorized data access in specific application contexts. The following scopes contain this property: ▪ sn_opp_market ▪ sn_jny ▪ sn_imt_vaccine ▪ sn_imt_health_test ▪ sn_hr_core ▪ sn_egd_goals ▪ sn_egd_core ▪ sn_egd_act ○ (New) Use system properties to prevent an impersonating user from viewing application data. Prevent admin level from accessing the application specific data belonging to that

Documentation	Updates

Disallow target cloning [New in Security Center 1.3]	• Description
	  ○ (Old)
	  If glide.db.clone.allow_clone_target is not set to the recommended value of false, then the instance can be used as a clone target, or a record that specifies the instance URL and credentials used for cloning. A system clone is when everything in a database is copied from one instance to another. This is a security risk because the instance database can be overwritten in the cloning process, leading to data loss and lack of data integrity. As a remediation, ensure that glide.db.clone.allow_clone_target is set to false.
	  ○ (New)
	  Protect your instance from being used as a clone target by setting the glide.db.clone.allow_clone_target system property to false. A system clone copies everything in a database from a source instance to the target instance. This is a security risk because the instance database on the target instance is overwritten in the cloning process, leading to data loss and lack of data integrity.
	• Remediation
	  ○ (Old)
	  Ensure the property "glide.db.clone.allow_clone_target" is set to "false".
	  ○ (New)
	  Set the glide.db.clone.allow_clone_target system property to false on production instances to disallow your instance from being selected as a clone target.
	• CVSS score

Documentation	Updates
	When the Glide Property 'com.glide.security.protected_table.enabled' is set to 'true', The Protected Tables plugin will be utilized to prevent higher privilege users on an instance from tampering with log tables. The following logging tables will have special protections when this property is set to 'true': ▪ syslog (config not modifiable) ▪ syslog_transaction ▪ sys_outbound_http_log ▪ sysevent ▪ sys_audit ▪ sys_push_notification ▪ protected_table_configuration (config not modifiable) ▪ syslog_app_scope The integrity of logs is important for determining malicious activity on an instance by a customer admin. • Remediation ○ (Old) Set the Glide Property 'com.glide.security.protected_table.enabled' to 'true'. ○ (New) Set the Glide Property 'com.glide.security.protected_table.enabled' to 'true'. This requires a user with the "security_admin" role. • CVSS Score ○ (Old) 4.5 ○ (New) 4
Ensure dashboards creation/deletion requires access check [New in Security Center 1.3 and updated in 2.0]	• Description ○ (Old) The property 'glide.processors.check_access_before_process' enables ACL enforcement for creating or deleting dashboards so long as a user is logged in. Disabling this property (i.e., setting it to false) effectively allows for an ACL bypass on dashboards which allows all authenticated low privileged users to arbitrarily delete and add dashboards. This property should always be set to true.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	○ (New) The property 'glide.processors.check_access_before_process' enables ACL enforcement for creating or deleting dashboards. When the property is set to "true", access control checks are performed on the dashboards. When this property is set to "false", authenticated users can arbitrarily delete and add dashboards. • Remediation ○ (Old) Ensure the Glide Property 'glide.processors.check_access_before_process' exists and is set to the value 'true'. If the property does not appear in the sys_properties table, add a new record. ○ (New) Set the glide.processors.check_access_before_process system property to true. If the property does not appear in the System Properties [sys_properties] table, the fallback value is true. • Security Risk ○ (Old) <blank> ○ (New) When this property is set to "false", authenticated users can arbitrarily delete and add dashboards. • Functional impact ○ (Old) <blank> ○ (New) Users may not have access to delete dashboards as before. To mitigate this functional impact, users can be granted standard access to dashboards. • Fallback Value ○ (Old) false ○ (New) true
Define active session timeout exception roles [New in Security Center 1.3]	• Description ○ (Old)Active session timeouts are a feature to ensure that a hijacked session cannot be used indefinitely without providing authentication information. This property

Documentation	Updates
	leading to data loss and lack of data integrity. As a remediation, ensure that *glide.db.clone.allow_clone_target* is set to **false**. Not setting this property to the recommended value of false enables the instance to be used as a clone target. This is a security risk because the instance database can be overwritten in the cloning process. • Description (Old): If *glide.db.clone.allow_clone_target* is not set to the recommended value of **false**, then the Instance can be used as a clone target. This risks the instance database being overwritten by cloning process, leading to integrity and availability loss.
Restrict oauth parameters to POST body [New in Security Center 1.3]	• CVSS Score (New): 4.2 • CVSS Score (Old): 7.4
Enforce URL allowlist check [Updated in Security Center 1.3, 1.5, and 2.0]	• Description (New): If *glide.security.url.whitelist.strict_check* is not set to the recommended value of **true** then all external URLs are allowed for redirection when *glide.security.url.whitelist* is empty. If *glide.security.url.whitelist* is not empty, then only external URLs in the whitelist are allowed. Thus either setting *glide.security.url.whitelist.strict_check* to true OR ensuring *glide.security.url.whitelist* is set to a non-empty value with the allowed external URLs leaves the instance in a secure state. If all external URLs are allowed for redirection, this could allow an attacker to redirect a user to a malicious website. • Description (Old): If *glide.security.url.whitelist.strict_check* is not set to the recommended value of **true**, and if *glide.security.url.whitelist* is not set to an organization's approved URL, then all external URLs are allowed for redirection. This could allow an attacker to redirect a user to a malicious website.

Documentation	Updates
	• CVSS Score (New): 6.3 • CVSS Score (Old): 8.3

Require XMLdoc2 entity validation with allowlistDisable entity expansion [Updated in Security Center 1.3]	• If the **glide.stax.whitelist_enabled** system property does not exist in the System Properties [sys_properties] table, or it is not set to the recommended value of **true**, then all external entities are allowed when the **glide.stax.allow_entity_resolution** system property is set to the value of **true**. If customizations do not require entity expansion, use the **glide.stax.allow_entity_resolution** system property to disable external entity expansion. The XML completes parsing but doesn't include any internal or external entities.
	  ○ If you set **glide.stax.allow_entity_resolution** to **true**, all external entities attempt to resolve or expand subject entities, subject to the setting of the **glide.stax.whitelist_enabled** property.
	  ○ If you set **glide.stax.allow_entity_resolution** to **false**, all entity resolution and expansion is blocked. To learn more about this property, see Disable Entity Expansion within the XMLDocument2 Streaming Parser [Updated in Security Center 1.5].
	  When **glide.stax.whitelist_enabled** is set to **true**, define a listing of comma-delimited FQDN in the **glide.xml.entity.whitelist** property, which are the only URLs that can be reached using the XML entity processing property. To learn more, see Restrict XML external entities [Updated in Security Center 1.3 and 2.0]. Attackers can use this vulnerability to expand data exponentially in an External Entities Expansion (XXE) attack, quickly consuming all system resources.
	• Description (Old): If *`glide.stax.whitelist_enabled`* is not set to the recommended value of **true**, then all external entities are allowed. This

Documentation	Updates
	could lead to External Entities Expansion (XXE) attacks. • Rule Script: Script has been updated to improve detection accuracy
Restrict XML external entities [Updated in Security Center 1.3 and 2.0]	• Protect against XXE attacks by using an allow list to prevent attackers from including arbitrary HTTP requests that the server may execute. This could lead to additional attacks using the server's trust relationship with other entities. Add `http://java.sun.com/j2ee/dtds/` to the value of the **glide.xml.entity.whitelist** system property, then set the **glide.xml.entity.whitelist.enabled** system property to **true**. Values other than `http://java.sun.com/j2ee/dtds/` can be included in the in the **glide.xml.entity.whitelist** property, but are unnecessary for the out of the box platform state. Review any additional values to determine if they are safe. **Warning:** This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible. • Description (Old): If "glide.xml.entity.whitelist" is not set to the recommended value of "http://java.sun.com/j2ee/dtds/" and "glide.xml.entity.whitelist.enabled" is not set to "true", then a malicious external entity can be allowed which could cause an XXE attack. An attacker can use the DTD to include arbitrary HTTP requests that the server may execute. This could lead to additional attacks using the server's trust relationship with other entities. • Rule Script: Script has been updated to improve detection accuracy
Restrict email domains for external user registration [Updated in Security Center 1.3, 1.5, and 2.0]	Rule Script: Script has been updated to improve detection accuracy

Documentation	Updates
Validate file mime type in AttachmentCreator soap web service [New in Security Center 1.3 and updated in 1.5]	• Ensure that MIME-types are validated for attachments to prevent dangerous files from being uploaded on your instance using wrong file extensions. Set the **glide.attachment.enforce_security_validation** system property to **true**. When set to **true**, files are uploaded with the correct file type extension. • Description (Old): If "glide.attachment.enforce_security_validation" is not set to the recommended value of "true", then there will be no validation for attachment mime-type and dangerous files could be uploaded on the system using wrong file extensions. When this property is set to 'true', files are uploaded with the correct file type extension. It is a security best practice to validate file uploads at least with MIME type validation. • CVSS Score (New): 6.7 • CVSS Score (Old): 7.5
Define allowed ServiceNow internal IP addresses [Updated in Security Center 1.3 and 1.5]	• Description (New) Prevent unnecessary exposure of instance access to wider group of people using the **glide.ip.authenticate.strict** and **glide.ip.authenticate.allow.secured** system properties. When the **glide.ip.authenticate.strict** system property is set to **true**, internal ServiceNow personnel and systems can only make inbound connections to your instance from essential IP ranges. This limits ServiceNow's visibility to essential internal infrastructure on your instance, and prevents access by broader ServiceNow personnel such as support and sales staff via corporate networks. The **glide.ip.authenticate.allow.secured** system property grants internal ServiceNow inbound connections, including regular authenticated access and unauthenticated diagnostic pages. If not set to **true**, then a broader ServiceNow internal IP range defined in the

Documentation	Updates
	glide.ip.authenticate.allow property is used to grant these internal ServiceNow inbound connections. Ensure the **glide.ip.authenticate.allow.secured** system property contains only trusted values and that the property **glide.ip.authenticate.strict** is set to **true**. • Description (Old): If "glide.ip.authenticate.strict" is set to "true", then internal ServiceNow personelle and systems can only make inbound connections to the instance from essential IP ranges. This limit's ServiceNow's visibility into the instance to essential internal infrastructure, and prevents access by broader ServiceNow personelle such as support and sales staff via corporate networks. When set to "true", the "glide.ip.authenticate.allow" property is used to grant internal ServiceNow inbound connections. If not set to "true", then a broader ServiceNow internal IP range as defined in "glide.ip.authenticate.allow" is used to grant internal ServiceNow inbound connections.
Disable Entity Expansion within the XMLDocument2 Streaming Parser [Updated in Security Center 1.5]	• Description (New): Disable entity expansion on your instance to secure your instance from attacks such as ability to read system files, and Denial of Service. Use the system property to disallow XML entities to be expanded during parsing by the streaming parser (XMLDocument2). Set the **glide.stax.allow_entity_resolution** system property to **false** to disable entity expansion on your instance. If this property does not appear in the System Properties [sys_properties] table, the default value is **true**. Create the property record and set the value to **false** to change it's value. • Description (Old): If "glide.stax.allow_entity_resolution" is not set to the recommended value of "False", then this property allow XML entities to be expanded during parsing by the streaming parser (XMLDocument2). XML entity

Documentation	Updates
	expansion can lead to attacks such as ability to read system files, and Denial of Service. • Remediation (New): Ensure the property *glide.stax.allow_entity_resolution* exists in the sys_properties table and is set to **false**. If the property does not appear in the sys_properties list the default value is **true**. • Remediation (Old): Ensure the property "glide.stax.allow_entity_resolution" is set to "false".
Deny by default with empty ACLs [Updated in Security Center 1.3]	• Description (New): Prevent your instance's legacy security manager from allowing access to resources when there are no ACLs defined for that resource, or if there are only wildcard table-level ACLs (for example, `incident.*`). When allowed access by default, anything that does not have explicit ACLs set is susceptible to manipulation. Set the **glide.sm.default_mode** system property value to **deny** to disallow access when there are no define ACL rules, or there are only wildcard table-level ACLs. • Description (Old): If "glide.sm.default_mode" is not set to the recommended value of "deny", then the instance's legacy security manager allows access to a resource when there are no ACLs defined for that resource; or only wildcards table-level ACLs. By setting this to "allow" anything that does not have explicit ACLs set is susceptible to manipulation. • CVSS Score (New): 6.3 • CVSS Score (Old): 8.8 • Rule Script: Script has been updated to improve detection accuracy
Restrict unauthenticated access to attachments	• Description (New): Secure the images on your instance to prevent sensitive information leak. Images on your instance are accessible via urls that end in `.iix`. Set the **glide.image_provider.security_enabled**

Documentation	Updates
	system property to **true** to prevent access to your images via these URLs. **Note:** This property is not honored for images from the attachment table if the origin table is one of: ○ Stationeries [sysevent_email_style] ○ Welcome Page Sections [sys_home] ○ System Properties [sys_properties] Restriction should be applied for unauthenticated users as some attachments might contain sensitive information. • Description (Old): If "glide.image_provider.security_enabled" is not set to the recommended value of "True", then all images are accessible via urls that end in ".iix". This would allow unauthenticated access to images leading to sensitive information leak.
Disable embedded HTML code [Updated in Security Center 1.3]	• Description (New): Disable support for displaying HTML code embedded using the `[code]` tag. This tag allows rendered HTML to display in journal fields and may lead to cross-site scripting (XSS) attacks. These attacks can enable foreign scripts to execute on a user session in the logged in browser's context. Attackers can use these scripts to steal session information and sensitive data. The HTML language was not designed to separate script from formatting, so allowing user-controlled HTML in any system has inherent risk. Setting the **glide.ui.security.codetag.allow_script** to **false** is compliant, and significantly reduces this risk, however some small risk remains. It disables only the script portion of a `code` tag, and relies on sanitizing all known conventions of script in the HTML. Set the **glide.ui.security.allow_codetag** system property to **false** to completely prohibit journal fields and forms from displaying rendered HTML.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Documentation	Updates
	The ServiceNow AI Platform mitigates many injection and cross-site attacks by implementing escaping and encoding techniques. As a result, users can't write/submit HTML formatted inputs for journal fields. But journal fields can render text enclosed within code tags as HTML. ○ However, there is an associated security risk. If set to `true`, malicious users can write harmful HTML JS code that may be executed on a different client browser after rendering of journal fields. ○ Set this property to `false` so that administrators can prevent journal fields from rendering HTML code by disabling support for the `[code]` tag. • Description (Old): Disables support for embedding HTML code created using the [code] tag. If "glide.ui.security.allow_codetag" is not set to the value of "false", then rendered HTML in journal fields and forms will not be displayed. Setting "glide.ui.security.allow_codetag" to "true" with display embedded HTML code with may lead to cross-site scripting (XSS) attacks.
Enable password reset policy checks [Updated in Security Center 2.0]	Rule Script: Script has been updated to improve detection accuracy
Enable email spam scoring and filtering [Updated in Security Center 1.3]	• Technical Configuration Name (New): com.glide.email_filter,glide.email.read.active • Technical Configuration Name (Old): com.glide.email_filter • Rule Script: Script has been updated to improve detection accuracy
Escape Excel Formulas [Updated in Security Center 1.3]	• Description (New): Prevent potentially malicious formulas in programs such as Excel from being executed after exporting and opening the file by escaping formulas in these files. Excel injection occurs when websites embed untrusted entries inside Excel files. When you use a spreadsheet application such as Microsoft Excel, or LibreOffice Call, to open a file, any cells starting with +, -, =, or @ are interpreted as a formula unless properly

Documentation	Updates
	escaped. Malicious formulas pose a risk even when the spreadsheet doesn't contain any sensitive information, as they can be used to compromise the viewer's computer through code execution. Set the **glide.export.escape_formulas** system property to **true** to escape these formulas from executing. • Description (Old): Setting the property "glide.export.escape_formulas" to the recommended value of "true" prevents potentially malicious formulas in programs such as Excel from being executed after exporting and opening the file. Cell values for CSV, Xls, and XLSX can be interpreted as formulas by spreadsheet applications unless properly escaped which can lead to malicious code execution. • CVSS Score (New): 6.4 • CVSS Score (Old): 6.5
Restrict JSONP Requests to Trusted URLs [Updated in Security Center 1.3]	• Description (New): Increase security on your instance by ensuring that only trusted URLs for the AngularJS $http service can allow/reject JSONP requests. JSONP requests are allowed to any URL if these properties are not configured and enabled. Use the value of the **angular.jsonp.inclusion_list.urls** system property to define a list of URLs that are trusted and allow for this purpose. Set the value of the **angular.jsonp.inclusion_list.enabled** system property to **true** to limit allowed JSONP to only the URLs listed in **angular.jsonp.inclusion_list.urls**. • Description (Old): This property specifies trusted URLs for the angularJS $http service to allow/reject JSONP requests. Property is necessary because this is a potentially breaking change for customers, so they need a way to add their trusted URLs. If "angular.jsonp.inclusion_list.enabled" is not set to the recommended value of "true", then JSONP requests are allowed to any URL.

Documentation	Updates
Enable SNC access control plugin [Updated in Security Center 1.3]	• Description (New): Prevent ServiceNow Customer Service and Support personnel from accessing the instances without your express permission by enabling the SNC Access Control (com.snc.snc_access_control) plugin. Although all access to your instance is audited, you may prefer to control this access. This access method is fully auditable and tracked. **Note:** Other authorized ServiceNow Operations personnel, in their capacity to support and manage the product, are required to perform administrative actions on the underlying infrastructure. Enabling this plugin may affect support service levels and the Availability SLA. Availability SLA is then measured from the time that Support staff personnel are granted access to your instance. Enable the SNC Access Control (com.snc.snc_access_control) plugin to restrict access to your instance without your express permission. For more details on this feature, see ServiceNow access control. For activation information, see Activate ServiceNow access control • Description (Old): The SNC Access Control (com.snc.snc_access_control) plugin prevents Customer Service and Support personnel from accessing the instances without your express permission. However, other authorized ServiceNow Operations personnel, in their capacity to support and manage the product, are required to perform administrative actions on the underlying infrastructure. This infrastructure includes servers and databases, among other infrastructure components that make up the SaaS solution. This access method is fully auditable and tracked.This plugin enables you to restrict access to your instance without your express permission, so it may affect support service levels and the Availability SLA. Availability SLA is then measured from the time that Support staff personnel are granted access to your instance.

	• Remediation (New): Ensure the plugin "com.snc.snc_access_control" is activated. Read the documentation on activating at https://www.servicenow.com/docs/csh?topicname=t_ActivateSNCAccessControl.html&version=lates • Remediation (Old): Ensure the plugin "com.snc.snc_access_control" is activated. • CVSS Score (New): 3.3 • CVSS Score (Old): 8.2
Maximize failed login unlock timeout duration [Updated in Security Center 1.3]	• Technical Configuration Name (New): glide.user.unlock_timeout_in_mins, sysevent_script_action • Technical Configuration Name (Old): glide.user.unlock_timeout_in_mins • Description (New): Help secure your instance against brute force attacks by defining a time period during which a user cannot attempt to log in after being locked out. The **glide.user.unlock_timeout_in_mins** system property unlocks the user account after the time period that is specified in it's value. If no value is specified, your instance unlocks the user account after the default period of 15 minutes. • Description (Old): If "glide.user.unlock_timeout_in_mins" is not set to the recommended value of "15", then it may be easier to brute force accounts in a faster timeframe. This property unlocks the user account after the time period that is specified for the glide.user.unlock_timeout_in_mins property. If no value is specified, then the system unlocks the user account after the default period of 15 minutes. • Remediation (New): Set the **glide.user.unlock_timeout_in_mins** system property value to a minimum of **15**. If **glide.user.unlock_timeout_in_mins** does not exist, the default lockout time is set to 15 minutes. Ensure that the **SNC User Lockout Check with Auto Unlock** script action (found on the Script Action [sysevent_script_action] table) is present and active. The **SNC User**

Documentation	Updates
	MultiSSOv2, including SAML 1.1 and SAML 2.0, do not follow best practice and use opensaml library versions with known CVEs. If the known CVEs were exploitable in outdated opensaml libraries, this could allow the attacker to forge messages and bypass authentication through XML Signature Wrapping attacks, impersonate entities or allow person-in-the-middle attackers to gain unauthorized access to the platform. • CVSS Score (New): 0 • CVSS Score (Old): 7.1
Prevent inactive users from logging in [New in Security Center 1.5]	Rule Script: Script has been updated to improve detection accuracy
Enable MID audit log [New in Security Center 1.3 and updated in 1.5]	Rule Script: Script has been updated to improve detection accuracy
Ensure archive table ACLs are checked [New in Security Center 1.3 and updated in 1.5]	Rule Script: Script has been updated to improve detection accuracy
Define active session timeout exception roles [New in Security Center 1.3]	• CVSS Score (New): 6.4 • CVSS Score (Old): 7.1
Limit HTTP response body size [New in Security Center 1.3 and updated in 1.5]	• Description (New): Prevent `OutOfMemoryExceptions` that can result from a request response body being too large using the **glide.http.response.get_body.limit.enabled** and **glide.http.response.get_body.limit** system properties. These exceptions can cause denial of service (DOS) attacks as well as other issues that may aid attackers in compromising an instance. Not setting these properties to the recommended values could make your instance vulnerable to OutOfMemoryExceptions and denial of service attacks. To protect your instance against these security vulnerabilities: ○ Set the **glide.http.response.get_body.limit.enabled** system property to **true**. ○ Ensure that the **glide.http.response.get_body.limit** system property set to no more than 524,288,000 megabytes (500 MB). • Description (Old): The properties glide.http.response.get_body.limit.enabled

Documentation	Updates
	and glide.http.response.get_body.limit were introduced to enable new functionality that prevents Out of memory exceptions being thrown as a result of a requests response body being too big. Out of memory exceptions can cause denial of service attacks as well as other issues that may aid attackers in compromising an instance. • CVSS Score (New): 3.1 • CVSS Score (Old): 6.4
Limit UI active session life span [New in Security Center 1.3]	• Description (New): Reduce the scope of potential security incidents by decreasing the lifespan of active HTTP sessions. The **glide.ui.active.session.life_span** system property enforces a maximum lifespan on active HTTP sessions irrespective of inactive timeout. Longer maximum lifespans can allow an attacker to use a stolen session a for longer time, increasing the scope of a security incident. The default value of **0** disables timeout of active sessions Set the **glide.ui.active.session.life_span** to a value between 1 and 720. This value represents the time in minutes that HTTP sessions can remain active. • Description (Old): This configuration will enforce max lifespan on active guest HTTP sessions irrespective of inactive timeout. The configured value is in minutes and the value of zero will disable timing out the active sessions. A larger maximum lifespan could allow an attacker to persist a stolen session for longer, increasing the scope of a security incident. This particular property is limited to UI session timeout.

Updated hardening settings for baseline version 5.0

Some hardening settings have been updated with the release of Security Center baseline version 5.0.

Baseline version 5 includes several updates to short descriptions for style and consistency across records. In addition, many property related scripts were updated to improve the accuracy of default values in cases where the property has been removed from the sys_property table.

Documentation	Updates
	secret key will be stored in security storage such as KMF. • Old description: UserCookie v3 is generated only when property *glide.ui.secure.cookies.use_kmf* is disabled. UserCookie v3 is not secure due to storing secret key for HMAC in source code and identical for all customers. That can support malicious actors to use this one secret key for attempts to hijacking user sessions. • New remediation: Ensure the property *glide.ui.secure.cookies.use_kmf* exists and is set to true. If the property does not appear in the sys_properties table, add a new record. • Old remediation: Ensure the property *glide.ui.secure.cookies.use_kmf* is set to true. Which means UserCookie v3.1 will be used and secret key will be stored in security storage such as KMF.
Set OTP lifetime for password reset to 1 hour [Updated in Security Center 2.0]	Rule Script: Script has been updated to improve detection accuracy.
Log user impersonation [Updated in Security Center 1.3 and 2.0]	• New remediation: Ensure the property *glide.sys.log_impersonation* exists and is set to true. If the property does not appear in the sys_properties table, add a new record. • Old remediation: Ensure the property *glide.sys.log_impersonation* is set to true.
Required jms connection factories [New in Security Center 1.3 and updated in 1.5 and 2.0]	Rule Script: Script has been updated to improve detection accuracy.
Ensure dashboards creation/deletion requires access check [New in Security Center 1.3 and updated in 2.0]	• New remediation: Ensure the Glide Property *glide.processors.check_access_before_proce* exists and is set to the value true. If the property does not appear in the sys_properties table, add a new record. • Old remediation: Ensure the value of *glide.processors.check_access_before_proce* is always true.
Proactively invalidate inactive sessions [New in Security Center 1.3 and updated in 1.5 and 2.0]	• New remediation: Ensure the Glide Property *glide.active.session.timeout.invalidate.se* exists and is set to the value true. If

Documentation	Updates
	the property does not appear in the sys_properties table, add a new record. • Old remediation: Set the Glide Property *glide.active.session.timeout.invalidate.se* to true.
Enforce Security Scope for Agent Workspace for HR Case Management [New in Security Center 1.5 and updated in 2.0]	Rule Script: Script has been updated to improve detection accuracy.
Enforce security scope license and permit playbook [New in Security Center 1.5 and updated in 2.0]	Rule Script: Script has been updated to improve detection accuracy.
Restrict downloadable MIME types [Updated in Security Center 1.3 and 2.0]	• New description: If the property *glide.ui.attachment.force_download_all_mi* is set to true, then the *glide.ui.attachment.download_mime_types* property will be overridden so that all MIME types will be downloaded rather than rendered by the browser. For example, downloading text/html forces an HTML file to be downloaded to the client as a file rather than viewed inline in the browser, preventing a XSS attack. XSS can lead to easily attained privilege escalation to higher roles such as admin where more lateral movement can be taken. • Old description: If the property *glide.ui.attachment.force_download_all_mi* is not set to true, then the *glide.ui.attachment.download_mime_types* property will be overridden so that all MIME types will be downloaded rather than rendered by the browser. For example, downloading text/html forces an HTML file to be downloaded to the client as a file rather than viewed inline in the browser, preventing a XSS attack. The ability to have XSS can lead to easily attained privilege escalation to higher roles such as admin where more lateral movement can be taken. • New remediation: Ensure the property *glide.ui.attachment.force_download_all_mi* is set to true. If the property does not exist in the sys_properties table, the default value is false.

Documentation	Updates
	• Old remediation: Ensure the property *glide.ui.attachment.force_download_all_mi* is set to true. • Rule Script: Script has been updated to improve detection accuracy.
Define restricted downloadable MIME types [Updated in Security Center 1.3, 1.5, and 2.0]	Rule Script: Script has been updated to improve detection accuracy.
Disallow infected file download [Updated in Security Center 1.5 and 2.0]	• New description: When the property *com.glide.snap.infected_download_allowed* is set to true, users can still download non-scanned attachments in the case that the antivirus service is down or unreachable. This means it is possible that a user downloads a malicious file and risks infecting the user's desktop (in the case there is no other endpoint protection on the device). • Old description: If *com.glide.snap.infected_download_allowed* is not set to the recommended value of False, then it is possible to download a malicious file that has not been scanned leading to a risk of infecting the user's desktop. • New remediation: Ensure the property *com.glide.snap.infected_download_allowed* is set to false. • Old remediation: Ensure the property *com.glide.snap.infected_download_allowed* is set to False.
Restrict access to GlideSystemUserSession scriptable API [Updated in Security Center 1.3 and 2.0]	• New description: *gs.addErrorMessageNoSanitizationMessaging(* and *gs.addInfoMessageNoSanitization()* are used within the scripting environment for logging and notifications. Both of these are available in the sandbox if this property is not set to the recommended value of false. The sandbox is a low privileged scripting environment available to unauthenticated and no role users. Both of these methods can be used to display unsanitized input to a user. Displaying unsanitized input to the user is dangerous, as unsanitized input may contain dangerous code that runs in the user's browser. This can be utilized for traditional reflected XSS attacks. Reflected XSS attacks can be used

Documentation	Updates
	in multiple scenarios, including session hijacking. • Old description: Messaging within the glide scripting sandbox is used for logging purposes. Calling this unsanitized error function exposes the platform to reflected XSS attacks. XSS attacks can allow for easy privilege escalation by stealing someone's session cookies. If `glide.sandbox.usersession.allow_unsanitize` is not set to the recommended value of false, then the unsanitized error messaging functions `addErrorMessageNoSanitization` and `addInfoMessageNoSanitization` are available to script.
Enable work order management query rules for service organizations [New in Security Center 1.5 and updated in 2.0]	• New description: When set to true, rules/ filters from sn_query_rule table will be used to determine read access to Field Service Management-related tables (Work Order and Work Order Task) to the logged in user through query business rules and read ACLs. When false, the records won't be filtered based on query rules. Query business rules add additional security validations. Specifically, this property will filter records for agents, qualifiers, and dispatchers based on their assigned territory or territory membership. It is best practice to follow the principle of least privilege when reading records. When this property is not set to true, there may be increased risk of data exposure from Field Service Management tables. • Old description: When set to true, rules/ filters from sn_query_rule table will be used to determine read access to Field Service Management-related tables (Work Order and Work Order Task) to the logged in user through query business rules and read ACLs. When false, the records won't be filtered based on query rules. Query business rules add additional security validations. Documentation	Updates
Restrict email domains for external user registration [Updated in Security Center 1.3, 1.5, and 2.0]	• New description: The *sn_ext_usr_reg.allowed_email_domains* property defines which email addresses are allowed to self-register to a ServiceNow instance. The format should be a comma separated list of acceptable email domains such as domain1.com,domain2.com where emails such as example@domain2.com will be accepted. If *sn_ext_usr_reg.allowed_email_domains* is not set with a list of acceptable domains, then users with any email address are allowed to register accounts on the instances. If not defined, malicious actors could perform registration using emails addresses from unwanted domains to gain authenticated access to the instance. • Old description: The *sn_ext_usr_reg.allowed_email_domains* property defines which email addresses are allowed to self-register to a ServiceNow instance. If *sn_ext_usr_reg.allowed_email_domains* is not set with a list of acceptable domains, then users with any email address are allowed to register accounts on the instances. If not defined, malicious actors could perform registration using emails addresses from unwanted domains to gain authenticated access to the instance.
Apply domain separation on dot walked fields [Updated in Security Center 1.3, 1.5, and 2.0]	• New description: This property controls whether join queries are given domain separated conditions or not, in order to ensure they apply domain separation functionality for dot walked fields. If *glide.sys.domain.include_domain_condition_* is not set to the recommended value of true on an instance using domain separation, then sensitive information could be disclosed that is not to be shared with a specific domain. There may be moderate functional impact to the instance if components are reliant on the unsafe cross domain queries. Instances should be tested in subproduction environments before enabling. • Old description: This property controls whether join queries are given domain separated conditions or not, in order to ensure they apply domain separation functionality for dot walked fields. If

Documentation	Updates
Verify certificate chain and hostname [New in Security Center 1.3 and updated in 2.0]	• New description: When the Glide Property *com.glide.communications.httpclient.verify* is not set to the secure value of true, the hostname and certificate chain presented by remote hosts during a TLS connection initiated from the ServiceNow instance are not validated. This could compromise the security of the TLS connection and allow person-in-the-middle attacks, where communications between two parties are intercepted. This may lead to sensitive data disclosure. • Old description: If *com.glide.communications.httpclient.verify* is not set to true this could allow person-in-the-middle attacks where communications between two parties are intercepted. Setting this property to an insecure value disables the certificate verification process which evaluates all certifications in the certificate chain through checking revocation status. Set this property to true to prevent the http client from connecting to a potentially harmful hostname.
Control Lockout Time for Invalid Password Reset Attempts [Updated in Security Center 1.3 and 2.0]	• New short description: *Control Lockout Time for Invalid Password Reset Attempts* • Old short description: *Minimize Reset Password Request Max Attempts Window Duration* • New description: The *password_reset.request.max_attempt_window* property defines the number of minutes a user must wait to reset or change their password after exceeding the maximum number of unsuccessful attempts that is set with the *password_reset.request.max_attempt property*. A small number of minutes for the *password_reset.request.max_attempt_window* property increases the risk of successfully brute forcing a password as a greater number of password reset attempts can be made. The default of 1440 minutes is recommended. • Old description: If *password_reset.request.max_attempt_window* is not set to the recommended value of 1440 or less, then it could be possible to perform

Documentation	Updates
	account bruteforce as the account will not be locked after a maximum number of wrong authentication attempts. • New remediation: Ensure the property *password_reset.request.max_attempt_window* is set to 1440 or greater. • Old remediation: Ensure the property *password_reset.request.max_attempt_window* is set to 1440 or less. • Rule Script: Script has been updated to improve detection accuracy.
Disable GlideRecord Scope Fencing Legacy Behavior [New in Security Center 1.3 and updated in 1.5 and 2.0]	• New short description: *Disable GlideRecord Scope Fencing Legacy Behavior* • Old short description: *Enable GlideRecord Scope Fencing Legacy Behavior* • New remediation: Set the Glide Property *glide.record.legacy_cross_scope_access_pol* to false. When not present in the sys_properties table, the default value is true. • Old remediation: Set the Glide Property *glide.record.legacy_cross_scope_access_pol* to false.
Limit Invalid Password Reset Attempts [Updated in Security Center 1.3 and updated in 2.0]	• New short description: *Limit Invalid Password Reset Attempts* • Old short description: *Minimize Reset Password Request Max Attempt Allowance*

Updated hardening settings for baseline version 4.0

Some hardening settings have been updated with the release of Security Center baseline version 4.0.

Baseline version 4.0 includes several updates to short descriptions for style and consistency between records. In addition, many property related scripts were also updated to improve accuracy of the default value for cases where the property has been removed from the sys_property table.

Documentation	Updates
Require authorization for SOAP requests [Updated in Security Center 1.3, 1.5, and 2.0]	• New technical configuration name: *glide.basicauth.required.soap, glide.soap.require_ws_security* • Old technical configuration name: *glide.basicauth.required.soap* • New description: The glide property *glide.basicauth.required.soap* controls whether basic authentication is required to make a SOAP request to an instance. If *glide.basicauth.required.soap* is not set to the recommended value of true, then unauthenticated users performing SOAP operations will be mapped to the soap.guest user. This may enable an unauthenticated user to perform operations on the instance as if a logged in user to the instance. There may be additional impact if the user define within *com.glide.soap.guest_user* is assigned additional roles. • Old description: The glide property *glide.basicauth.required.soap* controls whether authentication is required to make a SOAP request to an instance. If *glide.basicauth.required.soap* is not set to the recommended value of true, then authentication is disable for SOAP requests on the instance. It allows unauthenticated access to administrator or maint level operations; thereby negating security controls within the instance. • New remediation: Ensure the property *glide.basicauth.required.soap* is set to the value true. Alternatively, configure the instance for WS Security by setting the property *glide.soap.require_ws_security* to true and following the product documentation to configure WS Security Profiles. • Old remediation: Ensure the property *glide.basicauth.required.soap* exists in the sys_properties table and is set to true. • Rule Script: Script has been updated to improve detection accuracy.

Documentation	Updates
Escape jelly script [Updated in Security Center 1.3 and 1.5]	• New description: This property escapes all the JS and HTML strings included in before they are written to the output stream, preventing several XSS issues from occurring. If *glide.ui.escape_all_script* is not set to the recommended value of true, then escaping of scripts injected into Jelly is disabled. Without this mitigation, the platform becomes widely open to a variety of script injection attacks. An attacker could execute arbitrary Rhino scripts on the instance. • Old description: The following property escapes all the JS and HTML strings included in <j:jelly> ... </j:jelly> before they are written to the output stream, preventing several XSS issues from occurring. If *glide.ui.escape_all_script* is not set to the recommended value of "true", then escaping of scripts injected into Jelly is disabled. Without this mitigation, the platform becomes widely open to a variety of script injection attacks. An attacker could execute arbitrary Rhino scripts on the instance.
Prevent Users From Accepting Warning To Bypass CSRF Validation [Updated in Security Center 1.3 and 1.5]	• New short description: Prevent Users From Accepting Warning To Bypass CSRF Validation • Old short description: Enforce CSRF Token Strict Validation • New description: This property prevents users from being able to accept a warning which allows a potentially malicious request to be sent to the instance. This warning appears when a POST request fails due to having a mis-matched anti-CSRF token belonging to one of the victim's other active sessions. If *glide.security.csrf.strict.validation.mode* is not set to the recommended value of true, then an attacker can formulate a CSRF attack utilizing a leaked anti-CSRF token from a different active session belonging to the victim.A POST request to an instance contains an anti-CSRF token within sysparm_ck or X-UserToken which matches the user's current session. If the anti-CSRF token is instead tied to one of the user's other active sessions, the POST request will return a 302 redirection to

Documentation	Updates
	a secure token to identify and validate incoming requests. This token is used to prevent cross site request forgery attacks. If *glide.security.use_csrf_token* is not set to the recommended value of true, then CSRF is possible.
Enable HTML Sanitizer within Virtual Agent [Updated in Security Center 1.3 and 1.5]	• New short description: Enable HTML Sanitizer within Virtual Agent • Old short description: Enable HTML Sanitizer • New description: This property controls the whether the HtmlSanitizerService is enabled. If *com.glide.cs.html.sanitizer.enabled* is not set to true, then a Stored Cross-Site Scripting (XSS) attack is possible in the VA web client. • Old description: This property controls the whether the HTMLSanitezerService is enabled. If *com.glide.cs.html.sanitizer.enabled* is not set to true, then a Stored Cross-Site Scripting (XSS) attack is possible in the VA web client.
Deny internal access to explicit external roles [Updated in Security Center 1.3 and 1.5]	• New technical configuration name: *glide.security.explicit_roles.enable_intei* • Old technical configuration name: *glide.security.explicit_roles.enable_intei* • New description: This property prevents external users from being assigned the snc_internal role. When *glide.security.explicit_roles.enable_intei* is set to the recommended value of true, then it enforces the parameters of the maint-protected *glide.security.explicit_roles.internal_use property* which assigns the snc_external role to a list of untrusted user classes. If the value is set to false, the *glide.security.explicit_roles.internal_use* property is ignored. Misconfiguration of this propery increases the risk that an external user account gains access to internal information. • Old description: This prevents external users from being assigned the snc_internal role. If *glide.security.explicit_roles.enable_intei*

Documentation	Updates
Disable MultiSSO Debugging [Updated in Security Center 1.3 and 1.5]	• New short description: Disable MultiSSO Debugging • Old short description: Disable MultiSSO Debugging (Plugin Applicability: Multiple Provider Single Sign-On)
Define allowed ServiceNow internal IP addresses [Updated in Security Center 1.3 and 1.5]	• New technical configuration name: *glide.ip.authenticate.strict* • Old technical configuration name: *glide.ip.authenticate.strict,glide.ip.auth* • New description: If *glide.ip.authenticate.strict* is set to true, then internal ServiceNow personelle and systems can only make inbound connections to the instance from essential IP ranges. This limit's ServiceNow's visibility into the instance to essential internal infrastructure, and prevents access by broader ServiceNow personelle such as support and sales staff via corporate networks. When set to "true", the *glide.ip.authenticate.allow* property is used to grant internal ServiceNow inbound connections. If not set to true, then a broader ServiceNow internal IP range as defined in *glide.ip.authenticate.allow* is used to grant internal ServiceNow inbound connections. • Old description: If *glide.ip.authenticate.strict* is set to true, then only IP ranges specified in *glide.ip.authenticate.allow.secured* can make inbound connections to the instance. This property contains a list of only essential ServiceNow internal IP ranges (Secure VPN, DC). If *glide.ip.authenticate.allow.secured* is not set to the recommended value or permutation of "10.0.0.0/8, 37.98.232.0/21, 103.23.64.0/22, 149.96.0.0/17, 149.96.0.0/16, 199.91.136.0/21, 148.139.0.0/16, 127.0.0.1" or the newer value list "10.0.0.0/8, 37.98.232.0/21, 103.23.64.0/22, 149.96.0.0/17, 149.96.0.0/16, 199.91.136.0/21, 148.139.0.0/16, 127.0.0.1, 0:0:0:0:0:0:0:1, ::1" which adds IPv6 localhost to Utah, then it may allow untrusted sources outside of SN DataCenter and secure VPN to access sensitive monitoring endpoints on instances.

	URI parameter on /ess/catalog.do. If *glide.cms.catalog_uri_relative* is not set to the recommended value of true, then the URL will not be sanitized with the enforceRelativeURL(url) function. Absolute URLs can pose a security risk when used as a part of parameter or a field value, thus redirecting the source page to an adversary-controlled website.
Minimize Entity Expansion Threshold for GlideXMLUtil Scriptable [Updated in Security Center 1.3, 1.5, and 2.0]	• New short description: Minimize Entity Expansion Threshold for GlideXMLUtil Scriptable • Old short description: Minimize Entity Expansion Threshold • New description: This property controls the maximum amount of entity expansion within an XML Parser. If *glide.xmlutil.max_entity_expansion* is not set to the recommended value of 3000 or less, then the GlideXMLUtil parsing scriptable may be vulnerable to denial of service attacks. • Old description: This property controls the maximum amount of entity expansion within an XML Parser. If *glide.xmlutil.max_entity_expansion* is not set to the recommended value of 3000 or less, then XML parser may be vulnerable to denial of service attacks. • Rule Script: Script has been updated to improve detection accuracy.
Disable GlideRecord Scope Fencing Legacy Behavior [New in Security Center 1.3 and updated in 1.5 and 2.0]	• New description: GlideRecord provided cross scope create/update access to tables that were not configured with that level of access. In order to prevent customers from having applications broken when this scoped access behavior was patched, the property *glide.record.legacy_cross_scope_access_pol* was created. When true, cross scope access falls back onto legacy behavior (insecure). This property disables scope fencing, allowing scoped apps to access global script interfaces. It is best security practice to have scope fencing restrictions in place. Scoping ensures applications can only access resources with explicit access or within their scope, following the principle of least privilege. Disabiling this feature

Deleted hardening settings

Some hardening settings are removed from Security Center baselines.

Deleted hardening settings for baseline version 7.0

Some hardening settings have been removed with the release of Security Center baseline version 7.0.

- Disable Password-Less Authentication
- Escape XML Response
- Minimize One-Time Out of Band Verifier Lifetime Duration

Deleted hardening settings for baseline version 6.0

Some hardening settings have been removed with the release of Security Center baseline version 6.0.

- Enforce ACL on HR Lifecycle Events Data
- Enforce Security Scope License and Permit Playbook
- Enforce ACL on HR Core Data
- Restrict Global Administrators from Bypassing Scoped App Access Restrictions
- Disable Legacy AngularJS Behavior
- Enforce Field Level ACLs in GlideRecordSandbox
- Enforce Scope Security for Public Sector Digital Services
- Restrict Downloadable Files Types in Static Content
- Enforce Scoped ACL Access for Information Request Playbooks
- Minimize SAML "notBefore" or "notOnOrAfter" Constraint Duration
- Restrict Delegated Developers Read Access
- Enforce Password Policy on All Methods
- Enforce Security Scope for Service Application Information
- Require Obfuscation of Classic Mobile App UI
- Enable SSL in LDAP Authentication
- Enforce Security Scope for Agent Workspace for HR Case Management
- Limit Attachment Size in Training and Prediction Flows
- Remove Credentials From Welcome Page
- Enforce ACL on HR Virtual Agent Data
- Check Impersonation on ACL Evaluation in HR App

- Restrict Allowed Java Packages
- Enforce Strict Code Signing Checks

Deleted hardening settings for baseline version 5.0

Some hardening settings have been removed with the release of Security Center baseline version 5.0.

- Require Authentication on Event Management HTTP Processor
- Restrict Access to Custom Journal Entries
- Do Not Apply Password Policy at Login
- Disable Raw Database Query Execution
- Log HTML Sanitization
- Enable Anti-CSRF Token
- Enforce Certificate Trust
- Unset LDAP Initial Distinguished Name
- Set Minimal Password Length

Deleted hardening settings for baseline version 4.0

Some hardening settings have been removed with the release of Security Center baseline version 4.0.

- LDAP Initial Password
- Mobile Offline Roles
- Restrict Access to Critical Data through Zero Trust Access Policies (Plugin Applicability: Adaptive Authentication)
- Read Only Tables Allowlist For Write
- Allowed JDBC Probe Operations (Plugin Applicability: MID Server)
- Set Allowed Domains which Create Users from Incoming Emails
- Set Complex "Default" Password
- Accessible Properties in GraphQL Allowlist
- Cross Origin Messaging Allowlist
- Limit Attachment Size in Training and Prediction Flows for GraphQL Enpoints (Plugin Applicability: Platform Document Intelligence)
- Edit Content Roles Allowlist (Plugin Applicability: Communities)
- Ensure Database Queries Do Not Trigger a OutofMemory Exception Due to Query Size
- Role Allowlist for Script Execution
- Downloadable File Type Allowlist
- Read Only Tables Allowlist For Delete
- Enforce Authentication for Roleless ACL
- Minimize LDAP One-Time Token Expiry Time
- Allow Only Trusted IP Addresses for Authentication
- Set Mobile Password Reset URL
- Password Complexity of Service Accounts (Plugin Applicability: Service Bridge)

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Notify Users During Password Reset/Change Process
- Enforce Application Scope Restrictions
- Access Control Requirements (Plugin Applicability: Communities)
- Record History Access Role Allowlist
- Restrict Role Access for Attachments
- Only Allow PDFs from Predefined List of Trusted URLs
- Prevent Emailing One-Time Password During LDAP Server Outage
- Convert Inbound Email Images to Attachments
- Review Extraneous Explicit Role Access Control Condition

Deleted hardening settings for baseline version 2.0

Some hardening settings have been removed with the release of Security Center baseline version 2.0.

- Enable Code Signing for Application Configuration Data and Scripts
- Enable Glide KMF encrypter
- Disable the Use of Instance Level Encrypter
- Enable Explicit Roles Internal Denylist
- Block Direct Inserts to MID ECC Queue for Code Signing Requirement
- Log All Outbound HTTP Request Fields

Access control

The access control category audits the process of protecting resources from unauthorized access through granting and denying requests based on a permission model. This includes ensuring an entity accessing a resource holds valid credentials to do so, creating and protecting a well-defined set of roles or permissions and ensuring role or permission controls are protected from replay and tampering.

Access controls determine whether access to a particular resource should be granted or denied. It only allows access to resources to those users permitted to use them.

Anti-CSRF token validation time [New in Security Center 1.3]

The *glide.security.csrf_previous.time_limit* property specifies the time in seconds for a secure token to expire.

When a user session expires, the secure token expires with it unless the **allowing reuse of expired tokens are allowed** property is enabled, and it is within the time frame described by this property. This token is used to prevent cross site request forgery attacks.

More information

Attribute	Description
Configuration name	*glide.security.csrf_previous.time_limit*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Recommended value	86400 seconds or 1 day
Default value	86400 seconds or 1 day
Category	Access control
Security risk	• Severity score: 5.3 • CVSS score: Medium • Security risk details: Not setting this property to the recommended value disables the token validation used to prevent cross site request forgery attacks.
Dependencies and prerequisites	None
Functional impact	This property determines the duration in seconds for a secure token to remain valid. The secure token expires when the user session expires unless the **allowing reuse of expired tokens** property is enable, and the token is within the time frame specified in this property. This token prevents cross-site request forgery attacks. It has a default value of 86400 seconds or 1 day.

Apply domain separation on dot walked fields [Updated in Security Center 1.3, 1.5, and 2.0]

The *glide.sys.domain.include_domain_condition_on_join* property controls whether join queries are given domain separated conditions or not in order to ensure they apply domain separation functionality for dot walked fields.

This property controls whether join queries are given domain separated conditions or not, in order to ensure they apply domain separation functionality for dot walked fields. If *glide.sys.domain.include_domain_condition_on_join* is not set to the recommended value of true on an instance using domain separation, then sensitive information could be disclosed that is not to be shared with a specific domain. There may be moderate functional impact to the instance if components are reliant on the unsafe cross domain queries. Instances should be tested in subproduction environments before enabling.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.sys.domain.include_domain_condition_on_join*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	True, when domain separation is installed, otherwise the property won't exist.
Default value	false

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Access control
Purpose	Controls whether join queries are given domain separated conditions or not, in order to ensure they apply domain separation functionality for dot walked fields.
Security risk	• Severity score: 6.5 • CVSS score: Medium • Security risk details: If *glide.sys.domain.include_domain_condition_on_joi* is not set to the recommended value of **true**, then sensitive information could be disclosed that is not to be shared with a specific domain.
References	Domain separation for service providers

Block access for delegated developers

This configuration affects access for delegated developers that are updating user roles through script. When the configuration is compliant, the developer will not be able to update or insert records into the sys_user_has_role table without also having the user_admin role.

The value of this property affects whether a delegated developer is allowed to grant or receive unexpected access to functionality in the instance. When the property contains roles, only those roles may execute script modules.

More information

Attribute	Description
Property name	*com.glide.sys.security.delegateddev.block_grant_ro*
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control
Purpose	The value of this property affects whether a delegated developer is allowed to grant or receive unexpected access to functionality in the instance.
Type	toggle switch
Default value	true
Recommended value	true
Security Dependencies	none
Security risk rating	6.7
Functional impact	When a user with the delegated_developer role is attempting to modify a record in the sys_user_has_role table, this property enables additional security checks against the operation. The additional security checks validate that the user has been granted the

Attribute	Description
	user_admin role if they're trying to create or update the sys_user_has_role table. If they do not have the user_admin role, the access will be denied. When the property is false, these additional checks are not validated.
Security risk	(Moderate) Without appropriate authorization, unauthorized users may access sensitive content/data on the instance.
References	Access control

To learn more about adding or creating a system property, see Add a system property.

Block Expired Anti-CSRF Tokens [Updated in Security Center 1.5]

Block expired CSRF tokens to prevent cross-site request forgery attacks.

Overview

Cross-site request forgeries are a type of malicious exploit whereby unauthorized commands are performed on behalf of an authenticated user.

Configuration details

Attribute	Description
Overview	Controls the usage of an expired secure token to identify and validate incoming requests. Set to **false** to prevent a previously expired token to validate an incoming request.
Configuration name	*glide.security.csrf_previous.allow*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	**false**
Default value	**true**
Category	Access control
Security risk	**Severity score**: 6.5
	Severity rating per CVSS score: Medium
	Security risk details: Enforces a strong anti-CSRF mechanism to protect authenticated functionality, and effective anti-automation or anti-CSRF protects unauthenticated functionality.
Dependencies and prerequisites	None
References	Enable Anti-CSRF token [New in Security Center 1.3, updated in 1.5, and removed in 2.0], cross-site request forgery.

Check UI action conditions before execution

Use the *glide.security.strict.actions* property to enable checking of UI actions conditions in forms and lists before they execute. When you set this property to true, it adds an extra layer of validation on the table UI actions before they are executed.

More information

Attribute	Description
Property name	*glide.security.strict.actions*
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control
Purpose	To ensure an extra layer of validation on the table UI actions before they are executed.
Data type	Boolean
Recommended value	true
Default value	true
Security risk rating	3.3
Functional impact	This remediation only adds an extra layer of validation to check for UI actions on the target table/page on the instance. As long as the access controls are set appropriately on the customer instance, there should not be an impact here.
Security risk	(Low) Access request is always checked when transactions happen between two zones. This operation validates any UI actions before the form renders for the end user.
References	High security plugin

To learn more about adding or creating a system property, see Add a system property.

Configure event management assignment group admin roles [New in Security Center 1.5]

Use the *evt_mgmt.connector_assignment_group_admin_roles* property to set which roles are authorized for admin access over the assignment group field in connector instances.

The *evt_mgmt.connector_assignment_group_admin_roles* property contains a comma separated string which indicates the role names that have admin access over the assignment group field in connector instances. Changing the default roles in this list may enable unauthorized users to alter event integrations on the instance. To prevent unauthorized access to roles, set *evt_mgmt.connector_assignment_group_admin_roles* to the value of admin,evt_mgmt_admin,sn_sow_srm.srm_admin. Review any additional roles in the recommended value string to ensure that the role should be included.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*evt_mgmt.connector_assignment_group_admin_roles*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	admin,evt_mgmt_admin,sn_sow_srm.srm_admin
Default value	admin,evt_mgmt_admin,sn_sow_srm.srm_admin
Category	Access control
Security risk	• Severity score: 3.1 • CVSS score: Low • Security risk details: Changing the default roles could enable unauthorized users to alter event integrations on the instance.
Dependencies and prerequisites	None
References	Creating groups

Configure Service Portal Widgets Allow List [New in Security Center 2.0]

Learn how to configure the glide.service_portal.widget.allow_list property securely so that the access control lists (ACLs) for the tables do not expose sensitive information.

The *glide.service_portal.widget.allow_list* property identifies the widgets that can access any table within the instance. However, the access control lists (ACLs) for these tables will continue to apply. If the ACLs are incorrectly configured or absent, widgets on this list might enable access to these tables, potentially exposing sensitive information. This property is effective only if the widget uses SNCACLWidgetUtil and the *glide.service_portal.widget.enforce_public_check* property is enabled (set to true).

More information

Attribute	Description
Configuration name	*glide.service_portal.widget.allow_list*
Configuration type	System Properties (/sys_properties_list.do)
Data type	array
Recommended value	Empty
Default value	Empty - in some customer's cases there might be some values.
Category	Access control

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: Not configuring this property to the recommended values could enable widgets to access any table within the instance.
Dependencies and prerequisites	For the *glide.service_portal.widget.allow_list* setting to be applicable, the *glide.service_portal.widget.enforce_public_check* property must be set to true.
Functional impact	This property enables customers to access any table information if the widget is set to public and is included in the property's value.

Configure Service Portal Widgets Table Allow List [New in Security Center 2.0]

Learn how the *glide.service_portal.widget.table_allow_list* property enhances security by listing tables accessible to unauthenticated users through Service Portal widgets, dependent on additional checks and specific glide property settings.

The *glide.service_portal.widget.table_allow_list* property contains a list of tables that unauthenticated users can access through Service Portal widgets, which utilize the additional security checks in the SNCACLWidgetUtil script. This property is enforced only if the glide property *glide.service_portal.widget.enforce_public_check* is set to true. Including unnecessary tables in this property may lead to the disclosure of sensitive information. Nonetheless, Table ACLs will continue to be evaluated as they were previously.

More information

Attribute	Description
Configuration name	*glide.service_portal.widget.table_allow_list*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Access control
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: If this property is not set to the secure value, unnecessary tables may be included, potentially leading to the disclosure of sensitive information.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Dependencies and prerequisites	The *glide.service_portal.widget.enforce_public_check* property must be set to true for the *glide.service_portal.widget.table_allow_list* setting to take effect.
Functional impact	The table list controls access to the tables from which the widget is allowed to retrieve data.

Deny internal access to explicit external roles [Updated in Security Center 1.3 and 1.5]

Use system properties to determine whether external users can be assigned the snc_internal role.

Use the *glide.security.explicit_roles.enable_internal_user_blacklist* system property to prevent external users from being assigned the *snc_internal* role. When this property is set to **true**, it enforces the parameters of the maint-protected *glide.security.explicit_roles.internal_user_blacklist* property. This property assigns the *snc_external* role to a list of untrusted user classes. If *glide.security.explicit_roles.enable_internal_user_blacklist* is set to **false**, the *glide.security.explicit_roles.internal_user_blacklist* property is ignored.

Note:
Instances without Explicit Roles installed are not affected. As of the Paris release, new installations of Explicit Roles get the property with a default value of true.

More information

Attribute	Description
Configuration name	*glide.security.explicit_roles.enable_internal_user*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false
Category	Session management
Security risk	• Severity score: 5.4 • CVSS score: Medium • Misconfiguration of this property increases the risk that an external user account gains access to internal information.
Dependencies and prerequisites	None

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Deny unauthorized access to request items [Updated in Security Center 1.3]

The *glide.sc.req_for.roles.default* property defines a default behavior for the *retrieveAddress* API.

This property is functional only when *glide.sc.req_for.roles* has no values. If *glide.sc.req_for.roles* has values, then this property has no significance and users with only defined roles are given access to the API.

More information

Attribute	Description
Property name	*glide.sc.req_for.roles.default*
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control
Purpose	When there are no roles given in the property, the Client Callable Script Include *ScriptServiceCatalogGetLocation* can be called by any unprivileged logged-in user and can retrieve the address of any other users in the system. This property protects this API to be exposed to unprivileged users.
Recommended value	deny
Default value	deny
Configuration type	Choicelist (allow | deny)
Security risk	(Moderate) If *glide.sc.req_for.roles.default* is not set to the recommended value of **deny** (allow) and the value of *glide.sc.req_for.roles* is empty, then any user can request items for other users allowing unauthorized resource access.
References	Client-callable script includes

To learn more about adding or creating a system property, see Add a system property.

Display recommendations for high risk UI pages

Decrease the likelihood of authorization errors, and unintended information disclosure by displaying recommendations for high risk UI pages.

Use the **glide.script.ui_page.customer_scoped.security_msgs_enabled** system property to determine whether to display security recommendations to users configuring UI pages when:

- An ACL is missing
- GlideRecord/GlideDBQuery APIs are used instead of GlideRecordSecure
- the page is configured as public in the "sys_public" table

When the property is enabled, recommendations when the preceding conditions are met, decreasing the likelihood of authorization errors, and helping prevent unintended information disclosure.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Set the system property **glide.script.ui_page.customer_scoped.security_msgs_enabled** to **true** to display these recommendations.

More information

Attribute	Description
Technical configuration name	glide.script.ui_page.customer_scoped.security_msgs_enabled
Plugin applicability	None
Security risk	Setting this system property to **false** increase the likelihood of authorization errors, and unintended information disclosure.
Common Vulnerability Scoring System (CVSS) score	5.3
Common Vulnerability Scoring System (CVSS) rating	Medium
Functional impact	Displays security recommendations to users configuring UI pages.
Dependencies and prerequisites	None
Data type	Boolean
Base system value	true
Fallback value	true
Recommended value	true

To learn more about adding or creating a system property, see Add a system property.

Disable inbound emails for locked out users

Use the *glide.pop3.process_locked_out* property to control inbound email actions for locked out, active users.

Set this property to **false** to disable inbound emails for locked out users.

Note:
Consider the security implications of allowing users from untrusted domains, and why they were locked out, before allowing emails from them to trigger inbound email actions.

More information

Attribute	Description
Property name	*glide.pop3.process_locked_out*
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control
Purpose	This property controls inbound email actions for locked out users.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	Boolean
Recommended value	false
Default value	false
Security risk	(High) When you set this property to **true**, there may be an information disclosure as inbound emails would be received by users with locked accounts.
Security risk rating	7.5

To learn more about adding or creating a system property, see Add a system property.

Double check inbound transactions [Updated in Security Center 1.3]

Use the *glide.security.strict.updates* property to enable double-checking of security on inbound transactions during form submission. When you set this property to **true**, it adds an extra layer of table validation before a form renders in the browser.

Ensure the property *glide.security.strict.updates* exists in the sys_properties table and is set to true.

More information

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

Attribute	Description
Property name	*glide.security.strict.updates*
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control
Purpose	To ensure an added layer of verification of user permissions before presenting the form in the browser.
Data type	Boolean
Recommended value	true
Default value	true
Security risk rating	8.1
Functional impact	This remediation adds an extra layer of validation to check for user permissions on the target table/page on the instance. As long as the access controls are set appropriately on the customer instance, there should be no impact.
Security risk	(High) You should always check access request when transactions happen between two zones. This operation checks for permissions when the form is requested and before form rendering happens.

Enable scoped admin application ACLs [Updated in Security Center 1.3]

The *glide.security.scoped_administration.honor_global_acl* determines whether an application administration app can inherit global access control list (ACL) rules.

This property is especially useful when there are no scoped admin application ACLs defined for the record scope.

Set *glide.security.scoped_administration.honor_global_acl* to true to prevent a low privileged user with permissions to the application to potentially access sensitive records.

More information

Attribute	Description
Property name	*glide.security.scoped_administration.honor_global_*
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control
Purpose	Controls ACL access rule in scoped admin application.
Recommended value	True
Default value	True
Configuration type	Boolean
Security risk	(Low) When the property value is true and there are no scoped admin application ACLs defined for the record scope, the global ACLs will be honored. If set to false, with no scoped admin application ACLs defined for the record scope, ACL checks will be ignored.
Security risk rating	3.8
References	Access control rules in application administration apps

To learn more about activating a plugin, see Activate a plugin

Enable work order management query rules for service organizations [New in Security Center 1.5 and updated in 2.0]

Use the *sn_fsm.use_query_rules* property to apply rules and filters to the Field Service Management tables.

When set to **true**, rules/filters from sn_query_rule table will be used to determine read access to Field Service Management-related tables (Work Order and Work Order Task) to the logged in user through query business rules and read ACLs. When **false**, the records won't be filtered based on query rules. Query business rules add additional security validations. Specifically, this property will filter records for agents, qualifiers, and dispatchers based on their assigned territory or territory membership. It is best practice to follow the principle of least privilege when reading records.

Set the *sn_fsm.use_query_rules* system property to **true**.

More information

Attribute	Description
Configuration name	*sn_fsm.use_query_rules*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Access control
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details: There may be increased risk of data exposure from Field Service Management tables.
Dependencies and prerequisites	None
Functional impact	When set to true, rules/filters from sn_query_rule table are used to determine read access to Field service management related tables. For example, Work Order (WO) and Work Order Table (WOT) to the logged-in user through query business rules and READ ACLs. When false, the records aren't filtered based on query rules. Enabling this property secures the data, and all data (wm_task and wm_order) won't be visible to their users.

Enable ACLs to Control Live Profile Details [Updated in Security Center 1.3]

Use the *glide.live_profile.details* property to designate whether a user should be able to view all detail fields, such as company name and phone numbers, in a live profile.

Depending on the setting of the *glide.live_profile.details* property, the following occur:

- If the value is set to Show, access to the live profile information is granted, regardless of the ACLs created for the user profile.
- If the value is set to ACL, access to the live profile information is restricted, as per the ACLs created for the user profile.
- If the value is set to Hide, access to the live profile information is restricted, regardless of the ACLs created for the user profile.

More information

Attribute	Description
Property name	*glide.live_profile.details*

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control
Purpose	The purpose is to enable only authorized users to access the details of a Live Profile (such as Company name, Phone numbers)
Data type	choicelist
Recommended value	ACL
Default value	ACL
Security risk rating	4.3
Functional impact	If property is not enabled, unauthorized users can access the Live profile details of all other users.
Security risk	(Moderate) API requests should always honor table ACLs. Restriction must be applied to prevent unauthorized users accessing details of a Live Profile.

To learn more about adding or creating a system property, see Add a system property.

Enable ACLs for Encoded Query in Simple List Widget [New in Security Center 2.0]

Learn how to set the *glide.service_portal.enable_acls_for_encoded_query_in_list* property to the secure value to prevent users from bypassing access control list (ACL) evaluations on a query condition in the Simple List Widget.

When the *glide.service_portal.enable_acls_for_encoded_query_in_list* property is not set to the secure value of true, a user may be able to bypass access control list (ACL) evaluations on a query condition in the Simple List Widget. If the property is set to false, it reverts to previous behavior, enforcing ACL checks for an encoded query based on the enforce_acl checkbox value.

It is a best practice to evaluate ACLs within queries to ensure that a user has access to the fields being queried, thereby preventing unauthorized data leakage.

Ensure that the glide property *glide.service_portal.enable_acls_for_encoded_query_in_list* is set to true. If the property does not exist in the sys_properties table, the default value is true.

More information

Attribute	Description
Configuration name	*com.glide.script.fencing.cross_scope_access.shared*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	true
Default value	true

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Access control
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details: Not setting this property to the recommended value of true.
Dependencies and prerequisites	None
Functional impact	The Simple List Widget may not display any data depending on the user's role and the underlying ACLs. Additionally, users might encounter security warnings if the Simple List query contains filter conditions with properties that are not accessible to the current user.

Enable URL allowlist for cross-origin iframe communication

Use the *glide.ui.concourse.onmessage_enforce_same_origin* property to enable cross-origin communication between `iframes`.

`Openframe` can only process messages from trusted domains that are specified in the *glide.ui.concourse.onmessage_enforce_same_origin_whitelist* property. To learn more, see Enable URL allowlist for cross-origin iframe communication.

More information

Attribute	Description
Property name	*glide.ui.concourse.onmessage_enforce_same_origin*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Category	Access control
Purpose	To enable inclusion listing of trusted domains, so they can communicate between iframes for openframe.
Recommended value	true
Default value	true
Security risk rating	4.2
Functional impact	If you do not inclusion list intended domains, the ability to embed other pages within ServiceNow AI Platform instances may be limited.
Security risk	(High) If a web page contains event handlers that do not perform proper origin validation, a web page, or script from any origin, can communicate with it. It can also initiate any functionality performed by the event handler.
References	OpenFrame overview

To learn more about adding or creating a system property, see Add a system property.

Enable Anti-CSRF token [New in Security Center 1.3, updated in 1.5, and removed in 2.0]

Use the *glide.security.use_csrf_token* property to ensure the use of a secure token to identify and validates incoming requests, which in turn are used to prevent these attacks.

Cross-Site Request Forgery (CSRF) is an attack that forces authenticated users to submit a request to a Web application against which they are currently authenticated. CSRF attacks exploit the trust a Web application has in an authenticated user.This property enables usage of a secure token to identify and validate incoming requests. This token is used to prevent cross site request forgery attacks. If *glide.security.use_csrf_token* is not set to the recommended value of true, then CSRF is possible.

More information

Attribute	Description
Property name	*glide.security.use_csrf_token*
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control
Purpose	To protect the application from potential CSRF attack.
Security risk rating	8.1
Recommended value	true
Default value	true
Functional impact	This remediation enables an extra validation step before the instance user submits a write request to the instance. Every write request contains a CSRF token (i.e a validation/CSRF ID tied to the user session). When the user session expires, the secure token expires with it.
Security risk	(High) Cross Site Request Forgery is a significant security risk that violates the integrity of the instance data. An attacker can launch the CSRF attack by abusing the trust of an instance user. With the help of social engineering attacks, a user can submit a malformed request on behalf of the attacker on the instance.

To learn more about adding or creating a system property, see Add a system property.

Enable contextual security plugin [Updated in Security Center 1.3]

Activate the Contextual Security Plugin (*com.glide.role_management*) plugin to enable contextual security, which secures a record/information using create, read, write, and delete functionality.

After it is installed and activated, the dictionary roles (created by simple security manager) are no longer tested. Instead, the ServiceNow AI Platform looks for ACL rules on fields and tables. It secures the data with the help of ACL rules instead of traditional, role-based dictionary rules implemented by simple security manager. Even if you configure the dictionary form and add roles to a dictionary entry, no change in rights occurs.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Plugin ID	*com.glide.role_management*
Configuration type	System Definition > Plugins
Category	Access control
Purpose	Unlike the simple security manager, the contextual security manager is aware of the system table hierarchy. You can potentially have different security rules for a field based on where in the hierarchy it appears.
Recommended value	Active
Default value	There is no default value as this is a plugin, not a Glide property.
Security risk rating	8.1
Functional impact	This remediation enforces functional level of access controls, which would let application determine the access restrictions based on ACL table alone.
Security risk	(High) Functional level access controls must be enforced from the server side prior to executing CRUD operations, ensuring the appropriate level of access to instance users.
References	Contextual Security Manager

Enable Cross Scope Privilege Checks on Service Portal Form [New in Security Center 7.0]

Use a system property to enforce cross scope privilege checks on the Service Portal form widget and prevent unauthorized retrieval of forms and table data between scopes.

In Yokohama and later releases, queries enforce cross scope privilege checks on the table before reading the given sys_id information.

When the *glide.service_portal.enforce_cross_scope_check_in_form* property is set to the recommended value of **true**, cross scope privilege checks are enforced on the table. When set to **false**, the cross-scope privilege check isn't enforced.

Set the *glide.service_portal.enforce_cross_scope_check_in_form* system property to **true** or confirm that the property doesn't exist in the System Properties [sys_properties] table. If a record doesn't exist in the sys_properties table, the value defaults to **true**.

More information

Attribute	Description
Configuration name	*glide.service_portal.enforce_cross_scope_check_in*
Configuration type	System Properties (/sys_properties_list.do)

Attribute	Description
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control
Security risk	• Severity score: 3.1 • CVSS score: Low • Security risk details: A lack of cross scope privilege checks could lead to unauthorized retrieval of forms and table data between scopes.
Dependencies and prerequisites	None

Enforce ACL on HR Lifecycle Events Data [New in Security Center 2.0]

Learn how to prevent unauthorized access to data in the Human Resources Lifecycle Events application by verifying that the *glide.enforce_security_scope.sn_hr_le property* is set to the secured value.

The *glide.enforce_security_scope.sn_hr_le* property limits the access control lists (ACLs) of several HR tables so that only the "sn_hr_le" scope is considered. If *glide.enforce_security_scope.sn_hr_le* isn't set to the recommended value of true, then the data from the Human Resources: Lifecycle Events application will be exposed to ACLs from all other scopes which could lead to unauthorized users accessing sensitive data. For example, an IT administrator gaining access to HR data.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.enforce_security_scope.sn_hr_le*

Attribute	Description
	Lifecycle Events application data to be exposed to ACLs from all other scopes. This could lead to unauthorized users accessing sensitive data.
Dependencies and prerequisites	None

Enforce ACL on HR Core Data [New in Security Center 2.0]

Learn how to configure the *glide.enforce_security_scope.sn_hr_core* property so that the Human Resources Scoped App: Core (com.sn_hr_core) plugin does not expose sensitive data to access control lists (ACLs) from all other scopes.

The *glide.enforce_security_scope.sn_hr_core* property restricts the access control lists (ACLs) of several global data tables like sys_attachment and sys_email to only consider the sn_hr_core scope. If this property is not set to the recommended value of true, then data from the Human Resources Scoped App: Core plugin will be exposed to ACLs from all other scopes. For instance, this could result in the IT administrator gaining access to human resources data.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.enforce_security_scope.sn_hr_core*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control
Security risk	• Severity score: 6.5 • CVSS score: Medium • Security risk details: If this property is not set to the secure value of true, then data from the Human Resources Scoped App: Core plugin will be exposed to ACLs from all other scopes.
Dependencies and prerequisites	None
References	Activate Case and Knowledge Management

Enforce ACL on HR Virtual Agent Data [New in Security Center 2.0]

Discover how to set the *glide.enforce_security_scope.sn_hr_va* property to a secure value, preventing data leakage from the Virtual Agent Conversations scoped application.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The *glide.enforce_security_scope.sn_hr_va* property restricts the access control lists (ACLs) of several human resources (HR) tables to only consider the sn_hr_va scope. If this property is not set to the recommended value of true, then data from the Human Resources: Virtual Agent Conversations scoped application will be exposed to ACLs from all other scopes. For example, this could allow the IT Administrator to access HR data.

More information

Attribute	Description
Configuration name	*glide.enforce_security_scope.sn_hr_va*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Access control
Security risk	• Severity score: 6.5 • CVSS score: Medium • Security risk details: Failing to set this property to the secure value true could expose data from the Human Resources: Virtual Agent Conversations scoped application to ACLs from all other scopes.
Dependencies and prerequisites	None

Enforce application specific ACLs only for application data

Avoid unauthorized or undesired access to application data by enforcing application-specific access control lists (ACLs) only for application data.

Control the behavior of application data residing in primary tables outside the application. When these properties have a value of **true**, only the application-specific ACLs are evaluated for access to the application data residing in these tables. Not all applications are designed to work in this configuration or use a System Property [sys_properties] record for this purpose.

These system properties use the **glide.enforce_security_scope.<scope>** naming format. For example, use the **glide.enforce_security_scope.sn_hr_sp** property for the Employee Center Core (sn_hr_sp) scope. The following application scopes contain this property:

- sn_doc
- sn_egd_act
- sn_egd_core
- sn_egd_goals
- sn_em
- sn_gsm
- sn_gsm_info_req
- sn_hc_professional
- sn_hr_agent_ws
- sn_hr_ai_agents
- sn_hr_awa
- sn_hr_core
- sn_hr_ef
- sn_hr_er
- sn_hr_le_ent
- sn_hr_mii_base
- sn_hr_na_galileo
- sn_hr_pad
- sn_hr_pj
- sn_hr_sp
- sn_hr_va
- sn_ja
- sn_jny
- sn_lg_contracts
- sn_lg_matter
- sn_lg_ops
- sn_opp_market
- sn_professional

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- sn_gsm_lic_prmt
- sn_gsm_lic_prmt_ex
- sn_gsm_soc_bnfts
- sn_hr_gen_ai
- sn_hr_hc
- sn_hr_le
- sn_hr_ws
- sn_imt_health_test
- sn_imt_tracing
- sn_imt_vaccine
- sn_svc_appl_info
- sn_svc_appl_pgm_mg
- sn_talent_aia
- sn_uni_req
- sn_uni_task

For each application installed with the *glide.enforce_security_scope* property in the System Properties [sys_properties] table, (for example, *glide.enforce_security_scope.sn_hr_core*), ensure the property value is set to **true**.

Note:
These properties can only be modified by the scoped administrator for the specific application. If a sys_properties record does not exist for the given application and respective property, it must be created.

Use this script can to find which properties need to be updated or created on the instance:

```
var properties = [
       'glide.enforce_security_scope.sn_uni_task',
       'glide.enforce_security_scope.sn_uni_req',
       'glide.enforce_security_scope.sn_svc_appl_info',
       'glide.enforce_security_scope.sn_professional',
       'glide.enforce_security_scope.sn_opp_market',
       'glide.enforce_security_scope.sn_lg_ops',
       'glide.enforce_security_scope.sn_lg_matter',
       'glide.enforce_security_scope.sn_lg_contracts',
       'glide.enforce_security_scope.sn_jny',
       'glide.enforce_security_scope.sn_ja',
       'glide.enforce_security_scope.sn_imt_vaccine',
       'glide.enforce_security_scope.sn_imt_tracing',
       'glide.enforce_security_scope.sn_imt_health_test',
       'glide.enforce_security_scope.sn_hr_ws',
       'glide.enforce_security_scope.sn_hr_va',
       'glide.enforce_security_scope.sn_hr_sp',
       'glide.enforce_security_scope.sn_hr_pj',
       'glide.enforce_security_scope.sn_hr_pad',
       'glide.enforce_security_scope.sn_hr_mii_base',
       'glide.enforce_security_scope.sn_hr_le',
       'glide.enforce_security_scope.sn_hr_le_ent',
       'glide.enforce_security_scope.sn_hr_hc',
       'glide.enforce_security_scope.sn_hr_gen_ai',
       'glide.enforce_security_scope.sn_hr_er',
       'glide.enforce_security_scope.sn_hr_ef',
       'glide.enforce_security_scope.sn_hr_core',
       'glide.enforce_security_scope.sn_hr_awa',
       'glide.enforce_security_scope.sn_hr_agent_ws',
       'glide.enforce_security_scope.sn_hc_professional',
       'glide.enforce_security_scope.sn_gsm_soc_bnfts',
       'glide.enforce_security_scope.sn_gsm_lic_prmt_ex',
       'glide.enforce_security_scope.sn_gsm_lic_prmt',
       'glide.enforce_security_scope.sn_gsm_info_req',
       'glide.enforce_security_scope.sn_gsm',
       'glide.enforce_security_scope.sn_em',
```

```
        'glide.enforce_security_scope.sn_egd_goals',
        'glide.enforce_security_scope.sn_egd_core',
        'glide.enforce_security_scope.sn_egd_act',
        'glide.enforce_security_scope.sn_doc',
        'glide.enforce_security_scope.sn_talent_aia',
        'glide.enforce_security_scope.sn_hr_na_galileo',
        'glide.enforce_security_scope.sn_svc_appl_pgm_mg',
        'glide.enforce_security_scope.sn_hr_ai_agents',
        'glide.enforce_security_scope.sn_hr_mii_base'
    ];

    var pm = new GlidePluginManager();

    for (var i = 0; i < properties.length; i++) {
        var property = properties[i];
        var application = property.split('.')[2];
        var propertyValue = gs.getProperty(property, 'false');

        if (pm.isActive(application) &&
propertyValue.toLowerCase() != 'true') {
            gs.print(property);
        }
    }
```

More information

Attribute	Description
Configuration name	*glide.enforce_security_scope.<scope>*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control
Security risk	• Severity score: 4.1 • CVSS score: Medium • Security risk details: When these properties don't have a value of **true**, the ACLs on the primary table are still evaluated for access, potentially allowing unauthorized or undesired access to application data.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Enforce application scope restrictions [New in Security Center 1.3 and removed in 1.5]

Use the *glide.record.legacy_cross_scope_access_policy_in_script* property to control the permissions of scoped apps.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

If the *glide.record.legacy_cross_scope_access_policy_in_script* property is set to true, scoped apps can call APIs which should only be available to global apps. This property bypasses the intended access controls for creating and updating developers for those scoped apps.

More information

Attribute	Description
Configuration name	*glide.record.legacy_cross_scope_access_policy_in_s*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	true (when the property does not exist in the sys_properties table.)
Category	Access control
Security risk	• Severity score: 3.5 • CVSS score: Low • Security risk details: If this property is not set to the recommended value, then scoped apps and delegated developers for those scoped apps can create and update records in global tables such as Incident.
Dependencies and prerequisites	None

Enforce Read Roles for Catalog Variable Search [New in Security Center 7.0]

Use system properties to ensure that only catalog variables with an empty read role are indexed for search.

When the property *glide.ais.ingestion.ignore_catalog_variables_read_roles* is set to the recommended value of **false**, only catalog variables with an empty read role are indexed for search. If this property is set to **true** then all variables are indexed for search regardless of any read roles specified on the variable.

Verify that the *glide.ais.ingestion.ignore_catalog_variables_read_roles* system property does not exist in the System Properties [sys_properties] table, or exists and is set to **false**.

More information

Attribute	Description
Configuration name	*glide.ais.ingestion.ignore_catalog_variables_read_*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false

Attribute	Description
Default value	false
Category	Access control
Functional impact	This property affects the indexing of searchable content from catalog variables that require specific roles for read access.
Security risk	• Severity score: 2.6 • CVSS score: Low • Security risk details: Users will be able to search for variables that they do not have read roles to access to causing information disclosure.
Dependencies	None
References	Service catalog variables

Enforce security rules to sharing dashboards [New in Security Center 1.3]

Use the *glide.cms.dashboards.sharing_with_secure_search* property to control whether users can share dashboards.

When the *glide.cms.dashboards.sharing_with_secure_search* property is not set to **true**, users can share dashboard groups and roles that they do not have access to. Enabling this property enforces access control lists (ACLs) when searching the sys_user, sys_user_role, and sys_user_group tables during the dashboard sharing process. Sharing a dashboard excessively can lead to users, groups, or roles accessing data that they should not have permission to view, potentially compromising sensitive information. Therefore, it is recommended to set *glide.cms.dashboards.sharing_with_secure_search* to true so that dashboards are shared only with those who have the appropriate permissions.

More information

Attribute	Description
Configuration name	*glide.cms.dashboards.sharing_with_secure_search*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Access control
Security risk	• Severity score: 3.5 • CVSS score: Low • Security risk details: Not setting this property to the recommended value of true causes access control lists to not be enforced when searching the sys_user,

Attribute	Description
	sys_user_role, and sys_user_group tables. This could lead to dashboards being shared with unauthorized users, exposing sensitive information.
Dependencies and prerequisites	None
References	Access control
Functional impact	This property applies security rules to the list of users, user groups, and roles that are visible when sharing dashboards.

Enforce scope security for public sector digital services [New in Security Center 1.3]

Use the *glide.enforce_security_scope.sn_gsm* property to control how the application data from the Public Sector Digital Services application is accessed.

The ServiceNow Public Sector Digital Services application lets you develop public sector applications that deliver digital services to constituents, businesses, and agencies.

When *glide.enforce_security_scope.sn_gsm* is set to false, access to the application data within the global tables of the Public Sector Digital Services app may be accessible based on the access control lists (ACLs) of those global tables. When this property is set to true, access to data residing in global tables are only evaluated based off the ACLs shipped directly in the Public Sector Digital Services app. Setting this property to false may lead to information disclosure from over permissive ACLs.

To remediate this security risk, set *glide.enforce_security_scope.sn_gsm* to true.

More information

Attribute	Description
Configuration name	*glide.enforce_security_scope.sn_gsm*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control
Security risk	• Severity score: 4.2 • CVSS score: Medium • Security risk details: Not setting this property to the recommended value could lead to information disclosure from over permissive ACLs.
Dependencies and prerequisites	None

Enforce scoped ACL access for information request playbooks [New in Security Center 1.3 and updated in 1.5]

Use the *glide.enforce_security_scope.sn_gsm_info_req* property to control access to playbook data for the Information Request playbooks feature.

The Information Request Playbook application enables public sector end users to submit and track public record requests and provides government agents with a pre-defined process for handling and resolving these requests. If *glide.enforce_security_scope.sn_gsm_info_req* is not set to true, unexpected access could be granted to playbook data for the Information Request playbooks application. Set this property to true to only consider ACLs from the sn_gsm_info_req scope when granting access.

More information

Attribute	Description
Configuration name	*glide.enforce_security_scope.sn_gsm_info_req*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details: If this property is set to false, then ACLs from all scopes are considered when granting access to playbook data in the scope master table. This would expose information request playbook data.
Dependencies and prerequisites	None
References	• Using Information Request Playbook • Configure Information Requests service channel

Enforce strict elevate privilege [New in Security Center 1.3]

Use the *glide.security.strict_elevate_privilege* property to control whether roles marked as privileged must be manually elevated for the user to be granted the role's capabilities.

Set this property to true to add an extra layer of security validation when a privileged user elevates their role.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.security.strict_elevate_privilege*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control
Security risk	• Severity score: 6.7 • CVSS score: Medium • Security risk details: When *glide.security.strict_elevate_privilege* is set to false, roles marked as privileged are automatically elevated upon an admin user new session, and do not need to be manually elevated (with the exception of security_admin).
Dependencies and prerequisites	None
Functional impact	This property strictly requires admin role users to elevate privileges when needed.

Enforce security scope license and permit playbook [New in Security Center 1.5 and updated in 2.0]

Use this property to determine if only the access control lists (ACLs) within the License and Permit plugin will be used in determining access to the scope, or if ACLs from all scopes will be considered.

When the *glide.enforce_security_scope.sn_gsm_lic_prmt* property is set to the recommended value of true, then only ACLs within the License and Permit plugin are used to determine access to the scope. When this setting is configured to false, then License and Permit Playbooks data in scope master tables are exposed because ACLs from all scopes are granted access. To reduce data exposure, set *glide.enforce_security_scope.sn_gsm_lic_prmt* to the recommended value of true.

More information

Attribute	Description
Configuration name	*glide.enforce_security_scope.sn_gsm_lic_prmt*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Access control
Security risk	• Severity score: 2.7 • CVSS score: Low • Security risk details: Configuring this setting to the recommended value of true secures the License and Permit Playbooks data in scope master tables by considering only ACLs from *sn_gsm_lic_prmt* scope for granting access. Setting this to false exposes the License and Permit Playbooks data in scope master tables by considering the ACLs from all scopes for granting access. For example, the IT Administrator can access License and Permit Playbooks data when this setting is false.
Dependencies and prerequisites	None
References	• Using License and Permit Playbook • Application scope

Enforce Security Scope for Agent Workspace for HR Case Management [New in Security Center 1.5 and updated in 2.0]

Configure the Agent Workspace for HR Case Management plugin so that data in scope master tables can only be accessed by users with the correct permissions, enforcing the principle of least privilege.

When the *glide.enforce_security_scope.sn_hr_agent_ws* plugin is configured to the recommended value of true, then only the access control lists (ACLs) within the Agent Workspace for HR Case Management plugin are used to determine access to a resource. When this setting is set to false, then Agent Workspace for HR Case Management data in scope master tables are exposed because the ACLs from all scopes are granted access.For example, an IT Administrator can access Agent Workspace for HR Case Management data when this setting is set to false. To prevent this from happening, set *glide.enforce_security_scope.sn_hr_agent_ws* to the recommended value of true which ensures that the principle of least privilege exists as users can only access resources they have permission to.

More information

Attribute	Description
Configuration name	*glide.enforce_security_scope.sn_hr_agent_ws*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 2.7 • CVSS score: Low • Security risk details: Configuring this setting to false causes the Agent Workspace for HR Case Management data in scope master tables to be exposed because the ACLs from all scopes are granted access.
Dependencies and prerequisites	Agent Workspace for HR Case Management
Functional impact	Configuring this setting to true will enforce global ACLs to be executed for a table, if scoped ACLs do not exist for it.
References	• https://owasp.org/www-project-proactive-controls/#div-numbering • Add a component to Agent Workspace

Enforce Security Scope for Service Application Information [New in Security Center 2.0]

Use the *glide.enforce_security_scope.sn_svc_appl* property to ensure that the data in master scope tables is secured.

When the *glide.enforce_security_scope.sn_svc_appl_info* property is set to true, access to resources within the scope is determined solely by the access control lists (ACLs) from the Service Application Information plugin (sn_svc_appl_info). This ensures the security of data in master scope tables by restricting access permissions to those defined within the sn_svc_appl_info scope.

If set to the insecure value of false, ACLs from all scopes are considered when granting access to data in master scope tables such as sys_attachment. This could lead to unauthorized access to sensitive information by users who do not have permissions for the Service Application Information data.

More information

Attribute	Description
Configuration name	*glide.enforce_security_scope.sn_svc_appl_info*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Access control
Security risk	• Severity score: 4.3 • CVSS score: Medium

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	• Security risk details: If this property is set to the insecure value of false, it can lead to unauthorized access to sensitive data by users who do not have permissions for the Service Application Information data.
Dependencies and prerequisites	The Service Applicant Information plugin (*com.sn_svc_appl_info*) must be activated for the *glide.enforce_security_scope.sn_svc_appl_info* property to be effective.

Enforce field level ACLs in GlideRecordSandbox

Manage field level ACLs in GlideRecordSandbox on your instance.

Use the *glide.sandbox.fields.check_acl* property to enforce field level ACLs in GlideRecordSandbox. An example in which this property is applied is when a user can provide a script, like in *sysparm_query*. If this property is not set to the recommended value of **true**, ACL restrictions can be bypassed, which enables sensitive data to be compromised, such as a *sys_user.user_password* from an unauthorized user.

Warning:
The value for this property is a no DB override. It can't be altered or overridden.

More information

Attribute	Description
Configuration name	*glide.sandbox.fields.check_acl*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control
Security risk	• Severity score: 7.5 • CVSS score: High • Security risk details: Setting this property to **false** enables ACL restrictions to be bypassed which could expose sensitive data.
Dependencies and prerequisites	None

Enforce GroupBy ACLs

Configure your instance to conduct ACL checks on groupby columns.

Use the *glide.security.groupby_acl_check* system property to configure your instance to conduct ACL checks on groupby columns. If this property is set to the recommended value of **true**, then ACLs on groupby columns are honored

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

by default. A table's *groupby_acl_check* attribute takes precedent over the *glide.security.groupby_acl_check* property. If the property is set to **false**, then ensure that any table which should have ACL checks on groupby columns has the *groupby_acl_check* attribute set to **true**.

Ensure the property *glide.security.groupby_acl_check* is set to **true**.

More information

Attribute	Description
Configuration name	*glide.security.groupby_acl_check*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: Setting this property to **false** will disable ACLs check on groupby columns which could lead to information leakage.
Dependencies and prerequisites	None

Ensure archive table ACLs are checked [New in Security Center 1.3 and updated in 1.5]

The *glide.security.enable_archive_table_acls* property controls whether access control lists (ACLs) of the original table, the table the archive table was created from, are evaluated to false.

The *glide.security.enable_archive_table_acls* property should not be set to false since the original table's ACLs will be evaluated regardless of its value. You can avoid additional ACLs for an archive table by not adding them.

More information

Attribute	Description
Configuration name	*glide.security.enable_archive_table_acls*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 3 • CVSS score: Low • Security risk details: If the property is set to false, ACLs added to archived tables will be ignored, an action that is counter intuitive and therefore may lead to authorization bypass.
Dependencies and prerequisites	None
Functional impact	When this property is set to true, any active read ACLs on archive tables will be honored. If no active read ACLs exist or the property is set to false, the original table's (table from which data was archived) will apply to the archive table. **Note:** Only read ACLs are supported on archive tables. Other operations on archive tables are governed internally through an Access Handler.

Ensure dashboards creation/deletion requires access check [New in Security Center 1.3 and updated in 2.0]

The *glide.processors.check_access_before_process* system property enables access control list (ACL) enforcement for creating or deleting dashboards when a user is logged in.

Set the *glide.processors.check_access_before_process* system property to **true**. If the property does not appear in the System Properties [sys_properties] table, the fallback value is **true**.

More information

Attribute	Description
Configuration name	*glide.processors.check_access_before_process*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Access control
Security risk	• Severity score: 6.3 • CVSS score: Medium

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	• Security risk details: Disabling this property by setting it to false, enables an ACL bypass on dashboards. This allows all authenticated users with low privileges to delete and add dashboards.
Dependencies and prerequisites	None
Functional impact	This property controls the ability to create new sys_dashboards and delete existing dashboards when a user lacks the necessary access rights. When the value is set to false, users with inappropriate roles can add and delete sys_dashboard entries (though the GlideRecord layer should recheck the existing ACLs). A value of true restricts add and delete operations for users without the required access rights.

Exclude Sensitive Tables and Fields from Data Generation [New in Security Center 7.0]

Use system properties to exclude tables and fields from Data Generation, which is used to generate fake data sets based on existing data. Tables and fields that are added to these exclusion lists can't be used for Data Generation feature.

Tables included in the *glide.data.generation.excluded.tables* system property are excluded from Data Generation in addition to metadata tables.

Fields included in a comma separated list for *glide.data.generation.excluded.fields.<TABLE-NAME>* are excluded from Data Generation in addition to any of these fields, if applicable:

- number
- roles
- sys_class_name
- sys_created_by
- sys_id
- sys_mod_count
- sys_tags
- sys_updated_by

Review the list of tables included in the property *glide.data.generation.excluded.tables*. Add any tables which should be excluded from Data Generation to the comma separated list of tables. In addition, metadata tables will be ignored for data generation.

Review the list of fields for each table by looking at properties with the format: `glide.data.generation.excluded.fields.<TABLE-NAME>`. Add any sensitive fields for the specified table as a comma-separated list of values.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	• *glide.data.generation.excluded.tables* • *glide.data.generation.excluded.fields.**
Configuration type	System Properties (/sys_properties_list.do)
Data type	• Comma-separated list of table names • Comma-separated list of fields for a given table
Recommended value	• Comma-separated list of table names which should be excluded from Data Generation • Comma-separated list of field names which should be excluded from Data Generation for each applicable table
Default value	"","
Category	Access control
Security risk	• Severity score: 2.6 • CVSS score: Low • Security risk details: Data in tables used in the Data Generation feature can have real or fake values populated as intended by the feature. Sensitive values in tables which should not be visible or replicated could be revealed to other instance users.
Dependencies and prerequisites	Data Generation plugin is in use

Prevent Users From Accepting Warning To Bypass CSRF Validation [Updated in Security Center 1.3 and 1.5]

Use the *glide.security.csrf.strict.validation.mode* property to enable CSRF token strict validation. If the CSRF token doesn't match, it prevents resubmission of the request.

This property prevents users from being able to accept a warning which allows a potentially malicious request to be sent to the instance. This warning appears when a POST request fails due to having a mis-matched anti-CSRF token belonging to one of the victim's other active sessions. If *glide.security.csrf.strict.validation.mode* is not set to the recommended value of true, then an attacker can formulate a CSRF attack utilizing a leaked anti-CSRF token from a different active session belonging to the victim. A POST request to an instance contains an anti-CSRF token within "sysparm_ck" or "X-UserToken" which matches the user's current session.

If the anti-CSRF token is instead tied to one of the user's other active sessions, the POST request will return a 302 redirection to security_interceptor.do with a Continue button available to the user when this property is set to false. Clicking this button will re-submit the request to the instance, except it will now having a valid anti-CSRF token. When this property is set to true, the

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

302 redirection to the security_interceptor.do page will not display a Continue button and the user will not be allowed to resubmit the request.A successful CSRF attack will allow an attacker to effectively perform any operation that the victim is able to perform.

More information

Attribute	Description
Property name	*glide.security.csrf.strict.validation.mode*
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control
Purpose	To enforce strict validation of CSRF token, and prevents its reuse.
Data type	Boolean
Recommended value	true
Default value	true
Security risk rating	(Medium) Cross site Request Forgery is a significant security risk that violates the integrity of the instance data. An attacker can launch the CSRF attack on any instance user by abusing the trust of the instance user. With the help of social engineering attacks, a user can submit a malformed request to the instance on behalf of the attacker.
Security risk rating	3.7
Functional impact	This remediation enables an extra validation step before the instance user submits a write request to the instance. It checks whether the current CSRF token has been used previously. If Yes, it prevents submission of further write requests.
Security risk	(Medium) Cross site Request Forgery is a significant security risk that violates the integrity of the instance data. An attacker can launch the CSRF attack on any instance user by abusing the trust of the instance user. With the help of social engineering attacks, a user can submit a malformed request to the instance on behalf of the attacker.

Return to Configure and upload your customer supplied key to upload your wrapped key.

Restrict delegated developers read access [Updated in Security Center 1.3]

If *com.glide.dd_allow_global_access_tables* does not contain the recommended value of wf_activity, wf_activity_definition, wf_workflow, wf_workflow_version, sp_portal, sp_widget, and sp_page, then those tables could be read by a delegated developer. This could provide the delegated developer read access to sensitive information.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Property name	*com.glide.dd_allow_global_access_tables*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	wf_activity, wf_activity_definition, wf_workflow, wf_workflow_version, sp_portal, sp_widget, sp_page
Default value	wf_activity, wf_activity_definition, wf_workflow, wf_workflow_version, sp_portal, sp_widget, sp_page
Category	Access control
Security risk	• Severity score: 2.7 • CVSS score: Low • Security risk details: Ensure that *com.glide.dd_allow_global_access_tables* is set to wf_activity, wf_activity_definition, wf_workflow, wf_workflow_version, sp_portal, sp_widget, sp_page.

Require AJAXGlideRecord ACL checking [Updated in Security Center 1.3]

Use the *glide.script.secure.ajaxgliderecord* property to perform access control rule (ACL) validation when server-side records, such as tables, are accessed using GlideAjax APIs within a client script.

From client scripts, it is possible to query arbitrary data from the server using the AJAXGlideRecord (GlideAjax - Client) API, by using a syntax such as a server-side glide record. It is a powerful and useful tool in many deployments.

If you choose to apply Access Control Lists (ACL) to GlideAjax API calls, you can only query data to which the currently connected user has access. For example, if an ESS user who has no rights to read the cmn_location table is logged in, any GlideAjax API call to that table would fail.

If the ServiceNow AI Platform is running without GlideAjax ACL call checking, an API can return information that the currently logged in user could not otherwise access.

Use GlideRecordSecure when querying data to ensure the highest level of security. GlideRecord relies on ACL enforcement through configurations whereas GlideRecordSecure applies stricter security controls. GlideRecordSecure offers a more secure, out-of-the-box solution for handling sensitive data.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Property name	*glide.script.secure.ajaxgliderecord*
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control
Purpose	Ensure security ACLs are checked and validated even when the records are accessed through Client Side APIs.
Recommended value	true
Default value	true
Security risk rating	8.1
Functional impact	This remediation enforces the ACL relationship with server-side records when the requests are made using the AJAXGlideRecord API calls. If the ACL configuration is not properly configured, then there is potential impact. For more details on its impact, and how to identify it, see Refer to the Audit and review client-side GlideRecord (AJAXGlideRecord) transactions [KB0550828] article in the HI Knowledge Base .
Security risk	(High) Through client scripts, it is possible to query arbitrary data from the server through the GlideAjax API. Server-side resources can be accessed without proper authorization, so using ACL validation helps the application validate the request based on the configured authorization.
Workaround	Ensure that proper ACLs are created for script includes, processors, and other entities used by a GlideAjax (AJAXGlideRecord) API so that it executes under proper authorization. Implement methods like `canRead ()`, `canWrite()`, `canCreate ()`, and `canDelete ()` to perform user authorization before accessing table records using GlideRecord. Another method is to use GlideRecordSecure. The class is inherited from the GlideRecord Server that performs the same functions as GlideRecord, and also enforces ACLs.
References	Apply ACLs to AJAXGlideRecord (client-side Glide record) This property belongs to the same family of properties that secure and restrict execution of scripts originating from the client, such as *glide.script.allow.ajaxevaluate*. For more information, see Enable AJAXEvaluate.

Restrict write access on system fields to admin users [New in Security Center 7.0]

Use the *glide.rest.table_api.admin_only_sys_fields* system property to control write access the fields generated by the system.

The *glide.rest.table_api.admin_only_sys_fields* property controls write access to these fields:

- sys_id
- sys_created_by
- sys_created_on
- sys_updated_by
- sys_updated_on

When this property is set to **true**, only an admin can write to these fields that are system-generated values. When the property is set to **false** or it doesn't exist in the System Properties [sys_properties] table, users who have create or write access to a table can write to these system values using the Table API.

Set the property *glide.rest.table_api.admin_only_sys_fields* to **true** to prevent non-admin users from updating system fields on records.

More information

Attribute	Description
Configuration name	*glide.rest.table_api.admin_only_sys_fields*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Fallback value	false
Category	Access control
Security risk	• Severity score: 2.7 • CVSS score: Low • Users without the admin role could update fields such as sys_created_by or sys_updated_on. This access can impact the integrity of the created or updated record metadata, making records appear as if they were created by another user or updated at a different time.
Functional impact	Any integrations or users without the admin role that use the Table API to create or update records and change these fields are impacted. These requests to the Table API set the query parameter

Attribute	Description
	sysparm_suppress_auto_sys_field to **false** and set those fields in the request body.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Require approval for agent-based Office 365 group membership changes [New in Security Center 7.0]

Enable the approval flow for adding or removing Office 365 group members through the Microsoft 365 group membership AI Agent using a system property.

Use the *sn_itsm_aia.office_365_group_member_approval.required* system property to control whether the approval flow for adding or removing Office 365 group members through the AI agent is on or off. When the approval workflow is enabled, an approval record must be set to approved by a member of the group specified in the *sn_itsm_aia.office_365_group_member_approval.group_id* system property. If the *sn_itsm_aia.office_365_group_member_approval.group_id* property isn't configured, the *Microsoft 365 group member approvers* group is used.

More information

Attribute	Description
Configuration name	*sn_itsm_aia.office_365_group_member_approval.requi*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Access control
Security risk	• Severity score: 4.9 • CVSS score: Medium • Any user who can access the Microsoft 365 group membership AI Agent can and add and remove Office 365 group members from the Azure AD group if explicit approval from the specified approvers group isn't required. Ensure that these changes are approved to reduce the risk of elevation of privilege by adding/removing members without proper authorization.
Functional impact	When *sn_itsm_aia.office_365_group_member_approval.requi* is set to **true**, a member of the group specified in *sn_itsm_aia.office_365_group_member_approval.<grou* must approve the Incident requesting addition

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	or removal of Office 365 group members. If *sn_itsm_aia.office_365_group_member_approval.requi* is set to **false** then no approval is required and the AI Agent can autonomously handle the process of adding or removing members from an Office 365 group.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Prevent impersonating user from viewing application data

Use system properties to prevent an impersonating user from viewing application data.

Prevent admin level from accessing the application specific data belonging to that user when impersonating an account. This permission can be set at the application level by creating a system property specific to the application.

These system properties use the *<scope>.impersonateCheck* naming format (for example *sn_hr_core.impersonateCheck*). Create a system property with a value of **true** to prevent users from accessing the application-specific data belonging to another user when impersonating an account.

Note:
Not all applications are designed to work in this configuration or have a System Properties [sys_properties] record for this purpose. The following scopes are configured to work with this property.

- sn_opp_market
- sn_jny
- sn_imt_vaccine
- sn_imt_health_test
- sn_hr_core
- sn_egd_goals
- sn_egd_core
- sn_egd_act
- sn_em
- sn_talent_aia

For each application with the *<scope>.impersonateCheck* property in the System Properties [sys_properties] table, ensure the property value is set to **true**.

Note:
These properties can only be modified by the scoped administrator for the specific application.

Use this script to find which properties need to be updated or created on the instance:

```
var properties = [
    'sn_opp_market.impersonateCheck',
    'sn_jny.impersonateCheck',
    'sn_imt_vaccine.impersonateCheck',
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
    'sn_imt_health_test.impersonateCheck',
    'sn_hr_core.impersonateCheck',
    'sn_egd_goals.impersonateCheck',
    'sn_egd_core.impersonateCheck',
    'sn_egd_act.impersonateCheck',
'sn_em.impersonateCheck',
'sn_talent_aia.impersonateCheck'
];

var pm = new GlidePluginManager();

for (var i = 0; i < properties.length; i++) {
    var property = properties[i];
    var application = property.split('.')[0];
    var propertyValue = gs.getProperty(property, 'false');

    if (pm.isActive(application) &&
 propertyValue.toLowerCase() != 'true') {
        gs.print(property);
    }
}
```

More information

Attribute	Description
Configuration name	*<scope>.impersonateCheck*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Access control
Security risk	• Severity score: 3.8 • CVSS score: Low • A value of **false** for these properties allows an admin level user to impersonate another user and access application data with the impersonated user's access. This may be undesirable or allow for unauthorized data access in specific application contexts.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Enforce oauth state parameter validation

Configure the *glide.oauth.state.parameter.required* property to prevent your instance from cross-site request forgery (CSRF) attacks.

The *glide.oauth.state.parameter.required* property enables the State parameter to be required in an OAuth request for authorization code flow. The State parameter is a string

value that should not contain special characters or be empty. Setting this property to **true** ensures that an attacker cannot perform Cross-site request forgery (CSRF) attacks during authentication, which protects your instance from attacks from an impersonated user.

More information

Attribute	Description
Configuration name	*glide.oauth.state.parameter.required*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control
Security risk	• Severity score: 4.2 • CVSS score: Medium • Security risk details: Set this property to **true** to ensure that CSRF attacks are prevented.
Dependencies and prerequisites	None

Enforce Strict User Image Upload

Use the *glide.security.strict.user_image_upload* property to enable Access Control for the upload/update of a profile picture when performed on a user record.

This setting opens the possibility of an unauthorized user uploading an image to another user's profile.

- When you set this property to **true**, the table ACLs are enforced when uploading photos, only allowing authorized users to upload an image.
- When you set it to **false**, ACLs are not enforced on image uploads to the Photo field.

More information

Attribute	Description
Property name	*glide.security.strict.user_image_upload*
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control
Purpose	To restrict uploading of user image only to authorized users.
Recommended value	true
Security risk rating	3.7
Functional impact	No functionality impact as authorized users are still able to upload images to their user profile.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	(Low) When you set this property to **false**, an authenticated user could upload an image to another user's account without authorization.

To learn more about adding or creating a system property, see Add a system property.

Restrict email domains for external user registration [Updated in Security Center 1.3, 1.5, and 2.0]

Use the *sn_ext_usr_reg.allowed_email_domains* property to list acceptable external email domains.

The **sn_ext_usr_reg.allowed_email_domains** system property defines which email addresses are allowed to self-register to a ServiceNow instance. The format should be a comma separated list of acceptable email domains such as `domain1.com,domain2.com` where emails such as `example@domain2.com` will be accepted. If **sn_ext_usr_reg.allowed_email_domains** is not set with a list of acceptable domains, then users with any email address are allowed to register accounts on the instances. If not defined, malicious actors could perform registration using emails addresses from unwanted domains to gain authenticated access to the instance.

More information

Attribute	Description
Property name	*sn_ext_usr_reg.allowed_email_domains*
Configuration type	System Properties (/sys_properties_list.do), Communities Properties
Category	Access control
Purpose	List email domains to allow user email for registration.
Recommended value	Enter a list of domains in a comma-separated format, for example `domain1.com, domain2.com, domain3.com`. This format works with or without spaces between elements.
Configuration type	String
Security risk	(High) Malicious actors could perform registration using emails addresses from unwanted domains. Ensure that **sn_ext_usr_reg.allowed_email_domains** is not set to an empty value.
Functional impact	Email addresses from domains that are not included in the comma separated list defined in the property aren't allowed to self-register to a ServiceNow instance.
Security risk rating	7.5
References	Communities

To learn more about adding or creating a system property, see Add a system property.

Enable High Security Plugin [Updated in Security Center 1.3]

When you activate the High Security plugin, it creates or updates hundreds of different configurations to control the level of security on your instance. These configurations mitigate many of the top OWASP attacks by enabling strict access control, input validation, and output encoding.

These configurations include:

- Access Control
- Business rules
- System properties
- UI policy action
- script actions
- script includes

Example

Refer to the examples for the following properties:

Property	Topic
glide.ui.escape_all_script	Escape jelly script [Updated in Security Center 1.3 and 1.5]
glide.security.strict.actions	Check UI action conditions before execution
glide.security.csrf_previous.allow	Enable Anti-CSRF token [New in Security Center 1.3, updated in 1.5, and removed in 2.0]
glide.security.csrf.strict.validation.mode	Prevent Users From Accepting Warning To Bypass CSRF Validation [Updated in Security Center 1.3 and 1.5]

More information

Attribute	Description
Plugin Name	com.glide.high_security
Configuration type	System Definition > Plugins - Development
Category	Access control
Purpose	It is mandatory to activate this plugin. It increases the security level of an instance, which reduces the attack surface by mitigating owasp top 10 attacks, including CSRF, XSS, Securing Session Cookies, and File uploads.
Recommended value	Active
Security risk rating	9.8
Functional impact	This plugin enables several system security configurations, which may impact UI and functionality as well.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	(High) Many security configurations are unintentionally left open, which may open the door for some of the critical vulnerabilities.
References	Activating High Security Settings High Security Settings

To learn more about activating a plugin, see Activate a plugin

Honor Admin Override ACLs

The *glide.security.admin.override.accessterm* property controls admins to be unable to override ACL evaluation even where the override should be in effect.

More information

Attribute	Description
Property name	*glide.security.admin.override.accessterm*
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control
Purpose	Controls admins to be unable to override ACL evaluation.
Data type	Boolean
Recommended value	True
Default value	True
Security risk	(Low) ACLs are evaluated cumulatively. If there are number of ACLs on any given field and the Admin Overrides option is false (not selected) on one of them, then the effective admin overrides for all the ACLs are considered to be false.
Security risk rating	3.8
References	Access Control List Rules

To learn more about adding or creating a system property, see Add a system property.

Prevent inactive users from logging in [New in Security Center 1.5]

Configure this property to control if inactive users can authenticate on your instance.

When the system property *glide.authenticate.only.allow.active.user.login* is not set to a value of **true**, users in the User [sys_user] table marked inactive can still login to the instance. Users may be marked inactive if they no longer have permission to login (such as during termination from a company). If the property is not set to **true**, then these users may still access the instance and any data they could previously access.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Set the *glide.authenticate.only.allow.active.user.login* property value to the recommended value of **true** (recommended), to ensures the users in the User [sys_user] table marked inactive cannot log in to the instance and are locked out.

More information

Attribute	Description
Configuration name	*glide.authenticate.only.allow.active.user.login*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control
Security risk	• Severity score: 7.5 • CVSS score: High • Security risk details: Not setting this property to the recommended value of true, could enable inactive users like a terminated employee to still be able to access the instance and any data.
Dependencies and prerequisites	None

Prevent Unauthenticated Access to Virtual Agent Embedded Web Client

Learn how to configure the *sn_va_web_client_app_embed* table to block unauthenticated users from accessing embedded web clients.

The UI page, *sn_va_web_client_app_embed*, which is an embedded web client for Virtual Agent, contains the access control lists (ACLs) marked true in the sys_public table out of the box. It has been confirmed that there are use cases where public accessibility is needed however this is not a standard to set it to default publicly accessible.

If the embedded web client is not needed for unauthenticated users, open the *sn_va_web_client_app_embed* record (sys_id `04b1905473222300e985658b4cf6a7ef`) in the Public Pages [sys_public] table and deselect the **Active** field to deactivate the page.

More information

Attribute	Description
Configuration name	**sn_va_web_client_app_embed**
Configuration type	UI Page(sys_ui_page_list.do)
Data type	table
Recommended value	The **sn_va_web_client_app_embed** public page [sys_public] (sys_id `04b1905473222300e985658b4cf6a7ef`) does not exist or is not active.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Default value	Not available (this is a table value)
Category	Access control
Security risk	• Severity score: 7.5 • CVSS score: High • Security risk details: It is recommended to deactivate the UI page, *sn_va_web_client_app_embed*, if an embedded web client is not needed for unauthenticated users.
Dependencies and prerequisites	None

Restrict JSONP Requests to Trusted URLs [Updated in Security Center 1.3]

Specify trusted URLs for the AngularJS $http service to allow or reject JSONP requests.

Increase security on your instance by ensuring that only trusted URLs for the AngularJS $http service can allow/reject JSONP requests. JSONP requests are allowed to any URL if these properties are not configured and enabled.

Use the value of the **angular.jsonp.inclusion_list.urls** system property to define a list of URLs that are trusted and allow for this purpose. Set the value of the **angular.jsonp.inclusion_list.enabled** system property to **true** to limit allowed JSONP to only the URLs listed in **angular.jsonp.inclusion_list.urls**.

More information

Attribute	Description
Configuration name	*angular.jsonp.inclusion_list.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control
Security risk	• Severity score: Medium • CVSS score: 5.4 • Security risk details: Setting this property to **false** enables JSONP requests to any URL.
Dependencies and prerequisites	None

Prevent users from accepting warning to bypass CSRF validation

Reduce the risk of Cross-Site Request Forgery (CSRF) by preventing users from accepting warning to bypass CSRF validation.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Enable CSRF token strict validation to prevent Cross-Site Request Forgery (CSRF) tokens from being reused, which may allow CSRF attacks.

Set the **glide.security.csrf.strict.validation.mode** system property value to **true** to enable CSRF token strict validation. If this property doesn't exist on your System Properties [sys_properties] table, the default value is **true** starting in Xanadu.

More information

Attribute	Description
Technical configuration name	glide.security.csrf.strict.validation.mode
Plugin applicability	None
Security risk	Cross-site request forgery is a significant security risk that violates the integrity of the instance data. An attacker can launch the CSRF attack on any instance user by abusing the trust of the instance user. With the help of social engineering attacks, a user can submit a malformed request to the instance on behalf of the attacker.
Common Vulnerability Scoring System (CVSS) score	3.7
Common Vulnerability Scoring System (CVSS) rating	Low
Functional impact	This remediation enables an extra validation step before the user submits a write request to the instance. It checks whether the current CSRF token has been used previously. If it has, then it prevents submission of further write requests.
Dependencies and prerequisites	None
Data type	Boolean
Base system value	true
Fallback value	true
Recommended value	true

To learn more about adding or creating a system property, see Add a system property.

Disable raw database query execution [Updated in Security Center 1.3 and removed in 2.0]

Control whether a user can perform raw SQL queries on the database.

The *glide.db.allow_unsafe_dbi_execute_sql* property enables users to perform raw SQL queries on the database, which can give access to tables and data outside of GlideRecord restrictions. If this property is not set to the recommended value of *false*, this allows for the calling of *dbi.executeStatement()* from a Glide Scriptable which can lead to malicious SQL statements being executed.

Warning:
This property is both safe and no db override.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.db.allow_unsafe_dbi_execute_sql*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Category	Access control
Security risk	• Severity score: 7.2 • CVSS score: High • Security risk details: Not setting this property to **false** enables calling of *dbi.executeStatement()* from a Glide Scriptable.
Dependencies and prerequisites	None
References	Access Control List Rules

Hide user comments on articles [New in Security Center 1.3]

Use the *glide.knowman.show_user_feedback* property to control whether feedback comments are visible.

When *glide.knowman.show_user_feedback* is not set to never, feedback comments will be visible on knowledge base (KB) articles to users with roles defined in the Glide property, *glide.knowman.show_user_feedback.roles*. As feedback comments may contain sensitive information, you may not want the feedback to be visible. If this property is not set to never, there could be confidentiality impacts if sensitive information is disclosed in feedback.

More information

Attribute	Description
Configuration name	*glide.knowman.show_user_feedback*
Configuration type	System Properties (/sys_properties_list.do)
Data type	choicelist
Recommended value	never
Default value	onload
Category	Access control

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 3.5 • CVSS score: Low • Security risk details: Not setting this property to never could lead to sensitive information being disclosed in feedback comments.
Dependencies and prerequisites	None
Functional impact	Shows user comments on KB articles based on choices mentioned in the configuration.

Require authentication by default for client-callable script includes [Updated in Security Center 1.3]

By default, client-callable script includes that do not explicitly set visibility, are public. If needed, add the *glide.script.ccsi.ispublic* property to enable privacy control over all client-callable script includes accessed by public pages.

When you add this property, you must set its value to **false**, which designates that all client-callable script includes are private, and changes their visibility in public pages.

Note:
You cannot add the property with a value of **true**, or change its value from **false** to **true**. If you attempt to do so, an error message appears.

If needed, you can change the privacy setting for an individual client-callable script include by adding the `isPublic()` function.

- The `isPublic()` setting takes precedence over the *glide.script.ccsi.ispublic* property.
- For example, if you set `isPublic()` to **true** in an individual script, it makes it public, which overrides the *glide.script.ccsi.ispublic* property that makes all other client-callable script includes private.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.script.ccsi.ispublic*
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control
Purpose	Making client-callable script includes private means that guests who access public pages can't access the client-callable script include. A non-logged-in user can't execute a private script.
Recommended value	false

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Default value	false
Security risk rating	7.5
Functional impact	If the client-callable script includes are designated as public (that is, this property is missing), then unauthenticated users can execute client scripts. Add the property restricts the execution of scripts by a non-logged-in user.
Security risk	(High) If you do not add this property, client-side script includes circumvent ACLs, which may result in unintended public functionality. If the client script provides confidential information, it could have an adverse potential security risk.
Workaround	Setting the *glide.script.ccsi.ispublic* property to **false** makes all client-callable script includes private. You can change the privacy setting for an individual client-callable script include by adding the `isPublic()` function. The `isPublic` function takes precedence over the *glide.script.ccsi.ispublic* property. Add the following syntax to the script include: `isPublic:function(){return[true/false];},`

Enforce production instance behavior [Updated in Security Center 1.3 and 1.5]

Configure whether your instance should be handled like a production or non-production instance.

If the *glide.installation.production* property is not set to the recommended value of **true**, the instance is not treated as a production instance, therefore permitting zboot and other potentially dangerous scripts to run. Enabling a production instance to be evaluated as a non-production instance can lead to information leakages or Denial of Service (DoS) attacks.

More information

Attribute	Description
Configuration name	*glide.installation.production*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 6.3 • CVSS score: Medium • Security risk details: Setting this property value to **false** causes the instance to be treated as a non-production instance which enables zboot and other potentially dangerous scripts to run.
Dependencies and prerequisites	None

Restrict access to background script [Updated in Security Center 1.3 and 2.0]

Configure the *glide.script_processor.admin* property to set the role required for accessing the Script Background module.

This property holds the required role to access Script Background module. If *glide.script_processor.admin* is not set to the recommended and default value of admin, then users having a lower privileged role will be able to run background scripts on the instance. This will lead to a complete bypass of the ACL system allowing full access to tables.

Ensure the property *glide.script_processor.admin* is set to the admin. This is the default value on instances.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.script_processor.admin*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	admin
Default value	admin
Category	Access control
Security risk	• Severity score: 8.8 • CVSS score: High • Security risk details: Not setting this property to the recommended value of **admin** lets any user run background scripts on the instance.
Dependencies and prerequisites	None

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Restrict access to emails with empty target table

Activate the *glide.email.email_with_no_target_visible_to_all* property to restrict user access to emails, unless they were the one who sent the email or have an admin role.

Unauthorized users are able to access emails in the sys_email_list table that are missing a target record. Instead of enforcing ACLs on email entries, this property restricts access only to the email sender and users with the admin role.

Note:
Emails sent to and received by the instance appear in the sys_email_list table. However, only received emails that were marked with an Error and Ignored state should have an empty target table.

More information

Attribute	Description
Property name	*glide.email.email_with_no_target_visible_to_all*
Configuration type	System Properties (/sys_properties_list.do)
Configure	Access control
Purpose	To block email client from showing emails when user doesn't authorize access.
Recommended value	true
Default value	true
Security risk rating	6.5
Functional impact	Users are no longer able to see emails where target table is empty unless they are an admin or were the sender of the email.
Security risk	(Moderate) If the property is not enabled, unauthorized users are able to access any email where the target_table field is empty.
References	Advanced email properties https://support.servicenow.com/kb_view.do?sysparm_article=KB0690043

To learn more about adding or creating a system property, see Add a system property.

Restrict access to specific IP ranges plugin [Updated in Security Center 1.3]

Use the *com.snc.ipauthenticator* plugin to restrict access to specific IP ranges. Unless public access is intended for the instance, administrators should limit access to their assigned IP net blocks.

Prerequisites

This plugin when set to true restricts access to specific IP ranges. Unless public access is intended for the instance, administrators should limit access to their assigned IP net blocks.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

An exclusion list (Deny) or an inclusion list (Allow) of IP addresses can be created through IP Address Access Control (ip_access_list.do).

Before setting this property, you must activate the IP Range Based Authentication (com.snc.ipauthenticator) *com.snc.ipauthenticator* plugin. To learn more, see IP range based authentication and in the Steps to configure section (below).

Ensure the plugin *com.snc.ipauthenticator* is activated and there is at least one active IP access policy in the table ip_access.

More information

Attribute	Description
Plugin Name	• com.snc.ipauthenticator • ip_access
Configuration type	System Security > IP Address Access Control
Category	Access control
Purpose	To add the range of IP address that can or can't access the instance to the trusted and untrusted domain lists.
Recommended value	Active
Default value	None. This is a plugin, not a Glide property; therefore, there is no default value.
Security risk rating	5.3
Functional impact	Customer-denied IP ranges are used for this remediation item. No impact as customer defines the target list.
Security risk	(Low) Unnecessary exposure to the target instance on the internet should be restricted with the help of IP access controls functionality.
References	IP range based authentication

Steps to configure

1. Ensure that the com.snc.ipauthenticator plugin is active.
2. Navigate to **System Security** > **IP Address Access Control**.
3. Click **New** to create an exclusion list (Deny) or an inclusion list (Allow) of IP addresses.
4. Click **Submit**.

Restrict knowledge bases access [New in Security Center 1.3]

The *glide.knowman.block_access_with_no_user_criteria* property is used to control the read/write access of users on knowledge based articles.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.knowman.block_access_with_no_user_criteria*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Access control
Security risk	• Severity score: 9.1 • CVSS score: Critical • Security risk details: If this property is not set to the recommended value of true, then any user can read and contribute to a KB.
Dependencies and prerequisites	None
Functional impact	Denies access to a knowledge base when either Can Read or Can Contribute isn't specified.

Restrict permissions for CMDB model [Updated in Security Center 1.3 and 1.5]

Use the *csm_cmdb_model.customer_visible_flag* system property to limit customer access to data in the Product Models table as an additional access control to the CMDB model.

Set the *csm_cmdb_model.customer_visible_flag* property to **true** to enable the Customer Visible field for the tables listed below:

- Product Models table [cmdb_model]
- Software Models table [cmdb_software_product_model]
- Application Models table [cmdb_application_product_model]
- Consumable Models table [cmdb_consumable_product_model]
- Facility Models table [cmdb_facility_product_model]
- Hardware Models table [cmdb_hardware_product_model]

Setting this property as **true** hides all cmdb_model values by default.

Set the property to **false** to not consider the customer_visible column/atrribute on the cmdb_model table and to rely on the bases cmdb_model ACLs which are accessible to sn_esm_user.

More information

Attribute	Description
Property name	*csm_cmdb_model.customer_visible_flag*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Access control
Purpose	When set to tue**true**, the system uses the setting in the Customer Visible field to determine access to product model data on the Customer Service Portal.
Recommended value	true
Default value	false
Configuration type	Boolean
Security risk	(Moderate) Any user with the sn_esm_user role and out of the box ACLs could have permissions to the CMDB model. **Note:** this role tends to be granted to external users. External users could unwillingly be given permissions to the CMDB model.
References	Limit access to product model data on the Customer Service Portal

To learn more about adding or creating a system property, see Add a system property.

Restrict unauthenticated access to attachments

Use the *glide.image_provider.security_enabled* property to control the security settings for images. If set to **true**, images are visible only to authenticated and authorized users. If set to **false**, images are visible to anyone with a URL to the attachment.

Secure the images on your instance to prevent sensitive information leak. Images on your instance are accessible via urls that end in `.iix`.

Set the **glide.image_provider.security_enabled** system property to **true** to prevent access to your images via these URLs.

Note:

This property is not honored for images from the attachment table if the origin table is one of:

- Stationeries [sysevent_email_style]
- Welcome Page Sections [sys_home]
- System Properties [sys_properties]

Restriction should be applied for unauthenticated users as some attachments might contain sensitive information.

More information

Attribute	Description
Property name	*glide.image_provider.security_enabled*

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control
Purpose	To prevent unauthenticated access of attachment when rendered using the `.iix` format.
Recommended value	true
Default value	false
Functional impact	No significant impact on the functionality. User experience might be affected a bit because the user who formerly directly accessed .iix must go through authentication.
Security risk	• Severity Score: 6.5 • Security Risk Details: Restriction must be applied for unauthenticated users as some attachment might contain sensitive information.
References	Administering attachments Available system properties

To learn more about adding or creating a system property, see Add a system property.

Restrict access to custom journal entries [Updated in Security Center 1.3 and removed in 2.0]

Use the `glide.live_feed.custom_journal.acl_check_enabled` property to respect ACL's on custom journal fields.

If `glide.live_feed.custom_journal.acl_check_enabled` is not set to the recommended value of true, then all users to be able to see all journal entries within the life feed feature. Setting property to true will respect ACL's on custom journal fields which is a good to have feature.

More information

Attribute	Description
Property name	`glide.live_feed.custom_journal.acl_check_enabled`
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control
Purpose	To control which users see which journal entries based on ACLs.
Recommended value	true
Default value	true
Configuration type	Boolean.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	(Moderate) When set to true, only the custom journal entries which pass ACL will be shown in Live Feed, otherwise, all users will be able to see all journal entries.

To learn more about adding or creating a system property, see Add a system property.

Restrict flow context read access [New in Security Center 1.5]

Use the *com.snc.process_flow.reporting.require_flow_access* property to enforce if an additional access check is required for a user to read a flow check.

When the *com.snc.process_flow.reporting.require_flow_access* property is set to the recommended value of true, there is an additional access check for a user trying to read a flow context. There may be minor information disclosure if this property is set to false.

More information

Attribute	Description
Configuration name	*com.snc.process_flow.reporting.require_flow_access*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control
Security risk	• Severity score: 2.7 • CVSS score: Low • Security risk details: Setting this property to false retains its existing behavior. Setting this property to true enforces the added security layer of read access.
Dependencies and prerequisites	None
Functional impact	When this property is enabled, the security for reading flow context records are increased. The instance enforces that a user trying to read the flow context has read access to the parent flow as well.

Restrict Impersonation to Admin [New in Security Center 2.0]

The *glide.sys.permissive.impersonate* property can be used to prevent non-admin roles from impersonating other users.

When the *glide.sys.permissive.impersonate* property is set to false, only users with the admin role can impersonate other users. When this property is set to true, users may be able to make use of application components that expose impersonation APIs to impersonate a user of higher privilege. This could result in unauthorized access if these application components are misconfigured because non-admin users can access the Impersonation functionality.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

You may want to set the property to the non-default value when you need non-admin users to have the capability to impersonate other users.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.sys.permissive.impersonate*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Category	Access control
Security risk	• Severity score: 6.7 • CVSS score: Medium • Security risk details: Failing to set this property to the recommended value of false may allow a non-admin user to utilize application components that expose APIs, enabling them to impersonate a user with higher privileges.
Dependencies and prerequisites	None
Functional impact	Non-admin users can access Impersonation features with some customizations to other scripts and UI pages. However, it is essential to ensure that only the correct users are granted access to these features. **Note:** When *glide.sys.permissive.impersonate* is set to true, Non-admin users with the *impersonate* role can still impersonate.

Enable security jump start plugin (ACL Rules) [Updated in Security Center 1.3]

Activate the Security Jump Start (ACL Rules) (com.snc.system_security *com.snc.system_security*) plugin to create several important ACLs that validate the Access Controls on some of the key system tables within the ServiceNow AI Platform.

These rules provide a jump-start on securing many system tables, making it easier for an organization to get an instance into production. The Security Jump Start (ACL Rules) plugin is installed automatically on all new instances.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Plugin ID	*com.snc.system_security*
Configuration type	System Definition > Plugins
Category	Access control
Purpose	Activate the Security Jump Start (ACL Rules) plugin to achieve proper security compliance. It provides some basic ACLs that secure system tables in the first place instead of creating manually for each system table that comes with default provisioning of an instance. These ACLs are helpful when the newly created instance must quickly move into production.
Recommended value	Active
Default value	None. This is a plugin, not a Glide property, so there is no default value. The plugin is installed by default on zBoot (resets).
Security risk rating	8.1
Functional impact	There is significant functional impact if this plugin is installed without auditing of the existing ACLs on the instance. Customer outreach and definitions are required before the remediation can occur.
Security risk	(High) Access control should be enforced to lock down the unintended access to the instance. ACL jumpstart rules were created to provide a starting point on securing many system tables to make it easier for an organization to quickly get into production.
References	Security jump start - ACL rules

Steps to configure

If this plugin is not activated on your instance, contact ServiceNow Support. Activating the plugin at this point might modify security access to tables already in use in a production environment. If an administrator is interested in the new ACL rules the plugin provides, you can manually create one or more of them in an existing instance if needed. This list of ACLs may be used as a guideline in that case.

Use of secure insert multiple operation within import set API [New in Security Center 1.3]

Use the *com.glide.import_set_api.insert_multiple_optimize* property to control whether *GlideRecordSecure* or *GlideRecord* is used for the Insert Multiple operation within the Import Set API.

If *com.glide.import_set_api.insert_multiple_optimize* is set to the recommended value of false, then *GlideRecordSecure* will be used to insert records, and table-level access control lists (ACLs) will be evaluated. If this property is set to true, *GlideRecord* will be used to insert records, and table-level ACLs will not be evaluated; In addition, you must ensure that Import Set API Insert Multiple REST Endpoint ACL (sys_id: 3101b770ff2211105cf343d0653bf182) is active and that users have the role, import_transformer.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*com.glide.import_set_api.insert_multiple_optimize*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Category	Access control
Security risk	• Severity score: 6.5 • CVSS score: Medium • Security risk details: If this property is not set to false, a low-privileged user could insert data into tables outside the scope of their privileged roles.
Revertible behavior	Both safe override and No DB Override.
Dependencies and prerequisites	None
Functional impact	This property optimizes the performance of Import Set API by using GlideRecord to save data. When the parameter is set, it requires an integration user to have the import_transformer role to access the API.
References	https://developer.servicenow.com/blog.do?p=/post/gliderecord-vs-gliderecordsecure

Enforce SOAP request strict security [Updated in Security Center 1.3]

Use the *glide.soap.strict_security* property to enforces web service security.

This property uses a combination of:

- Basic authentication challenge/response over the HTTP protocol and
- System level access controls in the Enable security jump start plugin (ACL Rules) [Updated in Security Center 1.3].

If you set this property to **true**, it performs the following actions:

- If the user has appropriate role to perform the operation, it checks incoming SOAP request for role authorization to validate. It occurs during SOAP web service calls/requests made against ServiceNow AI Platform tables when performing CREATE, READ, UPDATE or DELETE operations.
- Checks the system-level ACLs while retrieving data in the form of SOAP data on the table.
- Checks the field-level ACLs for any CRUD operation performed against a field of table.

ACL checks are only complete for standard Table API calls and not web services.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Property name	*glide.soap.strict_security*
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control
Default value	true
Recommended value	true
Functional impact	This remediation enforces the system-level access control while retrieving data from tables/pages in the form of SOAP data on the instance. If there are users currently accessing this data, they are restricted/allowed to access the data based on the ACL rules. For the default roles that have access to the SOAP data, see SOAP web service.
Security risk	(Moderate) Without appropriate authorization configured on the incoming SOAP requests, an unauthorized user can get access to sensitive content/data on the target instance.
References	Enforce strict security for inbound SOAP SOAP web service

To learn more about adding or creating a system property, see Add a system property.

Required jms connection factories [New in Security Center 1.3 and updated in 1.5 and 2.0]

The *mid.property.jms.command.allowed_factory_names* property controls the Java Messaging Service (JMS) connection factories that the MID Server can use.

It is intended for a few select factories needed by plugins for JMS activity or action. Including additional factories could be a step in a chain of attack for vulnerabilities such as JDNI insertion that rely on capabilities an attacker can leverage in allowed factories. To prevent the possibility of any leveraged vulnerability, do not include factories beyond the necessary defaults.

To remediate this security risk review the list of names provided to the mid property, *mid.property.jms.command.allowed_factory_names*. Ensure any additional Java factory names beyond the default of connectionFactory, queueConnectionFactory, and topicConnectionFactory are necessary.

More information

Attribute	Description
Configuration name	*mid.property.jms.command.allowed_factory_names*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	string
Default value	*connectionFactory*, *queueConnectionFactory*, *topicConnectionFactory*
Recommended value	*connectionFactory*, *queueConnectionFactory*, *topicConnectionFactory*
Category	Access control
Security risk	• Severity score: 4.1 • CVSS score: Medium • Security risk details: If the MID Server (*com.glideapp.agent*) plugin is active, review the list of names provided to the mid property *mid.property.jms.command.allowed_factory_names*. Ensure any additional factory names beyond the default of connectionFactory, queueConnectionFactory, and topicConnectionFactory are necessary.
Dependencies and prerequisites	None

Restrict Global App Development by Role [New in Security Center 2.0]

Use the *sn_g_app_creator.allow_global* property to control which users can create applications in the global scope using the Guided Application Creator.

If *sn_g_app_creator.allow_global* is set to the recommended value of false, users require the *sn_g_app_creator.global* role to create applications in the global scope. Conversely, if set to the insecure value of true, any user with the basic sn_g_app_creator.app_creator role can create global applications. Global applications lack scope protection, allowing developers access to extensive features and functions beyond specific scopes. Restricting global application development to users with the additional role adheres to the principle of least privilege.

Note:
This property does not come pre-configured in your instance. You must manually create and configure this property according to your organization's needs.

More information

Attribute	Description
Configuration name	*sn_g_app_creator.allow_global*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Access control
Security risk	• Severity score: 3.3 • CVSS score: Low • Security risk details: Failing to set this property to the recommended value could allow any user with the s*n_g_app_creator.app_creator* role to create global applications, which does not adhere to the principle of least privilege.
Dependencies and prerequisites	None
Functional impact	Enhanced the API (/api/now/templates) to validate the create global application ACL and property.

Review extraneous explicit role access control conditions [Removed in Security Center 1.5]

The Explicit Roles plugin is recommended to mandate that all users have either the snc_internal role to access internal resources, or the snc_external role to access external resources.

After the installation of this plugin, all existing users are assigned the snc_internal role, and existing access control lists (ACLs) are populated with the role conditions. Due to automation logic or intervention by an instance admin, the snc_internal or snc_external roles may be incorrectly added to an ACL that already contains a more strict role requirement. Since ACL role evaluation will pass for any user containing any role mapped to an ACL, the addition of snc_internal or snc_external may be too broad for the intended purpose of an ACL. This could lead to data leakage if a low privileged user is granted access through the ACL.

For example, it would be unnecessary for both the snc_internal and the admin roles to be mapped to the same ACL within a table. The ACL is meant to grant access to admins, in which case the snc_internal role is a mistake. Or, the ACL is meant to grant access to all snc_internal users which makes the admin role unnecessary. When the Explicit Roles plugin is installed, review the ACLs which contain a role condition for snc_internal or snc_external while also containing a condition for another role. If the roles are able to function for a specific use case, then the finding should be periodically reviewed.

Important:
This hardening setting will be removed in the next Security Center v1.5 store patch release and future versions. An Instance Scan suite called "Explicit Roles ACL Config Check Suite" is available in the Washington release. We recommend that you review the findings of this new Instance Scan.

Set guest user for soap requests [Updated in Security Center 1.3 and 2.0]

Configure this property to control the level of access of unauthenticated SOAP requests.

This property controls the level of access of unauthenticated SOAP requests. If it is not set to the recommended value of *soap.guest*, or is set to a user with limited privileges, then SOAP requests will execute on behalf of the user. If this property is blank, then it enables unauthenticated access to administrator or maintenance level operations which negates all security controls within the instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*com.glide.soap.guest_user*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	soap.guest
Default value	soap.guest
Category	Access control
Security risk	• Severity score: 8.1 • CVSS score: High • Security risk details: Setting this property to blank enables unauthenticated access to administrator or maintenance level operations.
Dependencies and prerequisites	None

Disable public access to favorites [Updated in Security Center 1.3 and 2.0]

Use the *glide.ui.magellan.favorites.allow_public* to specify whether unauthenticated users are allowed to see **Favorites** in the navigator.

Public Access to Favorites is compliant when *glide.ui.magellan.favorites.allow_public* is set to **false**.

More information

Attribute	Description
Property name	*glide.ui.magellan.favorites.allow_public*
Configuration type	System Properties (/sys_properties_list.do)
Configure in Instance Security Center	Yes
Purpose	Control if unauthenticated users are allowed to see **Favorites** in the navigator.
Type	true/false
Recommended value	*false*
Security Dependencies	Set *glide.ui.magellan.favorites.allow_public* to **false**.
Functional impact	(Medium) Enabling this property acts as a layer of protection from unauthorized users.
Security risk	(Medium) If this property isn't enabled, there's a risk of unauthorized access to sensitive data.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
References	Configure favorites option

Enable SNC access control plugin [Updated in Security Center 1.3]

Activate the SNC Access Control (com.snc.snc_access_control) plugin to control access to your instances by Customer Service and Support personnel.

Prevent ServiceNow Customer Service and Support personnel from accessing the instances without your express permission by enabling the SNC Access Control (com.snc.snc_access_control) plugin. Although all access to your instance is audited, you may prefer to control this access. This access method is fully auditable and tracked.

Note:
Other authorized ServiceNow Operations personnel, in their capacity to support and manage the product, are required to perform administrative actions on the underlying infrastructure. Enabling this plugin may affect support service levels and the Availability SLA. Availability SLA is then measured from the time that Support staff personnel are granted access to your instance.

Enable the SNC Access Control (com.snc.snc_access_control) plugin to restrict access to your instance without your express permission. For more details on this feature, see ServiceNow access control. For activation information, see Activate ServiceNow access control

More information

Attribute	Description
Plugin Name	`com.snc.snc_access_control`
Configuration type	System Definition > Plugins
Category	Access control
Purpose	Prohibits Customer Service and Support employees from accessing the instance
Recommended value	Active
Default value	None. This is a plugin, not a Glide property, so there is no default value. The plugin is not installed by default.
Role required	The customer administrator can't activate this plugin. It must be explicitly requested because it requires elevated privileges to activate the plugin.
Security risk rating	3.3
Functional impact	If this plugin is inactive, all Customer Service and Support employees can access the customer's instance. Enabling the plugin enables the customer to restrict access to authorized Customer Service and Support employees only.
Security risk	(High) Unnecessary exposure of instance access to wider group of people.
References	ServiceNow access control

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Steps to configure

1. To request the plugin, follow the steps in Activate ServiceNow access control. Customers must request the SNC Access Control plugin (com.snc.snc_access_control) from HI.
2. To enable SNC access control, follow the steps in Configure ServiceNow access control. Configure an access control record to specify one or more Customer Service and Support employees that have permission to log in your instance.

Use Document Classification to limit publicly accessible documents [New in Security Center 7.0]

Control public access to permalinked documents using system properties.

Note:
This hardening setting is not a part of the hardening baseline. It does not appear in Security Center hardening pages and affect your hardening score.

By default, the Document Management plugin includes these classifications:

- **public**
- **restricted**
- **confidential**
- **none** (no classification provided)

Use the *com.snc.documents.permalink.allowed_classifications* to create a list of document classifications. Documents under these classifications (and documents without classification) are publicly accessible to any unauthenticated users with an appropriate link.

Use this property to control public access to document permalinks. Previously, these links were publicly accessible to anyone with the link. The value of this property depends on your specific needs. You may have additional custom document categories that may need to be added to this property to enable public access.

Set the *com.snc.documents.permalink.allowed_classifications* property value to a comma-separated list of document classifications. Documents with these classifications are publicly accessible by unauthenticated users.

If this property isn't present in the System Properties [sys_properties] table, it defaults to an empty list. In this case, only documents with no classification are publicly accessible by unauthenticated users. The default value of this property is **public**, meaning that only documents classified as **public** or documents with no classification are accessible to unauthenticated users.

More information

Attribute	Description
Configuration name	*com.snc.documents.permalink.allowed_classificatio*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String list
Recommended value	public
Default value	public
Fallback value	<empty>

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Access control
Security risk	• Severity score: 5.3 • CVSS score: Medium • If a document category containing documents which shouldn't be publicly accessible is added to this property, it may expose sensitive information to unauthenticated users.
Functional impact	If a document category containing documents which should be publicly accessible isn't added to this property, it prevents those documents from being accessed.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Validate query ACLs on Glide DB functions [New in Security Center 7.0]

Control whether query ACLs are applied to Glide DB functions using system properties.

When the *glide.db.encoded_query.check_function_field_query_acls* system property is set to **true**, query ACLs (query_range and query_match) are validated by default on these Glide DB functions:

- glidefunction:position
- glidefunction:substring
- glidefunction:concat
- glidefunction:coalesce
- glidefunction:length

To validate these query ACLS on additional functions, add those functions to the *glide.db.encoded_query.force_query_range_on_functions* system property.

Set the *glide.db.encoded_query.check_function_field_query_acls* system property to **true**, or confirm that the property isn't on the System Properties [sys_properties] list.

More information

Attribute	Description
Configuration name	• *glide.db.encoded_query.check_function_field_quer* • *glide.db.encoded_query.force_query_range_on_func*
Configuration type	System Properties (/sys_properties_list.do)
Data type	• Boolean • String list

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Recommended value	• true • glidefunction:position, glidefunction:substring, glidefunction:concat, glidefunction:coalesce, glidefunction:length
Default value	• true • glidefunction:position, glidefunction:substring, glidefunction:concat, glidefunction:coalesce, glidefunction:length
Fallback value	• true • glidefunction:position, glidefunction:substring, glidefunction:concat, glidefunction:coalesce, glidefunction:length
Category	Access control
Security risk	• Severity score:5.3 • CVSS score: Medium • If the *glide.db.encoded_query.check_function_field_quer* system property exists and isn't set to a value of **true**, a logged-in user may be able to infer data blindly, leading to sensitive information disclosure.
Functional impact	Users may expect to see values from function fields but get blocked due to ACLs enforced on the function fields.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

API and web service

The API and Web Service category ensures that applications have appropriate authentication, authorization and session management, validate all input that traverses a trust boundary and include security controls for all API types.

Specific controls in this category address input validation by service type such as XDS schema validation for SOAP web services or Denial of Service protection for graphQL APIs.

Validate SOAP content type [Updated in Security Center 1.3]

Use the *glide.soap.require_content_type_xml* property to enable validation of a content type as text/xml and protect against invalid SOAP requests.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- When set to **true**, the ServiceNow AI Platform validates the content type as text/xml and protects against invalid SOAP requests.
- If set to **false**, any content-type value is allowed.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.soap.require_content_type_xml*
Configuration type	System Properties (/sys_properties_list.do)
Category	API and web service
Purpose	Protect against invalid SOAP requests
Recommended value	true
Default value	true
Security risk rating	8.8
Functional impact	This remediation enables validation of SOAP content type for all the inbound SOAP requests. • If you are using a content type other than text/xml for inbound requests, it may cause potential failure of SOAP transactions. • If you are not using the correct MIME type, it could disrupt third-party integrations.
Security risk	(Moderate) When accepting inbound SOAP requests, the appropriate validation is performed to ensure that the relevant content type is being defined as a part of the request. It restricts the invalid SOAP responses that can be viewed as a security risk.
Reference	Content types

To learn more about adding or creating a system property, see Add a system property.

Require authorization for pdf requests [Updated in Security Center 1.3]

Use the *glide.basicauth.required.pdf* property to designate if incoming PDF requests should require basic authentication.

Ensure the property *glide.basicauth.required.pdf* exists in the sys_properties table and is set to true.

More information

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Property name	*glide.basicauth.required.pdf*
Configuration type	System Properties (/sys_properties_list.do)
Category	API and web service
Purpose	To enforce basic authentication on PDF requests.
Recommended value	true
Default value	true
Security risk rating	7.5
Functional impact	This remediation enforces a combination of authentication methods, in the form of basic authentication and system level access control. • It performs this authentication while retrieving data from tables/pages in the form of PDF data on the instance. • It restricts any guest users who are currently accessing this data. If applicable, you may need to create a new account for users who need access to this content, with necessary access control permissions. To learn more, see Web service import sets.
Security risk	(High) Without appropriate authorization configured on the incoming PDF requests, an unauthorized user can get access to sensitive content/data on the target instance.

To learn more about adding or creating a system property, see Add a system property.

Require Authentication on Event Management HTTP Processor [New in Security Center 1.3, Updated in 1.5, and removed in 2.0]

Learn how to establish secure basic authentication for inbound Amazon Simple Notification Service (SNS) requests when the Event Management plugin (*com.glideapp.itom.snac*) is enabled.

If the *glide.basicauth.required.evtmgmthttpprocessor* property isn't set to the recommended value of **true**, and the Event Management plugin (*com.glideapp.itom.snac*) is active, then basic authentication is not required for all inbound Amazon Simple Notification Service (SNS) requests. This can lead to unauthenticated access to instance data.

To remediate this security risk, ensure that *glide.basicauth.required.evtmgmthttpprocessor* is set to**true** and that *com.glideapp.itom.snac* is active.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.basicauth.required.evtmgmthttpprocessor*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	API and web service
Security risk	• Severity score: 7 • CVSS score: High • Security risk details: Not setting*glide.basicauth.required.evtmgmthttpprocesso* to the recommended value of true, and not activating the *com.glideapp.itom.snac* plugin causes basic authentication not to be enabled for inbound SNS requests. This could lead to unauthenticated access to instance data.
Dependencies and prerequisites	None
References	• https://docs.aws.amazon.com/sns/latest/dg/welcome.html • Access control
Functional impact	If *glide.basicauth.required.evtmgmthttpprocessor* is not set to the recommended value of True, and if the Event Management plugin (com.glideapp.itom.snac) is active, then basic authentication is not required for all Inbound Amazon Web Services SNS requests. This can lead to unauthenticated access to instance data.

Require authorization for SOAP requests [Updated in Security Center 1.3, 1.5, and 2.0]

Use the *glide.basicauth.required.soap* property to designate if incoming SOAP requests should require basic authorization.

More information

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

Attribute	Description
Property name	*glide.basicauth.required.soapglide.soap.require_ws*
Configuration type	System Properties (/sys_properties_list.do)
Category	API and web service
Purpose	To enforce soap requests authorization.
Recommended value	true
Security risk rating	8.1
Functional impact	This remediation enforces a combination of authentication methods, in the form of basic authentication and system level access control. • It performs this authentication while retrieving data from tables/pages in the form of SOAP data on the instance. • It restricts any guest users who are currently accessing this data. • Create an account for a user who needs access to this content, with the necessary access control permissions. To learn more, see SOAP web service and MID Server authentication credentials and SOAP requests.
Security risk	(Medium) Without appropriate authorization configured on the data source SOAP requests, an unauthorized user can access sensitive content/data on the target instance.
References	Authentication

To learn more about adding or creating a system property, see Add a system property.

Require authorization for unload requests [Updated in Security Center 1.3]

Use the *glide.basicauth.required.unl* (useUnloadFormat) property to designate if incoming unload requests should require basic authentication.

More information

Attribute	Description
Property name	*glide.basicauth.required.unl*
Configuration type	System Properties (/sys_properties_list.do)
Category	API and web service
Purpose	To enforce basic authentication on unload requests.
Recommended value	true
Security risk rating	7.5

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	This remediation enforces a combination of authentication methods, in the form of basic authentication and system level access control. It performs this authentication while retrieving data from tables/pages in the form of unload data on the instance.
Security risk	(High) Without appropriate authorization configured on the datasource unload requests, an unauthorized user can get access to sensitive content/data on the target instance. Ensure that *glide.basicauth.required.unl* exists in the sys_properties_table and is set to true.
References	Authentication

Require authorization for csv requests [Updated in Security Center 1.3]

Use the *glide.basicauth.required.csv* property to designate if incoming CSV (Comma-Separated Values) requests should require basic authentication.

More information

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

Attribute	Description
Property name	*glide.basicauth.required.csv*
Configuration type	System Properties (/sys_properties_list.do)
Category	API and web service
Purpose	To enforce basic authentication on CSV requests.
Recommended value	true
Security risk rating	7.5
Functional impact	This remediation enforces a combination of authentication methods, in the form of basic authentication and system level access control. • It performs this authentication while retrieving data from tables/pages in the form of CSV data on the instance. • It restricts any guest users who are currently accessing this data. If applicable, you may need to create a new account for users who need access to this content, with necessary access control permissions. To learn more, see Retrieving data from a CSV formatted file.
Security risk	(High) Without appropriate authorization configured on the incoming CSV requests, an

Require authorization for excel requests [Updated in Security Center 1.3]

Use the *glide.basicauth.required.excel* property to designate if incoming Excel requests should require basic authentication.

More information

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

Attribute	Description
Property name	*glide.basicauth.required.excel*
Configuration type	System Properties (/sys_properties_list.do)
Category	API and web service
Purpose	To enforce basic authentication on Excel requests.
Recommended value	true
Security risk rating	7.5
Functional impact	This remediation enforces a combination of authentication methods, in the form of basic authentication and system level access control. • It performs this authentication while retrieving data from tables/pages in the form of Excel data on the instance. • It restricts any guest users who are currently accessing this data. If applicable, you may need to create a new account for users who need access to this content, with necessary access control permissions.
Security risk	(High) Without appropriate authorization configured on the incoming Excel requests, an unauthorized user can get access to sensitive content/data on the target instance.

To learn more about adding or creating a system property, see Add a system property.

Require authorization for import requests [Updated in Security Center 1.3]

Use the *glide.basicauth.required.importprocessor* property to designate if incoming import requests should require basic authentication.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

Attribute	Description
Property name	*glide.basicauth.required.importprocessor*
Configuration type	System Properties (/sys_properties_list.do)
Category	API and web service
Purpose	To enforce basic authentication on import requests.
Recommended value	true
Security risk rating	5.3
Functional impact	This remediation enforces a combination of authentication methods, in the form of basic authentication and system level access control. • It performs this authentication while importing data sources into the instance tables/pages. • It restricts any guest users who are currently accessing this data. If applicable, you may need to create a new account for users who need access to this content, with necessary access control permissions. To learn more, see Retrieving data from a CSV formatted file.
Security risk	(Moderate) Without appropriate authorization configured on the datasource import requests, an unauthorized user can get access to sensitive content/data on the target instance.

Require authorization for JSONv2 request [Updated in Security Center 1.3]

Use the *glide.basicauth.required.jsonv2* property to designate if incoming JSONv2 requests should require basic authorization.

More information

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

Attribute	Description
Property name	*glide.basicauth.required.jsonv2*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	API and web service
Purpose	To enforce JSONv2 requests authorization.
Security risk rating	7.5
Recommended value	true
Functional impact	This remediation enforces a combination of authentication methods, in the form of basic authentication and system level access control. • It performs this authentication while retrieving data from tables/pages in the form of JSON data on the instance. • It restricts any guest users who are currently accessing this data. • Create an account for a user who needs access to this content, with the necessary access control permissions. To learn more, see JSONv2 Web Service JSONv2 Web Service.
Security risk	(High) Without appropriate authorization configured on the data source JSON requests, an unauthorized user can access sensitive content/data on the target instance.
References	Authentication Requiring basic authentication for incoming JSONv2 requests

Require authorization for WSDL request [Updated in Security Center 1.3 and 1.5]

Use the *glide.basicauth.required.wsdl* property to designate if incoming WSDL (Web Services Description Language) requests should require basic authentication.

If *glide.basicauth.required.wsdl* is not set to the recommended value of true, then , then this will disable Basic Authentication for WSDL requests. WSDL is a protocol that is used to describe web services such as instance table schemas, and is not a mechanism for sharing the data within tables. Setting this property to true allows for disclosure of table schemas to unauthenticated users.

Note:
If you choose not to require basic authentication for incoming WSDL requests, you must modify Access Control (ACL) rules to enable guest users to access the WSDL content.

More information

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

© 2026 ServiceNow, Inc. All rights reserved.

Attribute	Description
Property name	*glide.basicauth.required.wsdl*
Configuration type	System Properties (/sys_properties_list.do)
Category	API and web service
Purpose	To enforce basic authentication on WSDL requests.
Recommended value	true
Security risk rating	5.3
Functional impact	This remediation enforces a combination of authentication methods, in the form of basic authentication and system level access control. • It performs this authentication while retrieving data from tables/pages in the form of WSDL data on the instance. • It restricts any guest users who are currently accessing this data. If applicable, you may need to create a new account for users who need access to this content, with necessary access control permissions.
Security risk	(Medium) Without appropriate authorization configured on the WSDL web services, an unauthorized user can get access to sensitive WSDL content/data on the target instance.
References	Web service security

Require authorization for XML requests [Updated in Security Center 1.3]

Use the *glide.basicauth.required.xml* property to designate if incoming XML requests should require basic authentication.

More information

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

Attribute	Description
Property name	*glide.basicauth.required.xml*
Configuration type	System Properties (/sys_properties_list.do)
Category	API and web service
Purpose	To enforce basic authentication on XML requests.
Security risk rating	7.5
Recommended value	true

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	This remediation enforces a combination of authentication methods, in the form of basic authentication and system level access control. • It performs this authentication while retrieving data from tables/pages in the form of XML data on the instance. • It restricts any guest users who are currently accessing this data. If applicable, you may need to create a new account for users who need access to this content, with necessary access control permissions. To learn more, see XML parser step.
Security risk	(High) Without appropriate authorization configured on the incoming XML requests, an unauthorized user can get access to sensitive content/data on the target instance.
References	Authentication

Require authorization for XML output requests [Updated in Security Center 1.3]

Configure this property so that basic authorization is required for all inbound XMLOutputProcessor requests.

If the *glide.basicauth.required.xmloutputprocessor* property is not set to the recommended value of **true**, then basic authorization is not required for inbound XMLOutputProcessor requests which could lead to unauthenticated information disclosure from the instance.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.basicauth.required.xmloutputprocessor*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	API and web service

© 2026 ServiceNow, Inc. All rights reserved.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 7.5 • CVSS score: High • Security risk details: Not setting the property to the recommended value of **true** could lead to sensitive information being leaked from the instance.
Dependencies and prerequisites	None

Require Authorization for XSD Requests [Updated in Security Center 1.3]

Use the *glide.basicauth.required.xsd* property to designate if incoming XSD (XML Schema Definition) requests should require basic authentication.

Ensure the property *glide.basicauth.required.xsd* exists in the sys_properties table and is set to true.

More information

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

Attribute	Description
Property name	glide.basicauth.required.xsd*glide.basicauth.required.xsd*
Configuration type	System Properties (/sys_properties_list.do)
Category	API and web service
Purpose	To enforce basic authentication on XSD requests.
Recommended value	true
Security risk rating	5.3
Functional impact	This remediation enforces a combination of authentication methods, in the form of basic authentication and system level access control. • It performs this authentication while retrieving data from tables/pages in the form of XSD data on the instance. • It restricts any guest users who are currently accessing this data. If applicable, you may need to create a new account for users who need access to this content, with necessary access control permissions. To learn more, see Non-interactive sessions.
Security risk	(Moderate) Without appropriate authorization configured on the incoming XSD requests, an unauthorized user can get access to sensitive content/data on the target instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description

Require authorization for SCHEMA requests [Updated in Security Center 1.3]

Use the *glide.basicauth.required.schema* property to require basic authorization for all Inbound Table Schema Processor requests.

The Inbound Table Schebma Processor handles incoming schema requests for the platform.

Set *glide.basicauth.required.schema* to the recommended value of **true** to require basic authorization for all Inbound Table Schema Processor requests. Set the value to **false** to not require basic authorization for all Inbound Table Schema Processor requests.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.basicauth.required.schema*
Configuration type	System Properties (/sys_properties_list.do)
Category	API and web service
Purpose	To require basic authorization for all Inbound Table Schema Processor requests.
Recommended value	True (default value).
Configuration type	Boolean
Security risk	(Moderate) Omitting authentication from this processor will lead to unauthenticated access to instance data.

Require authorization for RSS requests [Updated in Security Center 1.3]

Use the *glide.basicauth.required.rss* property to designate if incoming RSS requests should require basic authentication.

More information

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

Attribute	Description
Property name	*glide.basicauth.required.rss*
Configuration type	System Properties (/sys_properties_list.do)
Category	API and web service
Purpose	To enforce basic authentication on RSS requests.
Recommended value	true
Security risk rating	7.5
Functional impact	This remediation enforces a combination of authentication methods, in the form of basic authentication and system level access control. • It performs this authentication while processing RSS requests on the instance. • It restricts any guest users who are currently accessing this data. If applicable, you may need to create a new account for users who need access to this content, with necessary access control permissions.

Attribute	Description
	To learn more, see RSS feed generator.
Security risk	(High) Without appropriate authorization configured on the incoming RSS requests, an unauthorized user can get access to sensitive content/data on the target instance.
References	RSS basic authentication

Require authorization for API requests [Updated in Security Center 1.3]

Use the *glide.basicauth.required.api* property to enhance security for basic authorization for incoming REST requests.

Set the *glide.basicauth.required.api* property to **true** to require authorization for all REST requests. Set the property to **false** to bypass authorization for all REST requests.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.basicauth.required.api*
Configuration type	System Properties (/sys_properties_list.do)
Category	API and web service
Purpose	Basic authorization for incoming REST requests.
Recommended value	True (default)
Configuration type	String
Security risk	(High) If "glide.basicauth.required.api" is not set to the recommended value of "true", then this will disable Basic Authentication on API request and will lead to unauthenticated access to instance data.
Security risk rating	8.6

Architecture, design, and threat modeling

This broad control addresses high level design considerations and key elements to implement a secure application. This covers the tenants of availability, confidentiality processing integrity, non-repudiation and privacy. Additionally, elements of a secure software development lifecycle are included.

Certificate based authentication not enforced [New in Security Center 1.3]

The *glide.authenticate.mutual.enabled* property enables certificate based authentication, a type of mutual authentication for inbound REST connections to REST and SOAP APIs in the ServiceNow AI Platform.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Mutual authentication establishes trust between server and client by exchanging secure socket layer (SSL) certificates to validate the certificate with a trusted Certificate Authority. This allows verification that a trusted source is connecting to the ServiceNow AI Platform. If this instance is not set to the recommended value of true, an instance could be vulnerable to man-in-the-middle attacks (MitM).

To remediate this security threat, enable mutual authentication for inbound web services. If it's your first time installing the certificate-based authentication plugin (*com.glide.auth.mutual)* for the ServiceNow AI Platform, then follow the Set up Certificate-based authentication instructions. In addition, ensure that the *glide.authenticate.mutual.enabled* property is set to true to activate the plugin.

More information

Attribute	Description
Configuration name	*glide.authenticate.mutual.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 5.3 • CVSS score: Medium • Security risk details: If this property is not set to the recommended value of true, then certificate based authentication does not validate certificates with a trusted Certificate Authority. This increases the chances of a bad actor attacking an instance using MitM attacks.
Dependencies and prerequisites	None
References	• https://csrc.nist.gov/glossary/term/man_in_the_middle_attack • Certificate-based authentication • Configure mutual authentication

Check impersonation on ACL evaluation in HR App [New in Security Center 1.3 and updated in 1.5]

Use the *sn_hr_core.impersonateCheck* property to prevent a user from impersonating another user and accessing their HR information.

A secure setting prevents an admin from seeing another user's HR information while using impersonation. An insecure setting for this property allows an admin to impersonate a user and access HR data such as survey results or audit records with the impersonated user's access. Due to the nature of this type of data, such as information which should be available only to the user

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

themselves like email, this is not recommended. Setting *sn_hr_core.impersonateCheck* to true only allows access to HR information when the user is not impersonating any others.

More information

Attribute	Description
Configuration name	*sn_hr_core.impersonateCheck*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 2.7 • CVSS score: Low • Security risk details: An insecure setting for this property allows an admin to impersonate a user and access HR data such as survey results or audit records with the impersonated user's access.
Dependencies and prerequisites	None
Functional impact	When this property set to true, it prevents an admin from seeing another user's HR information while using impersonation. When set to false, it allows an admin to impersonate a user and access HR data such as survey results or audit records with the impersonated user's access. Due to the nature of this type of data, such as information which should available only to the user themselves like an email, this is not recommended. Setting sn_hr_core.impersonateCheck to true only allows access to HR information when the user is not impersonating any others.

Disable local login for users with Single Sign-On (SSO) enabled

Update user records to disable local login for users with Single Sign-On (SSO) enabled.

Users configured to use SSO authentication may be able to access the instance, or parts of the instance, with local credentials stored in the **user_password** field of their User [sys_user] record. This access applies to both interactive and non-interactive access for users who aren't locked out. Help prevent SSO-configured users from using local credentials to reduce the chance that valid local login credentials are stolen and used by malicious users.

Review Now Support Knowledge Base article KB1649420 for instructions on identifying and addressing accounts with local login still enabled on an instance with SSO enabled.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Security risk	When SSO authentication is enabled for a user, it's best practice to prevent that user from logging in locally. This reduces the chance that the valid local login credentials are stolen and used to login by a malicious user.
Common Vulnerability Scoring System (CVSS) score	4.2
Common Vulnerability Scoring System (CVSS) rating	Medium
Functional impact	SSO configured users are able to log in with local credentials.
Dependencies and prerequisites	Single Sign-On must be enabled (the **glide.authenticate.multisso.enabled** system property set to **true**.)
Data type	N/A
Base system value	N/A
Fallback value	N/A
Recommended value	N/A

Disable unauthenticated published reports [Updated in Security Center 2.0]

Deactivate this property to prevent the user from publishing or accessing reports. This property disables the published reports feature in reporting.

Enable publishing reports by setting the *glide.report.published_reports.enabled* to **true**.

Ensure the Glide Property *glide.report.published_reports.enabled* exists and is set to the value false. If the property does not appear in the sys_properties table, add a new record.

More information

Attribute	Description
Property name	*glide.report.published_reports.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Category	Architecture, design, and threat modeling
Purpose	Disables the published reports feature in reporting.
Type	true | false
Recommended value	**false**
Security risk rating	6.5
Functional impact	The user cannot publish reports.
Security risk	(Moderate) If this property is not enabled, users may be able to access or publish reports exposing sensitive

Attribute	Description
	data. Publishing a report creates a URL that anyone can use to access the report, including people who are not users. When anyone navigates to the URL, the report is generated with current data from the instance.
References	Publish a report

To learn more about adding or creating a system property, see Add a system property.

Enforce field ACLs for inbound query requests

Manage how incoming queries are validated on your instance.

Use the *glide.export.query.enforce_field_acl* property to check how incoming queries are validated on your instance. If the property is set to the recommended value of **true**, field ACLs are checked against incoming queries, and rejected if the user is unauthorized. If the property is set to **false**, ACLs are not checked against incoming queries and continue to execute which can lead to information disclosure to unauthorized parties.

More information

Attribute	Description
Configuration name	*glide.export.query.enforce_field_acl*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 4.4 • CVSS score: Medium • Security risk details: If this property is set to **false**, ACLs are not checked against incoming queries which can lead to information disclosure.
Dependencies and prerequisites	None

Enforce read ACLs on report views

Manage how Read ACLs are enforced on your instance.

Use the *glide.report.report_view.read_acl* property to enforce the Read ACL (table level) on reporting functions when there is no Report View ACL on the table or field. If this property is not set to **enforce**, ACLs could be bypassed leading to sensitive information leakage.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.

More information

Attribute	Description
Configuration name	*glide.report.report_view.read_acl*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	enforce
Default value	enforce
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 7.1 • CVSS score: High • Security risk details: Not setting this property to **enforce** could cause ACLs to be bypassed.
Dependencies and prerequisites	None

Enforce Query ACLs for Knowledge Quick Links

Enforce query ACLs for Knowledge Quick Links using a system property.

When the *com.glide.security.query_acl.enabled.knowledge_quick_links* system property is set to **true**, query ACLs are enforced for Knowledge Quick Links. If this property is set to **false**, an attacker can use blind queries to enumerate and exfiltrate data due to the default behavior of `GlideRecord.addEncodedQuery`.

If the property doesn't exist in the System properties [sys_properties] table, the secure default of **true** is used. A third option, **external_and_guests** enforces query ACLs only for external users and guests.

Verify that the *com.glide.security.query_acl.enabled.knowledge_quick_links* system property is set to **true**.

More information

Attribute	Description
Configuration name	*com.glide.security.query_acl.enabled.knowledge_qu*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String - Used as a ternary operator
Recommended value	true
Default value	true
Fallback value	true
Category	Architecture, design, and threat modeling

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 5.3 • CVSS score: Medium • Security Risk: ACLs can be bypassed, disclosing field data to users who don't have permissions to see it. This disclosure could include sensitive data depending on the table exploited.
Functional impact	Users aren't able to perform specific queries on fields where they don't have field level access.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Enforce Query ACLs for SubLists, List Counts and Widget Data Tables

Enforce query ACLs on sublist, list count, and widget data table queries using system properties.

Set *com.glide.security.query_acl.enabled.sub_lists* to **true** to enforce query ACLs on sublist queries, such as grouped lists and related lists.

Set *com.glide.security.query_acl.enabled.list_count* to **true** to enforce query ACLs on list count queries.

Set *glide.security.query_acl.enabled.data_table* to **true** to enforce query ACLs on widget data tables.

If any of these system properties are set to **false**, an attacker can use blind queries to enumerate and exfiltrate data due to the default behavior of `GlideRecord.addEncodedQuery`. If these properties don't exist in the System Properties [sys_properties] table, the secure default of true is used. A third option, *external_and_guests*, enforces ACLs only for external users and guests.

Ensure these system properties do not appear in the System Properties [sys_properties] table or are set to **true**.

More information

Attribute	Description
Configuration name	• *com.glide.security.query_acl.enabled.sub_lists* • *com.glide.security.query_acl.enabled.list_count* • *glide.security.query_acl.enabled.data_table*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Recommended value	• true • true • true
Default value	• true • true • true
Fallback value	• true • true • true
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 5.3 • CVSS score: Medium • Security Risk: ACLs can be bypassed disclosing field data to users who do not have permissions to see it. This could include sensitive data depending on the table exploited.
Dependencies and prerequisites	None

Enforce valid query string choice [New in Security Center 7.0]

Use a system property to ensure that any choice field value, when passed via a URL query string, is a valid active choice when a record is created.

When the *glide.ui.query_string.enforce_valid_choice_on_create* system property is set to **true**, the platform validates that any choice field value passed via a URL query string (for example, from a list filter) is a valid active choice when the record is created.

If invalid, the value is ignored and the field falls back to its default value. When the property is **false**, validation is inactive, and the system accepts any value, even invalid or inactive ones. This acceptance can potentially result in incorrect or unexpected data being stored on records.

Ensure *glide.ui.query_string.enforce_valid_choice_on_create* exists in the System Properties [sys_properties] table and is set to **true**. If the property doesn't exist in the table, the fallback value is **false**.

More information

Attribute	Description
Configuration name	*glide.ui.query_string.enforce_valid_choice_on_crea*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	Boolean
Recommended value	false
Default value	false
Fallback value	true
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 2.2 • CVSS score: Low • Security Risk: Set this property to **true** to ensure that only valid choices are used for new record creation. Invalid choices may lead to minor and unexpected data integrity issues, where a user is able to select an unintended value.
Functional impact	Existing instances and workflows may rely on new records being created based on a filter that contains an invalid or inactive choice. Use the following process to observe this behavior: **1.** Log in to an instance as an admin user. **2.** Create a String field on any table. For example, an incident with 2 choices: **Test1** and **Test2**. **3.** Create a list filter on incident table selecting the string field with value set to **Test2**. **4.** Go to dictionary field and deactivate the choice **Test2**. **5.** Go to the filter selected in step 3 and select **New** button. **6.** Check the value of the String type field in the newly opened record. When the property is set to **true**, the string field shouldn't have a value or should show the default value. When the property is set to **false** (default), the string field has the value set to **Test2**.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Define allowed ServiceNow internal IP addresses [Updated in Security Center 1.3 and 1.5]

Use the *glide.ip.authenticate.strict* property to specify IP ranges that can make inbound connections on an instance.

Use the *glide.ip.authenticate.strict* property to reduce the scope of the IP allow list of an instance and restrict the IP addresses that ServiceNow personnel can use to make inbound/outbound connections to an instance. The exact IP ranges removed from the IP allow

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

list by this property may be adjusted over time as the ServiceNow internal network changes. When set to true, *glide.ip.authenticate.strict* always guarantees an IP allow list that is equal to or more restrictive than the default.

When glide.ip.authenticate.strict is set to true:

A strict list of ServiceNow IP ranges replaces the default IP allow lists for inbound and outbound requests. This IP allow list, which starts with a more restrictive predefined set of allowed IP ranges, is replaced by the property glide.ip.authenticate.allow.secured.self_hosted_list if the instance is self-hosted.

When glide.ip.authenticate.strict is set to false:

The default IP allow list is used which contains a wider set of ServiceNow IP ranges. The default IP allow list is replaced by the contents of glide.ip.authenticate.allow.self_hosted_list if the instance is self-hosted.

Note:
Regardless of the value of *glide.ip.authenticate.strict* or if the instance is self-hosted, the allow list includes IP addresses in the *glide.custom.ip.authenticate.allow* and *glide.custom.ip.outbound.authenticate.allow* system properties, if defined.

All IP list properties share the same format, which is a comma separated range of IP addresses in IPv4 or IPv6 format. IP ranges are specified using a hyphen (10.0.10.14-10.0.10.19), using CIDR notation (10.0.10.0/24), or consist of a single IP address (10.0.10.5). At runtime, you can make additions to the IP allow list by adding entries to the IP Address Access Controls [ip_access] table. This table can also be used to explicitly deny IP ranges access to an instance.

Warning:
The value for this property is a no DB override. It can't be altered or overridden.

More information

Attribute	Description
Configuration name	• *glide.ip.authenticate.strict* • *glide.ip.authenticate.allow.secured*
Configuration type	System Properties (/sys_properties_list.do)
Data type	• Boolean • String
Recommended value	• true • Contains only trusted values
Default value	• <empty> • <empty>

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Fallback value	• <empty> • false
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security Risk Details: Broader access increases the risk of unauthorized or unnecessary access to the instance by non-essential internal users, such as support or sales staff, and reduces control over privileged access. Enforcing strict IP authentication limits connectivity to essential infrastructure, strengthening security and reducing exposure to insider threats or misconfiguration.
Functional impact	This should have no functional impact. It may restrict non-essential ServiceNow personal from accessing an instance. However, these are individuals that do not generally require access to such instances. If access is required, you can grant it on a case by case basis using the IP Address Access Controls [ip_access] table.
Dependencies and prerequisites	None

Note:
A deny all rule is needed to be added into IP access control to restrict access from any IP's not added into IP access control. All required allowed IP's are then needed to be added into IP access control.

To learn more about adding or creating a system property, see Add a system property.

Disable legacy JQuery behavior [Updated in Securty Center 1.3]

The *glide.jquery.legacy* is used to prevent older prepatched JQuery versions from being used which will introduce unpatched vulnerabilities in the library.

Set *glide.jquery.legacy* to the recommended value of **false** to prevent older prepatched JQuery versions from being used which introduce unpatched vulnerabilities in the library. Set the value to **true** to allow prepatched JQuery versions.

More information

Attribute	Description
Property name	*glide.jquery.legacy*
Configuration type	System Properties (/sys_properties_list.do)
Category	Architecture, design, and threat modeling

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Purpose	To prevent potential security risks arising from attacks on vulnerabilities discovered in outdated JQuery library versions.
Recommended value	False
Configuration type	Boolean
Security risk	(High) Prevent older prepatched JQuery versions from being used which introduce unpatched vulnerabilities in the library. The system property is a failsafe in case any organizations depend on the non-patched versions of angularJS to run their custom implementations.
Security risk rating	7.1

To learn more about adding or creating a system property, see Add a system property.

Disable GlideRecord Scope Fencing Legacy Behavior [New in Security Center 1.3 and updated in 1.5 and 2.0]

The *glide.record.legacy_cross_scope_access_policy_in_script* property disables scope fencing allowing scoped apps to access global script interfaces. It was created as a patch to GlideRecord's cross scope access.

GlideRecord provided cross scope create/update access to tables that were not configured with that level of access. In order to prevent customers from having applications broken when this scoped access behavior was patched, the property *glide.record.legacy_cross_scope_access_policy_in_script* was created. When true, cross scope access falls back onto legacy behavior (insecure). This property disables scope fencing, allowing scoped apps to access global script interfaces.

It is best security practice to have scope fencing restrictions in place. Scoping ensures applications can only access resources with explicit access or within their scope, following the principle of least privilege. Disabiling this feature could lead to confidentiality, availability, and integrity impacts.

Set the Glide Property *glide.record.legacy_cross_scope_access_policy_in_script* to false. When not present in the sys_properties table, the default value is true.

More information

Attribute	Description
Configuration name	*glide.record.legacy_cross_scope_access_policy_in_s*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	true (when the property does not exist in the sys_properties table.)
Category	Architecture, design, and threat modeling

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 5 • CVSS score: Medium • Security risk details: Scoping ensures applications can only access resources with explicit access or within their scope following the principle of least privilege. Disabling this feature could lead to confidentiality, availability, and integrity impacts.
Dependencies and prerequisites	None

Disable legacy AngularJS behavior [Removed in Security Center 2.2]

Use the *glide.angular.legacy* property to protect from potential security risks arising from attacks on vulnerabilities discovered in outdated AngularJS library versions.

Set *glide.angular.legacy* to the recommended value of **false** to prevent older prepatched angularJS versions from being used. Set the property to **true** to use older prepatched angularJS versions.

More information

Attribute	Description
Property name	*glide.angular.legacy*
Configuration type	System Properties (/sys_properties_list.do)
Category	Architecture, design, and threat modeling
Purpose	The system property is a failsafe in case any organizations depend on the non-patched versions of angularJS to run their custom implementations.
Recommended value	False
Configuration type	Boolean
Security risk	(High) Using older versions of angularJS could potentially lead to security risks arising from attacks on vulnerabilities discovered in outdated AngularJS library versions.
Security risk rating	7.1

Require authorization for data broker rest API [Updated in Security Center 1.3]

Use the *glide.basicauth.required.databrokerrestapiprocessor* property to require basic authorization for all inbound Data Broker Rest API requests.

If this property is set to **true**, then authorization is applied. If it is set to **false**, then no authorization is used which could lead to sensitive information being leaked from your instance.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.basicauth.required.databrokerrestapiprocesso*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 8.6 • CVSS score: High • Security risk details: If property is set to **false**, then API authentication will not be applied enabling a bad-actor to access sensitive data.
Dependencies and prerequisites	None

Restricted Binding functionality in case Bearer Authorization [New in Security Center 7.0]

Use a system property and restricted binding to ensure that an access token generated using that entity can't be used for UI calls.

Use the *glide.oauth.enforce_restricted_binding_for_ui* system property and enable restricted binding for an OAuth entity to prevent the access tokens generated by that entity from being used for UI calls (For example, `incident_list.do`).

When restricted binding is turned off, the access token generated can be used for UI calls regardless of the value of the system property.

Ensure that *glide.oauth.enforce_restricted_binding_for_ui* is set to **true** and **Enforce Token Restrictions** is set to **true** in all OAuth entity entries. For details on OAuth entity entries, see OAuth inbound.

More information

Attribute	Description
Configuration name	*glide.oauth.enforce_restricted_binding_for_ui*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Fallback value	false
Category	Architecture, design, and threat modeling

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 5.0 • CVSS score: Medium • Security risk details: When the *glide.oauth.enforce_restricted_binding_for_ui* system property isn't set to **true** or restricted binding is turned off, then a user with the access token to access an API (for example, mobile API) can get a session issued and use it to access other restricted resources on the instance (for example, `incident_list.do`).
Dependencies and prerequisites	None

Deny by default with empty ACLs [Updated in Security Center 1.3]

Use the *glide.sm.default_mode* property to control the default behavior of security manager when it finds that existing Access Control List (ACL) rules are a part of wildcard table ACL rules.

Prevent your instance's legacy security manager from allowing access to resources when there are no ACLs defined for that resource, or if there are only wildcard table-level ACLs (for example, `incident.*`). When allowed access by default, anything that does not have explicit ACLs set is susceptible to manipulation.

Set the **glide.sm.default_mode** system property value to **deny** to disallow access when there are no define ACL rules, or there are only wildcard table-level ACLs.

> ⚠ **Warning:**
> This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.sm.default_mode*
Configuration type	System Properties (/sys_properties_list.do)
Category	Architecture, design, and threat modeling
Purpose	Best security practice would be to restrict an Access to the tables by an unauthorized user. • If there are no ACL rules in place for tables, this property ensures that at least wildcard ACLs are validated for any CRUD operation performed on the table/field. • These rules restrict the read, write, create, and delete operations on all tables, unless the user has the admin role or meets the requirements of another table ACL rule.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Recommended value	deny
Functional impact	If you set this property to **Allow**, the wildcard table ACL rules allow CRUD operations on all tables unless there are specific table ACL rules in place to restrict such operations. **Note:** This plugin is not intended for existing instances, as it might modify security access to tables that are already in use in a production environment.
Security risk	6.3
References	Default deny property

To learn more about adding or creating a system property, see Add a system property.

Set Automatic Token Cleanup for Token Credentials [New in Security Center 2.0]

Use the *com.snc.platform.security.token.auth.cleanup* property to ensure that expired API keys and HMAC secrets are deleted, thereby limiting the potential for token reuse.

If the *com.snc.platform.security.token.auth.cleanup* property is set to the insecure value of false, expired API keys and HMAC secrets will not be deleted, creating a potential for token reuse. If a token was expired due to leakage or compromise, its reuse could expose the instance to anyone possessing the leaked token.

Expired tokens are retained for the number of days defined by *com.snc.platform.security.token.auth.days.expired.hmac_secret.is.kept* and *com.snc.platform.security.token.auth.days.expired.api_key.is.kept*. Valid values for these settings are integers of 0 or greater. A value of 0 results in the expired tokens being deleted on the same day, while a higher number of days increases the exposure period. A default value of 7 days or fewer is recommended.

More information

Attribute	Description
Configuration name	*com.snc.platform.security.token.auth.cleanup*, *com.snc.platform.security.token.auth.days.expired.*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	The recommended values are true, and any integer less than or equal to 7.
Default value	7
Category	Architecture, design, and threat modeling
Security risk	• Severity score: 5.1 • CVSS score: Medium

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	• Security risk details: Not configuring this property to the recommend value of true could prevent expired API keys and HMAC secrets from being deleted which increases the likelihood for token reuse.
Dependencies and prerequisites	None

Authentication

The authentication category covers the main elements of modern authentication to confirm an entity and its claims are authentic and correct, resistant to impersonation and prevent interception of passwords.

The ASVS standard builds on the NIST 800-63b (https://pages.nist.gov/800-63-3/sp800-63b.html) specification for this section.

Authentication includes password policy, controls and storage, proper implementation of authenticators and proper implementation of out of band or one time verifiers.

Activate role-based multi-factor authentication [Updated in Security Center 1.3]

Use the *glide.authenticate.multifactor* property to enforce role-based multi-factor authentication (MFA) for all users assigned to specific roles.

Enforce multi-factor authentication based on the roles assigned to the user. If a user has been assigned "admin", "security_admin" or "user_admin" roles in the multi-factor roles list, MFA will be enforced.

- Set this property to **true** to enforce role-based multi-factor authentication for all users assigned to specific roles.
- Set this property to **false** to disable role-based multi-factor authentication for all users assigned to specific roles.

More information

Attribute	Description
Property name	*glide.authenticate.multifactor*
Configuration type	System Properties (/sys_properties_list.do)
Category	Authentication
Purpose	Enforce role-based multi-factor authentication for all users assigned to specific roles.
Type	true/false
Recommended value	*true*
Security Dependencies	Activate **Role based multi-factor authentication** within the **Multi-factor Criteria table**.
Security risk rating	7.2

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	Enabling this property improves the experience of the user. It acts as an extra layer of protection and security against compromised credentials.
Security risk	(Moderate) If this property is not enabled, there is a risk of unauthorized access to sensitive data.
References	Configure role-based multi-factor criteria

To learn more about adding or creating a system property, see Add a system property.

Activate role based multi-factor authentication [Updated in Security Center 1.3]

Use the *glide.authenticate.multifactor* property to enforce role-based multi-factor authentication (MFA) for all users assigned to specific roles.

Enforce multi-factor authentication based on the roles assigned to the user. If a user has been assigned "admin", "security_admin" or "user_admin" roles in the multi-factor roles list, MFA will be enforced.

- Set this property to **true** to enforce role-based multi-factor authentication for all users assigned to specific roles.
- Set this property to **false** to disable role-based multi-factor authentication for all users assigned to specific roles.

More information

Attribute	Description
Property name	*glide.authenticate.multifactor*
Configuration type	System Properties (/sys_properties_list.do)
Category	Authentication
Purpose	Enforce role-based multi-factor authentication for all users assigned to specific roles.
Type	Boolean
Recommended value	*true*
Default value	false
Security Dependencies	Activate **Role based multi-factor authentication** within the **Multi-factor Criteria table**.
Security risk rating	7.2
Functional impact	Enabling this property improves the experience of the user. It acts as an extra layer of protection and security against compromised credentials.
Security risk	(Moderate) If this property is not enabled, there is a risk of unauthorized access to sensitive data.
References	Configure role-based multi-factor criteria

© 2026 ServiceNow, Inc. All rights reserved.

Anti-CSRF token (instance security hardening)

Use the *glide.security.use_csrf_token* property to ensure the use of a secure token to identify and validates incoming requests, which in turn are used to prevent these attacks.

Cross-Site Request Forgery (CSRF) is an attack that forces an end user to execute unwanted actions on a web application in which they're currently authenticated. CSRF attacks specifically target state-changing requests, not theft of data, since the attacker has no way to see the response to the forged request.

Note:
By default, the *glide.security.use_csrf_token* property is set to `true` for zBoot instance.

The following properties can be enabled for added controls over CSRF token:

- *glide.security.csrf_previous.time_limit*
- *glide.security.csrf_previous.allow*
- *glide.security.csrf.strict.validation.mode*

More information

Attribute	Description
Property name	glide.security.use_csrf_token
Configuration type	System Properties (/sys_properties_list.do)
Configure in Instance Security Center	Yes
Purpose	To protect the application from potential CSRF attack.
Recommended value	true
Functional impact	(Low) This remediation enables an extra validation step before the instance user submits a write request to the instance. Every write request contains a CSRF token (i.e a validation/CSRF ID tied to the user session). When the user session expires, the secure token expires with it.
Security risk	(High) Cross Site Request Forgery is a significant security risk that violates the integrity of the instance data. An attacker can launch the CSRF attack by abusing the trust of an instance user. With the help of social engineering attacks, a user can submit a malformed request on behalf of the attacker on the instance.

To learn more about adding or creating a system property, see Add a system property.

Control Lockout Time for Invalid Password Reset Attempts [Updated in Security Center 1.3 and 2.0]

The *password_reset.request.max_attempt_window* property controls the number of minutes a user must wait to reset or change their password after exceeding the maximum number of unsuccessful attempts that is set with the *password_reset.request.max_attempt* property.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The *password_reset.request.max_attempt_window* property defines the number of minutes a user must wait to reset or change their password after exceeding the maximum number of unsuccessful attempts that is set with the *password_reset.request.max_attempt property*. A small number of minutes for the *password_reset.request.max_attempt_window* property increases the risk of successfully brute forcing a password as a greater number of password reset attempts can be made. The default of 1440 minutes is recommended.

Ensure the property *password_reset.request.max_attempt_window* is set to 1440 or greater.

More information

Attribute	Description
Property name	*password_reset.request.max_attempt_window*
Configuration type	System Properties (/sys_properties_list.do)
Category	Authentication
Purpose	Denotes the lockout period in minutes after the maximum number of unsuccessful password reset attempts has been met.
Recommended value	1440
Default value	1440
Configuration type	Positive integer values
Security risk	(High) If the property is not set to the recommended value of 1440 or less, then it could be possible to perform account brute force as the account will not be locked after a maximum number of wrong authentication attempts.
Security risk rating	7.5
References	Configure Password Reset properties

To learn more about adding or creating a system property, see Add a system property.

Disable creating users from incoming emails [Updated in Securty Center 1.3]

Use the *glide.user.trusted_domain* property to specify the comma-separated list of trusted domains used in the creation of users from incoming emails.

An administrator can set an email property to automatically create users from incoming emails. If set this property to the insecure value, the instance will automatically create users from incoming email. Each user created will have the same hard coded default password which makes bypassing authentication through brute force easier.

More information

Attribute	Description
Property name	*glide.pop3readerjob.create_caller*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Authentication
Recommended value	false
Default value	false
Security risk rating	5.4
Functional impact	Once this property is configured, the instance only accepts emails from trusted domains. If you do not include the domain in the trusted list, there is an impact to guest users because accounts are created automatically.
Security risk	(Moderate) If the property is not enabled, an attacker might use an email spoofing/spamming campaign to send multiple emails resulting in the creation of more unnecessary guest users.
References	Inbound mail configuration

To learn more about adding or creating a system property, see Add a system property.

Disable password-less authentication

Use the *glide.login.no_blank_password* property to prevent users from logging into the NOW platform with blank passwords, or by leaving the **Password** field empty.

Even if the admin purposefully assigns an empty value or blank password in user records, a user can't log in without providing a value in the **Password** field.

More information

Attribute	Description
Property name	*glide.login.no_blank_password*
Configuration type	System Properties (/sys_properties_list.do)
Configure in Instance Security Center	Yes
Purpose	To ensure strong authentication as sometimes the username are easy to guess within an organization.
Recommended value	true
Functional impact	Operations should not use blank passwords because it is viewed as a critical security risk. However, if there is a valid case for such usage, there is a possibility of an outage. Users with blank passwords wouldn't be able to log in to the instance.
Security risk	(High) An attacker is able to log in to the instance with the default usernames, or by specific individual/group (usually firstname.lastname) without any password. Doing so is viewed as a critical security risk, because it

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	would enable a public user to violate the confidentiality and integrity of the instance data.

Disable resource owner password credentials (ROPC) in OAuth 2 token grants [New in Security Center 7.0]

Prevent Resource Owner Password Credentials (ROPC) from granting OAuth 2 tokens.

By default, Resource Owner Password Credentials (ROPC) are allowed to grant OAuth 2 tokens on your instances when a client application directly requests an access token using a user name and password. When the *glide.oauth.inbound.ropc.grant_type.disabled* is set to **true**, ROPC is inactive and can't be used to grant OAuth 2 tokens.

Ensure that the *glide.oauth.inbound.ropc.grant_type.disabled* system property is set to **true**. If the property doesn't exist on the System Properties [sys_properties] table, the default value is **false**. If this property exists on that table, it defaults to **false**.

More information

Attribute	Description
Configuration name	*glide.oauth.inbound.ropc.grant_type.disabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Fallback value	false
Category	Authentication
Security risk	• Severity score: 3.3 • CVSS score: Low • When the property is set to **false**, using ROPC to grant OAuth 2 tokens is allowed. ROPC is considered less secure that other authentication flows because the user's credentials are exposed to the application. This can lead to vulnerabilities in situations where the client is compromised and suffers from weaknesses similar to those of basic auth. OAuth 2.1 has deprecated ROPC.
Functional impact	When the property is set to **true**, ROPC is inactive and cannot be used to grant OAuth 2 tokens. This prevents any applications that are accessing the platform by granting OAuth 2 token using ROPC.
Dependencies and prerequisites	The OAuth 2.0 (com.snc.platform.security.oauth) plugin must be active.

To learn more about adding or creating a system property, see Add a system property.

Do not apply password policy at login [Updated in Security Center 1.5 and removed in 2.0]

Manage how password complexity is handled in your instance.

By setting the property *glide.apply.password_policy.on_login* to false there will be no password complexity enforcement at login time. Setting the property to true will enforce password complexity and lead to organization policy compliance issues.

As per ASVS 4.03 v2.1.9 recommendations:

"Verify that there are no password composition rules limiting the type of characters permitted. There should be no requirement for upper or lower case or numbers or special characters. (C6)"

Instead of password complexity enforcement, ASVS recommendations are to enforce a minimum length of 12 characters for password length.

Refer to OWASP ASVS v4.0 Authentication.

More information

Attribute	Description
Configuration name	*glide.apply.password_policy.on_login*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Category	Authentication
Security risk	• Severity score: 4.4 • CVSS score: Medium • Security risk details: Setting this property to **true** could enforce password complexity and lead to organization compliance issues.
Dependencies and prerequisites	None

Enable account recovery [Updated in Security Center 1.3 and 1.5]

The *glide.sso.acr.enabled* property controls the account recovery feature.

Set *glide.sso.acr.enabled* to the recommended value of **true** to allow account recovery by userid possible. Set the value to **false** to disallow account recovery by userid.

More information

Attribute	Description
Property name	*glide.sso.acr.enabled*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Authentication
Purpose	Controls the account recovery by userid feature.
Recommended value	True (default)
Configuration type	Boolean
Security risk	Critical (Without this property enabled, users will not be allowed to recover their account by userid.
Security risk rating	9.1
References	See Account recovery (ACR) for additional information.

Enable CAPTCHA for customer registration

Reduce the risk of requests by malicious bots by enabling CAPTCHA for customer registration.

Use the **sn_customerservice.captchaEnabled** system property to determine whether CAPTCHA validation is enabled for customer registration on the Customer Service Management Portal. Use CAPTCHA validation to help prevent potentially malicious bots from automatically submitting requests against an application.

Set the system property **sn_customerservice.captchaEnabled** to **true** to enable CAPTCHA validation. If the property isn't on the System Properties [sys_properties] table, the default value is **true**.

More information

Attribute	Description
Technical configuration name	sn_customerservice.captchaEnabled
Plugin applicability	Customer Service Management
Security risk	CAPTCHA validation helps prevent potentially malicious bots from automatically submitting requests against an application.
Common Vulnerability Scoring System (CVSS) score	3.7
Common Vulnerability Scoring System (CVSS) rating	Low
Functional impact	Registering users may have a negative experience from having to pass the CAPTCHA validation.
Dependencies and prerequisites	None
Data type	Boolean
Base system value	**true**
Fallback value	**true**
Recommended value	**true**

To learn more about adding or creating a system property, see Add a system property.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Enable a deny-list password validation check

Manage the deny-list passwords in the Excluded Password table.

Use the *glide.enable.blacklist_password* property to monitor deny-list passwords. When the property is set to **True**, the user's password is checked against a list of the deny-list passwords to prevent them from using a password from a set of breached passwords. The administrator can maintain the list by inserting passwords into the Excluded Password table.

More information

Attribute	Description
Configuration name	*glide.enable.blacklist_password*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Authentication
Dependencies and prerequisites	None
References	Exclude passwords through password policies on your instance

Enable Captcha for External User Registration [Updated in Security Center 1.3 and 1.5]

The *sn_ext_usr_reg.captchaEnabled* controls if CAPTCHA will be validated for external user registration.

Set *sn_ext_usr_reg.captchaEnabled* to the recommended value of **true** to help prevent automatic account creation attacks with requiring CAPTCHA for external user registration. Set the value to **false** to not require CAPTCHA for external user registration.

More information

Attribute	Description
Property name	*sn_ext_usr_reg.captchaEnabled*
Configuration type	System Properties (/sys_properties_list.do)
Category	Authentication
Purpose	This property is used to enable or disable CAPTCHA validation while doing external user registration on portals like CSP, Community. This is also used in store apps like VAM and CSM Guest Walkup to enable/disable captcha.
Recommended value	True
Configuration type	Boolean

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	(Low) The property controls CAPTCHA enablement in external user registration. Unideal value may result in security vulnerability.
Security risk rating	3.7

To learn more about adding or creating a system property, see Add a system property.

Enable CAPTCHA in password reset

Use the *password_reset.captcha.ignore* property to enable or disable requiring a CAPTCHA challenge when a user resets their password.

Set *password_reset.captcha.ignore* to the recommended value of **false** to require a CAPTCHA challenge for a user to reset their password. Set the value to **true** to ignore the CAPTCHA option for a password reset.

CAPTCHAs help prevent automation attacks by prompting the user for a challenge-response that is not easily answered by automated systems. If CAPTCHA is disabled, an attacker may be more successful during automated attacks against the password reset feature.

Note:
This property is used for password reset automation only.

More information

Attribute	Description
Property name	*password_reset.captcha.ignore*
Configuration type	System Properties (/sys_properties_list.do)
Category	Authentication
Purpose	This property is used to enable or disable CAPTCHA validation during password reset.
Recommended value	false
Configuration type	Boolean
Security risk	(Moderate) Unideal value may result in security vulnerability.
Security risk rating	5.5

To learn more about adding or creating a system property, see Add a system property.

Enable email OTP for multi-factor authentication

Manage how two-factor authentication is applied on your instance.

Use the *glide.authenticate.multifactor.email.otp.enabled* property to control whether a token for two-factor authentication is sent using email. Email is considered a weak MFA factor which an attacker is more likely to gain access into for bypassing MFA. By setting this property to **false**, the risk of an attacker bypassing MFA when they compromised a user's password is reduced.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.authenticate.multifactor.email.otp.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	true
Category	Authentication
Security risk	• Severity score: 3.1 • CVSS score: Low • Security risk details: Setting this property to **false** reduces the risk of a bad actor bypassing two-factor authentication.
Dependencies and prerequisites	None
References	Email as an MFA factor

Enable password reset policy checks [Updated in Security Center 2.0]

Use the **glide.enable.password_policy** property to enable password policy checks whenever a user changes their password using the user interface.

To define which password policy to use once this property is enabled, see Enable password policies on your instance. Ensure the Glide Property *glide.enable.password_policy* exists and is set to the value true. If the property does not appear in the sys_properties table, add a new record.

Note:
The **glide.enable.password_policy** does not apply when an administrator changes a password or adds a user through script.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.enable.password_policy*
Configuration type	System Properties (/sys_properties_list.do)
Category	Authentication
Purpose	To apply password policy at time of password change.
Recommended value	true (for higher strength passwords)
Security risk rating	7.4

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	Setting the property to true turns on password policy checks when a user resets their password.
Security risk	(Moderate) Without a password policy, a user can create a weak password which increases the likelihood of an adversary gaining access to the instance.

Steps to configure

If you configure this setting in the Hardening Compliance Configuration page in the Instance Security Center:

1. Under **Medium**, Select **Session Management**.
2. In the **Enable Password Reset Policy Check** setting, select **Medium** for medium strength passwords, or **Strong** for more robust, higher strength passwords. Selecting one of these options sets the **glide.enable.password_policy** property to true and starts a workflow that automatically updates your password policy.

Additionally, you can set the *glide.apply.password_policy.on_login* system property to enable password policy checks at the time of log in.

Enable policy based session access for mobile [New in Security Center 1.5]

Use the The Zero Trust- Policy Based Session Access plugin to control if users authenticating through a mobile app will have their roles reduced.

The Zero Trust- Policy Based Session Access plugin enables security admins to reduce user access in a session based on parameters such as IP address, location, identify provider attributes, and user attributes with adaptive authentication policies. When this plugin is enabled or set to true, users authenticating through a mobile device will have their roles restricted according to the plugin's policies. Instance admins may wish to restrict high privileged access when users authenticate through a mobile device as it could indicate an unsafe environment for sensitive operations.

More information

Attribute	Description
Configuration name	*glide.authenticate.session_access.mobile.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Access control
Security risk	• Severity score: 4.7 • CVSS score: Medium • Security risk details: If this hardening setting is set to true, then policy based session access is enforced on the instance for mobile logins, and users that are not coming from a trusted environment, or are not using

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	trusted devices will have their roles with reduced privileges. True is the secure setting. If this setting is configured to false, then policy based session access is disabled, and users will continue to have full roles including the high privileged roles like admin all the time.
Dependencies and prerequisites	None
Functional impact	If admin has configured the session access policy on the instance, then users will have their roles reduced after mobile login if they are not coming from a trusted environment or using a trusted device.
References	Adaptive authentication

Enable relay state in SAML requests to prevent replay attacks

Reduce the risk of replay attacks by enabling relay state in SAML requests to help prevent replay attacks.

Protect against SAML replay attacks using the **glide.authenticate.sso.saml2.enable_relay_state_with_id** system property. When this property is set to **true**, the relay state parameter contains the sys_id of a record in the MultiSSO Request Parameters [multisso_request_parameter] table, which the relay state URL redirects to.

Set the system property **glide.authenticate.sso.saml2.enable_relay_state_with_id** to **true**. This helps prevent attackers who have gained access to a SAML request from accessing your instance by resubmitting a valid request.

More information

Attribute	Description
Technical configuration name	glide.authenticate.sso.saml2.enable_relay_state_with_id
Plugin applicability	Multi-Provider SSO plugin (com.snc.integration.sso.multi.installer)
Security risk	The relay state enabled by this system property helps protect your instance against replay attacks. Enabling the property helps prevent attackers who have gained access to a SAML request from accessing your instance by resubmitting a valid request.
Common Vulnerability Scoring System (CVSS) score	3.8
Common Vulnerability Scoring System (CVSS) rating	Low
Functional impact	When this property is set to true, the relay state in a SAML request contains the sys_id of a record in the MultiSSO Request Parameters [multisso_request_parameter] table, which contains relay state URL to redirect to.

Attribute	Description
Dependencies and prerequisites	None
Data type	Boolean
Base system value	true
Fallback value	false
Recommended value	true

To learn more about adding or creating a system property, see Add a system property.

Enable SMS code notification for enrollment and verification [Updated in Security Center 1.3]

The *password_reset.sms.use_notify* property controls the usage of SMS code notifications for password reset.

If the *password_reset.sms.use_notify* property is set to the recommended value of **true**, the user is notified to do a password reset using SMS verification and new device enrollment which is more secure than email.

More information

Attribute	Description
Configuration name	*password_reset.sms.use_notify*
Configuration type	System Properties (/sys_properties_list.do)
Data type	booelan
Recommended value	true
Default value	true
Category	Authentication
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: Setting this property to**false** makes email the default method for password recovery which is less secure than SMS.
Dependencies and prerequisites	None

Enable SSL in LDAP authentication [Updated in Security Center 1.5 and 2.0]

Manage the encryption of LDAP authentication requests on your instance.

Use the *glide.ldap.use.ssl* property to enable or disable TLS encryption for LDAP authentication requests sent over the network. If this property is not set to the recommended value of **true**, LDAP authentication is susceptible to a man-in-the-middle attack.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.ldap.use.ssl*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Authentication
Security risk	• Severity score: 8.1 • CVSS score: High • Security risk details: Setting this property to **false**, makes LDAP authentication vulnerable to a man-in-the-middle attack.
Dependencies and prerequisites	None
References	Lightweight Directory Access Protocol integration

Enforce current password policy compliance requirements on login

Reduce the risk of brute force account login by enforcing current password policy compliance requirements on login.

Help prevent interactive users from logging in to the instance with passwords that don't meet current administrator requirements using the **glide.apply.password_policy.on_login** system property.

Set the **glide.apply.password_policy.on_login** system property to **true** to enforce current password policy compliance requirements. If this property doesn't exist on the System Properties [sys_properties] table, the default value is **false**.

More information

Attribute	Description
Technical configuration name	glide.apply.password_policy.on_login
Plugin applicability	None
Security risk	Interactive users may continue to log in to the instance with passwords that don't meet current administrator requirements. This may mean that the users have weak passwords that don't meet up-to-date security requirements, potentially leading to an increased risk of brute-force account logins by a malicious user.
Common Vulnerability Scoring System (CVSS) score	4.4

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Common Vulnerability Scoring System (CVSS) rating	Medium
Functional impact	If the existing passwords aren't in compliance with your current password policy, enabling this property forces users to change the passwords during their next login. This property is automatically set to **false**. Setting the value to **true** enforces a password policy during login. **Note:** Enabling this property might force a significant number of users who aren't in compliance with the new password policy to change their passwords.
Dependencies and prerequisites	None
Data type	Boolean
Base system value	false
Fallback value	false
Recommended value	true

To learn more about adding or creating a system property, see Add a system property.

Enforce device encryption and passcode requirements [New in Security Center 1.3]

The *glide.sg.device_encryption_enabled* property enforces the Federal Information Processing Standard (FIPS 140-2) Encryption. Mobile device encryption and passcode ensure that an unauthorized user cannot access the content of a device even if the device is physically obtained.

When *glide.sg.device_encryption_enabled* is set to true, the ServiceNow mobile app will check that device encryption and device passcode are enabled.

More information

Attribute	Description
Configuration name	*glide.sg.device_encryption_enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Authentication

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 4.2 • CVSS score: Medium • Security risk details: If encryption or passcode is not enabled, then the user will not be allowed to log into the instance on mobile
Dependencies and prerequisites	None

Functional impact	When this property is set to true, the mobile app will verify if device encryption is enabled. If encryption is not enabled, users will not be allowed to log into the current instance on mobile.
	
	Users are logged out and see the following warning message, suggesting that they set a device pin or encrypt the device and to try to login again.
	
	`You were logged out`
	`You need a passcode in order to use this instance on this device. Go to your device's settings to set one up`

Limit Invalid Password Reset Attempts [Updated in Security Center 1.3 and updated in 2.0]

The *password_reset.request.max_attempt* is used to control the maximum number of unsuccessful attempts that a user can reset or change their password before being locked out for a specified period of time.

More information

Attribute	Description
Property name	*password_reset.request.max_attempt*
Configuration type	System Properties (/sys_properties_list.do)
Category	Authentication
Purpose	Denotes the maximum number of unsuccessful password reset attempts that can be taken before the user is locked out of password reset process. The lockout period is determined by the value in *password_reset.request.max_attempt_window*.
Recommended value	Set to a positive integer value less than three. The default value is **3**. When you determine the limit for the upper range of the property, consider the task that the user is performing.
Configuration type	Positive integer values
Security risk	(High) If the property is not set to the recommended value of "**3**" or other reasonable small value, then it

Managing unlock timeout after failed logins [Updated in Security Center 1.3]

Two script actions are available that enable a site administrator to manage the number of times a user can provide an incorrect password before being locked out from the ServiceNow AI Platform. You can enable either of these script actions to manage failed login attempts.

More information

Attribute	Description
Property/Plugin Name	N/A
Configuration type	System Policy > Script Actions
Category	Authentication
Purpose	To enforce strict policy for failed login attempts to avoid brute forcing of credentials.
Recommended value	Active
Security risk rating	7.3
Functional impact	This remediation would enable administrator of the instance to monitor and report any malicious user access. No functionality impact, only User experience change.
Security risk	(Moderate) Apply a defined logging and auditing strategy so that you can identify and act on suspicious activity in a timely manner.

Steps to configure

1. Navigate to **System Policy** > **Script Actions.**
2. Search for the name *`*SNC User`*.
3. To enable management of failed login attempts, change the Active state of either the *`SNC User Lockout Check with Auto Unlock`* or *`SNC User Lockout Check`* scripts actions from **false** to **true**.
4. To reset the failed login counter after a successful login, you can activate the *`SNC User Clear`* script action.

Maximize failed login unlock timeout duration [Updated in Security Center 1.3]

A script action is available that enables site administrators to manage the number of times a user can provide an incorrect password before being locked out from the ServiceNow AI Platform. You can enable this script action to manage failed login attempts.

Help secure your instance against brute force attacks by defining a time period during which a user cannot attempt to log in after being locked out. The **glide.user.unlock_timeout_in_mins**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

system property unlocks the user account after the time period that is specified in it's value. If no value is specified, your instance unlocks the user account after the default period of 15 minutes.

Set the **glide.user.unlock_timeout_in_mins** system property value to a minimum of **15**. If **glide.user.unlock_timeout_in_mins** does not exist, the default lockout time is set to 15 minutes.

Ensure that the **SNC User Lockout Check with Auto Unlock** script action (found on the Script Action [sysevent_script_action] table) is present and active. The **SNC User Lockout Check with Auto Unlock** script action is installed with the High Security Settings (com.glide.high_security) plugin.

More information

Attribute	Description
Configuration name	• glide.user.unlock_timeout_in_mins (System Property) • sysevent_script_action (Script Action)
Configuration type	System Policy > Script Actions
Category	Authentication
Purpose	To enforce strict policy for failed login attempts to avoid brute forcing of credentials.
Recommended value	• **15** for the **glide.user.unlock_timeout_in_mins** system property • **Active** for the **SNC User Lockout Check with Auto Unlock** script action.
Functional impact	This remediation would enable administrator of the instance to monitor and report any malicious user access. No functionality impact, only User experience change.
Security risk	• Severity Score: 6.8 • Security Risk Details: If the property is not configured to a secure value and the lockout duration is not enabled, then it may be easier to brute force account logins in a faster time frame. This may allow a malicious user to eventually obtain unauthorized access to the instance. Impact on the instance will be limited to the privileged of the affected user login brute-forced.

Steps to configure

1. Navigate to **System Policy** > **Script Actions.**
2. Search for the name *`*SNC User`*.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. To enable management of failed login attempts, change the Active state of either the *SNC User Lockout Check with Auto Unlock* or *SNC User Lockout Check* scripts actions from **false** to **true**.
4. To reset the failed login counter after a successful login, you can activate the *SNC User Clear* script action.

Maximize reset password request retry window duration [Updated in Security Center 1.3]

The *password_reset.request.retry_window* property controls the number of minutes before the count for password reset attempts refreshes.

More information

Attribute	Description
Property name	*password_reset.request.retry_window*
Configuration type	System Properties (/sys_properties_list.do)
Category	Authentication
Purpose	Denotes the length of time in minutes before the count for password attempts refreshes from the last request before the retry count is reset to zero.
Recommended value	Set to a positive integer value of **1440** or more. The default value is **1440** minutes.
Configuration type	Positive integer values.
Security risk	(High) If the property is not set to the recommended value of 1440 or more, then it could be possible to perform account brute force against password reset process.
Security risk rating	7.5
References	Configure Password Reset properties

To learn more about adding or creating a system property, see Add a system property.

Maximize reset password request unlock window duration [Updated in Security Center 1.3]

The *password_reset.request.unlock_window* property controls the number of minutes a user must wait to start a reset request after the last successful unlock account action.

This property controls the number of minutes a user must wait to start a reset request after the last successful unlock account. If *password_reset.request.unlock_window* is not set to the recommended value of 1440 or more, it increases the opportunity for a malicious actor from brute forcing the user's password using automated tools.

More information

Attribute	Description
Property name	*password_reset.request.unlock_window*

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Configuration type	System Properties (/sys_properties_list.do)
Category	Authentication
Purpose	It denotes the time period in minutes that a user must wait after successfully resetting the password to reset the password again.
Recommended value	1440
Default value	1440
Configuration type	Positive integer values
Security risk	(High) If the property is not set to the recommended value of 1440 or greater, then it increases the opportunity of a malicious actor to brute force password access using automatic tools.
Security risk rating	5.9
References	Configure Password Reset properties

To learn more about adding or creating a system property, see Add a system property.

Maximize reset password SMS complexity [Updated in Security Center 1.3]

The *password_reset.sms.default_complexity* property controls the minimum required SMS code verification size required during password reset.

More information

Attribute	Description
Property name	*password_reset.sms.default_complexity*
Configuration type	System Properties (/sys_properties_list.do)
Category	Authentication
Purpose	Denotes the SMS code verification size required during password reset.
Recommended value	6
Default value	4
Configuration type	Integer value greater than zero
Security risk	(Low) If the property is not set to the recommended value, then a weak SMS validation token is used. This increases the possibility of token guessing which could lead to account takeover.
Security risk rating	3.8

To learn more about adding or creating a system property, see Add a system property.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Maximize reset password SMS pause window duration [Updated in Security Center 1.3]

Manage the time duration in minutes that a user must wait before they can request a new password reset code.

If this property is not set to the recommended value of **2** minutes or more, then a malicious user could initiate many passwords reset codes in a brief window of time. This increases the chance of a bad actor predicting the SMS reset code.

More information

Attribute	Description
Configuration name	*password_reset.sms.pause_window*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	2
Default value	2
Category	Authentication
Security risk	• Severity score: 4.8 • CVSS score: Medium • Security risk details: Ensure that *password_reset.sms.pause_window* is set to a value of 2 or more.
Dependencies and prerequisites	None

Maximize reset password verification delay duration [Updated in Security Center 1.3]

Configure the delay, in milliseconds, that a user must wait before submitting a new password reset request.

A bad actor could attempt to brute force login credentials by using automation tools like bots which the **reset password verification delay** property helps defend against. The property value represents the delay, in milliseconds, that a user must wait before they can place a request to reset the password. If this property is not set to the recommended value of **1000** or more, the login is more vulnerable to brute force attacks.

More information

Attribute	Description
Configuration name	*password_reset.verification.delay*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	1000

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Default value	1000
Category	Authentication
Security risk	• Severity score: 5.9 • CVSS score: Medium • Security risk details: Setting the property value to less than 1000 makes your login more vulnerable to brute force attacks.
Dependencies and prerequisites	None
References	Configure password for a user

Minimize external user registration link expiration duration [Updated in Security Center 1.3 and 1.5]

Manage the number of days that a registration link can be accessed.

Use the *sn_ext_usr_reg.Reg_link_expiration_days* property to manage who can access a registration link. If the link is set to the recommended value of **3**, a registration link could be used by someone other than the intended user if the link is discovered at a later date.

More information

Attribute	Description
Configuration name	*sn_ext_usr_reg.Reg_link_expiration_days*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Integer
Recommended value	3
Default value	3
Category	Authentication
Security risk	• Severity score: Medium • CVSS score: 6.6 • Security risk details: Not setting this property to the integer 3 could lead to the registration link being used by an unintended user.
Dependencies and prerequisites	None

Minimize reset password max SMS per day [Updated in Security Center 1.3]

Manage the maximum number of SMS codes sent for verification per day by user.

The *password_reset.sms.max_per_day* property represents the maximum number of SMS codes that can be sent for verification daily by a user.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*password_reset.sms.max_per_day*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	10
Default value	10
Category	Authentication
Security risk	• Severity score: 5.9 • CVSS score: Medium • Security risk details: If this property is not set to the recommended value of **10** or less, it's easier to brute force the SMS code.
Dependencies and prerequisites	None

Minimize failed login attempts for high assurance sessions

Decrease the likelihood of a brute force attack by minimizing failed login attempts for high assurance sessions.

Use the **glide.zta.high_assurance.session.max.login.failed_attempts** system property to limit the number of failed authentication attempts allowed before users are logged out when re-authenticating through Continuous Authentication.

Set the value of this system property to a low value (such as 5) to decrease the likelihood of a brute force attack.

More information

Attribute	Description
Technical configuration name	glide.zta.high_assurance.session.max.login.failed_attempts
Plugin applicability	Zero Trust - Continuous Authentication (com.snc.zero_trust_continuous_authentication)
Security risk	A high number of allowed authentication attempts increases the likelihood of a brute force attack.
Common Vulnerability Scoring System (CVSS) score	3.3
Common Vulnerability Scoring System (CVSS) rating	Low
Functional impact	Users are logged out of their sessions after the number of authentication failures selected in the property.
Dependencies and prerequisites	None

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	Integer
Base system value	5
Fallback value	5
Recommended value	5

To learn more about adding or creating a system property, see Add a system property.

Minimize reset password request expiration duration [Updated in Security Center 1.3]

The *password_reset.request.expiry* denotes the time period in minutes during which a user must perform the password reset process.

Note:
The setting for the *password_reset.request.expiry* property takes precedence over the setting for *glide.pwd_reset.onetime.token.validity* property that has a 12 hour default.

More information

Attribute	Description
Property name	*password_reset.request.expiry*
Configuration type	System Properties (/sys_properties_list.do)
Category	Authentication
Purpose	Denotes the time period in minutes during which a user must perform the password reset process.
Recommended value	Set to an integer of **10** or less. The default value is 10.
Configuration type	Integer values
Security risk	(Moderate) If the property is not set to the recommended value of 10 or less, then it increases the opportunity for someone else to guess and use the request and attempt to reset the password.
Security risk rating	4.2
References	Configure Password Reset properties

To learn more about adding or creating a system property, see Add a system property.

Minimize reset password request success window duration [Updated in Securty Center 1.3]

The *password_reset.request.success_window* property controls the number of minutes a user must wait to reset or change their password again after successfully resetting the password. The user will be blocked to reset the password again for the specified duration.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Property name	*password_reset.request.success_window*
Configuration type	System Properties (/sys_properties_list.do)
Category	Authentication
Purpose	It denotes the time period in minutes that a user must wait after successfully resetting the password to reset the password again.
Recommended value	1440
Default value	1440
Configuration type	Positive integer values
Security risk	(High) If the property is not set to the recommended value of 1440 or less,then it increases the opportunity of someone else abusing the password reset functionality to gain unauthorized access to a user account.
Security risk rating	4.9
References	Configure Password Reset properties

To learn more about adding or creating a system property, see Add a system property.

Minimize reset password SMS expiracy duration [Updated in Security Center 1.3]

Control the number of minutes remaining before the SMS code expires.

The *password_reset.sms.expiry* property represents the number of minutes remaining before the SMS code expires.

More information

Attribute	Description
Configuration name	*password_reset.sms.expiry*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	5
Default value	5
Category	Authentication
Security risk	• Severity score: 5.6 • CVSS score: Medium

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	• Security risk details: If this property is not set to the recommended value of **5** or less, the chances of a bad actor guessing and using the SMS code to reset the password increases.
Dependencies and prerequisites	None

Minimize one-time out of band verifier lifetime duration [Updated in Security Center 1.3]

Manage the time duration for out-of-band verifiers.

An out-of-band verifier is an alternative delivery method for one-time code situations. For example, resetting a multi-factor token. If this method is enabled by administrators in the Multi-factor authentication plugin, a one-time code is delivered by email. Set one-time out-of-band verifiers to expire after 10 minutes to limit the validity window. A larger time window allows more time for the code to be compromised through illicit means such as phishing, social engineering, or shoulder-surfing attacks.

More information

Attribute	Description
Configuration name	*glide.multifactor.onetime.code.validity*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	10
Default value	10
Category	Authentication
Security risk	• Severity score: 3.9 • CVSS score: Low • Security risk details: Set one-time out-of-band verifiers to expire after 10 minutes. Anything longer increases the risk of the code being compromised by a bad actor.
Dependencies and prerequisites	Multi-factor authentication
References	Multi-factor Authentication criteria

Minimize SAML notBefore or notOnOrAfter constraint duration [Updated in Security Center 1.3 and 1.5]

Configure this property to add a grace period in which SAML requests and responses are considered valid.

This property adds a grace period during which SAML requests and responses are considered valid. The property value represents the number of seconds to add to the *NotBefore* and *NotOnOrAfter* constraints to account for time differences between the Identity Provider

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

(IdP) clock, and Service Provider (SP) clock. These constraints defend against replay attacks by denying requests that aren't made within the specified time frame. If the IdP and SP clocks are significantly different, then the network latency may result in the SAML request being unauthorized.

More information

Attribute	Description
Configuration name	*glide.authenticate.sso.saml2.clockskew*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	less than 60
Default value	180
Category	Authentication
Security risk	• Severity score: 7.5 • CVSS score: High • Security risk details: Setting the property to a value of 60 or higher may prevent the constraints from defending against replay attacks.
Dependencies and prerequisites	None

Notify users during password reset/change process [Removed in Security Center 1.5]

Use this property to enable end users to reset or change passwords using a self-service process.

This property enables an end user to reset or change a password using a self-service process. Alternatively, your organization could implement a process that requires a service desk agent to reset passwords for end users. If a password change and or reset process doesn't notify users on password update, a bad actor may be able to lock that user out of their account without their knowledge. This would provide the bad actor more time to perform malicious activities. Ensure password reset process notifies users upon password change or reset.

More information

Attribute	Description
Configuration name	*pwd_process.change, pwd_process.reset*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Authentication

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 8.1 • CVSS score: High • Security risk details: A bad actor may be able to lock a user out of their account without their knowledge if no notification is sent to them when a password change is reset.
Dependencies and prerequisites	None

Reduce allowed bypasses for multifactor setup

Decrease the window of time an account is at risk of compromise by reducing allowed bypasses for multifactor setup.

Reduce the number of times a user can skip the multifactor passcode setup requirement to decrease the window of time an account is at risk of compromise. Multifactor authentication (MFA) protects against password-related attacks or weak passwords by requiring an additional form of verification. Reducing the length of time a user can skip this setup reduces this vulnerability.

Set the **glide.authenticate.multifactor.setup.bypass.count** system property to **0** to prevent users from skipping multifactor passcode setup.

More information

Attribute	Description
Technical configuration name	glide.authenticate.multifactor.setup.bypass.count
Plugin applicability	None.
Security risk	Multifactor authentication protects against password-related attacks or weak passwords by requiring an additional form of verification. A high number of allowed multifactor setup bypasses increases the risk of account compromise as the account isn't protected by multifactor. A small number of allowed bypasses reduces this window of time.
Common Vulnerability Scoring System (CVSS) score	3.9
Common Vulnerability Scoring System (CVSS) rating	Low
Functional impact	Users aren't allowed to login to an instance without setting up MFA if they've surpassed the number of logins specified in the property.
Dependencies and prerequisites	None
Data type	Integer
Base system value	0
Fallback value	0

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Recommended value	0

To learn more about adding or creating a system property, see Add a system property.

Remove credentials from Welcome page

Modify the default content on the Welcome page to remove the default credentials.

Two **How to Login** records are installed as part of the demo data for the CMS plugin.

Note:
If you do not install the demo data for an instance, these records do not exist. In that case, the configuration is considered as Security Compliant as per the recommended security practices.

More information

Attribute	Description
Name	*How to login*
Configuration type	Table: sys_home
Category	Authentication
Purpose	To remove default credentials from Welcome page that were added with demo data.
Recommended value	False or null if no demo data was utilized.
Default value	None. This is a table configuration, not a Glide property. Therefore, there is no value for default value.
Configuration type	Boolean
Security risk	(Moderate) Demo data is provided for the CMS plugin, which includes two default passwords included on the welcome page. If this is not removed, an unauthorized attacker could gain access to the instance.
References	https://support.servicenow.com/kb_view.do?sysparm_article=KB0550107 Welcome pages

To learn more about adding or creating a system property, see Add a system property.

Require captcha for guest walk-up experience in customer service application [New in Security Center 1.3 and updated in 1.5]

The captcha for the Guest Walk-up experience prevents unauthenticated guest users to create bookings by requiring users to complete a captcha verification.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*sn_guest_walkup_cs.captcha.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Authentication
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: If captcha is not enabled, this could lead to automated creation of spam appointments to overwhelm the system or fill up all available booking spots creating a Denial of Service (DoS) attack.
Dependencies and prerequisites	None
Functional impact	This property enables or disables the captcha on the CSM Guest Walkup Check-in widgets. By default, it is set to true.

Require obfuscation of classic mobile app UI [Updated in Security Center 1.3]

Use the *glide.ui.m.blur_ui_when_backgrounded* property to obfuscate all fields from the snapshot as the image is saved during the backgrounding process.

On Android devices, the Android operating system takes a screenshot for usage in the recent task menu when the application is sent to background. Users can also take manual screenshots of the application, which are stored publicly on the device.

On iOS devices, the iOS operating system also allows applications to save an image file. This file represents the last screen seen by the user when the application is sent to the background. While the intent is to provide a better user experience, it also creates a security risk because the images are saved as PNG image files.

Note:
This setting or configuration is per instance basis so the user must connect to the instance with the property configured.

To obfuscate all fields from the snapshot in the ServiceNow Classic app, see Configure the blur app option to improve security.

Example

When you set this property to true, the background application is obfuscated for iOS devices, and blacked out for Android iOS devices.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Property/Plugin Name	*glide.ui.m.blur_ui_when_backgrounded*
Configuration type	System Properties (/sys_properties_list.do)
Category	Authentication
Purpose	To obfuscate all fields from the snapshot as the image is saved during the backgrounding process.
Recommended value	true
Security risk rating	2.4
Functional impact	If the *glide.ui.m.blur_ui_when_backgrounded* property is set to true, the native apps use the parameter defined on the server to blur the screen when the app enters the background. • It blurs the screenshots taken by iOS and Android when the app enters the background. **Note:** Enabling this setting can prevent users from taking screenshots of the classic mobile app, which may be desirable for support purposes. • The user experience may be adversely affected because they would not be able to see the content when the app is sent to background.
Security risk	(Medium) A compromised (jailbroken) device would enable an attacker to have full access to the file system, with access those files/snapshots with sensitive information embedded in them.

To learn more about adding or creating a system property, see Add a system property.

Require obfuscation of mobile app UI [Updated in Security Center 1.3]

Configure the *glide.sg.blur_ui_when_backgrounded* property so that the UI of the app is blurred when the app is running in the background.

If this property is not set to the recommended value of **true**, the mobile app's user interface is visible when viewed from the app switcher. The UI is still visible even when the app is running in background which provides a lower level of security and confidentiality to end users.

More information

Attribute	Description
Configuration name	*glide.sg.blur_ui_when_backgrounded*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	Boolean
Recommended value	true
Default value	false
Category	File and resources
Security risk	• Severity score: 2.4 • CVSS score: Low • Security risk details: Setting the value to **true** provides a higher level of confidentiality and privacy on the local device by blurring the UI when the app is running in the background.
Dependencies and prerequisites	None
References	Require obfuscation of classic mobile app UI [Updated in Security Center 1.3]

Set minimal password length [Updated in Security center 2.2]

Set minimal password length to avoid compliance issues and reduce the risk of a successful brute force attack

Enforce a minimum password length of at least 12 characters to avoid compliance issues and reduce the risk of a successful brute force attack.

For every utilized Password credential store in use on your instance, ensure that a Password Policy is being enforced by selecting the **Enable password policy** field on the associated record in on Password Reset Credential Store [pwd_cred_store] table.

Next, open the record on the Password Policy [password_policy] record table and set the **Minimum Password Length** field to at least **12**. You can find the associated Password Policy record in the **Password policy** field of the Password Reset Credential Store [pwd_cred_store] record.

For more information configuring a password policy, see Enable password policies on your instance.

More information

Attribute	Description
Technical configuration name	Records on the Password Reset Credential Store [pwd_cred_store] and Password Policy [password_policy] tables.
Plugin applicability	None
Security risk	Setting the **Minimum Password Length** Policy [password_policy] records to value of less than 12 could lead to compliance issues and increases the risk of an attacker successfully brute forcing passwords.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Common Vulnerability Scoring System (CVSS) score	5.9
Common Vulnerability Scoring System (CVSS) rating	Medium
Functional impact	The instance will not suffer any impact from a minimum password length of 12.
Dependencies and prerequisites	None
Data type	Integer
Base system value	8
Fallback value	8
Recommended value	12

Set OTP lifetime for password reset to 1 hour [Updated in Security Center 2.0]

Control the time duration of the link in the password reset email.

The *glide.pwd_reset.onetime.token.validity* system property makes the link in the password reset email expire after the number of hours specified in the property. The validity time of a password reset token should be kept as short as possible while not disrupting normal user experience

Set the property value to 1 (in hours).

More information

Attribute	Description
Configuration name	*glide.pwd_reset.onetime.token.validity*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	1
Default value	1
Fallback value	1
Category	Authentication
Security risk	• Severity score: 4.6 • CVSS score: Medium • Security risk details: A longer validity time for password reset token gives malicious actors a wider window to perform account takeover if the email with the reset token is leaked or compromised.
Dependencies and prerequisites	None

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Business Logic

This category looks at the logic and flow unique to each application with general secure principles. Specifically ensure that the intended sequence of business logic flow cannot by bypassed, that limits exist to detect and prevent automated attacks, and that protections against spoofing, tampering, information disclosure and elevation of privilege attacks exist.

The following are some security controls that an administrator can configure to restrict unauthorized access to sensitive entities within the ServiceNow AI Platform.

Limit max comments per user per day

Configure the *sn_kb_social_qa.max_comments_per_user_daily* property to restrict the number of QA comments per day.

If this property is not set to the recommended value of **500** or less, there is no restriction on the number of QA comments per day which could lead to resource exhaustion.

More information

Attribute	Description
Configuration name	*sn_kb_social_qa.max_comments_per_user_daily*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	500
Default value	500
Category	Business Logic
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: Not setting the recommended value of this property to 500 or less places no limit on QA comments per day which could lead to resource exhaustion.
Dependencies and prerequisites	None

Limit max subscriptions per user per day

Configure the *sn_kb_social_qa.max_subscriptions_per_user_daily* property to limit the max number subscriptions a user can subscribe to in a day.

If this property is not set to the recommended value of **500** or less, there is no restriction on the maximum number of Q&A questions that a user can subscribe to in a day. This no limitation could lead to resource exhaustion and impact the availability of your instance.

More information

Attribute	Description
Configuration name	*sn_kb_social_qa.max_subscriptions_per_user_daily*

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	500
Default value	500
Category	Business Logic
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: Set the property value to 500 or less to prevent resource exhaustion.
Dependencies and prerequisites	None

Minimize SMTP Recipient Quantity [Updated in Security Center 1.3]

The *glide.email.smtp.max_recipients* specifies the maximum number of recipients the instance can list in the **To:** line for a single email notification.

Set *glide.email.smtp.max_recipients* to the recommended value of **100 or less**. Notifications that would exceed this limit instead create duplicate email notifications addressed to a subset of the recipient list. Each email notification has the same maximum number of recipients.

More information

Attribute	Description
Property name	*glide.email.smtp.max_recipients*
Configuration type	System Properties (/sys_properties_list.do)
Category	Business Logic
Purpose	If this property is set to an insecure value above the default value of 100, then its possible a denial of service could happen on the instance.
Recommended value	100
Default value	100
Configuration type	Integer
Security risk	(Moderate) Notifications that would exceed this limit instead create duplicate email notifications addressed to a subset of the recipient list.
Security risk rating	4.9

To learn more about adding or creating a system property, see Add a system property.

Timeout Guest Sessions

Use a system property to control the inactive session timeout for unauthenticated users.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Use the *glide.guest.session_timeout* system property to set the inactive session timeout duration (in minutes) for unauthenticated users. Raise the value of this property to extend the time your instance persists sessions beyond the default of 30 minutes. Avoid large timeout values, which can increase the number of sessions persisted by the instance, and cause minor availability concerns.

More information

Attribute	Description
Configuration name	*glide.guest.session_timeout*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Integer (in minutes)
Recommended value	30
Default value	30
Fallback value	0
Category	Business Logic
Security risk	• Severity score:4.3 • CVSS score: Medium • Security risk details: Large timeout values can increase the number of concurrent sessions on your instance, causing minor availability concerns.
Dependencies and prerequisites	None

Validate remote host

Set the property to true to prevent bad actors from using internal port scanning in your network.

If the *glide.update_set.remote.check_host* property is not set to the recommended value of **true**, then the remote instance test feature will allow internal port scanning which is a method bad actors can use to discover vulnerabilities in a network. It is then possible to enumerate all open ports on a given host, and in some cases pull response data which could lead to information leakage or unauthorized data access.

⚠ Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*glide.update_set.remote.check_host*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Default value	true
Category	Business Logic
Security risk	• Severity score: 6.3 • CVSS score: Medium • Security risk details: Not setting property to the recommended value of **true** could enable bad actors to use internal port scanning to gain access to unauthorized data.
Dependencies and prerequisites	None
References	https://support.servicenow.com/kb?id=kb_article_view&sysparm_article=KB0755132 Define a remote instance

Communications

This control ensures proper encryption using strong algorithms and ciphers. This includes ensuring the recommended version of TLS is used for client connectivity, use of strong cipher suites, use of trusted and signed certificates, ensuring connections are encrypted between components and logging of connection failures.

Enforce certificate trust [Updated in Security Center 1.3, removed in 2.0, added in 7.0]

Use system properties to ensure that certificate expiration and trust are checked for certificates received from outbound HTTPS call endpoints when host verification is not performed.

When *com.glide.communications.trustmanager_trust_all* is set to **true**, then certificate expiration and trust are not checked for the certificate received from an outbound HTTPS call endpoint when host verification is not performed.

Verify that the *com.glide.communications.trustmanager_trust_all* system property is set to the recommended value of **false**. This ensures that your instance only trusts certificates that it can verify against the JVM certificate store. Self-signed and enterprise-signed certificates are not trusted. This property only applies when *com.glide.communications.httpclient.verify_hostname* is set to **false**.

Note:
The values for these properties are and cannot be altered once changed (they are non-revertible). For security purposes, do not change this property value. If you have further questions, contact Customer Service and Support.

More information

Attribute	Description
Property name	*com.glide.communications.trustmanager_trust_all*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Communications
Purpose	To enforce certificate validation for outgoing requests.
Recommended value	false
Security risk rating	5.7
Functional impact	This remediation enforces strict validation on certificate CA (certificate authority) field. If a trusted entity (CA) issued the certificate, the instance accepts it for further use.
Security risk	(Medium) For confidentiality and integrity reasons, application should validate the certificate's CA before using the certificate for any transactional operations.
References	Certificates Verify certificate chain and hostname [New in Security Center 1.3 and updated in 2.0]

Disable outbound SSLv2/SSLv3 connections [Updated in Security Center 1.3]

Use the *glide.outbound.sslv3.disabled* property to force the MID Server to use TLS when making outbound connections, such as REST and SOAP requests. Normally, outbound connections from an instance are forced to use TLS instead of SSL.

More information

Attribute	Description
Property name	*glide.outbound.sslv3.disabled*
Configuration type	System Properties (/sys_properties_list.do)
Category	Communications
Purpose	To enforce the use if TLS during all outbound connections from ServiceNow instance.
Recommended value	true
Default value	false **Important:** The value for the *glide.outbound.sslv3.disabled* property is a safe override and cannot be altered once changed.
Security risk rating	6.5
Functional impact	This remediation enforces the usage of TLS protocol version when communicating on HTTPS. If there are devices that customer/users of the instance are using that do not support TLS communication, there may be a potential outage.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	(Moderate) Legacy versions of SSL were proven to be insecure when utilized for HTTP secure shell implementation, due to client-side attacks, including BEAST and SSL heart-bleed.

To learn more about adding or creating a system property, see Add a system property.

Do not use demo certificates for active saml configurations [Updated in Security Center 1.5]

Control whether demo certificates are used in production SAML configurations.

The demo certificates provided by ServiceNow should not be used in production SAML configurations because they are common among all instances with a known passphrase. If one of the SAML properties using a certificate keystore is active (*require_signed_authnrequest*, *require_signed_logoutrequest*, or *encrypt_assertion*), then the demo data shouldn't be used. Since demo data is shared among all instances, there is no integrity guarantee of requests signed with shared certificates. Therefore, any message encrypted by the IDP could be decrypted by a bad actor if intercepted.

More information

Attribute	Description
Configuration name	*glide.authenticate.sso.saml2.keystore*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	sys_id of a custom keystore
Default value	empty string
Category	Communications
Security risk	• Severity score: 3.9 • CVSS score: Low
Dependencies and prerequisites	None

Disable deprecated TLS versions

Avoid loss or leakage of sensitive data by disabling deprecated TLS versions.

Confirm that your instance only negotiates for communication via Transport Layer Security (TLS) versions 1.2 when communicating with other servers to help prevent data transfer over weaker TLS 1 and TLS 1.1 protocol versions.

Set the **com.glide.communications.disable.deprecated.tls** to **true** to use only TLS versions 1.2 and up.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Technical configuration name	com.glide.communications.disable.deprecated.tls
Plugin applicability	None
Security risk	Using outdated and unsupported TLS versions could result in loss and leakage of sensitive data.
Common Vulnerability Scoring System (CVSS) score	4.4
Common Vulnerability Scoring System (CVSS) rating	Medium
Functional impact	When this property is set to **true**, older insecure servers that require a weaker TLS 1 or 1.1 protocol aren't able to communicate with your instance.
Dependencies and prerequisites	None
Data type	Boolean
Base system value	true
Fallback value	true
Recommended value	true

To learn more about adding or creating a system property, see Add a system property.

Enforce OCSP check on network error [New in Security Center 1.3 and updated in 2.0]

Learn how to configure the *com.glide.communications.httpclient.ocsp_allow_network_error* property to prevent bad actors from bypassing Online Certificate Status Protocol (OCSP) checks.

If *com.glide.communications.httpclient.ocsp_allow_network_error* is not set to the recommended value of false, and the Online Certificate Status Protocol (OCSP) check encounters a network error (for example, a timeout or problem fetching the revocation information), it will bypass the OCSP security check and consider it successful. This could allow an attacker with a revoked certificate to break the Public Key infrastructure (PKI) and digital certificate trust that is foundational to the web. The use of revoked certificates is often an indicator of malicious activity unless the servers are out of sync.

Ensure the property *com.glide.communications.httpclient.ocsp_allow_network_error* exists and is set to false. If the property does not appear in the sys_properties table, add a new record.

More information

Attribute	Description
Configuration name	*com.glide.communications.httpclient.ocsp_allow_net*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	Boolean
Recommended value	false
Default value	true
Category	Communications
Security risk	• Severity score: 5.9 • CVSS score: Medium • Security risk details: Not setting this property to false could enable a bad actor to bypass the OCSP security check.
Dependencies and prerequisites	None
Functional impact	This property determines whether a request against the Authority Information Access (AIA) Online Certificate Status Protocol (OCSP) uri results in a pass or fail outcome in the event of a connection or timeout error. When set to false, the revocation status of the presented server certificate can't be validated and will lead to a communication failure with that endpoint. If a network error occurs when the property is set to its default value of true, the certificate is treated as valid from a revocation standpoint.

Verify certificate chain and hostname [New in Security Center 1.3 and updated in 2.0]

Configure the *com.glide.communications.httpclient.verify_hostname* property to prevent man-in-the-middle-attacks by ensuring that the certification verification process is executed.

When the Glide Property *com.glide.communications.httpclient.verify_hostname* is not set to the secure value of true, the hostname and certificate chain presented by remote hosts during a TLS connection initiated from the ServiceNow instance are not validated. This could compromise the security of the TLS connection and allow person-in-the-middle attacks, where communications between two parties are intercepted. This may lead to sensitive data disclosure.

More information

Attribute	Description
Configuration name	*com.glide.communications.httpclient.verify_hostnam*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Communications

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: High • CVSS score: 7.4 • Security risk details: Not setting *com.glide.communications.httpclient.verify_hostn* to the recommended value of true could make your instance vulnerable to man-in-the-middle-attacks.
Dependencies and prerequisites	None
Functional impact	Verifies hostname and certificate chain presented by remote secure socket layer (SSL) hosts. Set this property to true to secure against Man-in-the-middle (MITM) attacks. **Note:** This property overrides the *com.glide.communications.trustmanager_trust_ali* property.

Verify certificate revocation [New in Security Center 1.3]

The *com.glide.communications.httpclient.verify_revoked_certificate* property checks certificate revocation during the Transport Layer Security (TLS) handshake to ensure that security checks are not bypassed.

If *com.glide.communications.httpclient.verify_revoked_certificate* is not set to the recommended value of **true**, then certificate revocation will not be checked during the TLS handshake. TLS encrypts data sent over the Internet to ensure that bad actors are unable to see sensitive information such as passwords or credit card numbers. Bypassing the TLS handshake is a security risk because an attacker with a revoked certificate can neglect to provide a valid certificate and break public key infrastructure (PKI) and digital certificate trust.

More information

Attribute	Description
Configuration name	*com.glide.communications.httpclient.verify_revoked*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Communications
Security risk	• Severity score: 6.5 • CVSS score: Medium • Security risk details: Not setting *com.glide.communications.httpclient.verify_revok*

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	to the recommended value of true will cause certificate revocation to not be checked during the TLS handshake.
Dependencies and prerequisites	None
Functional impact	This property should be set to true to ensure that a Transport Layer Security (TLS) session is started with an authentic endpoint. If this property is set to false, then the certificate is not checked, which could compromise the security of the instance.

Configuration

The Configuration category ensures applications have a secure build environment and hardened third party library components. Specifically, ensuring a build and deploy pipeline is repeatable and includes automated testing and prevents known security issues from being deployed. This includes keeping dependencies up to date and free from known vulnerabilities.

Auto set content type options [Removed in Security Center 1.3.3]

Configure the Auto set content type options property on your instance to prevent MIME confusion attacks.

Use this property to control the X-Content-Type-Options response HTTP header. The X-Content-Type-Options response HTTP header is used by the server to indicate that the MIME types advertised in the Content-Type headers should be followed. If this property is set to false, then it is possible for an attacker to conduct MIME confusion attacks; if set to true then this header will prevent the browser from interpreting files as anything but the content type in the HTTP headers.

Warning:
The value for this property is a no DB override. It can't be altered or overridden.

More information

Attribute	Description
Configuration name	*glide.security.header.auto_set_x_content_type_opti*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Configuration
Security risk	• Severity score: 7.3 • CVSS score: High • Security risk details: Setting this property to **false** could make it possible for an attacker to conduct MIME confusion attacks.

Attribute	Description
Dependencies and prerequisites	None
References	Add a system property

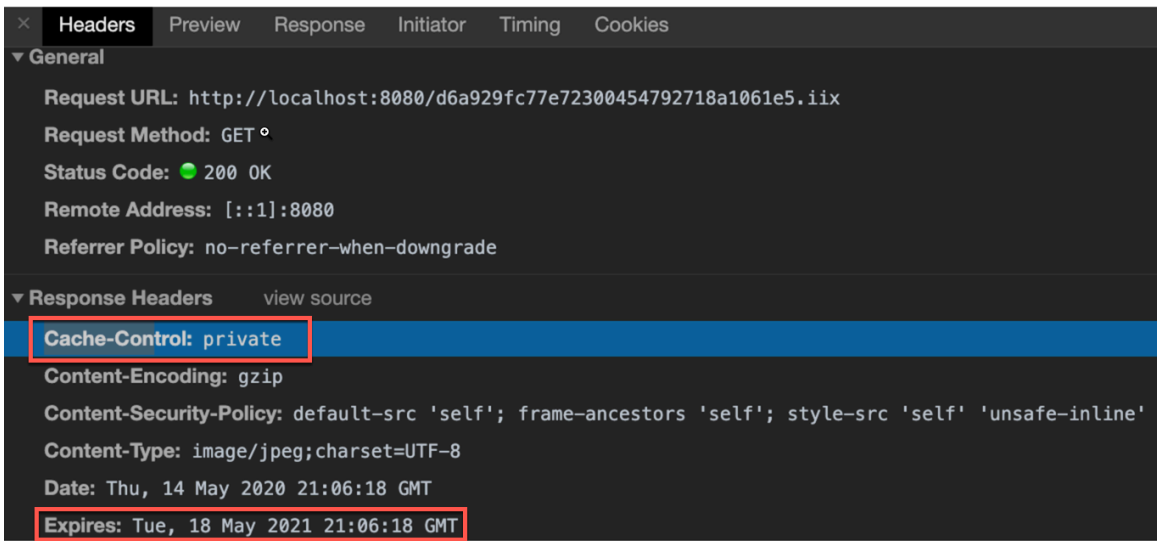
Cache-Control HTTP Header Value [Updated in Security Center 1.3 and removed in 1.5]

Use the *glide.http.cache_control* property to set the default cache-control value in the HTTP response headers that the ServiceNow AI Platform sends when requesting static content data for a page. Examples of static content include images, CSS, and JavaScript rendered from within, for a page.

The *glide.http.cache_control* property sets the default Cache-Control value in HTTP response headers to **private** or **public**. The default is **private**.

Value	Description
private	Static content can be cached at the browser (client) level, but not at the proxy server level.
public	Static content can be cached at the browser (client) level, and also at the proxy server level.

The Expires value in the HTTP response headers control when the static content expires, and has a default value of 369 days. To manually override the default value, use the *glide.http.expire.days* property.



Note:
You can use the *glide.http.cache* property designate whether to enable or disable setting of the Cache-Control and Expires values in HTTP response headers. Its default is **true**, which allows you to set the:

- Cache-Control value default using the *glide.http.cache_control* property.
- Expires value default using the *glide.http.expire.days* property.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Property name	*glide.http.cache_control*
Configuration type	System Properties (/sys_properties_list.do)
Category	Configuration
Purpose	To configure the Cache-Control HTTP response header value for static content.
Recommended value	private
Default value	private
Security risk rating	4.3
Functional impact	Sets the default Cache-Control value in an HTTP response header.
Security risk	(High) If you set this property to **public**, instances with CDN/proxies may cache static content and render without authentication. • **private** is a more appropriate setting for instances with CDN/proxy setup. • If an the instance does not have a CDN/proxy setup, either value should be fine.

To learn more about adding or creating a system property, see Add a system property.

Enable HTTP response headers configuration

Reduce the risk of cookie/session-related hijacking of web apps using a system property.

If *glide.http.headers_config.enabled* isn't set to **true**, then response header configurations defined in the HTTP Response Headers [sys_response_header] table aren't used. Security related HTTP response headers include Content Security Policy, which aids in XSS-related protections. For details on HTTP response headers, see HTTP Response Headers.

Verify that the property *glide.http.headers_config.enabled* is set to **true**.

More information

Attribute	Description
Configuration name	*glide.http.headers_config.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	true
Category	Session management

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 5.5 • CVSS score: Medium • Security Risk: The security risks of missing, incorrect, or weak HTTP response headers may allow for XSS, CSRF, and cookie/session related hijacking of web apps.
Dependencies and prerequisites	None

Disable legacy JQuery UI usage

Avoid the introduction of unpatched vulnerabilities in the library by disabling legacy JQuery UI usage.

Prevent the use of older prepatched JQuery UI versions, which introduce unpatched vulnerabilities in the library. Using old versions can potentially lead to security risks arising from attacks on vulnerabilities discovered in outdated JQuery UI library versions.

Confirm that the **glide.jquery_ui.legacy** system property is set to **false** to prevent older prepatched JQuery UI versions from being used. This system property is a failsafe in case organizations depend on the non-patched versions to run their custom implementations.

More information

Attribute	Description
Configuration name	*glide.jquery_ui.legacy*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String
Recommended value	false
Default value	false
Fallback value	true
Category	Configuration
Security risk	• Severity score: 3.9 • CVSS score: Low • Preventing older prepatched JQuery UI versions from being used can introduce unpatched vulnerabilities in the library.
Functional impact	This system property is a failsafe in case organizations depend on the non-patched versions to run their custom implementations.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Disable locked form elements debugging

Here's the description for *glide.security.explain.write.locks*.

Set *glide.security.explain.write.locks* to the recommended value of **false** to prevent the display of explanation of locked form elements. Set the value to **true** to display the explanation of locked form elements.

More information

Attribute	Description
Property name	*glide.security.explain.write.locks*
Configuration type	System Properties (/sys_properties_list.do)
Category	Configuration
Purpose	Limits display behavior of SecurityDebugger without dependence on other properties.
Recommended value	false
Default value	false
Configuration type	Boolean
Security risk	(Low) Will prevent the display of the explanation on locked form elements. This makes the application slightly more secure, as less information is being provided by the security debugger.
Security risk rating	3.5

To learn more about adding or creating a system property, see Add a system property.

Disable MultiSSO Debugging [Updated in Security Center 1.3 and 1.5]

The *glide.authenticate.multisso.debug* property controls debug logging for Multi-SSO.

More information

Attribute	Description
Property name	*glide.authenticate.multisso.debug*
Configuration type	System Properties (/sys_properties_list.do)
Category	Configuration
Purpose	Disables Multi-SSO debug.
Recommended value	false
Default value	false
Configuration type	Boolean
Security risk	(High) Set the property to the recommended value of "False", otherwise, MultiSSO debug is enabled which could lead to unintended sensitive information leak.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk rating	4.0
References	Multi-Provider SSO properties, tables, and scripts

To learn more about adding or creating a system property, see Add a system property.

Disallow target cloning [New in Security Center 1.3]

Configure the *glide.db.clone.allow_clone_target* property to prevent your instance from being used as a clone target.

Protect your instance from being used as a clone target by setting the **glide.db.clone.allow_clone_target** system property to **false**. A system clone copies everything in a database from a source instance to the target instance. This is a security risk because the instance database on the target instance is overwritten in the cloning process, leading to data loss and lack of data integrity.

Set the **glide.db.clone.allow_clone_target** system property to **false** on production instances to disallow your instance from being selected as a clone target.

More information

Attribute	Description
Configuration name	*glide.db.clone.allow_clone_target*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	true
Category	Configuration
Security risk	• Severity score: 4.4 • CVSS score: Medium • Security risk details: Not setting this property to the recommended value of false enables the instance to be used as a clone target. This is a security risk because the instance database can be overwritten in the cloning process.
Dependencies and prerequisites	None
References	• • Register target instance (legacy)
Functional impact	This property provides an additional safeguard which prevents a production instance from being cloned to. The default value is false for production instances and true for sub production instances such as dev or qa. To enable an instance to be used as a clone target set this property to true.

© 2026 ServiceNow, Inc. All rights reserved.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Disable soap fault stack trace display

Manage how stack traces are displayed in your instance.

Use the *glide.soapfault.display_stack_trace* property to manage stack traces in your instance. If this property is configured to **false**, then sensitive information could be leaked. If it is set to **true**, then no stack trace will display.

More information

Attribute	Description
Configuration name	*glide.soapfault.display_stack_trace*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Category	Configuration
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details: Setting this property to **false** could expose sensitive information from the stack trace.
Dependencies and prerequisites	None

Restrict performance monitoring access [Updated in Security Center 1.3]

Use the *glide.security.diag_txns_acl* property to control stats.do, threads.do, thread_pool_stats, and replication.do access from an unauthenticated connection.

When you set this property to **true**, the *glide.security.diag_txns_acl* property only allows access to the following by the administrator account:

- https://<instancename>.service-now.com/stats.do
- https://<instancename>.service-now.com/threads.do
- https://<instancename>.service-now.com/replication.do
- https://<instancename>.service-now.com/thread_pool_stats.do

Without enabling this setting, it is still possible to access these resources from an unauthenticated connection.

More information

Attribute	Description
Property name	*glide.security.diag_txns_acl*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Configuration
Purpose	Restrict the access to configuration pages to administrator account only
Recommended value	true
Default value	true
Security risk rating	5.3
Functional impact	This remediation enforces only administrator account to get access to the application sensitive data for logging and troubleshooting purposes.
Security risk	(Moderate) Sensitive data such as server details, threads, and processes executed on the server should never be visible or accessible to the end user without appropriate privileges.

To learn more about adding or creating a system property, see Add a system property.

Enable updated version of MultiSSO plugin [Updated in Security Center 1.3 and 1.5]

Verify that you're using v2 of the MultiSSO plugin and that it's set to true to reduce security vulnerabilities.

If the Multi SSO plugin is enabled on an instance, reduce security vulnerabilities by confirming that the v2 version is enabled. The latest version enhances security and has more features, such as Assertion encryption support, and IDP-initiated Single Logout (SLO). If the latest version is not enabled, the new security features cannot be used and the instance is at risk of using an plugin which is deprecated.

Follow the steps in KB0756504 to upgrade to the latest version. This process includes checking for and migrating any customization-related changes, then upgrading the version. When complete, the **glide.authenticate.multissov2_feature.enabled** system property is automatically set **true**.

More information

Attribute	Description
Configuration name	glide.authenticate.multissov2_feature.enabled
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Configuration
Security risk	If the latest version is not enabled, the new security features cannot be used and the instance is at risk of using an plugin which is deprecated
Dependencies and prerequisites	None

Enforce secure referrer policy [New in Security Center 1.3]

Use the *com.glide.security.referrerpolicy* property to ensure that the Referrer-Policy HTTP header sends the appropriate level of data to each ServiceNow® page to prevent data leaks.

When the *com.glide.security.referrerpolicy* property is set to default, it ensures that the Referrer-Policy HTTP header is managed with the appropriate level of information sent, specifically tailored for the ServiceNow AI Platform® request page. This prevents unauthorized data leaks that could be accessible from other parts of the full URL, such as the path and query string.

More information

Attribute	Description
Configuration name	*com.glide.security.referrerpolicy*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	default
Default value	default
Category	Configuration
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details: Ensure that the *com.glide.security.referrerpolicy* property is set to default to prevent leaks of unauthorized data.
Dependencies and prerequisites	None
References	Referrer-Policy
Functional impact	This property controls how much information is sent via the referrer header when a request is sent from a page: • default: Instance will take care of the referrer headers • same-origin: Send full referrer URL within the instance/same domain and no referrer to outside origin • origin: Send only the origin as a referrer inside and outside the origin • origin-when-cross-origin: Send full referrer URL within the instance/same domain and only the origin outside the origin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Ensure minimum private key size

Use a system property to determine the minimum size of the private key used for Certificate Signing Request (CSR) generation with the Certificate Inventory Management application.

The *sn_disco_certmgmt.private_key_size* system property determines the minimum size of the private key used for CSR generation with the Certificate Inventory Management application. Valid choices are 512, 1024, 2048, or 4096.

Verify that this property is set to a value of 2048 or higher. Valid choices for this property are 512, 1024, 2048, or 4096. If the property doesn't exist in the System Properties [sys_properties] table, or the value is invalid, the value is 2048 by default.

More information

Attribute	Description
Configuration name	*sn_disco_certmgmt.private_key_size*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Integer, representing the size of the private key generated. Use values of 512, 1024, 2048, or 4096.
Recommended value	2048
Default value	2048
Fallback value	2048
Category	Communications
Security risk	• Severity score: 3.1 • CVSS score: Low • Security Risk: Using keys smaller than 2048 can result in future information disclosure in the event the key is brute forced. Use a valid value greater than or equal to 2048 to future proof the key for a longer time period.
Functional impact	Legacy systems and applications may not handle keys greater than or equal to 2048.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Implement the x-frame-options: SAMEORIGIN security header [Updated in Security Center 1.3]

Use the *glide.set_x_frame_options* property to set the X-Frame-Options response header to SAMEORIGIN for all UI pages.

Use the X-Frame-Options HTTP response header to indicate whether browser should be allowed to render a page in a `<frame>` or `<iframe>`. Sites can use this function to avoid clickjacking attacks by ensuring that their content is not embedded into other sites. An attacker could embed your page into their own page and make your page elements perform maliciously. The end user may think the page is legitimate because it resembles your page. The end user may click on elements like usual only to have malicious scripts or elements run.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Property name	*glide.set_x_frame_options*
Configuration type	System Properties (/sys_properties_list.do)
Category	Configuration
Purpose	To mitigate against ClickJacking attacks.
Recommended value	true
Default value	true
Security risk rating	5.9
Functional impact	This remediation enforces the restriction for rendering a ServiceNow AI Platform application in a third-party application in the form of an iFrame. If you have such an integration, the application wouldn't render in the customized third-party app.
Security risk	(Medium) The Same Origin policy enables you to restrict a domain from retrieving a script or a resource from another domains. All modern browsers support this functionality. The policy validates the connection based on protocol, port, and host. CORS (Cross Origin Request) is a modification to Same Origin Policy that enables access to resources/scripts from another domain when explicitly stated as a part of header value. • In this case, the X-Frame-Options header controls whether the ServiceNow AI Platform application can be rendered on the third-party website. • It reduces the sensitive exposure, because the property value, when set to **SAMEORIGIN** doesn't enable the rendering to happen.
References	Available system properties Configure iFrames

To learn more about adding or creating a system property, see Add a system property.

Require write access to access service catalog add item page [New in Security Center 1.3]

Use the *glide.sc.request.add_item_write_access* property to prevent unauthorized operations from being performed on catalog items.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.sc.request.add_item_write_access*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Configuration
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details: When the *glide.sc.request.add_item_write_access* property is set to false, any logged in user can access the Add Catalog Item UI page. This could result in unauthorized operations performed on catalog items. To remediate this security risk, set this property to true.
Dependencies and prerequisites	None
Functional impact	When the property is true, the user must have write access to the record in the context of the UI page.

Set Xframe options to prevent embedding third-party websites [Updated in Security Center 1.3]

Configure this property to prevent the content of a web-application from being embedded in a third-party site.

If *com.glide.cs.embed.xframe_options* is not set to the recommended value of DENY or SAMEORIGIN, then content of the web application could be embedded in a third-party site using an ALLOW-FROM uri. Allowing untrusted third-party sites could enable attacks such as clickjacking.

More information

Attribute	Description
Configuration name	*com.glide.cs.embed.xframe_options*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	sameorigin
Default value	sameorigin
Category	Configuration

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 3.1 • CVSS score: Low • Security risk details: Not setting this property to the recommended value could enable the content of a web application to be embedded in a third-party site enabling attacks such as click-jacking.
Dependencies and prerequisites	None

Data protection

The data protection category addresses the elements of confidentiality, integrity and availability (CIA) of data.

The CIA components are:

- Confidentiality: Data is protected from unauthorized access in transit and at rest.
- Integrity: Data is protected from unauthorized creation, deletion or change.
- Availability: Data is accessible when required.

Remove remember me

Use the *glide.ui.forgetme* property to remove the **Remember Me** check box from the login page to prevent login information from being cached.

More information

Attribute	Description
Property name	*glide.ui.forgetme*
Configuration type	System Properties (/sys_properties_list.do)
Category	Data protection
Purpose	To ensure that no authentication information is cached.
Security risk rating	3.5
Recommended value	true
Default value	true
Functional impact	This remediation would change the user experience by automatically logging them out of the instance when their session expires. The session expiration would solely depend on the value set in the system property as detailed in Managing user sessions.
Security risk	(Low) When you select the **Remember me** check box at login, an extra cookie is stored on the user's computer.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	• Its purpose is to automatically re-establish the session for the subsequent visits of the logged-in user. • It poses a security risk as it allows the user session to be active until they deliberately log out. The likelihood of an attack for this scenario increases when the end user has left the browser unattended, or if it is compromised from a different attack.
References	Remove the Remember me check box

To learn more about adding or creating a system property, see Add a system property

Require clearing pasteboard when backgrounding mobile application [New in Security Center 1.3 and updated in 1.5]

The *glide.sg.clear_pasteboard_when_backgrounded* property controls if text copied from ServiceNow mobile app is kept in the clipboard and pasteboard after the app is in background mode. If it is not set to the recommended value of true, then sensitive information may be disclosed to the Android or iOS clipboard where it can be exposed to other applications on the device.

More information

Attribute	Description
Configuration name	*glide.sg.clear_pasteboard_when_backgrounded*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Data protection
Security risk	• Severity score: 3.5 • CVSS score: Low • Security risk details: If this property is not set to the recommended value of true, then sensitive information may be disclosed to the Android or iOS clipboard where it can be exposed to other applications on the device.
Dependencies and prerequisites	None
Functional impact	This property clears the copy and paste clipboard when the ServiceNow app enters the background.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Restrict HR case updates from personal emails [New in Security Center 1.3 and updated in 1.5]

Use the *sn_hr_core.restrict_guest_email* property to control whether a user can respond back to a HR case with their personal email.

When the *sn_hr_core.restrict_guest_email* property is not set to true, a user can send an email from a personal account referencing the HR case to be included in the work notes. This could result in minor confidentiality or integrity issues if the personal email is compromised or communicating insecurely. An admin may want to restrict the ability of users to respond to HR cases from their personal email, since they cannot be confident of the user accessing the personal email account.

More information

Attribute	Description
Configuration name	*sn_hr_core.restrict_guest_email*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Data protection
Security risk	• Severity score: 3.5 • CVSS score: Low • Security risk details: Not having this property set to true could result in minor confidentiality or integrity issues if the personal email is compromised or communicating insecurely.
Dependencies and prerequisites	None
Functional impact	This property controls whether or not a reply from a personal email address will update an HR Case. Set to true, any reply from personal email will be added to the case notes. If false, the case and notes will not be updated.

Restrict oauth parameters to POST body [New in Security Center 1.3]

Use the *glide.oauth.allow.parameters.in.post.body.only* property to control the inbound OAuth authentication's acceptance of access tokens. Access tokens are sensitive and should only be accepted when located within a POST request body.

More information

Attribute	Description
Configuration name	*glide.oauth.allow.parameters.in.post.body.only*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	Boolean
Recommended value	true
Default value	true
Category	Data protection
Security risk	• Severity score: 4.2 • CVSS score: Medium • Security risk details: If *glide.oauth.allow.parameters.in.post.body.only* isn't set to the recommended value of **true**, access tokens could be present in the GET request parameter. These access tokens could linger in client and infrastructure logs and potentially lead to account takeover if those logs are leaked.
Dependencies and prerequisites	None
References	• OAuth 2.0 • Manage OAuth tokens
Functional impact	Ensures that oauth_token.do processor accepts only POST body parameters as input for all supported grant types.

Error handling and logging

The error handling and logging category addresses the quality and verbosity of logged information exposed to stakeholders.

This includes ensuring logs and error messages do not collect sensitive information, correctly protect data according to classification and have an appropriate lifetime. Additionally, this category relates to appropriate error handling and not revealing sensitive errors to end users, such as verbose stack traces for unhandled exceptions with security implications.

Disable logger for low privilege users in script sandbox [Updated in Security Center 1.3]

Manage Glide System's ability to log scripts being executed in the sandbox environment.

Use the *glide.security.sandbox_no_logging* property to control Glide System's ability to log scripts being executed in the sandbox environment. If *glide.security.sandbox_no_logging* is set to **false**, logging is available for lower-privileged users using sandboxed scripts. This is a potential security vulnerability because low privileged users can inject logs allowing a bad actor to potentially obfuscate an attack. Configure the property to **true** to prevent lower-privileged users that are using a sandboxed script from having logging functionality.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.security.sandbox_no_logging*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Error handling and logging
Security risk	• Severity score: 2.2 • CVSS score: Low • Security risk details: Setting this property to **false** enables logging for lower-privileged users which could allow a bad actor to obfuscate an attack.
Dependencies and prerequisites	None

Disable secure cookie debugging

Manage the log messages related to cookies in your instance.

Use the *glide.secure_cookie.debug* property to manage your log messages related to cookies. If this property is set to **false**, no log messages are displayed. If it is set to **true**, messages in the `SecureUserCookie` and `Cookie` classes are logged. This could lead to sensitive information being exposed in your instance.

More information

Attribute	Description
Configuration name	*glide.secure_cookie.debug*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Category	Error handling and logging
Security risk	• Severity score: 4.2 • CVSS score: Medium • Security risk details: Configuring this property to **true** could lead to sensitive information being exposed.
Dependencies and prerequisites	None

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Disable SQL Error Messages [Updated in Security Center 1.3 and 1.5]

Use the *glide.db.loguser* property to disable SQL error messages from rendering in a browser.

If *glide.db.loguser* is not set to the recommended value of false, then sensitive server-side error messages could be displayed to end-users. Error messages can include stack traces and information about the structure of the database that could provide an attacker the knowledge needed to perform successful SQL Injection should the preconditions exist. As defense in depth, these error messages should not be displayed to the end user.

More information

Attribute	Description
Property name	*glide.db.loguser*
Configuration type	System Properties (/sys_properties_list.do)
Category	Error handling and logging
Purpose	To disable SQL error messages from displaying within the browser.
Type	Boolean
Recommended value	false
Default value	true
Security risk rating	3.1
Functional impact	This remediation disables rendering of SQL error messages. There is no impact to any functionality.
Security risk	(Medium) No sensitive SQL information that could help an attacker should appear as a part of error message on a web page.

To learn more about adding or creating a system property, see Add a system property.

Enable MID audit log [New in Security Center 1.3 and updated in 1.5]

The MID Server command audit log records details such as the command name, command hash, name of credential used, and execution status.

Once enabled, audit logs can be viewed by users with the role agent_security_admin in the ecc_agent_command_audit_log table or by navigating to **Mid Server** > **Command Audit Logs**.

Set *mid.log.command_audit.enable* to true in the MID Server Properties [ecc_agent_property] table to turn on auditing for commands run by the MID server.

More information

Attribute	Description
Configuration name	*mid.log.command_audit.enable*
Configuration type	MID Server Property [ecc_agent_property] record
Data type	Boolean

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Recommended value	true
Default value	false
Category	Error handling and logging
Security risk	• Severity score: 2.2 • CVSS score: Low • Security risk details: In the event of security investigation, this table can be used by incident response teams to audit the commands run on the MID server. Without this log, there might not be sufficient details to respond to situations such as unauthorized account use.
Dependencies and prerequisites	None

Enable protected tables plugin [New in Security Center 1.3]

Use the *com.glide.security.protected_table.enabled* property to prevent higher privilege users from tampering with log tables.

When the *com.glide.security.protected_table.enabled* property is set to **true**, the protected tables plugin will be used to prevent higher privilege users on an instance from tampering with log tables. The following log tables have special protections when this property is set to **true**:

- syslog (No DB Override)
- syslog_transaction
- sys_outbound_http_log
- sysevent
- sys_audit
- sys_push_notification
- protected_table_configuration (No DB Override)

The integrity of logs is important for determining malicious activity on an instance by a customer admin.

More information

Attribute	Description
Configuration name	*com.glide.security.protected_table.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Error handling and logging

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 4.5 • CVSS score: Medium • Security risk details: Not setting *com.glide.security.protected_table.enabled* to the recommended value of true enables higher privilege users on an instance to tamper with log tables.
Dependencies and prerequisites	None
References	System logs

Log all outbound http request fields [Removed in Security Center v1.3.2]

Configure the *glide.outbound_http.security.log.allow.all.fields* property to false to prevent sensitive Outbound HTTP fields from being logged in plain text.

If this property is not set to the recommended value of **false**, sensitive Outbound HTTP fields might be logged in plaintext. This can decrease the security posture of your enterprise network because outbound requests with sensitive data and credentials can be logged in plaintext which is unencrypted, and can be viewed by lower-privileged users.

More information

Attribute	Description
Configuration name	*glide.outbound_http.security.log.allow.all.fields*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Category	Error handling and logging
Security risk	• Severity score: 6.8 • CVSS score: Medium • Security risk details: Not setting this property to **false** increases the chance of sensitive outbound fields being logged in plaintext which is a security risk.
Dependencies and prerequisites	None

Log html sanitization [Removed in Security Center 2.0]

Configure *glide.html_sanitize.discarded_log.enable* property to determine if HTML sanitization events will be logged in your instance.

If this property is not set to the recommended value of **true**, HTML sanitization events are not logged in the *sys_log* table. Lack of logging could negatively impact your instance automated security detection and investigation capabilities.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.html_sanitize.discarded_log.enable*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Error handling and logging
Security risk	• Severity score: 2.4 • CVSS score: Low • Security risk details: If this property is not set to the recommended value of **true**, HTML sanitization events are not logged in the *sys_log* table which could impact automated security detection and investigation capabilities.
Dependencies and prerequisites	None
References	Enabling HTML sanitizer

Log session audit events [New in Security Center 1.3 and updated in 1.5]

Set the *glide.authenticate.session_access.log_audit_event* property to **true**, so that session audit events will be created in the *sys_session_access_audit* table.

When the Glide Property *glide.authenticate.session_access.log_audit_event* is set to true, session audit events will be created in the sys_session_access_audit table. It is best practice to log information about who accessed a session to assist in malicious actor investigations. Information logged will include user, session ID (non-sensitive), IP address, roles, and policies.

Note:
The *glide.authenticate.session_access.log_audit_event* system property is specific to Zero trust access. For more information, see Zero Trust Access (ZTA).

More information

Attribute	Description
Configuration name	*glide.authenticate.session_access.log_audit_event*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Error handling and logging

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 6.3 • CVSS score: Medium • Security risk details: Not setting this property to the recommended value of true prevents events from being logged. This could prevent you from finding bad actors in the event of a cyber attack.
Dependencies and prerequisites	None

Log user impersonation [Updated in Security Center 1.3 and 2.0]

Configure *glide.sys.log_impersonation* to control if user-impersonating events are logged in your instance.

If this property is not set to the recommended value of **true**, user-impersonating events are no longer logged. The absence of logging could impact the automated security detection and investigation capabilities on your instance. Ensure the property *glide.sys.log_impersonation* exists and is set to true. If the property does not appear in the sys_properties table, add a new record.

More information

Attribute	Description
Configuration name	*glide.sys.log_impersonation*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Error handling and logging
Security risk	• Severity score: 6.4 • CVSS score: Medium • Security risk details: If this property is not set to **true**, user-impersonating events are no longer logged which could impact your instance's security detection and investigation capabilities.
Dependencies and prerequisites	None
References	Impersonating users

Prevent verbose HTTP request logging

Help prevent access to sensitive information by reducing verbose HTTP request logging.

Control the level of logging for outbound HTTP requests to help prevent access to sensitive information, such as authorization headers or cookies. This information can be used like credentials to access the requested resource.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The logging level for these requests is controlled by the **glide.outbound_http_log.override** and **glide.outbound_http_log.override.level** properties. When **glide.outbound_http_log.override** is set to **true**, the log level for requests and responses is controlled by the **glide.outbound_http_log.override.level** property. If **glide.outbound_http_log.override.level** is set to **all** or **elevated**, then request and response headers are logged.

Set **glide.outbound_http_log.override** to **false** and **glide.outbound_http_log.override.level** to **basic**. If these properties don't appear in the System Properties [sys_properties] table, they are in a secure state by default.

More information

Attribute	Description
Technical configuration name	• glide.outbound_http_log.override • glide.outbound_http_log.override.level
Plugin applicability	None
Security risk	Outbound HTTP request headers logged with verbose settings can include sensitive information such as Authorization headers or cookies. This information can be used like credentials to access the requested resource. Users with access to the Outbound HTTP Logs [sys_outbound_http_log] table can view this information. The severity depends on what type of outbound requests are made.
Common Vulnerability Scoring System (CVSS) score	5
Common Vulnerability Scoring System (CVSS) rating	Medium
Functional impact	The **glide.outbound_http_log.override** system property enables you to override outbound http request log level. A value of **false** defaults the log level to basic. If **glide.outbound_http_log.override** is set to **true**, the level of logging is determined by the value of the **glide.outbound_http_log.override.level** property. This value can be **basic**, **elevated**, or **all**. All 3 are string/text based values. Any value other than these is interpreted as **basic**. For additional details, see Configure outbound logging.
Dependencies and prerequisites	None
Data type	• Boolean • String

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Base system value	• false • <blank>
Fallback value	• false • <blank>
Recommended value	• false • basic

To learn more about adding or creating a system property, see Add a system property.

Turn off verbose SQL error messages for import processor [Updated in Security Center 1.3]

Configure this property to control whether verbose SQL error messages are displayed.

If the property is set to **false**, then a verbose SQL error message will display which can leak sensitive information. To avoid this, set the property to **true** to display a generic message.

More information

Attribute	Description
Configuration name	*glide.import.error_message.generic*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Error handling and logging
Security risk	• Severity score: 3.1 • CVSS score: Low • Security risk details: Setting the property to **false** enables verbose SQL messages which can lead to information leakage.
Dependencies and prerequisites	None

File and resources

The file and resources category ensures applications handle untrusted file data securely and store untrusted data from untrusted sources with limited permissions in an appropriate location.

This includes controls such as avoiding denial of service through large or unexpected file types, validating file type and preventing against path traversal.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Disallow infected file download [Updated in Security Center 1.5 and 2.0]

Control whether users can download non-scanned attachments if the antivirus service is down or unreachable.

When the *com.glide.snap.infected_download_allowed* property is set to true, users can still download non-scanned attachments in the event that the antivirus service is down or unreachable. This situation potentially exposes users to the risk of downloading a malicious file, thereby risking the infection of their desktop, especially if there is no other endpoint protection installed on the device.

Ensure the property *com.glide.snap.infected_download_allowed* is set to false.

More information

Attribute	Description
Configuration name	*com.glide.snap.infected_download_allowed*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Category	File and resources
Security risk	• Severity score: 6.7 • CVSS score: Medium • Security risk details: Not setting this property to the recommended value of false could expose your instance to downloading malicious files.
Dependencies and prerequisites	None

Enable email spam scoring and filtering [Updated in Security Center 1.3]

Install the Email Filter (*com.glide.email_filter*) plugin to install email filtering within the instance. This filtering identifies existing headers, which enables you to decide what to do with the email based on the associated header. Alternatively, set *com.glide.email_filter* to false.

Every message sent through ServiceNow AI Platform email servers is assessed for the likelihood of being spam.

Note:
If an instance uses a private email server, this topic is not applicable. For more information, see Email Spam Scoring and Filtering.

Prerequisites

Before setting this property:

Set the *glide.email.read.active* property to true. To learn more, see Enable using your own POP3 server.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Plugin Name	com.glide.email_filter, glide.email.read.active
Configuration type	System Definition > Plugins
Category	File and resources
Purpose	To enforce filtering to avoid spamming of emails.
Recommended value	Either: • The **glide.email.read.active** property to **false** • The **glide.email.read.active** property to **true** and activate the **Email Filter** (com.glide.email_filter) plugin. Active
Default value	None. This is a plugin, not a Glide property so there is no default value.
Security risk rating	8.1
Functional impact	Email is never filtered, blocked, or quarantined from the instance as part of spam scoring. It is only scored and then sent on to the instance. All filtering is done within the instance with the Email Filters plugin.
Security risk	(Moderate) Email filters enable administrators to use a condition builder or conditional script to specify when to ignore malicious incoming emails from known/unknown sender.
References	Email filters https://support.servicenow.com/kb_view.do?sysparm_article=KB0549426

To learn more about activating a plugin, see Activate a plugin.

Enable antivirus scan

The *com.glide.snap.enable_scan* property activates the antivirus scan functionality.

Set *com.glide.snap.enable_scan* to the recommended value of **true** to enable antivirus scanning.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*com.glide.snap.enable_scan*

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Configuration type	System Properties (/sys_properties_list.do)
Category	File and resources
Purpose	To enable or disable antivirus scanning on the specific instance.
Recommended value	true
Default value	true
Data type	Boolean
Security risk	(High) Antivirus scanning helps protect your instance against virus infections that can be introduced by file attachments to your system records, such as incidents, problems, and stories.
Security risk rating	7.7

Restrict downloadable files types in static content [Updated in Security Center 1.3]

Use the *glide.ui.strict_customer_uploaded_static_content* property to enable restrictions on the file types that can be downloaded when they have been uploaded using the Upload File functionality.

You use this property with the *glide.ui.strict_customer_uploaded_content_types* property, which creates a comma-delimited list of restricted downloadable file types.

Warning:
The value for this property is a no DB override. It can't be altered or overridden.

More information

Attribute	Description
Property name	*glide.ui.strict_customer_uploaded_static_content*
Configuration type	System Properties (/sys_properties_list.do)
Category	File and resources
Purpose	To ensure that safe file types are permitted to be downloaded from the application.
Recommended value	true
Default value	true
Security risk rating	3.1
Functional impact	This remediation enforces restriction of file downloads based on the values specified in the *glide.ui.strict_customer_uploaded_content_types* property.
Security risk	(Low) File download restrictions should be applied to any untrusted user input sources.

© 2026 ServiceNow, Inc. All rights reserved.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Limit attachment size in training and prediction flows for GraphQL endpoints [New in Security Center 1.3 and updated in 1.5]

The *glide.platform_ml_di.max_attachment_size_graphql* property controls the maximum allowed size limit for returning attachments in GraphQL endpoints of training or prediction flows.

More information

Attribute	Description
Configuration name	*glide.platform_ml_di.max_attachment_size_graphql*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	5,242,880
Default value	5,242,880
Category	File and resources
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details: If this property is not set to the recommended value of 5,242,880 or less, then returning large files could cause a denial of service (DoS).
Dependencies and prerequisites	None

Limit attachment size in training and prediction flows [New in Security Center 1.3 and updated in 1.5]

The *glide.platform_ml_di.max_attachment_size* property controls the maximum allowed size limit for returning attachments in training and prediction flows.

More information

Attribute	Description
Configuration name	*glide.platform_ml_di.max_attachment_size*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	4,000,000
Default value	4,000,000
Category	File and resources
Security risk	• Severity score: 4.3 • CVSS score: Medium

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	• Security risk details: If *glide.platform_ml_di.max_attachment_size* is not set to the recommended value of 4,000,000 or less, then returning large files could cause a denial of service (DoS) attack.
Dependencies and prerequisites	None

Limit HTTP response body size [New in Security Center 1.3 and updated in 1.5]

Configure the *glide.http.response.get_body.limit.enabled* and *glide.http.response.get_body.limit* properties to protect your instance against *OutOfMemoryExceptions*.

Prevent `OutOfMemoryExceptions` that can result from a request response body being too large using the **glide.http.response.get_body.limit.enabled** and **glide.http.response.get_body.limit** system properties. These exceptions can cause denial of service (DOS) attacks as well as other issues that may aid attackers in compromising an instance. Not setting these properties to the recommended values could make your instance vulnerable to OutOfMemoryExceptions and denial of service attacks.

To protect your instance against these security vulnerabilities:

- Set the **glide.http.response.get_body.limit.enabled** system property to **true**.
- Ensure that the **glide.http.response.get_body.limit** system property set to no more than 524,288,000 megabytes (500 MB).

More information

Attribute	Description
Configuration name	• **glide.http.response.get_body.limit.enabled** • **glide.http.response.get_body.limit**
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	File and resources
Security risk	• Severity score: 3.1 • Security risk details: Not setting these properties to the recommended values could make your instance vulnerable to *OutOfMemoryExceptions* and denial of service attacks.
Dependencies and prerequisites	None

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	This property reduces the chances of an *OutOfMemoryException* due to a customer accidentally loading a large file into memory.

Limit maximum number of attachments in email

Configure the number of inbound email attachments allowed per Email [sys_email] record on your instance.

Use the *glide.email.inbound.max_attachment_count* system property to control the maximum number of inbound email attachments allowed per Email [sys_email] record on your instance.

Set the value of this property to **30** or less to help avoid instance performance degradation.

More information

Attribute	Description
Configuration name	*glide.email.inbound.max_attachment_count*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	30 or less
Default value	30
Fallback value	50
Category	File and resources
Security risk	• Severity score: 5.3 • CVSS score: Medium • Security risk details: Setting the property value to greater than 30 can lead to degradation issues.
Dependencies and prerequisites	None
References	Email properties

Maximum allowed attachment size [Updated in Security Center 1.3]

Configure the *com.glide.attachment.max_size* property to control the maximum size (in megabytes) permitted for an uploaded attachment.

This property controls the maximum size (in megabytes) of an uploaded attachment. If this property is not set to the recommended value of **1024** (1 gigabyte) or less, the platform can accept large files that could fill up storage and lead to a Denial of Service (DoS) attack.

More information

Attribute	Description
Configuration name	*com.glide.attachment.max_size*

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.

Set Allowed MIME Child Types [New in Security Center 2.0]

Learn how to configure the *glide.security.mime.type.allowed_child_types* property to a secure setting so that file types will not pass the Multipurpose Internet Mail Extensions (MIME) type checking. This reduces the risk of remote code execution on an uploaded file.

The *glide.security.mime.type.allowed_child_types* property defines the MIME file types that may have a file extension not matching the data within an uploaded file. This allows such file types to bypass MIME type checking. The property accepts a comma-separated list of file type pairs, such as *application/zip=application/java-archive*. In this example, if the property is set to such a value, files with a `.zip` extension that are technically `.jar` files are allowed to pass MIME type checking despite the inconsistency. If not set properly, this bypass can lead to remote code execution of an uploaded file. Therefore, it should always be set to an empty string ("") unless a valid use case arises. For instance, if a certain MIME type must be allowed under a different file extension and is valid as per the Tika configuration, then those key-value pairs will be updated as part of this property value.

More information

Attribute	Description
Configuration name	*glide.security.mime.type.allowed_child_types*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	""
Default value	""
Category	File and resources
Security risk	• Severity score: 4.6 • CVSS score: Medium

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	• Security risk details: Not setting this property to the secure value could cause files with incorrect configurations to lead to remote code execution of an uploaded file.
Dependencies and prerequisites	Yes, when *glide.security.mime.type.detection.allow_child_typ* is set to true, the values of this property will be used to validate against the configured list of allowed MIME child types.
Functional impact	To support MIME types whose file extensions do not match the content of the files but are valid according to the Tika sub-type configurations in *tika-mimetypes.xml*.

Validate file mime type in AttachmentCreator soap web service [New in Security Center 1.3 and updated in 1.5]

The *glide.attachment.enforce_security_validation* property determines whether Multipurpose internet Mail Extensions (MIME) files undergo validation.

Ensure that MIME-types are validated for attachments to prevent dangerous files from being uploaded on your instance using wrong file extensions.

Set the **glide.attachment.enforce_security_validation** system property to **true**. When set to **true**, files are uploaded with the correct file type extension.

More information

Attribute	Description
Configuration name	*glide.attachment.enforce_security_validation*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	File and resources
Security risk	• Severity score: 6.7 • CVSS score: Medium • Security risk details: If the property is set to false, there's no validation for MIME files during uploads. This could enable malicious files to be disguised by changing their file extension.
Dependencies and prerequisites	None
References	https://developer.mozilla.org/en-US/docs/Web/HTTP/Basics_of_HTTP/MIME_types/Common_types

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	Set this hardening setting to true to run mime-type and file extension validations on uploaded file attachments. No validations are run if this property is set to false. This property is set to true by default.

Malicious code

The Malicious Code category ensures that best efforts are made to confirm that your code is free of vulnerabilities and unwanted functionality.

This includes ensuring secure and proper handling for malicious activity, no time based attacks, no outbound communications to untrusted destinations, and that no unauthorized or attacker-controlled code is included. This category includes audit or third party libraries from the application codebase.

Block rooted or jailbroken mobile devices

Secure your instance by preventing unauthorized access from jailbroken devices.

Use the *glide.sg.allow_rooted_jailbroken_device* property to secure your instance from unauthorized access by jailbroken devices. If a user tries to authenticate into an instance using a mobile app while this property is set to **false**, they receive the following alert: `This device appears to be jailbroken and cannot be used to access this instance. Please contact your ServiceNow Administrator.` The app is frozen while the alert message is displayed, and the only way to dismiss this message is to select **Log out**. If this property is set to **true** users authenticate into an instance using a jailbroken device.

More information

Attribute	Description
Configuration name	*glide.sg.allow_rooted_jailbroken_device*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	false
Category	Malicious code
Security risk	• Severity score: 4.5 • CVSS score: Medium • Security risk details: The lack of security on jailbroken devices makes them a prime target by bad actors. Having unauthorized entities accessing corporate data can weaken the security posture of a corporate network.
Dependencies and prerequisites	None
References	Access control

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Enable Code Signing for application configuration data and scripts [Removed in Security Center 1.3]

Manage Code Signing for application configuration data and scripts on your instance.

Code Signing can help improve security by validating sensitive application configuration data and scripts before they are used. Code Signing creates digital signatures for the data which later are checked to confirm the authenticity and integrity of the data. This verification prevents malicious data or scripts from being used on the instance which may lead to full compromise of the instance.

Enable Code Signing on your instance by following the steps in Configuring Code Signing. This results in the *com.snc.kmf.signature.validation.flag* system property being set to true.

> ⚠ **Warning:**
> This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	*com.snc.kmf.signature.validation.flag*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Malicious code
Security risk	• Severity score: 6 • CVSS score: Medium • Security risk details: Setting this property to **true** enables Code Signing, which helps improve security by validating sensitive application configuration data and scripts.
Dependencies and prerequisites	None

Session management

This category looks at the security of the application state for a user. Sessions should be unique to each individual, unable to be guessed or shared, and invalidated after periods of inactivity or when not required. This includes factors such as cookie attributes for cookie-based sessions, session token generation, and storage and requirements for federated re-authentication.

Apply continuous authentication policies to mobile sessions

Reduce the risk of session hijacking by applying continuous authentication policies to mobile sessions.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Ensure that mobile users are using the high assurance session feature of the Zero Trust - Continuous Authentication plugin by setting the **glide.zta.high_assurance.mobile.session.allowed** system property to **false**. To bypass continuous authentication policies for mobile sessions, set this property to **true**.

Set the **glide.zta.high_assurance.mobile.session.allowed** system property to **false**. This action decreases the risk of session hijacking and persistent access if a session is compromised. If this property doesn't appear in the System Properties [sys_properties] table, the default value is **false**.

More information

Attribute	Description
Technical configuration name	glide.zta.high_assurance.mobile.session.allowed
Plugin applicability	Zero Trust - Continuous Authentication (com.snc.zero_trust_continuous_authentication)
Security risk	If this system property set to **true**, the high assurance session feature isn't applied to mobile sessions. Reauthentication doesn't happen as defined in policies for high role sessions. This increases the risk of session hijacking and persistent access if a session is compromised.
Common Vulnerability Scoring System (CVSS) score	3.9
Common Vulnerability Scoring System (CVSS) rating	Low
Functional impact	If set to **true**, the high assurance session feature doesn't apply to mobile sessions, which increases the risk of session hijacking and persistent access if a session is compromised.
Dependencies and prerequisites	None
Data type	Boolean
Base system value	false
Fallback value	false
Recommended value	false

To learn more about adding or creating a system property, see Add a system property.

Minimize absolute session timeout duration [Updated in Security Center 1.3]

Use the *glide.ui.user_cookie.max_life_span_in_days* property to set a maximum life span for user cookies created when users log in with the **Remember Me** checkbox selected. When the cookie expires, users who have selected the **Remember Me** checkbox are forced to reauthenticate into the instance.

It enables the user cookie to be valid for the duration of specified days, starting when the cookie was first issued. The default value is 30 days, and the maximum cap is at 365 days.

Note:
To enforce a maximum session time for any active user sessions, see Managing user sessions.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Property name	*glide.ui.user_cookie.max_life_span_in_days*
Configuration type	System Properties (/sys_properties_list.do)
Category	Session management
Purpose	To force users who have selected the **Remember Me** checkbox to reauthenticate after specific days.
Recommended value	Less than or equal to 30
Default value	30 days
Functional impact	This property enforces mandatory relogin by avoiding any sort of cookie rotation after a given timeframe.
Security risk rating	4.2
Security risk	(Medium) The user cookies being active for an indefinite amount of time is a security risk and should expire on a time-based configuration.
References	Available system properties Remember me

To learn more about adding or creating a system property, see Add a system property.

Define active session timeout exception roles [New in Security Center 1.3]

Use a system property to exempt roles from active session timeout limits.

Use the *glide.active.session.timeout.exception.roles* system property to exempt roles from an active session timeout limit. The active session timeout feature helps ensure that a hijacked session cannot be used indefinitely without providing authentication information. It is best practice to only consider an active session timeout limit exception for internal integration account roles.

Configure the *glide.active.session.timeout.exception.roles* property to roles which should be exempt from active session timeouts. This property value is a comma separated list of roles. The default value is *edge_encryption,mid_server,maint*.

More information

Attribute	Description
Configuration name	*glide.active.session.timeout.exception.roles*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	edge_encryption,mid_server,maint
Default value	edge_encryption,mid_server,maint
Fallback value	edge_encryption,mid_server,maint

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Session management
Security risk	• Severity score: 6.4 • CVSS score: Medium • Consider an active session timeout limit exception only for internal integration account roles. If a user is a victim of a session hijacking attempt, and has a role with an exception, attackers using that session can continue to authenticate to that session indefinitely. This may increase the impact of a security incident by enabling an attacker more time to make use of a hijacked account.
Dependencies and prerequisites	None

Enable UserCookie version 3.1 [Updated in Security Center 2.0]

Manage the version of UserCookie that is enabled on your instance to secure the storage of the secret key in the source code.

UserCookie v3 is generated only when property *glide.ui.secure.cookies.use_kmf is disabled*. UserCookie v3 is not secure due to storing secret key for HMAC in source code and identical for all customers. That can support malicious actors to use this one secret key for attempts to hijacking user sessions. By setting the property *glide.ui.secure.cookies.use_kmf* to true UserCookie v3.1 will be used and secret key will be stored in security storage such as KMF.

More information

Attribute	Description
Configuration name	*glide.ui.secure.cookies.use_kmf*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Session management
Security risk	• Severity score: 7.1 • CVSS score: High • Security risk details: Setting this to **false** is a security vulnerability due to the secret key for hash-based message authentication codes (HMAC) being stored in the source code.
Dependencies and prerequisites	None

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Enforce password reset on api requests [Updated in Security Center 1.5]

Manage how the password reset functionality operates on your instance.

When a user is marked for **Password needs reset**, they must provide a new password at the next authentication attempt. This property controls whether the password reset is mandatory before making API calls. If this property is not set to the recommended value of **true**, user accounts marked as **Password needs reset** can still perform operations by querying the table API through basic authentication. This security vulnerability could enable information leakage if an inactive account is compromised.

More information

Attribute	Description
Configuration name	*glide.authenticate.api.user.reset_password.mandato*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Session management
Security risk	• Severity score: 8.1 • CVSS score: High • Security risk details: Setting this property to **false** could lead to information leakage if an inactive account is compromised.
Dependencies and prerequisites	None

Enable HTTP Only Cookie Flag [Updated in Security Center 1.3]

Use the *glide.cookies.http_only* property to enable the HTTPOnly attribute for sensitive cookies.

Use the HTTPOnly attribute to prevent attacks, such as cross-site scripting, because it doesn't allow access to the cookie using a client-side script, such as JavaScript. It does not eliminate cross site scripting risks but does eliminate some exploitation vectors.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.cookies.http_only*
Configuration type	System Properties (/sys_properties_list.do)
Category	Session management

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Purpose	To mitigate the risk of client-side script accessing the protected cookie.
Recommended value	true
Default value	true
Security risk rating	8
Functional impact	This remediation adds an extra HTTPOnly flag in on session cookies, thus protecting them from being stolen. • If you have custom functionality that requires JavaScript to access the user's cookie, it breaks that functionality. It should not be the case under normal circumstances. • The ServiceNow AI Platform handles session management and there shouldn't be a reason for a custom script to access the user's cookies.
Security risk	(Moderate) Session cookies in the application authenticate an end user and provide implicit access permissions on the application. That means there is a need to secure them from being stolen or exported. HTTP Only flags protect the session cookies from JavaScript injections or cross site scripting vulnerabilities stealing them.
References	Available system properties

To learn more about adding or creating a system property, see Add a system property.

Invalidate Session After OAuth Token Expiration [New in Security Center 2.0]

Configure the *glide.authenticate.oauth.post.token.expiration.cookie_auth.disabled* property to the secure value to prevent users from continuing to use a session via cookies after the OAuth token used to create the session expires.

When the *glide.authenticate.oauth.post.token.expiration.cookie_auth.disabled* property is not set to the secure value of true, a user may continue to use a session via cookies after the OAuth token used to create the session expires. This increases the risk of cookies being leaked and the session being hijacked by a malicious user to access unauthorized resources. Ensure that the glide property *glide.authenticate.oauth.post.token.expiration.cookie_auth.disabled* is set to true. If the record does not exist in the sys_properties table, the default value is false.

More information

Attribute	Description
Configuration name	*glide.authenticate.oauth.post.token.expiration.coo*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Recommended value	true
Default value	For zboot instances, the property is true. For the update instances, the property is false by default.
Category	Session management
Security risk	• Severity score: 5.4 • CVSS score: Medium • Security risk details: When this property is not set to the secure value of true, a user may continue to use a session even after the OAuth token used to create the session has expired, increasing the likelihood of the session being hijacked by a malicious user.
Dependencies and prerequisites	None
Functional impact	True: Cookie authentication is only honored until the OAuth access token expires; after the expiration, authentication is not honored. False: Cookie authentication is honored even after the OAuth access token expires.

Minimize concurrent interactive session quantity [Updated in Security Center 1.3]

Use this property with the Limit Concurrent Sessions plugin to control the number of active sessions that can be opened by a user.

Use the **Glide Authenticate Max Concurrent Interactive Sessions** property with the **Limit Concurrent Session** (*com.glide.limit.concurrent.sessions*) plugin to control the number of active sessions opened for a user. The recommended value is **1**, which reduces the number of sessions opened (a greater number increases the likelihood that a session could be hijacked).

More information

Attribute	Description
Configuration name	*glide.authenticate.max.concurrent.interactive.sess*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	1
Default value	1
Category	Session management

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: Setting the default value of the property greater than 1 increases the chance of session hijacking.
Dependencies and prerequisites	The **Concurrent Interactive Sessions** (*com.glide.limit.concurrent.sessions*) plugin should be active.
References	Limit concurrent sessions

Limit concurrent sessions across all nodes [Updated in Security Center 1.3]

Use the *glide.authenticate.limit.concurrent.sessions.across.all.nodes* property with the Limit Concurrent Sessions plugin to manage the number of sessions tracked across all nodes.

When the Limit concurrent sessions plugin is active, the number of open sessions can be limited per user. Ensure that when this plugin is active that the (**Glide authenticate limit concurrent sessions across all nodes**) property is set to **true** so that the number of open sessions are tracked across all nodes instead of a single application node. If this property is set to **false**, multiple sessions can be open across multiple nodes, which increases the chances of session hijacking.

More information

Attribute	Description
Configuration name	*glide.authenticate.limit.concurrent.sessions.acros*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Session management
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: When using the **Limit Concurrent Sessions** plugin, setting this property to **false** enables multiple sessions across multiple nodes to be open which increases the chance of a security vulnerability like a session hijacking.
Dependencies and prerequisites	None
References	Limit concurrent sessions

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Limit concurrent sessions plugin

Configure the com.glide.limit.concurrent.sessions plugin to reduce the chance of session hijacking on your instance.

When the Limit Concurrent Sessions (com.glide.limit.concurrent.sessions) plugin is not active, the *glide.authenticate.limit.concurrent.interactive.sessions* property is not set to **true**, or the *glide.authenticate.max.concurrent.interactive.sessions* property is set beyond an organizationally-defined threshold, then ServiceNow instance user accounts are not limited to a defined number of concurrent interactive sessions.

1. Navigate to **All** > **System Definition** > **Plugins**.
2. Find and select the Limit Concurrent Sessions plugin. The plugin ID is *com.glide.limit.concurrent.sessions*
3. On the System Plugin form, review the plugin details and then select the **Activate/Upgrade** related link.
4. Select **Activate**.
5. After the plugin has successfully activate, navigate to **All** > **System Properties** > **All Properties**.
6. Open the *glide.authenticate.limit.concurrent.interactive.sessions* system property, and set the value to **true**.
7. Open the *glide.authenticate.max.concurrent.interactive.sessions* system property, and set the maximum concurrent sessions. This value depends on the needs of your organization.

More information

Attribute	Description
Configuration name	• *com.glide.limit.concurrent.sessions* (plugin) • *glide.authenticate.limit.concurrent.interactive.* property) • *glide.authenticate.max.concurrent.interactive.se* property)
Configuration type	System Properties (/sys_properties_list.do)
Data type	• plugin • system property (Boolean) • system property (Integer) plugin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Recommended value	• *com.glide.limit.concurrent.sessions* is enabled • *glide.authenticate.limit.concurrent.interactive.* system property set to **true** • *glide.authenticate.max.concurrent.interactive.se* set to a numeric value depending on the needs of your organization.
Default value	None
Category	Session management
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: A greater number of open sessions means there are more sessions that could potentially be hijacked. Limiting the number of allowed sessions per user is helpful in limiting risks related to denial-of-service (DoS) attacks.
Dependencies and prerequisites	None

Limit guest's active session life span [New in Security Center 1.3]

Use the *glide.guest.active.session.life_span* property to control the duration of an active guest's HTTP sessions.

The *glide.guest.active.session.life_span* property enforces a maximum lifespan on active guest HTTP sessions, irrespective of their session inactivity or the amount of time a user is inactive before their session times out and closes.

The configured value is in minutes. A value of zero will disable timing out the active sessions. A larger value could allow an attacker to remain in a stolen session for longer, increasing the possibility of a security incident. This property is limited to guest users, which have low privilege access to an instance.

To remediate this security vulnerability, set *glide.guest.active.session.life_span* to a value greater than 0 and less than or equal to 720.

More information

Attribute	Description
Configuration name	*glide.guest.active.session.life_span*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	1-720 (minutes)
Default value	0
Category	Session management

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 4.2 • CVSS score: Medium • Security risk details: Setting the maximum lifespan to a large value gives a bad actor more time within an instance in the event that they steal a session.
Dependencies and prerequisites	None
Functional impact	This configuration enforces max life-span on active guest HTTP sessions irrespective of inactive timeout. The configured value is in minutes. A value of zero will disable timing out the active sessions. The max life-span should be more than the inactive timeout *glide.ui.session_timeout* (default 30 minutes).

Limit concurrent interactive sessions [Updated in Security Center 1.3]

Manage the number of interactive sessions on your instance.

This property is meant to be used with the Limit Concurrent Sessions (*com.glide.limit.concurrent.sessions*) plugin. When the plugin is active and the property is set to false, a user can have any number of concurrent interactive sessions on an instance. A greater number of open sessions means there is a great possibility for session hijacking to occur.

More information

Attribute	Description
Configuration name	*glide.authenticate.limit.concurrent.interactive.se*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Session management
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: When the plugin is active and the property is set to **false**, a user can have any number of concurrent interactive sessions which increases the possibility for a session hijacking.
Dependencies and prerequisites	None
References	Limit concurrent interactive sessions [Updated in Security Center 1.3]

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Limit integrations' active session life span [New in Security Center 1.3]

The *glide.integrations.active.session.life_span* property enforces max lifespan on active guest HTTP sessions irrespective of inactive timeout. The configured value is in minutes. A value of zero will disable timing out the active sessions.

More information

Attribute	Description
Configuration name	*glide.integrations.active.session.life_span*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	0 to 720
Default value	0
Category	Session management
Security risk	• Severity score: 4.2 • CVSS score: Medium • Security risk details: A larger maximum lifespan could allow an attacker to persist in a stolen session for longer, increasing the scope of a security incident. This property is limited to integrations that have low-privilege access to an instance. Set the glide property, *glide.integrations.active.session.life_span* to a value of 0, and less than or equal to 720.
Dependencies and prerequisites	None

Limit policy based session access mobile refresh token interval [New in Security Center 1.5]

Use the *glide.authenticate.session_access.mobile.refresh_token_interval* property to govern the length of time that must elapse before a mobile device user will be forced to re-authenticate.

A user will be asked to re-authenticate only if the admin has configured the Identity Provider attributes in the session policy (attributes can vary each login), and the user authenticates using Single Sign On (SSO). The default value represents the time in seconds that a user has before being re-authenticated. A larger default value provides a bad actor more time for session access in the event of a session hijacking.

More information

Attribute	Description
Configuration name	*glide.authenticate.session_access.mobile.refresh_t*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Recommended value	1800 (seconds)
Default value	1800 (seconds)
Category	Session management
Security risk	• Severity score: 4.3 • CVSS score: Medium • Security risk details: If the ZTA policy is enabled on the instance, then users who are using SSO during mobile login will be forced to logout and re-login after the default value of 1800 seconds (30 minutes) have eclipsed. If a higher value is used, then users will be forced to wait that elapsed time.
Dependencies and prerequisites	Zero Trust- Policy Based Session Access
Functional impact	This setting governs the time in seconds after login, that users will be forced to logout from mobile devices if they are using Single Sign On to authenticate, and admin has configured the Identify provider attributes in the session access policy.

Limit UI active session life span [New in Security Center 1.3]

The *glide.ui.active.session.life_span* property enforces max lifespan on active authenticated HTTP sessions irrespective of inactive timeout.

Reduce the scope of potential security incidents by decreasing the lifespan of active HTTP sessions. The **glide.ui.active.session.life_span** system property enforces a maximum lifespan on active HTTP sessions irrespective of inactive timeout. Longer maximum lifespans can allow an attacker to use a stolen session for a longer time, increasing the scope of a security incident. The default value of **0** disables timeout of active sessions

Set the **glide.ui.active.session.life_span** to a value between 1 and 720. This value represents the time in minutes that HTTP sessions can remain active.

Note:
The **glide.ui.active.session.life_span** is limited to UI session timeout.

More information

Attribute	Description
Configuration name	*glide.ui.active.session.life_span*
Configuration type	System Properties (/sys_properties_list.do)
Data type	integer
Recommended value	1-720
Default value	0
Category	Session management

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 4.2 • CVSS score: Medium • Security risk details: A larger maximum lifespan could allow an attacker to remain in a stolen session longer, increasing the possibility of a security incident.
Dependencies and prerequisites	None
Functional impact	Enforces max life-span on active authenticated HTTP sessions irrespective of inactive timeout. The configured value is in minutes. A value of zero will disable timing out the active sessions. The max life-span should be more than inactive timeout glide.ui.session_timeout (default 30 minutes).

Limit session length for high assurance sessions

Reduce the risk of account takeover in high assurance sessions by limiting session length

Reduce the risk of account takeover in high assurance sessions by limiting the length of the session. After the specified length of time, end-users must re-authenticate.

Use the **glide.zta.high_assurance.session.timeout** system property to set a time, in minutes, after which users must re-authenticate. The value of this property must be between 1 and 480 minutes. Consider limiting this value to 30 or lower to reduce the risk of account takeover.

More information

Attribute	Description
Technical configuration name	glide.zta.high_assurance.session.timeout
Plugin applicability	Zero Trust - Continuous Authentication (com.snc.zero_trust_continuous_authentication)
Security risk	Shorter session lengths reduce the risk of account takeover by forcing users to re-authenticate.
Common Vulnerability Scoring System (CVSS) score	3.3
Common Vulnerability Scoring System (CVSS) rating	Low
Functional impact	Users in high assurance sessions must re-authenticate at the interval set by this property.
Dependencies and prerequisites	None
Data type	Integer
Base system value	30
Fallback value	30
Recommended value	30 or lower

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

To learn more about adding or creating a system property, see Add a system property.

Proactively invalidate inactive sessions [New in Security Center 1.3 and updated in 1.5 and 2.0]

The *glide.active.session.timeout.invalidate.session* property controls if a timeout session is proactively invalidated before the Tomcat server.

When *glide.active.session.timeout.invalidate.session* is not set to **true**, there can be a small interval of time where a timed out session is not invalidated (60 or more seconds depending on queue size). If a session is hijacked, an attacker may be able to use a session during this small period of time. To remediate this security risk, set *glide.active.session.timeout.invalidate.session* to **true**.

More information

Attribute	Description
Configuration name	*glide.active.session.timeout.invalidate.session*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Session management
Security risk	• Severity score: 4.6 • CVSS score: Medium • Security risk details: Not setting this property to the recommended value of true could cause a timed out session to not be validated. This increases the chances of a bad actor hijacking a session.
Dependencies and prerequisites	None

Rotate HTTP session identifiers

Use the *glide.ui.rotate_sessions* property to enable rotation of the HTTP session identifiers to reduce security vulnerabilities.

If an unauthenticated user's session ID doesn't change after authentication, a web application is vulnerable to a session fixation attack. A malicious user could start an unauthenticated session and give the associated session ID to the victim. Once the victim authenticates, the malicious user now shares that authenticated session.

More information

Attribute	Description
Property name	*glide.ui.rotate_sessions*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Session management
Purpose	To achieve more secure session authentication.
Recommended value	true
Default value	true
Security risk rating	8.8
Functional impact	This remediation modified the SessionID when user navigates from unauthenticated page to authenticated pages. • If you are using a proxy or hardcoding the SessionID when a user first logs in, or for any purpose, then there can be a potential functionality impact. • If you are using the SAML 2.0 plugin for Single Sign-on authentication, it might interfere with the session information sharing between the instance and the Identity Provider. In such case, you can set this property to false.
Security risk	(Moderate) SessionID is used to process and authenticate the instance user by maintaining the session state on the browser. Thus, SessionID is deemed as sensitive data and should be secure by default. Session Rotation is a security control that enforces the alteration of sessionID whenever the user navigates from unauthenticated pages to authenticate pages.
References	Authentication with SAML

To learn more about adding or creating a system property, see Add a system property.

Minimize concurrent interactive session quantity [Updated in Security Center 1.3]

Use this property with the Limit Concurrent Sessions plugin to control the number of active sessions that can be opened by a user.

Use the **Glide Authenticate Max Concurrent Interactive Sessions** property with the **Limit Concurrent Session** (*com.glide.limit.concurrent.sessions*) plugin to control the number of active sessions opened for a user. The recommended value is **1**, which reduces the number of sessions opened (a greater number increases the likelihood that a session could be hijacked).

More information

Attribute	Description
Configuration name	*glide.authenticate.max.concurrent.interactive.sess*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	integer
Recommended value	1
Default value	1
Category	Session management
Security risk	• Severity score: 3.7 • CVSS score: Low • Security risk details: Setting the default value of the property greater than 1 increases the chance of session hijacking.
Dependencies and prerequisites	The **Concurrent Interactive Sessions** (*com.glide.limit.concurrent.sessions*) plugin should be active.
References	Limit concurrent sessions

Minimize session activity timeout duration [Updated in Security Center 1.3]

Use the *glide.ui.session_timeout* property to designate, in minutes, activity timeout value.

There are several functional impacts from setting this property:

- The longer the specified session time-out, the greater the amount of memory is utilized during a processing session. The base system uses a default Apache Tomcat timeout duration of 30 minutes.
- The ServiceNow AI Platform still logs out users out with Remember Me. After 30 minutes of inactivity in the application, the platform logs the user out automatically, unless the **Remember Me** check box in the login page is selected. What 's different is that they don't log in again to continue.
- If there are gauges or content on users' home pages that refresh automatically, then this timeout may never be reached.

More information

Attribute	Description
Property name	*glide.ui.session_timeout*
Configuration type	System Properties (/sys_properties_list.do)
Category	Session management
Purpose	To enforce session timeout.
Recommended value	User specified timeout in minutes. 60 minutes is the recommended value, but this value may vary depending on functionality and security requirement. Do not set this value to more than one day.
Security risk rating	7.5

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	This remediation enforces timely expiration of user account. No functionality impact, however User experience is altered.
Security risk	(High) User sessions being active for indefinite amount of time is a security risk and should expire on a time-based configuration.
References	Manage user sessions

To learn more about adding or creating a system property, see Add a system property.

Minimize session window timeout duration [Updated in Security Center 1.3]

Use the *glide.ui.user_cookie.life_span_in_days* property to set the expiration time period for the Remember Me cookie. The default value is 15 days and the maximum cap is at 30 days.

More information

Attribute	Description
Property name	*glide.ui.user_cookie.life_span_in_days*
Configuration type	System Properties (/sys_properties_list.do)
Category	Session management
Purpose	To enable the default expiry of the **remember me** cookie.
Data type	Integer
Recommended value	15
Default value	15
Security risk rating	4.9
Functional impact	This property is enabled by the end user when the end user checks the **Remember me** check box from the login page and logs in to the ServiceNow AI Platform.
Security risk	(Moderate) The user cookies being active for an indefinite amount of time is a security risk and should expire on a time-based configuration.
References	Available system properties Remember me

To learn more about adding or creating a system property, see Add a system property.

Stored cryptography

This category focuses on the encryption of stored data. It encompasses several key aspects, such as employing established algorithms and cryptographic modules, ensuring the proper generation of pseudo-random values, implementing encryption based on data classification, and securely storing and isolating key material.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Enable glide KMF encrypter [Removed in Security Center 1.3.2]

Manage the encrypters used for Password2 fields on your instance.

Use the *glide.kmf.encrypter.enabled* property to set KMF encrypter as the default encrypter for Password2 fields. This property ensures that strong and compliant encryption standards are being used instead of a legacy encrypter. To ensure that KMF encrypter is used instead of the legacy encrypter, set this property to **true**.

More information

Attribute	Description
Configuration name	*glide.kmf.encrypter.enabled*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Stored cryptography
Security risk	• Severity score: 4.9 • CVSS score: Medium • Security risk details: Setting this property to **true** ensures that KMF encrypter is being used instead of legacy encrypter.
References	Password2 encryption with the Key Management Framework (KMF)

Disable use of TripleDES/3DES encryption algorithm

Avoid the security risks of outdated encryption methods by disabling the use of the TripleDES/3DES encryption algorithm.

Disable the use of legacy, deprecated Triple Data Encryption Standard (3DES or Triple-DES) on your instance, which may lead to loss and leakage of sensitive information.

The National Institute of Standards and Technology (NIST) has advised against using Triple DES (3DES) to encrypt data. For more details, refer to NIST 800-131A Rev 2.#3DES is now banned for encryption in federal systems. Going forward, TDES can only be used for historical purposes, such as decrypting old messages, key unwrapping, and MAC verification.

The **glide.security.3des.encryption.allow** system property controls whether 3DES encryption is enabled on your instance, however there are several steps which may need to be taken to verify that your instance is ready for deprecation. Review KB1704481 for further information on the deprecation process before setting this property.

More information

Attribute	Description
Technical configuration name	glide.security.3des.encryption.allow

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Plugin applicability	None
Security risk	Usage of outdated and weak encryption like 3DES may lead to loss and leakage of sensitive information.
Common Vulnerability Scoring System (CVSS) score	4.2
Common Vulnerability Scoring System (CVSS) rating	Medium
Functional impact	Setting this property to **false** helps prevent your instance from use of outdated and weak encryption. This affects how Password2 data is stored. Review KB1704481 for further information on functional impact of 3DES deprecation.
Dependencies and prerequisites	Perform the tasks outlined in KB1704481 before changing the value of this property.
Data type	Boolean
Base system value	false
Fallback value	false
Recommended value	false

To learn more about adding or creating a system property, see Add a system property.

Prevent usage of 3DES keys [New in Security Center 7.0]

Disable the use of 3DES static keys on your instance with a system property.

Use the *glide.security.3des.static_keys_usable* system property to disable the usage of 3DES static keys on your instance. This property should be set automatically by a scheduled job, the status of which can be checked via the property *glide.security.3des.removal_job_status*. In cases where this property isn't configured to **false**, after the scheduled job runs and the status is KEYS_DEACTIVATED, the scheduled job waits until this property is configured to **false** before proceeding with deletion of the 3DES static keys.

Ensure the *glide.security.3des.static_keys_usable* exists on the System Properties [sys_properties] table and is set to a value of **false**. Review KB1704481 for further information on 3DES deprecation.

More information

Attribute	Description
Configuration name	*glide.security.3des.static_keys_usable*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	true
Fallback value	true

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Stored cryptography
Security risk	• Severity score: 5 • CVSS score: Medium • 3DES is deprecated, and the use of 3DES and 3DES static keys outside of temporary backwards compatibility isn't recommended. Continued use may lead to situations of sensitive information disclosure if a user were to obtain access to encrypted data.
Functional impact	When set to **false**, there may be unlikely situations where code and data residing on the instance still relied on by 3DES static keys are now inaccessible.
Dependencies and prerequisites	None

To learn more about adding or creating a system property, see Add a system property.

Validation, sanitization, and encoding

Validation, sanitization, and encoding addresses input validation to prevent against vulnerabilities like Cross-Site Scripting (XSS), SQL injection and other attacks.

This control ensures input validation and output encoding are in place and correctly configured, such as encoding or escaping output data. This category also includes checks for items such as deserialization of objects and positive validation through allow lists.

Allow HTML Links to Trusted Domains in the Description Fields of the Impact Workspace Module [New in Security Center 7.0]

Use a system property to help sanitize the HTML allowed in the descriptions fields. This property limits the allowed links to only those from the trusted domains listed in the property.

Note:
This hardening setting is not a part of the hardening baseline. It does not appear in Security Center hardening pages and affect your hardening score.

The Impact Workspace module allows HTML in a number of description-related fields. When configured, the *sn_impact_common.whitelisted.url_HTML_injection* system property contains a comma-separated list of domain names. Description fields for the Impact Workspace module are allowed to contain HREFs with URLs only from the domains listed in the property.

Ensure the *sn_impact_common.whitelisted.url_HTML_injection* system property is set to a comma-separated list of domain names that represent the domains allowed in HTTP reference URLs of description fields for the Impact Workspace module.

To disallow HREFs in these fields, set the property to an empty string. If the property doesn't exist on the System Properties [sys_properties] table, it defaults to this list: `servicenow.com, service-now.com, youtube.com, google.com, youtu.be, soti.net, dpdhl.sharepoint.com, documentation.avaya.com, www.juniper.net, servicenow.sharepoint.com, servicenow-my.sharepoint.com, scaledagileframework.com`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*sn_impact_common.whitelisted.url_HTML_injection*
Configuration type	System Properties (/sys_properties_list.do)
Data type	String list
Recommended value	servicenow.com, service-now.com, youtube.com, google.com, youtu.be, soti.net, dpdhl.sharepoint.com, documentation.avaya.com, www.juniper.net, servicenow.sharepoint.com, servicenow-my.sharepoint.com, scaledagileframework.com
Default value	servicenow.com, service-now.com, youtube.com, google.com, youtu.be, soti.net, dpdhl.sharepoint.com, documentation.avaya.com, www.juniper.net, servicenow.sharepoint.com, servicenow-my.sharepoint.com, scaledagileframework.com
Fallback value	servicenow.com, service-now.com, youtube.com, google.com, youtu.be, soti.net, dpdhl.sharepoint.com, documentation.avaya.com, www.juniper.net, servicenow.sharepoint.com, servicenow-my.sharepoint.com, scaledagileframework.com
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 4.4 • CVSS score: Medium • If an untrusted domain is added to the property, this opens these fields up to containing links to risky sources which can lead HTML injection attacks. The exact risk is dependent on the customer instance.
Functional impact	If the property is empty, no HREFs are allowed in the field text and all HREFs are removed. Any links using domains not listed in the property are removed. An improper value for this field could result in corrupted data for the affected fields.
Dependencies and prerequisites	If the *sn_impact_common.blacklist_tags_HTML_injection* system property contains HTML tags that surround HREF links, then all links within those tags will be removed.

To learn more about adding or creating a system property, see Add a system property.

Restrict access to GlideSystemUserSession scriptable API [Updated in Security Center 1.3 and 2.0]

The client callable GlideSystemUserSessionSandbox scriptable API exposes GlideSystemUserSession's addErrorMessageNoSanitization and addInfoMessageNoSanitization methods to the JavaScript sandbox. This allows all users to call this method via script.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

gs.addErrorMessageNoSanitizationMessaging() and *gs.addInfoMessageNoSanitization()* are used within the scripting environment for logging and notifications. Both of these are available in the sandbox if this property is not set to the recommended value of false. The sandbox is a low privileged scripting environment available to unauthenticated and no role users. Both of these methods can be used to display unsanitized input to a user. Displaying unsanitized input to the user is dangerous, as unsanitized input may contain dangerous code that runs in the user's browser. This can be utilized for traditional reflected XSS attacks. Reflected XSS attacks can be used in multiple scenarios, including session hijacking.

Set **glide.sandbox.usersession.allow_unsanitized_messages** system property to **false**. If there is not record of this property in the System Properties [sys_properties] table, create one.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.sandbox.usersession.allow_unsanitized_messag*
Configuration type	System Properties (/sys_properties_list.do)
Category	Access control
Purpose	This property will restrict unsanitized informational or error messages from being called in a sandboxed user session.
Type	Boolean
Recommended value	false
Default value	true
Security risk rating	8.1
Functional impact	Set the property with the value false will result in no message creation or logging should those functions get called.
Security risk	(High) Without appropriate sanitization, potentially dangerous content may be accessed and the unsanitized error function is available to script.
References	Access control

Disable JavaScript tags in embedded HTML [Updated in Security Center 1.3]

Use the *glide.ui.security.codetag.allow_script* property to disable support for embedding HTML JavaScript code created using of the [code] tag.

The ServiceNow AI Platform mitigates many injection and cross-site attacks by implementing escaping and encoding techniques. As a result, users can't write and submit HTML formatted inputs for journal fields. However, journal fields can render text enclosed within code tags as HTML. Ensure the *glide.ui.security.codetag.allow_script* property exists in the sys_properties table and is set to false.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- However, there is an associated security risk. If set to **true**, malicious users can write harmful HTML JavaScript code that may be executed on a different client browser after rendering of journal fields.
- Set this property to **false** so that administrators can prevent journal fields from rendering HTML JavaScript code by disabling support for the `[code]` tag.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.ui.security.codetag.allow_script*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	Protects against cross-site scripting and malicious script execution
Recommended value	false
Default value	false
Security risk rating	8.8
Functional impact	This remediation enforces JavaScript escaping to occur on the UI and renders the encoded results to the user. It can have a functionality impact based on the instance user interaction with the resulted data.
Security risk	(High) Input validation must occur in the application to defend against cross-site scripting attacks. These attacks enable foreign scripts to execute on the user session in the logged in browser's context. Attackers can use it to steal session information and sensitive data.
References	Restrict the CODE tag in journal fields Render journal field entries as HTML High Security Settings

To learn more about adding or creating a system property, see Add a system property.

Enable the hardened java security manager [New in Security Center 1.3]

The *glide.security.manager* property contains the Java classname of the current Java security manager.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.security.manager*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	*com.glide.sys.security.ContextualSecurityManager*
Default value	*com.glide.sys.security.ContextualSecurityManager*
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 7.2 • CVSS score: High • Security risk details: If *glide.security.manager* is not set to the recommended value of *com.glide.sys.security.ContextualSecurityManager* then the instance may be using an obsolete Java security manager which is missing expected hardening policies. Without this hardening, a malicious actor with script execution access could get remote code execution on the instance.
Dependencies and prerequisites	None

Enforce HTML Sanitization [Updated in Security Center 1.3]

Use the *com.glide.security.check_unsanitized_html* property to enforce sanitization behavior of translated_html fields on a global level for field assignments.

HTML is one of the types that can be assigned to the dictionary fields. Assigning HTML fields to any field type provides the functionality to format content using HTML tags (for example, `<p>`, `<a href>`, `<b>`, `<font>`, `<img>`). To prevent malicious activity, certain HTML tags can be disallowed using a block list. This property will prevent disallowed tags from being used in translated_html fields on your instance.

- Set this property to **enforce** to enforce sanitization behavior of translated_html fields.
- Set property to **disable** to turn off the html sanitization to allow blocked html tags on translated_html fields.

> ⚠ **Warning:**
> This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*com.glide.security.check_unsanitized_html*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Validation, sanitization, and encoding
Purpose	Prevents the use of insecure HTML tags to protect against attacks such as cross-site scripting.
Type	String
Recommended value	enforce
Default value	enforce
Security risk rating	7.3
Functional impact	This remediation enforces HTML sanitization to occur on the UI and renders translated html fields to the user. It can have an impact on readability and formatting.
Security risk	(High) Input validation must occur on the application to defend against cross-site scripting attacks. These attacks enable foreign scripts to execute on user sessions in the logged in browser's context. Attackers can use it to steal session information and sensitive data.
References	HTML sanitizer

Ensure Contextual Search Do Not Contain An Unvalidated Redirect [New in Security Center 7.0]

Prevent Contextual Search results from containing referral links outside the current domain with a system property.

The Contextual Search plugin displays search results in a new window using the *cxs_new_window* UI page. This UI page contains a referral link which can be set by providing a value to *sysparm_url*. When the *com.snc.contextual_search.cxs_new_window.force_relative_link* system property is set to **true**, *sysparm_url* can only contain links that are relative to the current domain. This restriction prevents the UI page from being used as an unvalidated redirect to an attacker-controlled website. When the property is set to **false**, *sysparm_url* can link to any website.

Set the *com.snc.contextual_search.cxs_new_window.force_relative_link* property to **true**. If the property doesn't exist on the System Properties [sys_properties] table, the default value is **false**. If the property exists on the table, it defaults to **true**.

More information

Attribute	Description
Configuration name	*com.snc.contextual_search.cxs_new_window.force_rel*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Fallback value	false

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 3.1 • CVSS score: Medium • When set to **false**, *sysparm_url* can link to any website, which allows the UI page to be used as an unvalidated redirect to an attacker-controlled website.
Functional impact	When set to **true**, *sysparm_url* is only allowed to contain links that are relative to the current domain. This restriction means that the UI page can only ever link to web pages on the current domain. However, the UI page is meant to display search results from the current domain and should only ever link to the current domain.
Dependencies and prerequisites	The Contextual Search (com.snc.contextual_search) plugin must be active.

To learn more about adding or creating a system property, see Add a system property.

Disable AJAXEvaluate

Use the *glide.script.allow.ajaxevaluate* to protect the system API from vulnerabilities of Client script execution through AJAX calls.

Elevation to the security_admin role is required to edit the property.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.script.allow.ajaxevaluate*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	To prevent a user from executing scripts as an admin privilege.
Recommended value	false
Default value	false
Configuration type	Boolean
Functional impact	This remediation forces the AJAXEvaluate processor to be turned off. It could impact functionality if you are explicitly using the AJAX evaluate processor as part of any customized scripts.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	(High) The AjaxEvaluator processor executes Client scripts in sandbox, however there are several additional properties which can allow the scope of activities in the sandbox to expand.
Security risk rating	7.3
References	This property belongs to the same family of properties that secure and restrict execution of scripts originating from the client, such as *glide.script.allow.ajaxevaluate*. For more information, see Enable AJAXEvaluate.

To learn more about adding or creating a system property, see Add a system property.

Disable Entity Expansion within the XMLDocument2 Streaming Parser [Updated in Security Center 1.5]

If customizations do not require entity expansion, use the *glide.stax.allow_entity_resolution* property to completely disable external entity expansion. The XML completes parsing but doesn't include any internal or external entities.

Disable entity expansion on your instance to secure your instance from attacks such as ability to read system files, and Denial of Service. Use the system property to disallow XML entities to be expanded during parsing by the streaming parser (XMLDocument2).

Set the **glide.stax.allow_entity_resolution** system property to **false** to disable entity expansion on your instance. If this property does not appear in the System Properties [sys_properties] table, the default value is **true**. Create the property record and set the value to **false** to change it's value.

Prerequisites

Before setting this property:

- Set the *glide.xml.entity.whitelist.enabled* and *glide.stax.whitelist_enabled* properties to true. To learn more, see Restrict XML external entities [Updated in Security Center 1.3 and 2.0] and Require XMLdoc2 entity validation with allowlistDisable entity expansion [Updated in Security Center 1.3].
- Define a listing of comma-delimited FQDN in the *glide.xml.entity.whitelist* property, which is the only URLs that can be reached using XML Entity processing. property. To learn more, see Restrict XML external entities [Updated in Security Center 1.3 and 2.0].

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.stax.allow_entity_resolution*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Category	Validation, sanitization, and encoding
Purpose	This remediation control must be enabled to defend against an XML Entity Expansion/Billion Laugh attack.
Recommended value	false
Default value	true
Functional impact	If the customization is using entity expansion, then, the ServiceNow AI Platform might block further processing.
Security risk	(Critical) An attacker can use this vulnerability to expand data exponentially, quickly consuming all system resources.
Workaround	If the customization requires entity expansion, set this property to true and follow the steps documented in Require XMLdoc2 entity validation with allowlistDisable entity expansion [Updated in Security Center 1.3].

To learn more about adding or creating a system property, see Add a system property

For more information about OWASp resources, see OWASp.

Disable external content url [Updated in Security Center 2.0]

Manage how external link metadata is used in your instance with Connect Chat.

Use the *glide.ui.url.external.content* property to manage external link metadata in your instance. If the property is set to the recommended value of **false**, then no external link metadata will be rendered. If set to **true** then Connect Chat will retrieve external link metadata from sources such as YouTube or news articles to render richer messages. This could lead to Server Side Request Forgery (SSRF) attacks.

Ensure the Glide Property *glide.ui.url.external.content* exists and is set to the value false. If the property does not appear in the sys_properties table, add a new record.

More information

Attribute	Description
Configuration name	*glide.ui.url.external.content*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	false
Default value	true
Category	Validation, sanitization, and encoding

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	• Severity score: 7.2 • CVSS score: High • Security risk details: Setting this property to **true** could expose your instance to Server Side Request Forgery (SSRF) attacks.
Dependencies and prerequisites	None
References	Connect Chat

Restrict downloadable MIME types [Updated in Security Center 1.3 and 2.0]

The *glide.ui.attachment.download_mime_types* property will force the specified list of dangerous file types to be downloaded to the client and not viewed inline in the browser.

If the property *glide.ui.attachment.force_download_all_mime_types* is set to true, then the *glide.ui.attachment.download_mime_types* property will be overridden so that all MIME types will be downloaded rather than rendered by the browser. For example, downloading text/html forces an HTML file to be downloaded to the client as a file rather than viewed inline in the browser, preventing a XSS attack. XSS can lead to easily attained privilege escalation to higher roles such as admin where more lateral movement can be taken.

New remediation: Ensure the property *glide.ui.attachment.force_download_all_mime_types* is set to true. If the property does not exist in the sys_properties table, the default value is false.

Note:
The security_admin role is required to edit the property.

More information

Attribute	Description
Property name	*glide.ui.attachment.download_mime_types*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	Maintaining the list properly of dangerous file types that cannot be viewed in the browser will prevent cross site scripting attacks (XSS).
Recommended value	List of applicable MIME types or the recommended value: `text/html,image/svg,image/svg+xml,application/xml`
Default value	List of applicable MIME types for the default value: `text/html,image/svg,image/svg+xml,application/xml`
Configuration type	String: any comma separated values of application mime types.
Functional impact	This remediation enforces performance of validation checks before performing an action when you click an

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	attachment in a ServiceNow AI Platform application. There is no potential impact, but the user experience is altered.
Security risk	(Moderate) Attackers can abuse MIME types and place unintended script content in the attachment on the victim's side to capture sensitive information. The ability to have XSS can lead to easily attained privilege escalation to higher roles, such as admin, where more lateral movement can be taken. In the current context, populate the property with a list of comma-separated attachment MIME types that should not render inline in the browser.
Security risk rating	6.4
Related properties	• *glide.ui.attachment.force_download_all_mime_type* • *glide.ui.attachment.tables_ignore_force_download*
References	Define restricted downloadable MIME types [Updated in Security Center 1.3, 1.5, and 2.0].

Disable embedded HTML code [Updated in Security Center 1.3]

Use the *glide.ui.security.allow_codetag* property to disable support for embedding HTML code created using the [code] tag.

Disable support for displaying HTML code embedded using the `[code]` tag. This tag allows rendered HTML to display in journal fields and may lead to cross-site scripting (XSS) attacks. These attacks can enable foreign scripts to execute on a user session in the logged in browser's context. Attackers can use these scripts to steal session information and sensitive data. The HTML language was not designed to separate script from formatting, so allowing user-controlled HTML in any system has inherent risk.

Setting the **glide.ui.security.codetag.allow_script** to **false** is compliant, and significantly reduces this risk, however some small risk remains. It disables only the script portion of a `code` tag, and relies on sanitizing all known conventions of script in the HTML.

Set the **glide.ui.security.allow_codetag** system property to **false** to completely prohibit journal fields and forms from displaying rendered HTML.

The ServiceNow AI Platform mitigates many injection and cross-site attacks by implementing escaping and encoding techniques. As a result, users can't write/submit HTML formatted inputs for journal fields. But journal fields can render text enclosed within code tags as HTML.

- However, there is an associated security risk. If set to `true`, malicious users can write harmful HTML JS code that may be executed on a different client browser after rendering of journal fields.
- Set this property to `false` so that administrators can prevent journal fields from rendering HTML code by disabling support for the `[code]` tag.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Property name	glide.ui.security.allow_codetag
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Configure in Instance Security Center	Yes
Purpose	Protect against cross-site scripting and malicious script execution
Recommended value	false
Default value	true
Security risk rating	4.2
Functional impact	This remediation enforces HTML encoding to occur on the UI and renders the encoded results to the user. This property is set to `true` by default. In this state, your instance displays rendered HTML in journal fields and forms. If this property is set to `false`, HTML is not rendered properly and HTML tags may appear in journal fields on forms. It can have an adverse impact on functionality, and on user interactions with the resulting data.
Security risk	(Medium) Input validation must occur in the application to defend against cross-site scripting attacks. These attacks enable foreign scripts to execute on a user session in the logged in browser's context. Attackers can use it to steal session information and sensitive data.

Enable HTML Sanitizer within Virtual Agent [Updated in Security Center 1.3 and 1.5]

Use the *com.glide.cs.html.sanitizer.enabled* property to enable HTMLSanitizerService.

This property controls the whether the HtmlSanitizerService is enabled. If *com.glide.cs.html.sanitizer.enabled* is not set to true, then a Stored Cross-Site Scripting (XSS) attack is possible in the VA web client.

More information

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

Attribute	Description
Property name	*com.glide.cs.html.sanitizer.enabled*

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	Prevents application against cross site scripting and HTML injection attacks.
Recommended value	true
Default value	true
Security risk rating	8
Functional impact	This remediation enforces HTML-output encoding mechanism before the user data is rendered back to the user. If customer has any customization that involves rendering of the HTML attribute or content data, then there is a functionality impact.
Security risk	(High) User input should be securely treated when the data is being stored and processed on the application. This reduces client-side cross-site scripting attacks by output encoding the data.

To learn more about adding or creating a system property, see Add a system property.

Enable Jelly JS Interpolation Protection

Use the *glide.ui.jelly.js_interpolation.protect* property to ensure that any JavaScript about to be executed on a Jelly page is protected from injection with the help of Jelly interpolation.

When you set property to **true**, an application goes through a Jelly script tree (nested). It wraps potentially dangerous Jelly expressions with a filter that:

- Escapes their results to be safe, or
- If their safety can't be guaranteed, generates a SecurityException because the expression that was going to be evaluated represents a possible security issue.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.ui.jelly.js_interpolation.protect*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	To mitigate against malicious code execution attacks that can occur using Jelly Injection.
Recommended value	true
Default value	false

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk rating	9
Functional impact	This property makes a best guess at whether an expression is quoted. It may wrongly quote legitimate expression. In that case manually marking an expression as safe may be necessary.
Security risk	(Moderate) JEXL injection is a form of input injection unique to the ServiceNow AI Platform that can lead to both cross-site request forgery and code execution. Completely turning off the protection may potentially open many P1 security vulnerabilities.
Workaround	To manually mark an expression as safe add SAFE prefix to Jelly expression: `${SAFE:sysparm_input};` Blindly adding SAFE to each expression is the wrong way to approach the problem, because it may open a security vulnerability. • Only add SAFE to an expression if you can guarantee that the expression does not contain input from the client. • If it does, it's possible for a malicious client to cause evaluation of privileged JavaScript.
References	Jelly tags High Security Settings

To learn more about adding or creating a system property, see Add a system property.

Enable Jelly JS interpolation protection for nested expressions [Updated in Security Center 2.0]

Manage the interpolation protection on your instance.

Use the *glide.ui.jelly.js_interpolation.protect_nested_expressions* property to manage interpolation protection. Interpolation protection ensures that when Jelly expressions are used in JavaScript, that they must be deemed as safe by either falling under certain categories or being marked as SAFE in the expression itself. Without this mitigation enabled, a bad actor can send a GET parameter to a Jelly page and cause the contents of that parameter to be evaluated as server-side JavaScript with admin privileges. If this property is not set to the recommended value of **true**, malicious Jelly expressions interpolated in JavaScript are allowed and a user can execute code using a Jelly template.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*glide.ui.jelly.js_interpolation.protect_nested_exp*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	false
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 9 • CVSS score: Critical • Security risk details: If the property is set to **false**, then malicious Jelly expressions are allowed.
Dependencies and prerequisites	None

Enforce relative links [Updated in Security Center 1.3 and 1.5]

Use the *glide.cms.catalog_uri_relative* property to enforce relative links from the URI parameter on `/ess/catalog.do`.

The *glide.cms.catalog_uri_relative* property enforces relative links from the URI parameter on /ess/catalog.do. If *glide.cms.catalog_uri_relative* is not set to the recommended value of true, then the URL will not be sanitized with the enforceRelativeURL(url) function. Absolute URLs can pose a security risk when used as a part of parameter or a field value, thus redirecting the source page to an adversary-controlled website.

More information

Attribute	Description
Property name	*glide.cms.catalog_uri_relative*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	To restrict attempts to link external unauthorized content.
Recommended value	true
Default value	false
Security risk rating	2.6
Functional impact	This remediation enforces validation on Catalog page such that only Relative URLs are permitted. Existing links to external web applications become broken.
Security risk	(High) Absolute URLs can pose a security risk when used as a part of parameter or a field value, thus

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	redirecting the source page to an adversary-controlled website.

To learn more about adding or creating a system property, see Add a system property.

Enforce URL allowlist check [Updated in Security Center 1.3, 1.5, and 2.0]

Use the *glide.security.url.whitelist* system property to add extra layer of validation to ensure whether any external URL introduced should be a part of inclusion listed URLs.

Protect your users from client-side open redirection, which enable attackers to redirect your users to untrusted and malicious pages.

If **glide.security.url.whitelist.strict_check** is not set to the recommended value of **true**, all external URLs are allowed for redirection as long as the **glide.security.url.whitelist** system property is empty. If **glide.security.url.whitelist** is not empty, then only external URLs listed in that property are allowed.

Set **glide.security.url.whitelist.strict_check** to **true** or ensure that **glide.security.url.whitelist** is configured with the allowed external URLs to help secure your instance from open redirection attacks.

This property is applicable in the following cases:

- `/logout.do?sysparm_goto_url={External URL}`
- `/cms_login_redirect.do?sysparm_goto_url={External URL}`

Users are directed to an external trusted site after they log out of the instance:

- `/logout_redirect.do?sysparm_url={External URL}`
- `/saml_redirector.do?sysparm_uri={External URL}`
- `/logout_success.do?RelayState={External URL}`

When SAML is enabled, it invokes an identity provider (IDP) logout URL.

Ensure the property *glide.security.url.whitelist.strict_check* is set to true or the property *glide.security.url.whitelist* is set to a value.

More information

Attribute	Description
Property name	*glide.security.url.whitelist*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	To implement safe URL redirect during login, logout, or other redirects. This property mitigates one of the OWASP top 10 attacks called Invalidated Redirects and forwards.
Type	String
Default value	true
Recommended value	true

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Value	Your organization's approved URLs [Some Defined FQDN (Fully Qualified Domain Name) Ex. http://www.servicenow.com]
Security risk rating	6.3
Functional impact	This remediation enforces validation on logout page. It might have a functional impact on a user of an instance with an SSO/SAML configuration.
Security risk	(High) Client-side open redirection can enable attacker to redirect victims/users to attacker-controlled website and is viewed as a security risk.
References	Multi-SSO (SAML 2.0) errors and fixes

To learn more about adding or creating a system property, see Add a system property.

Escape Excel Formulas [Updated in Security Center 1.3]

Use the *glide.export.escape_formulas* property to prevent Excel Injection, also, known as formula injection.

Prevent potentially malicious formulas in programs such as Excel from being executed after exporting and opening the file by escaping formulas in these files. Excel injection occurs when websites embed untrusted entries inside Excel files. When you use a spreadsheet application such as Microsoft Excel, or LibreOffice Call, to open a file, any cells starting with +, -, =, or @ are interpreted as a formula unless properly escaped. Malicious formulas pose a risk even when the spreadsheet doesn't contain any sensitive information, as they can be used to compromise the viewer's computer through code execution.

Set the **glide.export.escape_formulas** system property to **true** to escape these formulas from executing.

More information

Attribute	Description
Property name	*glide.export.escape_formulas*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	To prevent application against the Excel or formula injection.
Recommended value	true
Default value	false
Security risk rating	6.4
Functional impact	Maliciously crafted formulas can be used for hijacking the user's computer by exploiting vulnerabilities in the spreadsheet software.
Security risk	(Moderate) Malicious formulae pose a risk even when the embedding spreadsheet doesn't contain

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	any sensitive information, as they can be used to compromise the viewer's computer.
Workaround	As an alternative consider stripping all trailing white spaces where possible, and limiting all client-supplied data to alpha-numeric characters.
References	Available system properties

To learn more about adding or creating a system property, see Add a system property.

Escape HTML in list views [Updated in Security Center 1.3 and 1.5]

Use the *glide.ui.escape_html_list_field* property to force HTML escapes for HTML fields in a list view.

Set *glide.ui.escape_html_list_field* to **true** to prevent HTML from being rendered in HTML fields in list view. Leaving HTML sanitization inactive platform wide (via system property) or by field (via a schema attribute), may lead to XSS style attacks. XSS attacks may allow a low privileged user to hijack the session of a high privileged user or interfere in standard web application behaviors, including redirects or defacement.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It's non-revertible.

More information

Attribute	Description
Property name	*glide.ui.escape_html_list_field*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	To help prevent application against cross-site scripting attacks
Recommended value	true
Default value	true
Security risk rating	3.1
Functional impact	This remediation enforces HTML encoding to occur on the UI at the HTML parser level and thus renders back encoded results to the user. It can have a functionality impact based on the instance user interaction with the resulted data.
Security risk	(High) Input validation must occur on the application to defend against cross-site scripting attacks. These attacks enable foreign scripts to execute on user sessions in the logged in browser's context. Attackers can use it to steal session information and sensitive data.

To learn more about adding or creating a system property, see Add a system property.

Escape JavaScript [Updated in Security Center 1.3]

Use the *glide.html.escape_script* property to force escape from JavaScript (`<script></script>`) tags in HTML fields during list views.

The glide property *glide.html.escape_script* helps sanitize HTML fields. If *glide.html.escape_script* is not set to the recommended value of true, then inputs will not be sanitized for HTML fields (output encoding) from a backend Java context by removing embedded JavaScript. Javascript in HTML fields can lead to stored and reflected XSS. The ability to have XSS can lead to easily attained privilege escalation to higher roles such as admin where more lateral movement can be taken.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.html.escape_script*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	To prevent cross-site scripting attacks against an application.
Recommended value	true
Default value	true
Security risk rating	8.8
Functional impact	This remediation enforces JavaScript escaping to occur on the UI and renders encoded results to the user. It can have an impact on functionality, based on the instance user interaction with the resulting data
Security risk	(High) Input validation must occur in the application to defend against cross-site scripting attacks. These attacks enable foreign scripts to execute on user session in the logged in browser's context. Attackers can use it to steal session information and sensitive data.

Escape jelly script [Updated in Security Center 1.3 and 1.5]

Use the *glide.ui.escape_all_script* property to force escape of all scripts injected into Jelly.

This property escapes all the JS and HTML strings included in <j:jelly> ... </j:jelly> before they are written to the output stream, preventing several XSS issues from occurring. If *glide.ui.escape_all_script* is not set to the recommended value of true, then escaping of scripts injected into Jelly is disabled. Without this mitigation, the platform becomes widely open to a variety of script injection attacks. An attacker could execute arbitrary Rhino scripts on the instance.

Warning:
Be careful when using these tags. If user input is displayed here it can open a security vulnerability.

More information

Attribute	Description
Property name	*glide.ui.escape_all_script*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Category	Validation, sanitization, and encoding

Purpose	If the property is not set to **true**, developers have to perform several steps on each custom Jelly script to prevent XSS issues. These steps include locating the Jelly variables being sent to output stream to render on web pages, and performing escaping on each of the following tags:
	`$â {JS:expression}`
	`$â {HTML:expression}`
	OR
	`$â {JS,HTML:expression}`

Recommended value	true
Default value	true
Security risk rating	7.3
Functional impact	This remediation enforces Jelly escaping at the parser level. It can have a functionality impact on user interaction with the resulting data.
Security risk	(High) Input validation has to occur on all the user input being entered on the application. By doing so, injection attacks against the platform can be defended and protected.
Workaround	The UI may be affected because some of the scripts and HTML tags designed for rendering on a web page

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	may appear broken. This remediation sends the output encoded page to the browser to render. For example, instead of `'my string here'`, it might display `'<u>my string here</u>` as the `<u>` tag was properly escaped. In this case, to prevent escaping, add the NOESC prefix to Jelly expression to prevent JS escaping. For example: • Before: ($[jvar_context_menus]); • After: `($[NOESC:jvar_context_menus]);` • Before: $[jvar_ui_policy_scripts] • After: `$[NOESC:jvar_ui_policy_scripts]` **⚠ Warning:** Be careful when using these tags. If user input is displayed here it can open a security vulnerability.

Escape scripts in scratchpad [Updated in Security Center 1.3]

Learn how scratchpad factors into the security posture of your instance and how to manage it so that malicious scripts can't be executed on it.

The scratchpad is an easy way to set information on the server that you can access in the browser. An admin can script anything to be on it, including arbitrary records. If this property is not set to the recommended value of **true**, then it is possible to execute malicious scripts like a cross-site scripting vulnerability.

More information

Attribute	Description
Configuration name	*glide.ui.escape_scratchpad*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 6.5 • CVSS score: Medium

Attribute	Description
	• Security risk details: If the property is not set to the recommended value of **true**, then it is possible to execute malicious scripts like a cross-site scripting vulnerability.
Dependencies and prerequisites	None
References	Workflow administration

Escape XML markup [Updated in Security Center 1.3]

Use the *glide.ui.escape_text* property to force escape of XML values at the parser level before transmitting them to the client's browser.

Cross-site scripting occurs when an attacker injects malicious JavaScript into an entry point. The platform/application fails to escape the malicious JavaScript before transmitting it to the victim's browser for execution. Escaping in this context means the following:

- **&** --> `&`
- **<** --> `<`
- **>** --> `>`
- **"** --> `"`
- **'** --> `'`
- **/** --> `/`

Example: `<script>alert('XSS Attack');</script>`

Escaping: `<script>alert('XSS Attack');</script>`

Ensure the *glide.ui.escape_text* property exists in the sys_properties table and is set to true.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.ui.escape_text*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	Escaping XML ensures that browsers do not parse the malicious JavaScript embedded in untrusted data, and execute it as JavaScript.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
	• A malicious user may try XSS attack to either hijack other users' session or redirect the user to a malicious website. • The NOW Platform contains code to secure cookies, but escaping it relies on this property being set to **true**.
Recommended value	true
Security risk rating	8.8
Functional impact	This remediation enforces XML encoding at the XML parser level on the UI. It renders the encoded results for the user, which can have a functionality impact based on the instance user interaction with the resulted data.
Security risk	(High) Input validation must occur on the application to defend against cross-site scripting attacks. These attacks enable foreign scripts to execute on user session in the logged in browser's context. Attackers can use it to steal session information and sensitive data.

Workaround	After you set this property to **true**, rendering stops on the HTML tags in the catalog item description or in the catalog item variable help text. You may not be able to use HTML formatting for some fields.
	However, if the *glide.ui.escape_text* property is turned of, all JEXL expressions would be prefixed with an output encoder:
	`${JS:expression}`
	`${HTML:expression}`
	or
	`${JS,HTML:expression}`

Escape xml response

Manage how XML escapes are handled on your instance.

Use this property to manage if XML responses are escaped. If the property is set to the recommended value of **false**, then XML responses will not be escaped which can lead to XML injection attack. The injection of unintended XML content into an XML message can alter the intended logic of an application.

More information

Attribute	Description
Configuration name	*glide.soaprequest.unescape_xml_response*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	Boolean
Recommended value	false
Default value	false
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 6.4 • CVSS score: Medium • Security risk details: Setting this property to **false** disables XML escaping, which could lead to XML injection attack.
Dependencies and prerequisites	None

Enable HTML Sanitizer [Updated in Security Center 1.3]

Use the *glide.html.sanitize_all_fields* property to enable the HTMLSanitizer script include, which sanitizes HTML input based on exclusion listed and inclusion listed attributes configured in a script.

The field types available with dictionary/fields include HTML and Translated HTML. These HTML input fields enable users to write HTML formatted input, for example:

`<h1>Test</h1>`, using the most basic HTML tags such as `<img>`, `<a href ...>`, and `<iframe>`.

It can open a door for a malicious attacker to inject malicious vector with HTML tags such as:

`[<IMG SRC=" &#14; JavaScript:alert('XSS');">][<IMG onmouseover="alert('xss')">],[a href="" onclick=alert(/xss/)]`.

More information

Attribute	Description
Property name	*glide.html.sanitize_all_fields*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	Prevents application against cross site scripting and HTML injection attacks
Recommended value	true
Default value	true
Security risk rating	8.8
Functional impact	This remediation enforces HTML-output encoding mechanism before the user data is rendered back to the user. If customer has any customization that involves rendering of the HTML attribute or content data, then there is a functionality impact.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	(High) User input should be securely treated when the data is being stored and processed on the application.This reduces client-side cross-site scripting attacks by output encoding the data.
Workaround	This property sanitizes all HTML fields in the system. If you must enable HTML sanitization on individual fields, see Enable sanitization on individual fields. You can also configure the inclusion list or exclusion list to sanitize HTML tags and attributes as per your organizations policy.
References	Enabling HTML sanitizer HTML sanitizer

To learn more about adding or creating a system property, see Add a system property.

Restrict allowed Java packages [Updated in Security Center 1.3]

Configuring these properties protect from dangerous APIs being exposed to the scripting engine.

Configure the system tables and install the recommended plugin accordingly.

If the *sys_whitelist_member* and *sys_whitelist_package* table are not empty values, then dangerous APIs may be exposed to the scripting engine. Entries correspond to the Java namespace that have not been approved by ServiceNow security teams.

Install the Packages call removal tool. See Packages call removal tool for details.

Contact Customer Service and Support to edit these tables.

More information

Attribute	Description
Table, plugin name	Tables: • *sys_whitelist_member* • *sys_whitelist_package* Plugin: com.glide.script.packages_call_removal
Configuration type	Tabular Configuration, Plugins
Category	Validation, sanitization, and encoding
Purpose	Protect from dangerous APIs being exposed to the scripting engine.
Recommended value	Empty
Default value	None. This is a table configuration and not a Glide Property, so there is no default value.
Configuration type	table list, plugin

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Security risk	(High) Dangerous APIs may be exposed to the scripting engine. These supported APIs will likely introduce instability and insecurity within the instance.
Security risk rating	8.2

To learn more about adding or creating a system property, see Add a system property.

Packages call removal tool

Activate and run the Packages Call Removal Tool (*com.glide.script.packages_call_removal*) plugin, and then consider whether each of the proposed changes should be completed or rejected.

The Packages Call Removal Tool is a plugin that:

- Scans scripts for package calls to ServiceNow AI Platform Java classes.
- Proposes changes to replace them with preferred GlideScriptable names.
- Facilitates the script changes.

Note:
If this record is a base system record, using the recommendation from the tool causes the item to be marked as customer_update. However, it may still be useful to use this tool because it flags Packages,xxx calls.

The Packages Call Removal Tool might report some package calls used in `sa_mapping_ext_commands` and `sa_custom_operation`. These package calls belong to the MID Server. As there are no classes, the code runs in MID Server. If you find any of the following listed package calls in the Errors section, mark them as Rejected (Ignored). The tool doesn't report that package call again.

- `Packages.com.snc.sw.util.JSONUtil.toJSONPlain(file_content);`
- `Packages.com.snc.sw.util.JSONUtil.toJSONPlain(file_name);`
- `Packages.com.snc.sw.commands.HttpCallHandler;`
- `Packages.com.snc.sw.dto.ProviderType.SSH`

More information

Attribute	Description
Plugin Name	com.glide.script.packages_call_removal
Configuration type	System Definition > Plugins
Purpose	To remove/replace unauthorized package/member calls with Glide Acceptable (GlideScriptable) names that only allow authorized access to data.
Recommended value	Active
Functional impact	This remediation would replace the package calls with *GlideScriptable* APIs, and can affect the customizations that include package calls. The tool doesn't actually replace package calls automatically. Instead, it provides suggestions that are stored into the packages_call_item table. Your administrator can

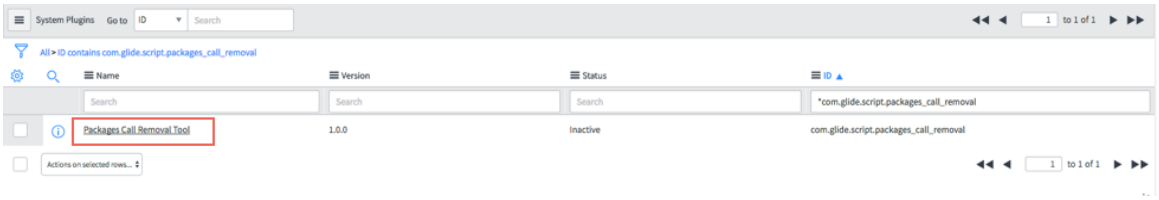
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

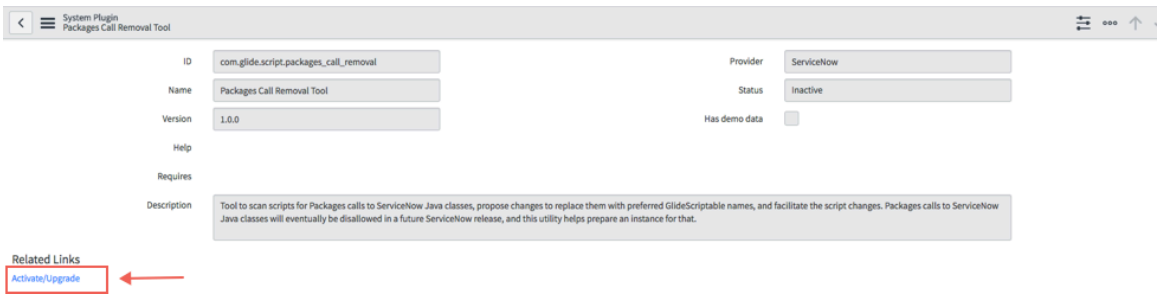
Attribute	Description
	then decide whether to accept or reject the proposed change.
Security risk	(Medium) Client-side API calls that result in data retrieval or object access on server are deemed to be dangerous from a security standpoint. They should be validated for authorization and restriction for sensitive object access.

Steps to configure

1. Navigate to **System Definition** > **Plugins**

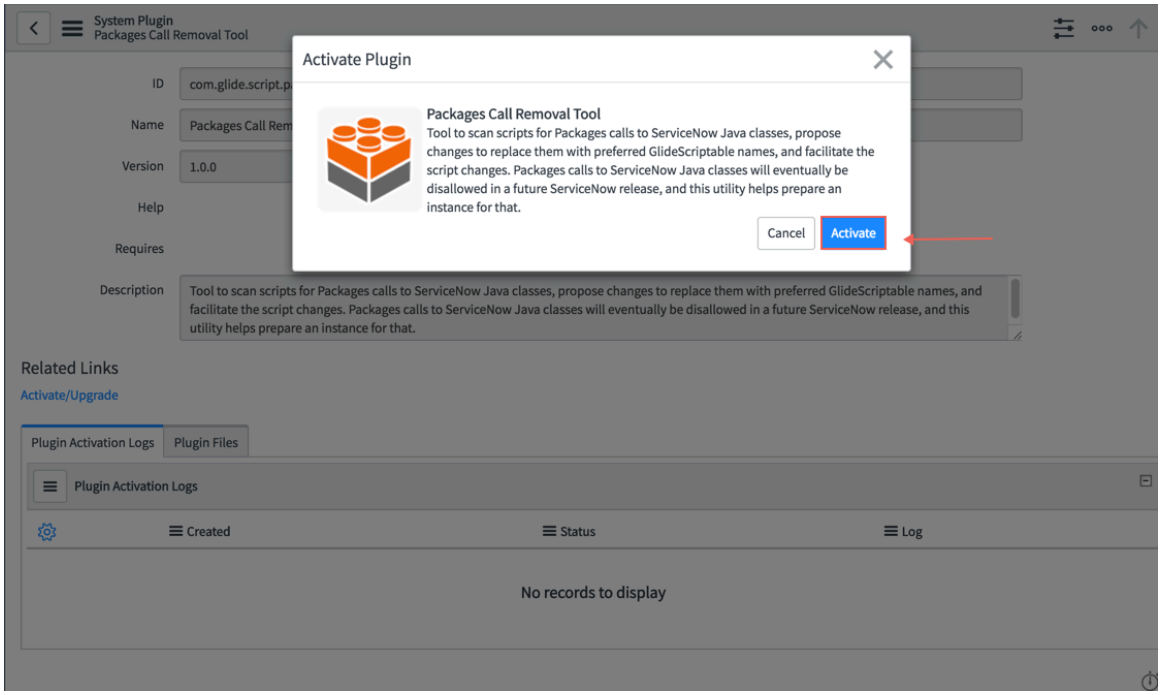


2. Search for the plugin ID = *com.glide.script.packages_call_removal*.



3. Click **Activate/Upgrade** to activate the plugin.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



4. To check inclusion list package calls and inclusion list member calls, complete the actions outlined in the Steps to Configure sections in Restrict allowed Java packages [Updated in Security Center 1.3].

Unset LDAP Initial distinguished name [Updated in Security Center 1.3 and removed in 2.0]

Use this property to manage the distinguished name of a LDAP Server record.

This property controls the distinguished name of a LDAP Server record which is inserted when running an out-of-the-box (OOB) fix script. If it is set to the recommended value of "" or blank, then LDAP server data can be enumerated by a lower privilege user.

More information

Attribute	Description
Configuration name	*glide.ldap.initial.dn*
Configuration type	System Properties (/sys_properties_list.do)
Data type	string
Recommended value	blank
Default value	blank
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 2.7 • CVSS score: Low • Security risk details: Setting the property value to "" or blank could make LDAP server data accessible to a lower privilege user.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.

Attribute	Description
Dependencies and prerequisites	None

Enforce strict security of session cookies [Updated in Security Center 1.3]

Use the *glide.ui.secure_cookies* property to require properly formatted cookies

When you set the property is to true, your instance will reject a session if the associated cookie is not in the expected format.

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.ui.secure_cookies*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	To achieve more secure session authentication.
Recommended value	true
Default value	true
Security risk rating	8.8
Functional impact	When the property is set to true, improperly formatted cookies are rejected. When such a cookie is rejected, the user must login again.

To learn more about adding or creating a system property, see Add a system property.

Minimize Entity Expansion Threshold for GlideXMLUtil Scriptable [Updated in Security Center 1.3, 1.5, and 2.0]

Use the *glide.xmlutil.max_entity_expansion* property to change the maximum entity expansion limit to a smaller number.

This property controls the maximum amount of entity expansion within an XML Parser. If *glide.xmlutil.max_entity_expansion* is not set to the recommended value of 3000 or less, then the GlideXMLUtil parsing scriptable may be vulnerable to denial of service attacks.

Ensure the property *glide.xmlutil.max_entity_expansion* is set to 3000 or less. If the instance is on Washington or later, the default implied value is 3000 if the sys_properties record does not exist. If the instance is not on Washington or later, the recommendaiton is for the instance admin to create a sys_properties record with name *glide.xmlutil.max_entity_expansion* and the value 3000.

Note:
500 is the default minimum imposed by the ServiceNow AI Platform, which is considered to be a safe threshold.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Property name	*glide.xmlutil.max_entity_expansion*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	This remediation control must be enabled to defend against XML Entity Expansion/Billion Laugh attack.
Recommended value	3000
Default value	100000
Security risk rating	5.3
Functional impact	If the customization is using large entity expansion, then, the ServiceNow AI Platform might block further processing.
Security risk	(Moderate) An attacker can use this vulnerability to expand data exponentially, quickly consuming all system resources.

To learn more about adding or creating a system property, see Add a system property.

Prevent Empty ACL Creation [New in Security Center 2.0]

Set the *glide.security.empty_acl.popup_window.enabled* property to the secure value of true to block attempts to create, update, or save an invalid ACL. This setting will also provide a client-side model to configure a role or security attribute for the ACL.

The *glide.security.empty_acl.popup_window.enabled* property determines whether users making form-based edits to access control lists (ACLs), specifically sys_security_acl, can create, update, or save an invalid ACL that has an invalid data condition, script, security attribute, or roles list. Otherwise, it remains unconfigured (an empty ACL). As of the Xanadu release, any empty ACL will deny access. In ServiceNow versions prior to Xanadu, an empty ACL will permit unconditional access.

When the *glide.security.empty_acl.popup_window.enabled* property is set to the secure value of true, it blocks attempts to create, update, or save an invalid or empty ACL, and provides a client-side model to configure a role or security attribute for the ACL. If the property is set to the unsecure value of false, then such attempts will be permitted, and no client-side model will be displayed.

Note: This property is case-sensitive. For example, a value of True (capital "T") will be evaluated as false. Moreover, this property only functions when the High Security (com.glide.high_security) plugin is installed and active.

More information

Attribute	Description
Configuration name	*glide.security.empty_acl.popup_window.enabled*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Data type	string
Recommended value	true
Default value	true
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 6.5 • CVSS score: Medium • Security risk details: If this property is set to true, the empty ACL warning popup will prevent the user from submitting an empty ACL on the client side. If it is set to false, the popup will no longer show.
Dependencies and prerequisites	None
Functional impact	This property allows the user to toggle the empty ACL warning popup on and off.
References	Prevent Empty ACL Creation [New in Security Center 2.0]

Define restricted downloadable MIME types [Updated in Security Center 1.3, 1.5, and 2.0]

Use the *glide.ui.attachment.force_download_all_mime_types* property to download MIME types and not to render inline in the browser.

If *glide.ui.attachment.download_mime_types* does include dangerous MIME types such as text/html, image/svg ,image/svg+xml,application/xml, then dangerous files could be rendered inline in the browser, which could lead to Cross Site Scripting attacks (XSS). This property is the list of comma-separated attachment mime types, which won't render inline in the browser. For example, including text/html forces HTML files to be downloaded to the client as attachments rather than viewed inline in the browser. Maintaining this list properly prevents cross-site scripting attacks.

If the *glide.ui.attachment.download_mime_types* system property doesn't include dangerous MIME types such as "text/html, image/svg,image/svg +xml,application/xml", then dangerous files could be rendered inline in the browser. This can lead to Cross Site Scripting (XSS) attacks. This check is only relevant when *glide.ui.attachment.force_download_all_mime_types* is set to **false**.

This property is a list of comma-separated attachment MIME types, which don't render inline in the browser. For example, including `text/html` forces HTML files to be downloaded to the client as attachments rather than viewed inline in the browser.

If *glide.ui.attachment.force_download_all_mime_types* is set to **false**, verify that the *glide.ui.attachment.download_mime_types* system property includes the dangerous MIME types `text/html`,`image/svg`,`image/svg+xml`,`application/xml`.

More information

Attribute	Description
Configuration name	*glide.ui.attachment.force_download_all_mime_types*

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Configuration type	System Properties (/sys_properties_list.do)
Data type	String (Comma-separated list of MIME types)
Recommended value	text/html,image/svg,image/svg+xml,application/xml
Default value	text/html,image/svg,image/svg+xml,application/xml
Fallback value	text/html,image/svg,image/svg+xml,application/xml
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 6.3 • CVSS score: Medium • Security Risk: Maintaining this list properly can prevent cross site scripting attacks.
Dependencies and prerequisites	This check is only relevant when *glide.ui.attachment.download_mime_types* is set to **false** or doesn't exist in the System Properties [sys_properties] table.

Restrict uploaded MIME types [Updated in Security Center 1.3 and 2.0]

Use the *glide.security.file.mime_type.validation* property to activate MIME type checking for uploads. You can enable (set the property to **true**) or disable (set it to **false**) MIME type validation for file attachments.

Prerequisites

Before setting this property, set the *glide.attachment.extensions* property. Only those extensions specified in *glide.attachment.extensions* are checked for MIME type during upload. To learn more, see Restrict file extensions.

Ensure the Glide Property *glide.ui.jelly.js_interpolation.protect_nested_expressions* exists and is set to the value true. If the property does not appear in the sys_properties table, add a new record.

More information

Attribute	Description
Property name	*glide.security.file.mime_type.validation*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	To enforce checking of MIME type / magic bytes during file uploads.
Recommended value	true
Default value	true
Security risk rating	5.4

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attribute	Description
Functional impact	This remediation enables MIME type verification on the attachments to the application. No functionality impact, unless there is a malicious intent in uploading the files as this validation is merely checking for mis-sync between the MIME type and the data.
Security risk	(Medium) To reduce vulnerabilities such as file inclusion and malicious file uploads, MIME type verification should be enabled.
References	Administering attachments

See Hardening settings for details on configuring properties for hardening.

To learn more about adding or creating a system property, see Add a system property.

Restrict XML external entities [Updated in Security Center 1.3 and 2.0]

Configure system properties to ensure that your instance only processes XML from trusted sources to help prevent XML external entity (XXE) attacks.

Use the *glide.xml.entity.whitelist* and *glide.xml.entity.whitelist* system properties to prevent your instance from processing XML from untrusted sources.

XML external entity (XXE) attacks occur when a malicious actor modifies incoming XML (such as adding HTTP requests) to access data or intact with otherwise restricted systems. To help prevent these attacks, the *glide.xml.entity.whitelist.enabled* system property limits the sources from which your instance executes XML. Use the *glide.xml.entity.whitelist* property to define a set of trusted sources.

Ensure that the *glide.xml.entity.whitelist* system property exists in the System Properties [sys_properties] table, and is set to `http://java.sun.com/j2ee/dtds/`. Ensure that the *glide.xml.entity.whitelist.enabled* system property exists in the System Properties [sys_properties] table and is set to the value `true`.

Tip:

Values other than `http://java.sun.com/j2ee/dtds/` can be included in the *glide.xml.entity.whitelist* property, but are unnecessary for the out of the box platform state. Review any additional values to determine if they are safe.

Warning:
s a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Configuration name	• *glide.xml.entity.whitelist* • *glide.xml.entity.whitelist.enabled*
Configuration type	System Properties (/sys_properties_list.do)

© 2026 ServiceNow, Inc. All rights reserved.

Attribute	Description
Data type	• String • Boolean String
Recommended value	• http://java.sun.com/j2ee/dtds/ • true
Default value	• http://java.sun.com/j2ee/dtds/ • true
Fallback value	• http://java.sun.com/j2ee/dtds/ • true
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 9.8 • CVSS score: Critical • Security risk details: An XML Eternal Entity (XEE) attack can allow attackers to access data or perform unauthorized actions via crafted XML payloads.
Functional impact	If the customization is using external entity, not inclusion listed in the *glide.xml.entity.whitelist* property, the NOW Platform might block further processing.
Dependencies and prerequisites	None

Require XMLdoc2 entity validation with allowlistDisable entity expansion [Updated in Security Center 1.3]

If customizations do not require entity expansion, use the *glide.xmlutil.max_entity_expansion* property to completely disable external entity expansion. The XML completes parsing but doesn't include any internal or external entities.

If the glide property *glide.stax.whitelist_enabled* doesn't exist in the System Properties [sys_properties] table, or is not set to the recommended value of **true**, then all external entities are allowed when the glide property *glide.stax.allow_entity_resolution* is set to the value of **true**.

If customizations don't require entity expansion, use the *glide.stax.allow_entity_resolution* property to completely disable external entity expansion. The XML completes parsing but doesn't include any internal or external entities.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- If you set *glide.stax.allow_entity_resolution* to **true**, all external entities attempt to resolve or expand subject entities, subject to the setting of the *glide.stax.whitelist_enabled* property.
- If you set *glide.stax.allow_entity_resolution* to **false**, all entity resolution and expansion is blocked. To learn more about this property, see Disable Entity Expansion within the XMLDocument2 Streaming Parser [Updated in Security Center 1.5].

When **glide.stax.whitelist_enabled** is set to **true**, define a listing of comma-delimited FQDN in the **glide.xml.entity.whitelist** property, which are the only URLs that can be reached using the XML entity processing property. To learn more, see Restrict XML external entities [Updated in Security Center 1.3 and 2.0]. Attackers can use this vulnerability to expand data exponentially in an External Entities Expansion (XXE) attack, quickly consuming all system resources.

Prerequisites

Before setting this property:

- Set the *glide.xml.entity.whitelist.enabled* and *glide.stax.whitelist_enabled* properties to **true**. To learn more, see Restrict XML external entities [Updated in Security Center 1.3 and 2.0].
- Define a listing of comma-delimited FQDN in the *glide.xml.entity.whitelist* property, which is the only URLs that can be reached using XML Entity processing property. To learn more, see Restrict XML external entities [Updated in Security Center 1.3 and 2.0].

Warning:
This is a safe harbor property, meaning the value can't be altered once it's changed. It is non-revertible.

More information

Attribute	Description
Property name	*glide.stax.whitelist_enabled*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	This remediation control must be enabled to defend against an XML Entity Expansion/Billion Laugh attack.
Recommended value	true
Default value	false
Security risk rating	9.8
Functional impact	If the customization is using entity expansion, then, the ServiceNow AI Platform might block further processing.
Security risk	An attacker can use this vulnerability to expand data exponentially in an External Entities Expansion (XXE) attack, quickly consuming all system resources.
Workaround	If the customization requires entity expansion, set this property to true and follow the steps documented in Restrict XML external entities [Updated in Security Center 1.3 and 2.0].

For more information about OWASp resources, see OWASp.

Sanitize All Translated HTML Fields [New in Security Center 2.0]

Learn how to configure the *glide.translated_html.sanitize_all_fields* property to the secure value to ensure that all *translated_html* elements are sanitized with an HTML sanitizer.

When the *glide.translated_html.sanitize_all_fields* property is set to true, all *translated_html* elements are sanitized with an HTML sanitizer. If the property is set to false, only elements with the dictionary attribute *html_sanitize* set to true will be sanitized. This sanitization helps prevent attackers from embedding malicious content that could lead to cross-site scripting (XSS) attacks.

More information

Attribute	Description
Configuration name	*glide.translated_html.sanitize_all_fields*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 4.6 • CVSS score: Medium • Security risk details: Not configuring this property to the secure value of true, doesn't sanitize all HTML elements, which increases the likelihood of a bad actor embedding malicious content in a field.
Dependencies and prerequisites	None
Functional impact	Allows customers to access any table information if the widget is set to public and included in the property's value.

Sanitize HTML in the Description Fields of the Impact Workspace Module [New in Security Center 7.0]

Sanitize the HTML in the description fields by removing HTML tags that are sources of HTML injection attacks with the *sn_impact_common.blacklist_tags_HTML_injection* property.

The Impact Workspace module allows HTML in the following description fields:

- The customer_notes field of the sn_impact_common_capabilities_map and sn_impact_common_par_version_phase_app_mapping tables.
- The manual_description field of the sn_impact_common_manual_capability_description table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

When this system property contains a comma-separated list of HTML tags (for example, scripts), those tags and their contents are removed from the HTML portions of the listed fields. Removing these tags helps sanitize the HTML in the description fields by removing HTML tags that are sources of HTML injection attacks. If this property isn't set in the System Properties [sys_properties] table, the value defaults to a default list of denied HTML tags. If the property is empty, all HTML tags are allowed.

Use the *sn_impact_common.blacklist_tags_HTML_injection* provide a comma-separated list of HTML tags which are removed from the description fields for the Impact Workspace module. This removal helps to prevent HTML injection attacks. At minimum, this list should contain the contents of the default list. If the property isn't set in the System Properties [sys_properties] table, it defaults to the list `script,iframe,object,embed,form,onerror,onload,style,img,video,audio,source,b`

More information

Attribute	Description
Property name	*sn_impact_common.blacklist_tags_HTML_injection*
Configuration type	System Properties (/sys_properties_list.do)
Category	Validation, sanitization, and encoding
Purpose	Sanitize the HTML in the description fields by removing HTML tags that are sources of HTML injection attacks.
Recommended value	At minimum, the default value of `script,iframe,object,embed,form,onerror,onload,sty`
Default value	`script,iframe,object,embed,form,onerror,onload,sty`
Security risk rating	4.4
Functional impact	If an HTML tag is added to default list, it may limit the required HTML functionality of the description fields. The exact impact is dependent on the customer instance.
Security risk	(Medium)
References	High Security Settings

To learn more about adding or creating a system property, see Add a system property.

Set safe content security policy for svg files [New in Security Center 1.3]

The *com.glide.csp.self_script_src_svg* property adds the **script-src none** directive to the HTTP Content-Security-Policy header when Scalable Vector Graphics (SVGs) are accessed through the Translation Memory Index (IIX) file extension.

The *com.glide.csp.self_script_src_svg* property prevents malicious file attachments that stores cross site scripting (XSS) attacks from running in an instance. Without this policy, a bad actor could cause a user to run arbitrary JavaScript code in their web browser which could lead to security vulnerabilities such as data exfiltration and session takeover.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Configuration name	*com.glide.csp.self_script_src_svg*
Configuration type	System Properties (/sys_properties_list.do)
Data type	Boolean
Recommended value	true
Default value	true
Category	Validation, sanitization, and encoding
Security risk	• Severity score: 7.1 • CVSS score: High • Security risk details: Not setting this property to the recommended value of true could cause a user to run arbitrary JavaScript code from a bad actor.
Dependencies and prerequisites	None
Functional impact	This property prevents scalable vector graphics (SVG) files from accessing external scripts.

Log Export Service (LES)

Log Export Service (LES) lets you seamlessly export your instance system and application logs into your enterprise security analytic tools.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Troubleshoot and get help

- Ask or answer questions about Log Export Service (LES) in the ServiceNow Community
- Search the Known Error Portal for known error articles
- For cloning recommendations for LES, including tables to preserve and exclude, see Tables to be preserved to keep the LES configuration.

Exploring Log Export Service (LES)

The LES service provides a highly scalable and near real-time integration with your analytic tools that is easy to set up and maintain. If you're new to LES, read this overview section to learn what the tool can do.

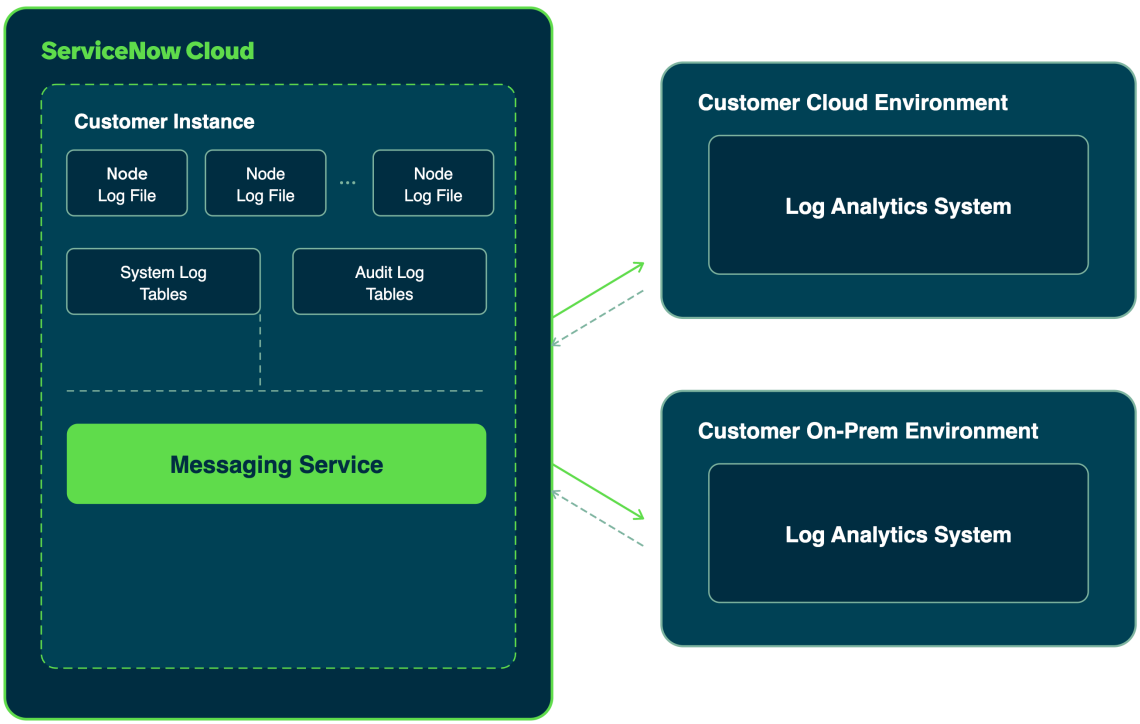
Check your entitlements to determine whether you have access to Log Export Service.

Log Export Service overview

The integration tool allows you to leverage your analytic solutions to perform the following:

- Detect ServiceNow security threats and analyze security incidents
- Troubleshoot and optimize ServiceNow app performance
- Monitor and optimize ServiceNow user experience

LES leverages a ServiceNow AI Platform capability called the Hermes Messaging Service, which is a multi-tenant, multi-cluster, data transport, and queuing service built on Apache Kafka that enables your instance to produce and consume large volumes of Kafka events. Apache Kafka is an open-source data streaming platform that provides a single integration point for exchanging data across business systems in your organization.



LES forwards a copy of the log events as they're generated to the Hermes Messaging Service.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

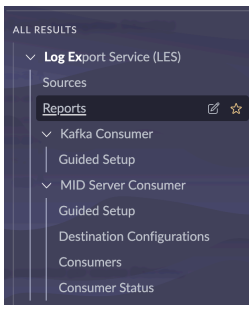
The Hermes Messaging Service is a multi-tenant, multi-cluster, data transport, and queuing service built on Apache Kafka that enables your instance to produce and consume large volumes of Kafka events. The Hermes Messaging Service is a ServiceNow AI Platform capability that is available as part of Stream Connect, Log Export Service (LES), and Instance Data Replication (IDR).

The external log analytic systems, either in the cloud or on-prem, can use and consume the log events from the Hermes Messaging Service. LES provides three connectivity options to consume the logs:

- Dedicated MID Server: A dedicated MID Server is installed on-prem or in the cloud that automatically connects to Hermes Messaging Service, pulls log events from it continuously and then pushes them to log analytic tools via a REST connection.
- Leverage Kafka connector from your log analytic solution (for example, Splunk): A Kafka connector from your log analytics product of choice is installed on-prem or in the cloud that automatically connects to Hermes Messaging Service, pulls log events from it continuously and then pushes them to log analytics tools.
- Directly from your Kafka system: Your Kafka system connect directly with the Hermes Messaging Service and use its native Kafka protocol commands and connectivity to pull logs events from it.

Note:
If your Kafka message exceeds the configured memory buffer, Hermes may return an error indicating that it's larger than the total memory buffer you've configured.

To configure and manage LES you need to install it from ServiceNow Store. The LES application provides Guided Setups to help you install the service, pages to configure the service (log sources, consumers and destinations) and reports to understand log creation and consumption.



Note:
You can also create a new source configuration. See Create a log source configuration for more information.

Log Export Service users

Log Export Service has the following users.

Users	Description
Application admin [sn_logstoanalytics.admin]	This role is installed along with the LES application and allows a non-admin to use the application.
System administrator [admin]	Admin role is required for the setup of the LES store application.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Log Export Service benefits

Benefit	Feature	Users
Create log source configuration to set filters on the logs	Create a log source configuration	Application admin
Experience guided setup for Kafka consumers	Guided setup for Kafka consumers	System administrator
Experience guided setup for MID server consumers	Guided setup for MID Server consumers	System administrator
Examine the log report dashboard to analyze the size of each data log	Review log report	System administrator or Application admin

What to explore next

To learn more about using Log Export Service, see:

- Administering Log Export Service (LES)
- Configuring Log Export Service (LES)
- Using Log Export Service (LES)
- Log Export Service (LES) references

Log sources

Log Export Service (LES) can export log sources from some System Log Tables, the Audit Table, and Application Node Log Files.

The following are the log sources that can be exported by LES.

- System Log Tables
  - syslog table: View warnings and errors for instance processes, records, and non-critical events, such as memory usage on the server machine
  - syslog_transaction table: view all browser activity for an instance
  - sys_outbound_http_log table: view all requests and responses for outbound web services such as REST and SOAP
- Audit Table: Use the sys_audit table view record changes made to tables chosen to be audited
- Application Node Log Files: Use the localhost log files to view application node errors. Your instance will have multiple nodes and each node will have multiple log files.

See System logs to learn more about the schema and purpose for the above log sources.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
LES forwards logs exclusively when they are generated through the logging framework. The following are the two sources for which logs are not getting forwarded:

Source name	Reason
datacollector	Data is inserted directly into the syslog child table, which causes it to appear in the syslog table as well. However, this bypasses the logging framework, so the records reach the syslog table but are not forwarded to the topic.
com.glide.ui.ServletErrorListener	Logs are inserted into the syslog table using the NoBroadcast logging variant, where the broadcast flag is set to false. In this mode, logs are written to syslog but are not forwarded to external consumers because they do not pass through the logging framework.

Administering Log Export Service (LES)

Use LES to create log source configuration and multi-topics for each source type.

Create a log source configuration

Regulate and set filters on the logs to be forwarded by creating a log source configuration.

Before you begin
Role required: admin or sn_logstoanalytics.admin

Procedure

1. Navigate to **All** > **Log Export Service**.
   A list of source configurations shows up.
2. Select **New** if you want to create a new source configuration.
   You can also select an existing source configuration if you want to modify it.
   The Source form shows up.
3. On the form, fill up the fields.

Source form

Fields	Description
Source Type	Types of log sources ○ Node Log ○ Table See Log sources for more information.
Log Level	A set of standard logging levels that can be used to control logging output. Following convention, each level will forward logs of equal or greater severity.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Fields	Description
	Note: This field is visible only when one of the following conditions is met. ○ When you select Node Log as the Source Type ○ When you select Table as the Source Type and the table is syslog
Accepts	Specifies the format in which the logs are forwarded to Hermes. They can either be sent as JSON or as plain text.
Table	Selection of table for table type logs. **Note:** This field is visible only when you select Table as the Source Type.
Filter Type	Conditions to forward logs selectively. **Note:** This field is visible only if you select either syslog or sys_audit as the table.

4. Review the Source Topics related list details.
   You can review each of the log tables and can create its own topics.

   Note:
   The related list is visible only if you select Log Table in the Filter Type field.

   The topic name is not auto-populated, and you can either select or create its own topics.

5. Select a topic for the log table.

   You can either select an existing topic or can create a new topic for a log table.

   a. Select **New** to create a new source topic for a log table. The Source Topics form shows up.
   b. Select the required table in the Log Table field.
   c. Select the lookup icon in the Topic field.

      Note:
      You can select an existing topic from the list. You can also create a new topic by selecting **New** in the Kafka Topics list. See Create source type and multi topics in the LES source table to create a new Kafka topic.

   d. Select **Submit** on the Source Topics form.

6. View the recently created log table and its corresponding topic in the Source Topics related list.
7. Select **Submit** to create a new source configuration.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Create source type and multi topics in the LES source table

Consume logs for each source type by creating multiple topics per source type. You can now leverage the option of customized selection of specific topics for different log sources during the debugging process, without impacting the other log tables.

Before you begin

Note:
If you delete a Log Source, the corresponding topic in the sys_kafka_topic table is not deleted. If you create the Log Source again, the existing topic can be reused, ensuring continuity and avoiding unnecessary topic recreation.

Role required: admin or sn_logstoanalytics.admin

Procedure

1. Navigate to **All** > **Log Export Service (LES)** > **Sources**.
2. Click **New** to create a new source.
   The Source form shows up. Previously, the **Topic** field was auto-filled once the **Source Type** is selected. Starting Yokohama, each source type can create their own topic. It doesn't populate by default on selecting the **Source Type** or the **Table** name. They can be created either directly from the Kafka topics or from the reference field.

   Note:
   Since sys_audit table has multiple log tables, no specific topic is shown in the Topic column of the Sources list. Previously, all the source types had the same topic. Now you can select different topics for different sources.

3. Select the lookup icon to go to the list of Kafka topics.
   The list of Kafka topics shows up.
4. **Optional:** Create the new Kafka topic with the following steps.

   Note:
   This step is applicable only if you want to create a new topic for a selected Source Type.

   a. Select **New** to create a new Kafka topic for the selected Source Type. The Kafka topic form shows up.
   b. On the form, fill up the fields.

Source form

Fields	Description
Name	Name of the topic you are creating
Application ID	Enter sn_logstoanalytics
Namespace	Enter Default Namespace
Partition	The partition field of a topic in Hermes refers to the partitions into which the topic's data is divided. It plays a key role in scalability and parallelism

   c. Select **Submit** to create the new Kafka topic.
5. Select the **Source Type** you want to create for a particular topic.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

6. Select the required topic from the list for the selected **Source Type**.
7. Select **Submit** to create the source type with the particular selections.
   The source type shows up on the Sources list with the selected topic name and other information.

Configuring Log Export Service (LES)

Use guided setup to step through the initial configuration of LES. Guided setup assists you with planning the roll-out of the product and performing the basic configuration to go live.

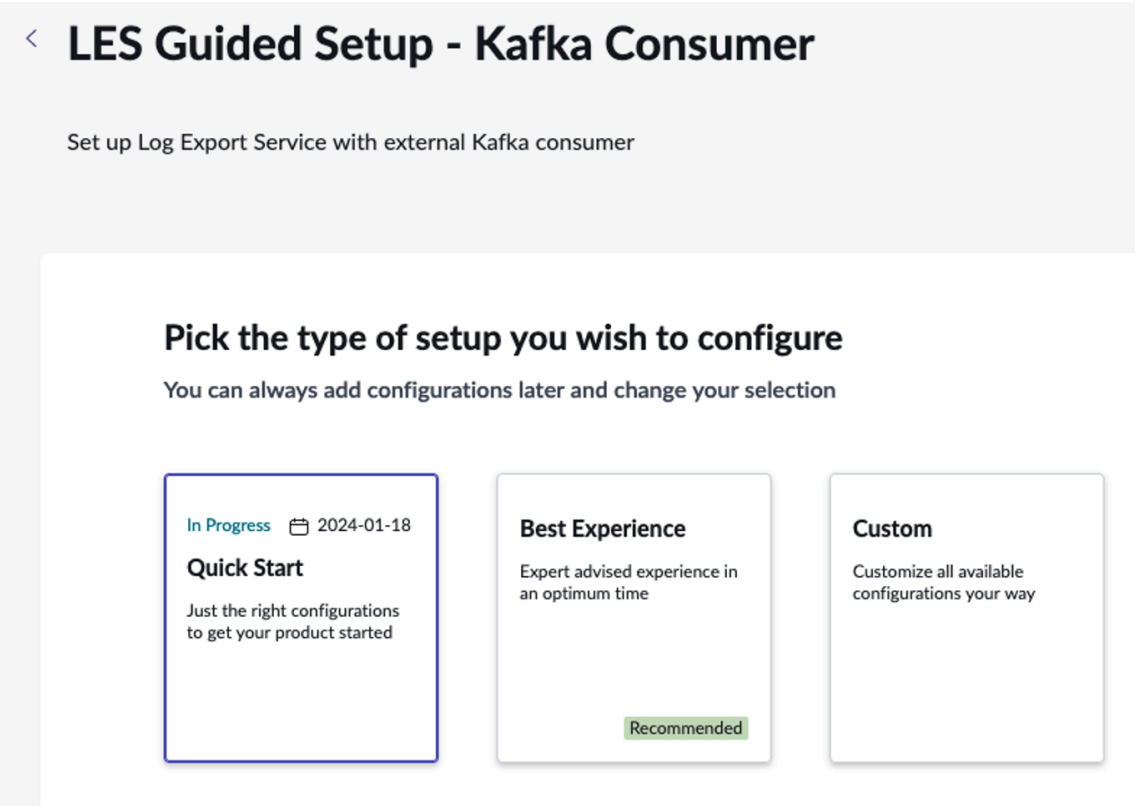
Guided setup organizes configuration activities into categories. Each category provides information, such as planning guidance, pre-setup steps, and links to useful help content. Categories also provide a set of links to the pages in your instance where you perform the configuration. The guided setup process keeps track of what you have completed, so you can stop and start again where you left off.

Kafka consumer

Use guided setup to step through the initial configuration of LES for Kafka consumers.

Guided setup home page

The home page for guided setup contains an overview of configuration types for your guided setup. You can select your guided setup type and select **Continue** to open the guided setup steps and begin configuration.



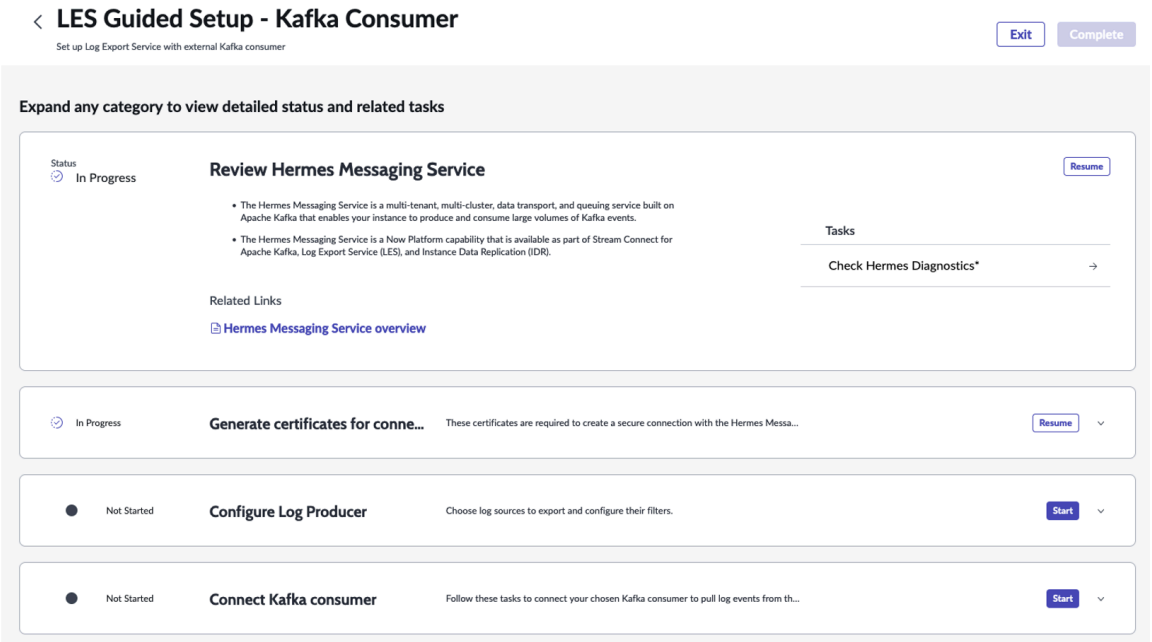
All three setups on this page, Quick Start/Best Experience/Custom provide the same tasks and functionality. It is required that to coordinate the integration between the ServiceNow instance and the destination log analytic tool with the respective administrator. The log analytic administrator must configure their tool to connect to the ServiceNow instance securely. It is recommended to share the Set up a secure connection to the Hermes Messaging Service

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

document with the log analytic administrator ahead of time. Even if you have marked a task as completed, you can go back and uncheck it back to in progress. To do so, first click on the **Edit** box in the upper right corner for the category. Then click on the **Edit** box for the task you want to uncheck. The **Mark as complete** box will no longer be marked.

Guided setup categories page

The categories page contains an overview and descriptions of the categories and associated tasks. You can click either the drop down arrow to view information about the category or the Start button to open the guided setup steps and begin configuration.



Complete the tasks under each category by following the setup instructions.

Guided setup for Kafka consumers

Implement the following steps for a complete guided setup for Kafka consumers.

Before you begin

Navigate to **Log Export Service (LES)** > **Kafka Consumer** > **Guided Setup**. Select the type of setup you wish to configure and select **Continue**.

> **Note:**
> During the Log Export Service application installation, ServiceNow will provision the underlying Hermes Messaging Service infrastructure. Be aware that this process can take up to a couple of hours to complete from the time you request the Log Export Service application installation.

Role required: admin

Procedure

1. Review Hermes Messaging Service Diagnostics.

   It is recommended that you verify that the Hermes Messaging Service is up and running with the Hermes diagnostic tool, which displays on screen during this step. If you see a "Page not found" error on this page, Hermes is not installed and you should contact your system admin.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Setup information: The following bootstrap information is used to connect to the Hermes Messaging Service. The "Producer Bootstrap" is the connection used to send messages into Hermes and "Consumer Bootstrap 1 & 2" are used to retrieve messages from Hermes.
  - Producer Bootstrap
  - Consumer Bootstrap 1
  - Consumer Bootstrap 2
- Instance PKI: The Instance Public Key Infrastructure (PKI) component allows a ServiceNow instance to act as an issuer in a X.509 trust hierarchy.
- Bootstrap Connectivity: Select **Run Test** to confirm external client is able to connect to the defined instance ports (producer and consumer).

  Note:
  Work with your network administrator to ensure that the following port ranges are open before you begin:
  - Consumer1: 4100-4150
  - Consumer2: 4200-4250

- Instance Connectivity: Select **Run Test** to confirm the instance is able to send and receive messages.
- View Topics: Select the listed topic to retrieve the timestamp of the last known message.

Note:
You can access Hermes Diagnostics in the future to troubleshoot potential connectivity issues by returning to this step of the guided setup or by navigating to **All** > *Hermes Messaging Service* > **Diagnostics**.

2. Generate certificates for a secure connection to Hermes Messaging Service and pull log events from it.

   You are going to use these certificates when connecting your external system.

   Setup secure connection to Hermes Messaging Service. See Set up a secure connection to the Hermes Messaging Service for LES for more information. You will need these certificates for authentication and authorization in the client which will pull the logs from Hermes.

   Note:
   admin or Hermes_admin roles are required for this step.

3. Configure Log Producer: Choose log sources to export and configure their filters. Complete the following tasks to configure the Log Producer.
   - Configure log sources to export: Create one Source record for each of the log sources that you want to export.

     Note:
     admin or sn_logstoanalytics.admin roles are required to complete this step

     a. Select **New** at the top right corner

     b. Select a Source Type

     c. Select a Table

     d. Select a Log Level that can be used to control logging output

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

e. Select or create a topic to which that log source will be exported. If you are creating a new topic, fill out the following fields:

- **Name**: Name of the topic you're creating
- **Application ID**: Enter `sn_logstoanalytics`
- **Namespace**: Enter Default Namespace
- **Partition**: The partition field of a topic in Hermes refers to the partitions into which the topic's data is divided. It plays a key role in scalability and parallelism.

f. Select a **Filter Type** condition to forward logs selectively.

> **Note:**
> Filters are different depending on the selected source type

g. Select Update
When successfully created, it will display the name of the Hermes topic to which that log source will be exported to. Write down the topic name, you will need it later when configuring your log consumer system.

The Active field controls whether or not that log source is going to be exported or not. If you see errors, go back to the Check Hermes Diagnostics task and verify Hermes status.

- Validate Log Producer: Once you have created a Source to produce logs from, you can see live log records in the topic using **Hermes Messaging Service** > **Hermes Topic Inspector**.

a. Select External Topics

b. Select List Topics

c. Select row with your topic from previous step (listed in Sources)

d. Adjust message start date if necessary

e. Select **View** to see a log message that was exported to the topic

4. Connect Kafka consumer: Follow these tasks to connect your chosen Kafka consumer to pull log events from the Hermes.
   - Identify Kafka consumer: You have two options based on your log analytics architecture.
     - If you have your own Kafka system and choose that for log aggregation, you can connect directly to the Hermes Messaging Service via the native Kafka protocol.
     - If you choose to have your log analytics tool connect directly to the Hermes Messaging Service then you need to deploy a Kafka connector supported by your log analytics system (i.e. Splunk Connect for Kafka).

     > **Note:**
     > In either case, you will need to work with the Administrator for those systems to coordinate the connection with the Hermes Messaging Service.

   - Import Hermes certificates to Kafka consumer system: Log into your Kafka consumer system and make sure you have appropriate admin entitlements to configure it and connect it to an external system. Import the certificates generated in "Set up secure connection to Hermes Messaging Service" task into your Kafka connector or Kafka server. Follow the instructions in the documentation for your chosen Kafka consumer.
   - Configure Kafka processes: The Hermes Messaging Service is designed for high availability. Two processes are required to consume messages from Hermes. Two processes are required because Hermes uses a pair of Kafka clusters for failover purposes. If one cluster goes down, data is produced to the other Hermes Kafka cluster.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

In your Kafka consumer system, you will need to create two separate consumer processes to connect to both Hermes Kafka clusters. For both processes you will specify the same Hermes Kafka topic but you will need to configure two separate bootstrap addresses:

- <instance_name>.service-now.com:4100,<instance_name>.service-now.com:4101,<instance_name>.service-now.com:4102,<instance_name>.service-now.com:4103
- <instance_name>.service-now.com:4200,<instance_name>.service-now.com:4201,<instance_name>.service-now.com:4202,<instance_name>.service-now.com:4203

Important notes:

- When accessing the Kafka topic from external systems, you must prepend “snc.<instance name>.” to the topic that the logs are being forwarded to.
- Configure each consumer with the same Kafka Consumer Group ID.
- Install your keystore and truststore files in a location where your consumers can access them.
- If your consumers require it, specify the Kafka JSON Converters properties to disable schemas: “key.converter.schemas.enable=false”, “value.converter.schemas.enable=false”

○ Verify Kafka consumer pulling logs from Hermes: Verify in your chosen Kakfa consumer that you can pull log events from the Hermes Messaging Service.

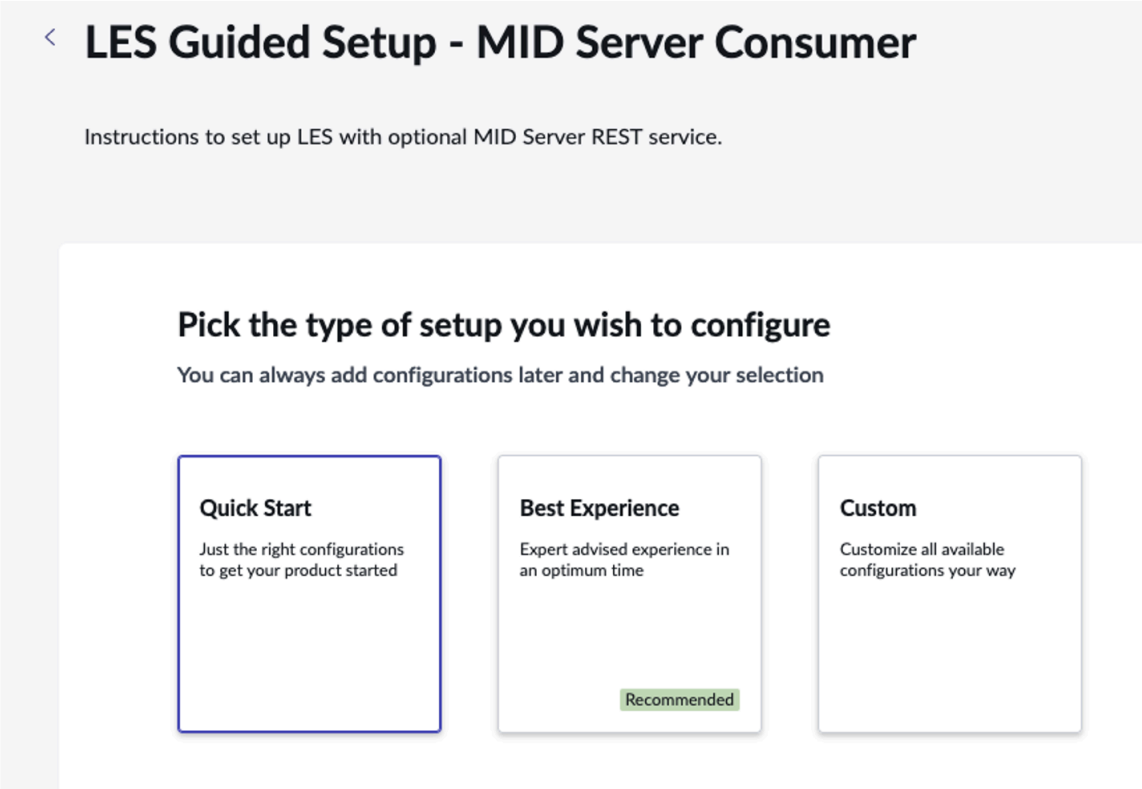
MID server consumer

Use guided setup to step through the initial configuration of LES for MID server consumer.

Guided setup home page

The home page for guided setup contains an overview of configuration types for your guided setup. You can select your guided setup type and select **Continue** to open the guided setup steps and begin configuration.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

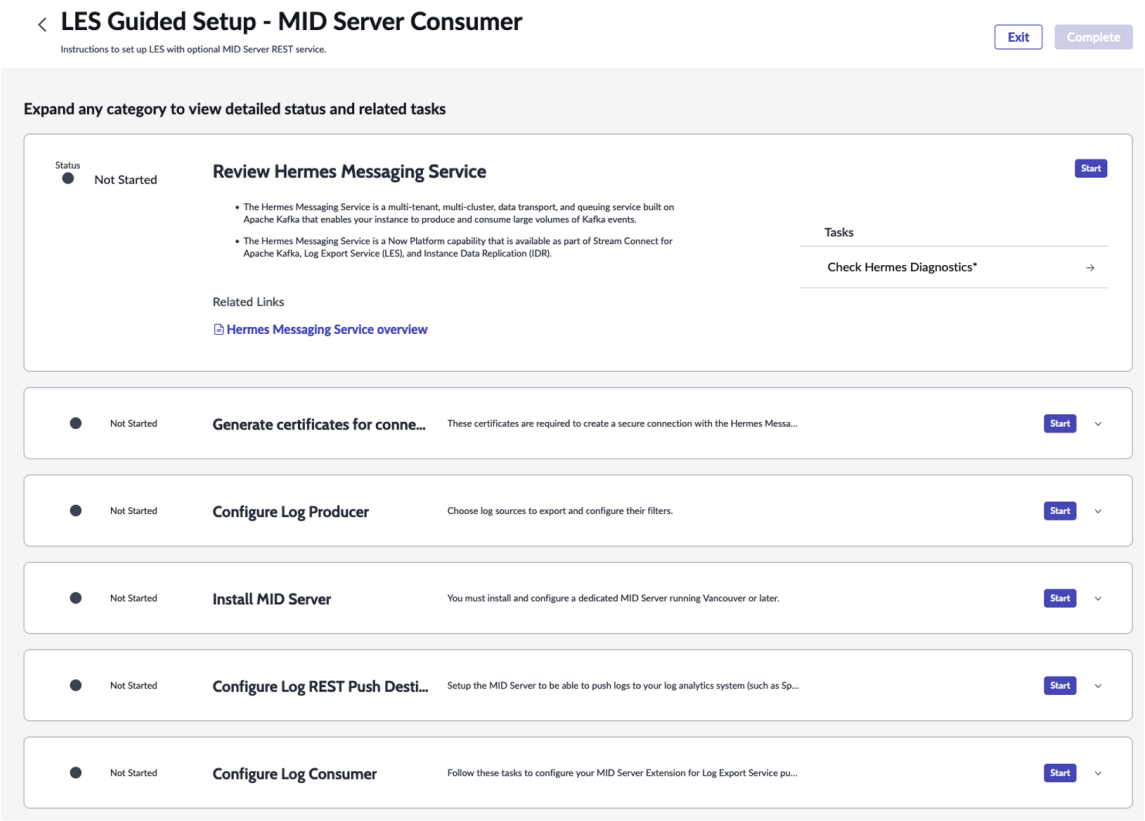


All three setups on this page, Quick Start/Best Experience/Custom provide the same tasks and functionality. A dedicated MID Server is required to continuously stream logs from your instance to your log analytic system. The MID Server needs a one-time setup to establish a secure connection to the Hermes Messaging Service. Even if you have marked a task as completed, you can go back and uncheck it back to in-progress. To do so, first click on the **Edit** box on the upper right corner for the category. Then click on the **Edit** box for the task you want to uncheck. The **Mark as complete** box will be no longer marked.

Guided setup categories page

The categories page contains an overview and descriptions of the categories and associated tasks. You can click either the drop down arrow to view information about the category or click **Start** to open the guided setup steps and begin configuration.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Complete the tasks under each category by following the setup instructions.

Guided setup for MID Server consumers

Implement the following steps for a complete guided setup for MID Server consumers.

Before you begin

Navigate to **Log Export Service (LES)** > **MID Server Consumer** > **Guided Setup**. Select the type of setup you wish to configure and select **Continue**.

> **Note:**
> During the Log Export Service application installation, ServiceNow will provision the underlying Hermes Messaging Service infrastructure. Be aware that this process can take up to a couple of hours to complete from the time you request the Log Export Service application installation.

Role required: admin

Procedure

1. Review Hermes Messaging Service Diagnostics.

   It is recommended that you verify that the Hermes Messaging Service is up and running with the Hermes diagnostic tool, which displays on screen during this step. If you see a "Page not found" error on this page, Hermes is not installed and you should contact your system admin.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Setup information: The following bootstrap information is used to connect to the Hermes Messaging Service. The "Producer Bootstrap" is the connection used to send messages into Hermes and "Consumer Bootstrap 1 & 2" are used to retrieve messages from Hermes.
  - Producer Bootstrap
  - Consumer Bootstrap 1
  - Consumer Bootstrap 2
- Instance PKI: The Instance Public Key Infrastructure (PKI) component allows a ServiceNow instance to act as an issuer in a X.509 trust hierarchy.
- Bootstrap Connectivity: Select **Run Test** to confirm external client is able to connect to the defined instance ports (producer and consumer).
- Instance Connectivity: Select **Run Test** to confirm the instance is able to send and receive messages.
- View Topics: Select the listed topic to retrieve the timestamp of the last known message.

Note:
You can access Hermes Diagnostics in the future to troubleshoot potential connectivity issues by returning to this step of the guided setup or by navigating to **All** > *Hermes Messaging Service* > **Diagnostics**.

2. Generate certificates for a secure connection to Hermes Messaging Service and pull log events from it.

   Setup secure connection to Hermes Messaging Service. See Set up a secure connection to the Hermes Messaging Service for LES for more information. You will need these certificates for authentication and authorization in the client which will pull the logs from Hermes.

   Note:
   admin or Hermes_admin roles are required for this step.

3. Configure Log Producer: Choose log sources to export and configure their filters. Complete the following tasks to configure the Log Producer.
   - Configure log sources to export: Create one Source record for each of the log sources that you want to export.

     Note:
     admin or sn_logstoanalytics.admin roles are required to complete this step

     To create a new Source, navigate to **Log Export Service** > **Sources**

     a. Select **New** at the top right corner

     b. Select a Source Type

     c. Select a Table

     d. Select a Log Level that can be used to control logging output

     e. Select or create a topic to which that log source will be exported. If you are creating a new topic, fill out the following fields:
        - **Name**: Name of the topic you're creating
        - **Application ID**: Enter `sn_logstoanalytics`

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **Namespace**: Enter Default Namespace
- **Partition**: The partition field of a topic in Hermes refers to the partitions into which the topic's data is divided. It plays a key role in scalability and parallelism.

f. Select a **Filter Type** condition to forward logs selectively.

> **Note:**
> Filter Type options differ depending on the selected source type.

g. Select Update
When successfully created, it will display the name of the Hermes topic to which that log source will be exported to. Write down the topic name, you will need it later when configuring your log consumer system.

The Active field controls whether or not that log source is going to be exported or not. If you see errors, go back to the Check Hermes Diagnostics task and verify Hermes status.

- Validate Log Producer: Once you have created a Source to produce logs from, you can see live log records in the topic using **Hermes Messaging Service** > **Hermes Topic Inspector**.

a. Select External Topics

b. Select List Topics

c. Select row with your topic from previous step (listed in Sources)

d. Adjust message start date if necessary

e. Select **View** to see a log message that was exported to the topic

4. Install MID Server: You must install and configure a dedicated MID Server running Vancouver or later.
Complete the following tasks to install the MID Server.
   - Install dedicated MID Server: The MID Server that Log Export Service uses should be dedicated for only this purpose and should not be expected to run other processes. This is important to ensure timely delivery of exported log messages to your REST endpoint. You can install the new MID Server either by using the Use MID Server guided setup or by installing it manually. For the manual installation, follow the Configure MID Server network connectivity documentation first and then the Installing the MID Server documentation after that.
   - Validate MID Server: You must manually validate the MID Server after it is installed to enable it to execute automation tasks. To validate the MID Server you are dedicating for LES, see Validate the MID Server
5. Configure Log REST Push Destination: Setup the MID Server to be able to push logs to your log analytics system (such as Splunk).
Complete the following tasks to configure log REST push destination.
   - Add MID Properties: You must add MID Server properties so that it's able to connect to Hermes. Navigate to **MID Server** >**Properties** and set the appropriate values for each of the properties listed below.

Name	Value
mid.les.kafka.ssl.truststore.password	<password>
mid.les.kafka.ssl.keystore.password	<password>
mid.les.kafka.ssl.key.password	<password>

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Name	Value
mid.les.kafka.ssl.truststore.location	<your_path>/<truststore>.p12
mid.les.kafka.ssl.keystore.location	<your_path>/<keystore>.p12
mid.les.kafka.ssl.truststore.type	PKCS12
mid.les.kafka.ssl.keystore.type	PKCS12
mid.les.kafka.client.id	<instance_name>
mid.les.kafka.group.id	snc.<instance_name>.group1
mid.les.kafka.bootstrap.servers	<instance_name>.servicenow.com:4100,<instance_name>.se
mid.les.kafka.set2.bootstrap.servers	<instance_name>.servicenow.com:4200,<instance_name>.se

Follow these notes on how to obtain some of the above values

- <password> is the password you set for the keystore and truststore
- <your_path> is the file path to the directory where you keep the keystore and truststore files you downloaded. The certificates need to be on the server where you are running MID
- <instance_name> is the name of your ServiceNow instance. If you are not sure, you can find it in the sys_properties table
- You can obtain the values for both mid.les.kafka.bootstrap.servers and mid.les.kafka.set2.bootstrap.servers from the Hermes Diagnostics page. Navigate to **Hermes Messaging Service** > **Diagnostics** and copy the strings under Consumer Bootstrap 1 and Consumer Bootstrap 2 respectively.

- Configure Destination: Create a new Destination Configuration record, which defines the REST endpoint that this Extension will forward logs to.

> **Note:**
> admin or sn_logstoanalytics.admin roles are required to complete this step.

a. Navigate to **Log Export Service (LES)** > **Destination Configurations**

b. Create a new configuration record

c. Specify the URL for your desired endpoint for the exported log sources

d. Search for or create new credentials to connect to your endpoint. When creating credentials for your endpoint, note that only the following credential types are valid with LES: Basic Auth and OAuth

e. Search for or create a new transform script. We ship with the prewritten script, **SplunkTransform** for Splunk

6. Configure LOG Consumer: Follow these tasks to configure your MID Server Extension for Log Export Service purposes.

- Configure LES Consumer Context: In this step, you will update the LES Consumer record to execute on the dedicated MID server you just installed for the Log Export Service. Navigate to **MID Server** > **Extensions** > **LES Consumer Context** and update the LES Consumer record by setting the following fields:
  - Select on 'LES Consumer' to open the MID Server context record
  - Select Specific MID Server for the "Execute on" field
  - Enter the name of the MID you validated in the previous step for the “MID Server” field

  Select **Update** to save.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
We ship with a prebuilt context. Don't create a second one. This can have unintended consequences.

- Configure Consumer: Create a new Consumer record, which represents the process that's part of the Log Export Service MID Server Extension. Navigate to **Log Export Service (LES)** > **Consumers** and create a new configuration record specifying the Hermes topic to retrieve log messages from and the Destination to relay them to. When you select the **Consumers** module, it shows information about the consumer name and the destination configuration.

  a. Create new Consumer record

  b. Choose a source topic from the dropdown

  c. Choose destination configuration

  d. Start Consumer

- Verify MID Server integration: Navigate to#**Log Export Service (LES)** > **Consumer Status** and view the#Status and Status Details fields of the record defined. The information in these fields reports the current state of the process running on the MID server, including any errors that may have been encountered while relaying messages to the REST endpoint. This is a status view page only. Navigate to **Log Export Service (LES)** > **Consumers** if you want to create a new consumer record. #If the Consumer status indicates that the process has started, you should be able to inspect your endpoint to view the logs that have been relayed to it.#Additionally, you can view the logs on the MID Server to see if there are additional details about any errors that might be encountered. You can also enable Debug logging on the MID Server to get additional information if needed.

  Note:
  If you make any change in one of the Consumer records, it shows up on the Consumer Status view page. If you select a consumer record name on the Consumer Status list, the Consumer form for the selected record opens. You can then update the Name and Destination Configuration of the selected record.

Multi-consumer support using unique mid servers

You can now precisely manage log consumption with a new multi-consumer system, enabling dedicated consumers and MID servers for each specific log stream.

The system now supports multi-consumer log consumption which means each log source can be consumed separately have its own dedicated topic.

Previously, all logs were consumed from the same topic. However, with the new multi-topic concept, you can create multiple consumers for different topics. To create a consumer, you can select the following:

- A specific topic from the dropdown menu
- Respective destination configuration
- Respective consumer context

Note:
Starting Zurich release, the **Consumer context** is a new field added in the Consumer form. Each consumer context is associated with one unique mid server.

To create multiple consumers, you are required to select distinct topics for each consumer, which in turn would require to create separate consumer context records and its corresponding unique mid servers.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Parallel processing with multiple MID servers

A major benefit of this multi-consumer architecture is the ability to run multiple consumers in parallel. This parallel processing significantly enhances the overall throughput and efficiency of log consumption, allowing the system to handle larger volumes of diverse log data more effectively than before.

Set up a secure connection to the Hermes Messaging Service for LES

Secure your Kafka topics by generating a ServiceNow® instance-signed certificate.

Before you begin

Setting up the Hermes Messaging Service requires coordination with your network administrator and with your Kafka administrator. Work with your network administrator to obtain required security certificates and open the required ports. Work with your Kafka administrator to ensure that your Kafka environment is configured correctly and that your applications can connect to the Hermes Messaging Service using the standard Kafka protocol.

Make sure the following setup is in place:

- The Hermes Messaging Service is activated. See Activating the Hermes Messaging Service.
- The Key Management Framework plugin (com.glide.kmf.global) is activated.
- The Certificates [sys_kmf_certificate] table contains a ServiceNow instance root CA certificate.
- The instance isn't configured with a Custom URL. Custom URLs are not supported with the Instance PKI Certificate Generator.

Role required: hermes_admin, sn_kmf.cryptographic_manager, or admin

For details on assigning KMF roles, see Roles installed with Key Management Framework.

Procedure

1. Navigate to **All** > **Certificate Generator** > **Instance PKI Certificate Generator**.
2. **Optional:** Control access to topics by configuring Access Control Lists (ACLs) at the namespace or topic-level.
   The bearer of the certificate is granted read or read/write access to the topics in the namespace or the existing topic that you selected.
3. Set up security for the Hermes Messaging Service.
   a. Navigate back to the Instance PKI Certificate Generator page.
   b. Enter a keystore password in the **Certificate Password** field.
   c. Select **Generate**.
   The system generates an instance-signed certificate in the Certificates [sys_kmf_certificate] table, creates a keystore, and creates a truststore.

   If Restricted Caller Access isn't allowed for the IPKI Certificate Generator, a cross scope access error appears. Contact Customer Service and Support for assistance with allowing Restricted Caller Access. To resolve this issue, Customer Service and Support can reference source_scope=76f9d51369115083f4ea77aab1677cc0 in the Restricted Caller Access Privileges [sys_restricted_caller_access] table.
4. Save a copy of the keystore by selecting **Download Keystore**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

5. Save a copy of the truststore by selecting **Download Truststore**.
6. Copy the keystore and truststore files to each producer and consumer client that will connect to the Hermes Messaging Service.

Result
You can now create a secure connection to the Hermes Messaging Service.

> **Note:**
> You must use the keystore that you generated using the Instance PKI Certificate Generator to connect to Hermes. Custom-generated keystores that aren't created according to the ServiceNow documentation aren't supported.

What to do next
.

Using Log Export Service (LES)

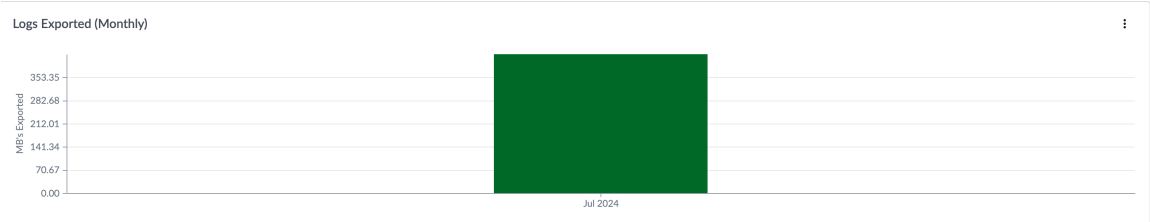
Use LES to review the log report dashboard.

Review log report

Analyze the size of each data log by reviewing the log report dashboard.

Before you begin
Role required: admin or sn_logstoanalytics.admin

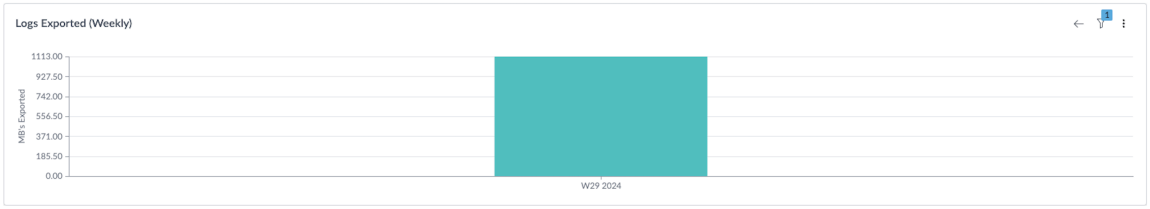
Procedure
1. Navigate to **All** > **Log Export Service** > **Reports**.
2. Review log data in the following widgets.
   - Logs Exported (Monthly): It shows the megabytes exported per month in the initial view. You can drilldown the graph to view the data for each week or daily data. You can view data from last 395 days.



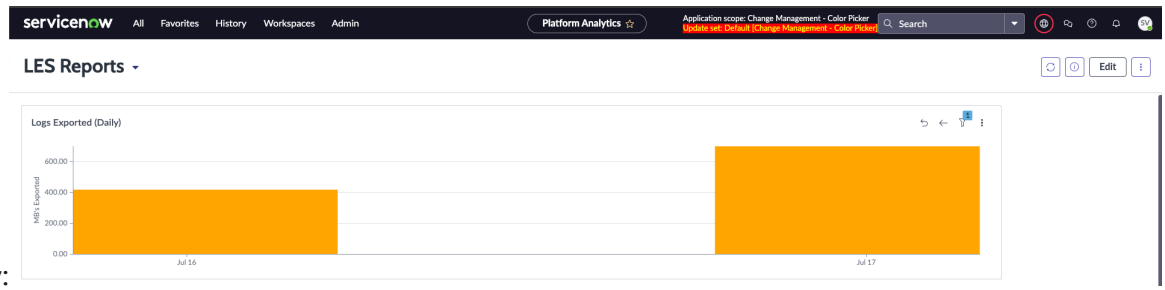
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
Click on the arrows on the up right corner of the widget to drill down the data. You can also move back up to the parent data.

Weekly:

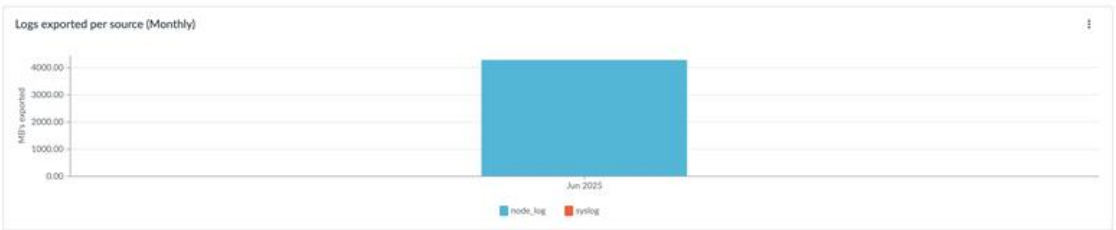


Daily:

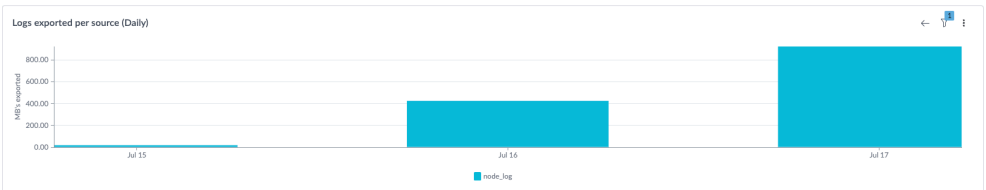


The data in this report reflects collection taken 4 hours prior.

- Logs exported per source (Monthly): This widget shows the kind of logs were exported on a monthly basis. You can also drilldown to see weekly and daily log data. You can view data from last 395 days.

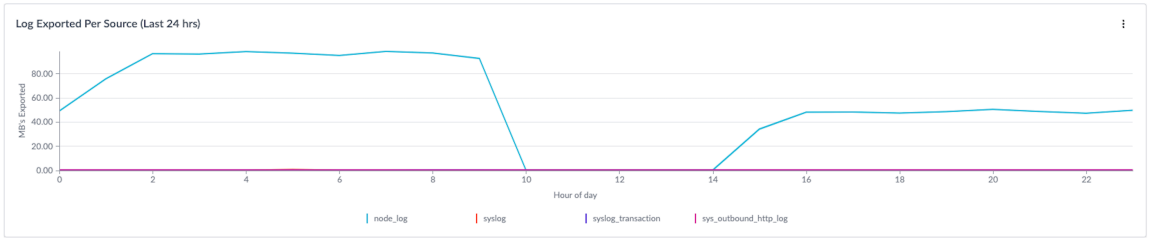


Note:
You can select or de-select the source you want to view the data from. The sources from which you can view the logs are: node_log, syslog, syslog_transaction, and sys_outbound_http_log.



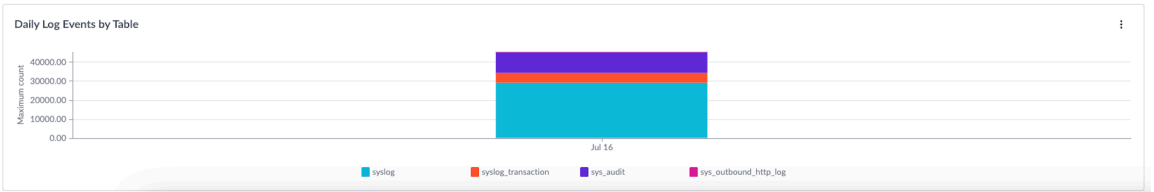
- Log Exported Per Source (Last 24 hrs): It shows the data from last 24 hrs. The graph progresses chronologically from left to right on a 24 hr scale, with the oldest data (24th hour) positioned on the right and the latest data on the left side of the report. You can select or de-select the source you want to view the data from. The sources from which you can view the logs are: node_log, syslog, syslog_transaction, and sys_outbound_http_log.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Note:
Depending on the hour of the day you check this data, the widget dynamically updates to reflect exactly the past 24 hours.

- Daily Log Events by Table: It shows the log events generated by each log tables per day. You can select or de-select the tables you want to view the data from.



Note:
The tables from which you can view the log events are: syslog, syslog_transaction, sys_audit, and sys_outbound_http_log.

Log Export Service (LES) references

Find all the miscellaneous information about LES in the reference section.

Log Export Service roles

Log Export Service is installed with these roles.

Application admin [sn_logstoanalytics.admin]

To learn more about managing per-user subscriptions, see Managing per-user subscriptions in Subscription Management and contact your account representative.

This role is installed along with the LES application and allows a non-admin to use the application.

Contains Roles

List of roles contained within the role.

None.

Groups

List of groups this role is assigned to by default.

None.

Elevated

Whether the role is an elevated role. Elevated roles aren't assigned to users or groups, and must be used by elevation. For details, seeElevate to a privileged role.

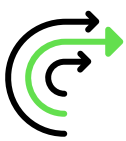
Logs

Logs module provides a variety of logs that you can use to troubleshoot and debug transactions and events that take place within the instance.

Get started

System Logs



Logging, auditing, and errors

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The System Logs module provides a variety of logs that you can use to troubleshoot and debug transactions and events that take place within the instance.

Apply a logging and auditing strategy so that you can identify and act on suspicious activity in a timely manner.

System logs

The System Logs module provides a variety of logs that you can use to troubleshoot and debug transactions and events that take place within the instance.

Access the following logs from the System Logs module:

Log	Description
Transactions	All application activity for an instance.
Email and Push	All email notifications and Push messages sent from all instances within the system.
Event Logs	All system events that occur within the system.
Import	Data import activity within the platform.
Table Changes	Changes made to all tables in the system.
Outbound web services logging	All outbound web services requests such as REST and SOAP requests.
Signature Images	Electronic signatures for the HR signature pad.
System	Warnings and errors for instance processes, records, and non-critical events, such as memory usage on the server machine.

Use the Log File Browser to search and download logs. You can also search archived logs in the log history.

Other logs

Your instance offers other logs in addition to those in the System Logs module. For example, the System Diagnostics module provides upgrade history and slow query logs, which you can use to gain insight into how queries are affecting platform performance. The Customer Updates table records every change that is made in the system.

System log

View warnings and errors for instance processes, records, and non-critical events, such as memory usage on the server machine.

The following information is tracked in the system log:

- Workflows
- Configuration
- Chats sessions
- Transactions for each view of each page in the system, including load times for network, server, and browser

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Inbound and outbound email
- Events triggered in the system
- Imports and integrations
- System warnings, errors, and script logs
- Upgrade information for any plugin activations, update sets, or system upgrades

Log entries appear for the current day only. To view other log files, use the log file browser. This log provides the following information for all occurrences:

System log

Field	Description
Created	Date and time of the logging activity for the locale of the machine running the instance.
Level	Type of message. The levels are Debug, Error, Warning, and Information. • A warning is an error that has been handled and recovered. • An error is something that must be fixed.
Message	System-generated message regarding the nature of the occurrence.
Source	Name of the process or area affected by the occurrence. For example, the source of the occurrence might be EMAIL or Memory.
Source Package	Name of the application package associated with the occurrence. Click on the name to view the Store Application [sys_store_app] record for this package.

Workflow logging

- Each activity executed, including:
  - Date and time started
  - Date and time ended
  - State, for example, Finished, Cancelled, Timed Out, Error
  - Result
  - Fault description, if there was an error
- Transition history, including:
  - Time of transition
  - Activity transitioned from
  - Activity transitioned to
  - Which transition was triggered
- Workflow log, including any log statements added to the workflow

Configuration information

- Action taken, including insert, update, and delete
- Category of change

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Comments recorded with the change
- Name of the change
- XML difference of the change
- Update set the change is associated to
- Date and time of the change
- User who made the change
- Table where the change was made
- Name of the object being changed
- Type of object being changed
- View the change was made in, for changes to forms or lists

Transaction logs

The transaction log records browser activity for an instance. To aid in debugging of system issues, you can filter transaction logs by application scope, limiting transactions that appear to only those transactions originating in specific scopes.

Note:
Background and scheduler transactions are logged only when their execution time exceeds 1000ms. For a complete list of logged transactions, see KB0778299.

Access the transaction logs by navigating to **All** > **System Logs** > **Transactions**. The transaction log provides the following information for all activities.

Field	Description
Created	Date and time of the application action for the locale of the machine running the instance.
Type	Type of recorded transaction.
Created by	User who created this activity.
Origin application	Application scope the transaction originated in. Global appears if the transaction originated in the global scope.
Response time	Round trip response time for the application request, in milliseconds.
Network time	Latency time of the network response after the application request is made, in milliseconds.
Output length	Size of the output string sent by the instance to the application, in bytes.
SQL count	Number of SQL server commands executed for this activity.
Business rule count	Number of business rules executed for this activity.
Business rule time	Elapsed time for the execution of the business rules for this activity.
URL	Application or module connected to by the client application.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
System ID	System generated identifier of the client instance making the request. This ID is used for cluster environments in which several instances (nodes) communicate with the database.
IP address	IP address of the client making the request.
GZipped	Indication of whether a compressed Web page was requested by the application.
Protocol	HTTP protocol used by the application for this instance.

Client transaction timings

The Client Transaction Timings plugin enhances the system logs by providing additional information about the durations of transactions taking place between the client and the server.

You can track down performance issues to their source by viewing where the time is being consumed, and how time was spent during a transaction.

This plugin requires the Response Time Indicator Response Time Indicator to be enabled, and collects information from the following browsers:

- Firefox
- Internet Explorer
- Chrome

Client Transactions Information

Installing the plugin adds the *Client Transactions* module to the *System Logs* application. It provides a list of every logged transaction between client and server within the last day:

Client Transactions Information

Field	Description
Created	Moment the transaction was recorded.
Response Time	Number of ms spent by the server in fulfilling the transaction.
Business Rule Time	Number of ms spent by business rules triggered by the transaction.
SQL Time	Number of ms spent by the SQL database.
Client Response Time	(Load_completion_time) - (start_time). It is inclusive of server time.
Client Network Time	Number of ms spent by the network the client is connecting through.
Browser Time	Number of ms spent by the browser during the transaction.
Client Script Time	The number of ms spent executing client scripts.
UI Policy Time	Number of ms spent executing ui policy.
Type	Type of transaction: • Form • List • Other
Table	Name of table that appeared. For example, incident, change_request.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Client Transactions Information (continued)

Field	Description
View	View for this form/list.

Client Detailed Information

A more detailed breakdown of the client timings for all Form rendering (but not list rendering) is also tracked. To see details, drill into a particular client transaction record and observe the related list at the base of the screen.

Client Detailed Information

Field	Description
Order	Order during the load in which this operation occurred.
Type	Type of operation.
Name	Descriptive name of this particular operation
Duration	Number of ms this operation took to complete.

Push logs

Consult the push log to track the status of push notifications that are queued to send from your system.

To view the push log, navigate to **System Logs** > **Push Notifications**. Users are required to have the push_admin or admin role to view the push log.

Push log fields

Field	Description
Claim	Identification number that is generated by the scheduled job that sends the push notification. This number is applied to the **Claim** field to ensure consistency across multiple push scheduled jobs.
Payload	Content of the push notification.
Queue count	Number of times that the system tried to send the push notification. The status of the push notification relates to its queue count. • If the queue count is 0 for longer than expected, then there are no scheduled jobs that are trying to send the push notification. • If the queue count is greater than 0 and the **Type** is **success**, then you can infer that this is how many times the system tried to send the push notification before finally sending. • If the queue count reaches 10, the system stops trying to send the push notification. The **Type** changes to **failure**.
Request ID	Unique identification number for the push notification. Similar to the message ID for an email, the request ID is used as a correlation token for the push notification.
Type	Status to indicate whether the push notification has been sent. The Type column can have these values:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Push log fields (continued)

Field	Description
	• **failure**: The message could not be sent. • **pending**: The message is queued for processing. • **success**: The message was successfully sent, although not necessarily received by the mobile device.

Related topics

Scheduled jobs

System email log and mailboxes

The system email log records all emails that the instance creates or receives. System mailboxes are filtered views of this log.

Every notification email that the instance creates or receives is recorded in an Email [sys_email] record. You can navigate to a log of these records at **System Logs** > **Emails**.

The System Mailboxes are filtered views of the Emails [sys_email] table. The instance assigns an email record to a system mailbox depending on the values of the **Type** and **State** fields. For more information, see System mailboxes.

The following fields can be included in the layout of the system log and any of the system mailboxes:

Email log

Field	Description
Mailbox	The system mailbox that lists this email record. The instance sets the value of this field according to the values of the **Type** and **State** fields.
State	The current state of the email (Error, Ignored, Processed, or Ready).
Receive type	The type of inbound email (None, Forward, New, or Reply).
Type	The status of the email. Choices are: • received: The server received this email. • received - ignored: The server received this email, but it was ignored by the instance for inbound email action purposes. Typically, these emails are either spam or auto-replies. See the Error String field for details. • send - failed: The server has attempted to send the email and failed. See the Error String field for details. • send - ignored: The server skipped sending this email. Typically, this is for an email which was generated but lacked a recipient email address or is a duplicate email. See the Error String field for details. • send - ready: The email is ready to be sent, but has not been sent out by the mail server. Typically, an email remains in this state for only a short time.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Email log (continued)

Field	Description
	• send - translation - ready: The email is generated during email translation and sent out. Typically, an email remains in this state for only a short time. • sent: The email was sent by the instance without any errors or issues.
Target	A Document ID reference to the record if the email is generated by an insert, update, or delete of a particular record.
User	The name of the user, from the user record, of the instance from which the email notification was sent. **Note:** This is a string field.
Notification Type	The type of notification. Choices are: • None • SMS • SMTP
UID	The unique ID of the email stored on the server.
Created	The date and time of the email activity for the locale of the machine running the instance.
Deleted	For inbound email, indicates whether the email was deleted from the email server.
Weight	The weight of the email, which determines the sending priority relative to other notifications on the same table.
Importance	An indication that the email was sent with a changed level of importance, such as Urgent.
Originating Event and Notification	For emails generated by notifications, an embedded list that stores the event and notification that created the email.
Subject	The email subject. For notifications, you create the subject text in **System Notification** > **Email** > **Notifications**.
Error String	The error string captured from the email server to determine why the email was not sent. This is logged only if the email is send-failed.
Recipients	The email addresses of the recipients.
Body	The body of the email, displayed in raw HTML markup. Use the related link Preview HTML Body to see the body text as rendered HTML.
Content type	The email content type.
Headers	Any headers embedded in the email.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Event logs

The event log records all system events that occur within the ServiceNow AI Platform.

This log provides the following information for all events that occur:

Event log

Field	Description
Created	Date and time of the event for the locale of the machine running the instance.
Name	Name of the event as listed in the Event Registry.
URI	HTTP query that generated the event.
Parm1	Event-specific value that depends on the event and the recipient.
Parm2	Event-specific value that depends on the event and the recipient.
Table	Database table acted on for this event.
Processed	Date and time the event started processing. This time reflects the locale of the machine running the instance.
Processing time	Time taken to process this event, in milliseconds.
Queue	Processor queue name.

Import logs

The import log displays information in a verbose format about any data import activity within the platform.

For a more detailed view of the import sets that produced a particular log, see **Import Sets** > **Transform History**.

This log provides the following information for all imports:

Import log

Field	Description
Created	Date and time of the import for the locale of the machine running the instance.
Level	Type of message displayed. For import files, the level is Information.
Message	System-generated message regarding the status of the import.
Source	Name of the external source of the import, such as an integration.

System Diagnostics module

The System Diagnostics application provides logs that relate to the platform.

These logs are available:

Upgrade History

Tracks every upgrade to an instance.

Slow Queries

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Provides insight into how queries affect platform performance. See Use a slow query log.

Customer Updates table

Changes made in the system are recorded on the Customer Updates [sys_update_xml] table chronologically. There are a few exceptions, as noted below.

To navigate to this table, enter sys_update_xml.list into the navigation filter. For information about update sets, see System update sets.

The following information is stored about each update:

Customer Updates table

Field	Description
Name	A name that identifies the updated record.
Created	The date and time the Customer Update record was created.
Created By	The user who performed the change.
Type	The type of the update.
Updated	The date and time the Customer Update record was updated.
Updated By	The user who performed the update.
Updates	The number of times the record has been updated.
Target Name	The name of the element that was altered.
View	The view of the form that was altered if it was a form layout change.
Payload	The XML contents of the record after the change.
Remote Update Set	A reference to that update set if the change was performed by a remote update set.
Local Update Set	The update set the change is associated with.

Note:
Some application changes are not represented by Customer Update records (sys_update_xml) Examples:

- Types of metadata where updateSynch = false
- Cascading changes to tables and fields such as display name changes
- Unresolved metadata references from other applications (resulting in no “display value” on the element)
- sys_id changes for coalescing files
- Changes to Flow/Flow Actions that may generate sys_documentation
- ua_table_license_config records generated on table creation
- Jobs running in the background such as natural language processing
- Cases where sys_update_xml is manually modified or removed

To learn more, see Commit changes.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Log history

The system uses table rotation and table extension to archive older logs.

By default, the system uses the following schedule to archive common logs:

Common log archive schedule

Table	Archive schedule	Rotations	Type
Event [ecc_event]	Every day	7	Rotation
Queue [ecc_queue]	Every day	7	Rotation
Event [sysevent]	Every day	7	Rotation
Log [syslog]	Every week	8	Rotation
Transaction Log [syslog_transaction]	Every week	8	Rotation
Email [sys_email]	Every 30 days	8	Extension

Use the log file browser

The instance provides the utilities log file browser and log file download.

Use **System Logs** > **Utilities** > **Node Log File Browser** to view any system log entry. You can search for log files by using the following filters:

Log file browser

Field	Description
Start time	Start date and time of the range you want to search, for the locale of the machine running the instance.
Session ID	System-generated hexadecimal string that identifies the session that generated the log entry.
End time	End date and time of the range you want to search, for the locale of the machine running the instance.
Message	System-generated description of the occurrence.
Level	Type of message displayed. The levels are Debug, Error, Warning, and Information. A warning is an error that has been handled and recovered. An error is something that must be fixed.
Thread name	System-generated identifier of the thread that created the log file.
Max rows	Maximum number of records returned for a particular filter.

The instance creates compressed archives of system logs every 2 days and purges log archives after 21 days.

Important:
When a node is retired, the node's log files are purged immediately, which means they aren't archived for an additional 21 days.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

You can download log file archives and view them with **System Logs** > **Utilities** > **Node Log File Download**. Select a log archive from the list, and then click **Download log** under *Related Links* to open or save the archive.

Note:
Log files are only available for the node you are currently logged into. To see the currently logged into node, navigate to **System Diagnostics** > **Stats**.

Use the new **Show Syslog Records** button on the Transaction and Active Transaction forms to view any System Log entries that were generated during the execution of the transaction. A transaction can have any number of syslog entries. The multiple syslog entries for all the transactions make it difficult to co-relate a transaction with their respective syslog entries. The **Show Syslog Records** UI action helps in co-relating the active and completed transactions to their respective syslog entries by building a URL to query the syslog table. Identifying the correct syslog entries for a particular transaction helps in debugging and addressing security concerns.

Enhanced logging security

Explore the **Attribution** field in the node log lines to identify the script or component that generated the log message. Transaction start lines include the new field to identify the type of request made.

Achieve the following using the new enhancements:

- Trace the source originator of each of the log lines
- In case the originator info is not available, print the Java class name and an attribution
- At the start of each transaction line, it contains the transaction ID and transaction type

Use the transaction ID of each log line to understand the information given at each log line. Once you identify the transaction type, you get the originator information of each log line. Both the transaction type and originator information of each log line together gives you the required source info of each node log line.

Note:
SYS_UI_MACRO and SERVICE_PORTAL_WIDGET script types in attribution are not reported.

Transaction types

The following is the list of transaction types:

- List
- Form
- XMLHttp
- Report
- SOAP
- Export
- Scheduler
- TextSearch
- Other
- REST
- JSON

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- AMB
- Archive
- Batch REST
- Instance Scan

System properties

The following are the system properties required for the feature:

- Glide.log.append.attribution: This property is enabled by default. It turns on/off the attribution information of each node line
- Glide.db.log.append.classname.attribution: This property is enabled by default. It turns on/off logging java class name attribution

Avoid log tampering

Configure system log table protection rules to limit the scope of modification and deletion of application log records. The rules enable you to determine the logging of changes or attempts to changes in these tables.

If you are a security_admin, activate the Protected Tables plugin (com.glide.protected_tables) that allows the platform to restrict update, insert and delete operations on the following system log tables:

- syslog
- syslog_transaction
- sys_outbound_http_log
- sysevent
- sys_audit
- sys_push_notification
- syslog_app_scope
- protected_table_configuration (config not modifiable)

Note:
The com.glide.protected_tables plugin gives protection only to the system log tables mentioned above. Any attempt to update, insert or delete a record logs a message in the protected_table_log table.

See Installing and configuring the log protection plugin for more details.

You can specify one of the following log protection levels for each of the system log table.

- Block and log the attempt: Blocks any modification and logs the attempt
- Only block the attempt: Blocks any modification and doesn't log the attempt
- Only log the attempt: Doesn't block the modification but logs the attempt
- Don't block and don't log the attempt: Doesn't block the modification and doesn't log the attempt

Platform uses the log protection levels specified for each of the system log tables to block and/or log any attempts to modify a record after being initially created.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
If you are a security_admin, you have the ability to override the default log protection levels in each of the system log tables to adapt to the customizations on your instance.

If there have been any attempts to modify the system log tables, they are logged into the protected_table_log table.

Note:
If the protection level is not specified for a table, any attempts of modification are not logged into the protected_table_log table.

In order to disable the plugin operations on tables in the Admin Panel, set the com.glide.security.protected_table.enabled property to false. See Create log protection property for more information.

Configuring the log protection plugin

Configure the protection rules for each table and operation to complete the configuration of the log protection plugin.

Before you begin
Role required: security_admin

Procedure

1. Navigate to **All** > **Protected Tables** > **Log Protection**.
   The Admin Panel page is displayed.

   Note:
   Starting in the Utah release, the Protected Tables plugin is installed by default, but disabled.

2. Elevate your role to security_admin in order to continue configuring the plugin.

   a. Select **System Administrator**.

   b. Select **Elevate role**.
   The Elevate role modal shows up.

   c. Select the security_admin option to elevate your role and select **Update**.

3. Configure the protection rules for each table and operation. The protection rules apply to update, insert and delete. The protection levels can't be changed for some tables. The syslog and syslog_app_scope tables have fixed values for update and delete protections. The protected_table_configuration table has fixed protection values for all three operations.

   Note:
   For sysevent table, insert protections can't be set to block.

   If you had **Apply to Child Tables** turned on for syslog in the previous release, the child tables are added to Log Protection with the same protection rules as syslog upon upgrade to the Utah release. This only happens for syslog, not for any other tables.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Enable the feature by selecting the **Enable Log Protection** toggle.

> **Note:**
> You can disable this plugin only by changing the com.glide.security.protected_table.enabled property in the sys_properties table.

Create log protection property

Create a log protection property to avoid the risk of log tampering.

Before you begin
Role required: admin

Procedure

1. If the *com.glide.security.protected_table.enabled* property doesn't exist in the System Properties list, select **New**.
   The new system property form shows up.
2. On the form, fill in the details

Fields	Description
Name	Name of the property as com.glide.security.protected_table.enabled
Application	Application that has the property.
Description	Description of the property
Choices	
Type	Value type - true or false
Value	Actual value of the property
Ignore cache	Option to ignore the cache content
Private	Option to make the property private ○ Read roles ○ Write roles

3. Select **Submit** to create the property.

Logging, auditing, and errors (instance security hardening)

Apply a logging and auditing strategy so that you can identify and act on suspicious activity in a timely manner.

To learn more about what can be logged in the instance, see System logs. Ensure that there is a schedule for monitoring system events such as logins and failed logins by using **System Logs** > **Events**.

Disabling SQL error messages (instance security hardening)

Use the *glide.db.loguser* property to disable SQL error messages from rendering in a browser.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

More information

Attribute	Description
Property name	glide.db.loguser
Configuration type	System Properties (/sys_properties_list.do)
Configurable in Instance Security Center	No
Purpose	To disable SQL error messages from displaying within the browser.
Type	true|false
Recommended value	false
Functional impact	(Low) This remediation disables rendering of SQL error messages. There is no impact to any functionality.
Security risk	(Medium) No sensitive SQL information that could help an attacker should appear as a part of error message on a web page.

To learn more about adding or creating a system property, see Add a system property.

Secrets Management

Use ServiceNow Secrets Management for granular management of access to your passwords to fit your business needs.

Important:

Secrets Management has begun its End of Life process, and has reached the End Of Sale and End of Renewal milestones as of the Yokohama release. For support storing passwords with two-way encryption, see Password2 encryption with the Key Management Framework (KMF).

Secrets Management has two available versions. Secrets Management Core is included on the ServiceNow platform at no additional cost and Secrets Management Enterprise is a premium, subscription version of the product. For more information on the difference between these versions, see Exploring Secrets Management.

Explore

Learn the key features and business value of Secrets Management.

Analyze

Configure

Plan your core configurations.

Exploring Secrets Management

Use ServiceNow Secrets Management for granular management of access to your passwords to fit your business needs.

Important:
Admins must have the role to see modules and records related to Secrets Management. For secrets management role information, see Secrets management roles.

Select from Core and Enterprise versions of Secrets Management

Choose from Secrets Management Core and Secrets Management Enterprise depending on your business needs.

The Secrets Management Core plugin (com.glide.sm.core) is available by default. No installation is required on the instance for use. The Secrets Management Enterprise plugin is only available with a ServiceNow Vault v1, PROD18537 license. Contact Customer Support for assistance with the Secrets Management Enterprise plugin.

Secrets Management Core	Secrets Management Enterprise

Secrets Management Core is available to install on your instance at no additional cost. The plugin provides the ability to use secrets groups with criteria in non-custom tables provided in the ServiceNow platform that have been created by ServiceNow application engineering teams.	Secrets Management Enterprise includes additional functions to help admins create and manage secrets groups. Enterprise provides the following features in addition to the features listed in Core.
	• Use granular access controls to create secrets groups based on the any of these criteria.
	  ○ Scope
	  ○ Table
	  ○ Column
	  ○ Record
	• Create client-accessible secrets that are encrypted using your own key which ServiceNow can't access.
	• Use the Secrets Management Dashboard to review the secret groups configured on your instance, and learn about potential security issues.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Secrets Management Core	Secrets Management Enterprise
	Note: Secrets Management Enterprise is a paid plugin that ServiceNow personnel must activate on your production instance.

Use secret groups to organize your secrets

Use Secrets Management to organize your secrets into groups, and then apply access policies to those secrets at a group level.

Basic secret group

These groups apply to all secrets in a scope. These secrets are decrypted by a common cryptographic module and module access policies.

Secret group with criteria

Secret groups with criteria function the same as a basic secret group, but further refine what is included using criteria. These criteria include:

- Application scope
- Package
- Table
- Secret column
- Filter record

Secret groups of either type can be made instance accessible or client accessible.

Instance side secret groups

Instance side secret groups contain secrets that can be decrypted by your instance.

Client-side secret groups

Client-side secrets groups use a public and private key pair to help ensure that secrets can only be decrypted by the client. When you create a client-accessible secrets group, you upload the public key to the instance, and retain the private key on your MID Server. The instance uses the public key to encrypt your secrets, but they can only be decrypted using the private key.

Note:
For more information on these group types, see Understanding client side Secrets Management.

Use secrets groups for more granular control

While password2 is available on the ServiceNow platform, Secrets Management provides these additional features.

Granular access controls	**Password2** With password2, admins can control access to an application scope, but can't restrict access to elements within the scope. **Secrets Management**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

	With Secrets Management, admins can restrict access based on criteria they define. Criteria types can be based on criteria such as package, table, or column.
Secure Storage	For client-side secret groups, Secrets Management uses a new encryption scheme. In this encryption scheme, ServiceNow doesn't save the encryption key. For this reason, the security of your data doesn't depend on ServiceNow security.

Apply module access policies to your groups

After you've grouped your secrets into a secret group, you can apply policies that determine how you can access them at a group level. Module access policies are the access control mechanisms that you apply to cryptographic modules to define instance-level controls, such as a validity time frame for the cryptographic key. For more information on module access policies, see Module access policy overview.

Tables installed with Secrets Management

Secrets Management adds or modifies these tables.

New Tables	
[sn_sm_secret_group]	Stores secret groups
[sn_sm_secret_group_criteria]	Stores criteria secret groups
[sn_sm_secret]	Stores wrapped secrets
[sn_sm_identity_group]	Defines the identity group for mapping a group of identities to the public key
[sys_kmf_wrapped_module_key]	Stores the wrapped symmetric cryptographic keys
Modified Tables	
[sys_kmf_crypto_module]	Added cryptographic module type. (Identity cryptographic module or secret group cryptographic module)
[sys_kmf_module_key]	• Stores conceptual secret encryption key (with no key material) • Stores the identity public key
[sys_kmf_crypto_caller_policy]	Added new module access policy type

Secrets Management use case examples

Help ensure secure ITOM Discovery

This infographic shows a simplified reference architecture of how ServiceNow IT Operations Management (ITOM) Discovery can be deployed by your organization. As shown in the infographic, multiple Windows and Linux servers connect to the Management, Instrumentation, and Discovery (MID) Server and several MID Server agents enable the discovery process to update the Configuration Management Database (CMDB). Every MID server transaction requires a secure authentication, hence managing the authentication credentials is critical from a security perspective.

Accelerating workflow connectivity with Integration Hub securely

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Use ServiceNow's Integration Hub to connect to different systems using automated application programming interface (APIs). Each time Integration Hub connects to a system using an API, an authentication credential is required to establish connectivity. Management of a multitude of applications and APIs for connectivity requires a secrets management solution.

Secrets Management is a key part of ensuring your organization's cybersecurity. It covers all processes and tools related to the creation, storage, transmission, and management of digital credentials such as encryption keys, API tokens, and passwords. To manage secrets both securely and effectively, you can build a core secrets management policy that establishes standard rules and procedures for all phases of a secret's lifecycle.

Understanding client side Secrets Management

Learn how use Secrets Management to manage access to secrets and groups.

Terminology

Client side secrets management is designed to provide a method for managing secrets without the use of proxies, and without giving ServiceNow access to your decrypted data. To understand this process, begin with the following encryption terms.

Term	Description
Symmetric encryption	Symmetric encryption uses a single same key both to encrypt and decrypt data. If data is encrypted with a symmetric key, this key is all that is needed to decrypt it.
Symmetric key	The symmetric key encrypts a secret, turning your clear text password into unreadable cyphertext.
Asymmetric encryption	Asymmetric Encryption uses two keys, one to encrypt and the other to decrypt.
Public key	The public key is one half of the asymmetric key pair. This key is stored on your instance, which uses the key to encrypt a symmetric key. This encrypted symmetric key can only be decrypted when paired with the private key.
Private key	The private key is one half of the asymmetric key pair. This key is stored in a keystore on your MID server. ServiceNow has not access to this key. Combined with the public key, the asymmetric key pair is used to decrypt your secrets.

Client side encryption process

A symmetric key encrypts a credential (in this case, an admin password), changing it from readable cleartext into encrypted cyphertext.
The symmetric key (represented in green) can be applied to the credential to encrypt or decrypt it.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

At this point, asymmetric encryption begins using public(yellow) and private key(blue) keys.	
The public key encrypts the credential along with the symmetric key. The symmetric key is now protected, so it can't be used to decrypt the credential. Although the public key can perform this encryption, it can't be used alone to decrypt.	
After being encrypted with the public key, the private key is needed to decrypt the credential. Since the customer alone has this key, they're the only ones who may access the encrypted credential.	

Configuring client accessible secrets

Learn how to configure your instance to use client accessible secrets.

Use this example implementation to configure Secrets Management without using proxies, or giving ServiceNow access to your decrypted data.

For more detail on using client-side Secrets Management to manage access to passwords and groups, see Understanding client side Secrets Management.

These instructions assume you have a MID server configured on your local network. For information on this process see MID Server.

Process overview

1. **Create encryption keys and certificate**

   Create encryption keys and a certificate using terminal commands on your local environment.

2. **Add your certificate to the ServiceNow Trusted Key Store**

   Upload your key and certificate to the ServiceNow Trusted Key Store.

3. **Create a secret group with criteria**

   Create a group for your secrets. Secret groups to organize your secrets into groups. Using these groups you can apply access policies to those secrets at a group level. Then associate your secrets group to an identity group, and add your MID server to that identity group.

4. **Upload the public/private keypair to the MID Server**

   Upload your public/private keypair to your MID server. This keypair enables the MID server to handle authentication requests from your instance.

5. **Create credentials and test credential encryption**

   Create a credential to authenticate into a third-party system and test that ServiceNow can't access the credential.

6. **Configure Flow Designer to manage the integration**

   On your instance, use Workflow Studio to manage an integration between your local network and your instance.

7. **Test the end-to-end client-side encrypted secrets integration**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Test your integration, and review the execution details to confirm your configuration is working.

Create encryption keys and certificate

Create encryption keys and a certificate using terminal commands on your local environment.

Before you begin

Role required: none

Procedure

1. In your local environment, open Terminal (On Mac or Linux), or Command Line (in Windows).
2. Using the terminal, use `cd` to move into the folder where you want to store your encryption keys.
3. Using the terminal, enter the following:

```
openssl req -newkey rsa:4096 -nodes -keyout sm_private_key.pem
 -x509 -days 365 -out sm_public_cert.pem
```

Note:
This example uses OpenSSL to generate keys and certificates. You may substitute other comparable tools based on your requirements.

The command generates a private key and a public certificate (with the matching public key). A series of prompts for required information follows, starting with "Country Name."

4. Fill in the prompts with the requested information.
The following prompts appear.
   - Country Name
   - State of Province Name
   - Locality Name (eg, city)
   - Organization Name (eg, company)
   - Organizational Unit name (eg, section)
   - Common Name (eg, fully qualified host name)
   - Email address

   Work with your security team to ensure you enter the correct certificate information.

5. Check the folder you that chose in step 2 to verify that the private key and public certificate have been created.
If you used the same file names as in the step 3 example, you should see the following files:
   - sm_private_key.pem
   - sm_public_cert.pem
6. In the same folder, use the following command:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Important:
The specific command to use depends on your operating system.

For Linux:	`cat sm_private_key.pem sm_public_cert.pem > sm_keypair_bundle.pem`
For Windows:	`sm_private_key.pem sm_public_cert.pem > sm_keypair_bundle.pem`

This command bundles the private key and public certificate into a single file to load into your MID Server in later steps.

7. Check the folder again to verify that the new file containing your private key (sm_keypair_bundle.pem) and public certificate has been created.

Add your certificate to the ServiceNow Trusted Key Store

Upload your key and certificate to the ServiceNow Trusted Key Store.

Before you begin

Role required: admin

The public certificate that you created in this example is considered a "self-signed" certificate (meaning it didn't come from a trusted root authority). You must add the certificate to the ServiceNow Trusted Key Store for it to be used. When using a certificate that came from a Certificate Authority, you don't need to complete this step.

Procedure

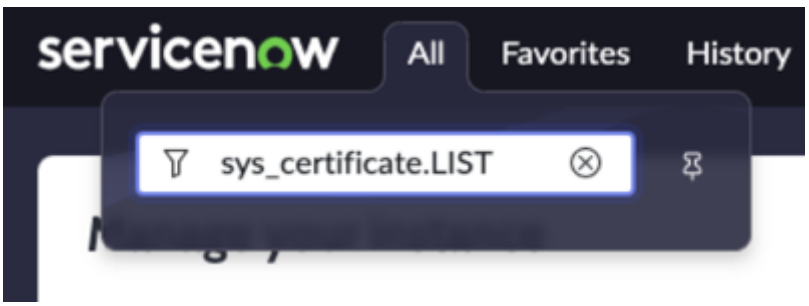
1. In your local environment, open Terminal (On Mac or Linux), or Command Line (in Windows).
2. Using the terminal, use `cd` to move into the folder where you have created your encryption keys.
3. In the terminal, enter the following command:

```
cat sm_public_cert.pem
```

You must view the contents of your public certificate to copy it into the trusted key store. This `cat` command displays the certificate.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Copy the certificate information to your clipboard.
   Start with and include the `-----BEGIN CERTIFICATE-----` line and end with and include the `-----END CERTIFICATE-----` line.
5. On your ServiceNow instance, navigate to the **X.509 certificate** list by entering `sys_certificate.LIST` in the navigation filter.



6. Select **New** to create a **X.509 Certificate** record.
7. In the form, fill in the following fields.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

X.509 Certificate fields

Field	Value
Name	Name of the certificate. This name can be any name you choose.
Format	Select **PEM** **Note:** Privacy Enhanced Mail (PEM) files are a type of Public Key Infrastructure (PKI) file used for keys and certificates. The records you created in the previous steps are of this file type.
Type	Select **Trusted Store Cert**
Short Description	Description of the certificate. Enter a value that lets you know what this certificate is being used for.
PEM Certificate	Paste the certificate information that you copied in step 4.

8. Select **Submit** to save the record.

Create a secret group with criteria

Create a group for your secrets. Secret groups to organize your secrets into groups, and enable you to apply access policies to those secrets at a group level. Then associate your secrets group to an identity group, and add your MID Server to that identity group.

Before you begin

Role required: admin, sn_kmf.admin, sn_secrets.admin

Procedure

1. Navigate to **All** > **Secrets Management** > **Secret Groups with Criteria**.
2. Select **New** to create a **Secret Group with Criteria** record.
3. In the form, fill in the following fields.

Secret Group with Criteria fields

Field	Value
Group name	Name of the secret group. This name can be any name you choose.
Secret type	Select **Client accessible**
Autogen module	Check the box
Short description	Description of the secret group. Enter a value that indicates what this group is being used for.
Criterion type	Select **Target table**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

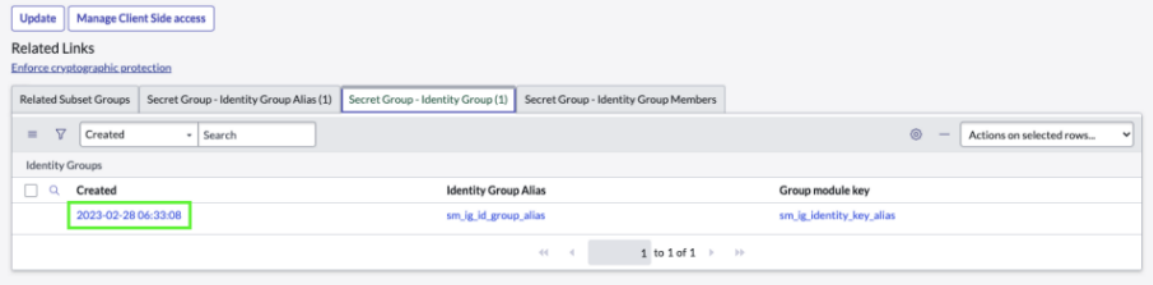
Field	Value
Target table	Select **SSH Credentials [ssh_credentials]**

4. Select and hold (or right-click) the form header and select **Save** from the context menu to save the record.
5. Make sure that the **Active** check box isn't checked.
6. Select the **Manage client side access** button to create an identity group.
   An **Identity group alias** window displays.
7. Select the **New** button.
8. Select the reference icon ( ) next to the **Identity group alias** field.
9. In the **Group Alias Name** field, enter a value.
   This name can be any value you want.
10. If you chose a unique name in Step 9, select **Submit**.
11. Select the **Upload identity key** button.
    The **Import identity public key certificate** window displays.
12. In the **Identity key alias** field, enter a value.

> **Important:**
> This value can be anything you want, but it must be an exact match for what you insert into the MID Server in later steps.

13. Select **Import**
    The **Attachment** window displays.
14. Select **Choose file**.
15. Select the public certificate that you created in the earlier steps.
    This certificate should be the `sm_public_cert.pem` file.
16. Select the X icon to close the window.
17. Select **OK** to close the **Import identity public key certificate** window.
    A blue **Keys and certificates are successfully imported to the instance** banner displays confirming a successful import.
18. Select **Submit**.
    The **Identity groups** list displays.
19. Select the check box to the left of your identity group record in the list.
20. Select the **Associate secret group** button.
    You're returned to your **Secret Group with Criteria** record. The **Secret Group – Identity Group Alias**" and **Secret Group – Identity Group** related lists are visible. These related lists display the records that you created in the previous steps.
21. In the **Secret Group – Identity Group** related list, select the **Created** field for the record on that list.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



An **Identity group** record displays.

22. In the **Identity group members** related list, select the **New** button.
A **Identity group member** record displays.
23. In the **Member table** field, select **MID Server [ecc_agent]**.
24. Select the reference icon ( ) next to the **Identity group member record** field, and select your MID Server.

> **Note:**
> If you enable the **Include all records** check box, all MID Servers connected to your instance are added to the identity group.

25. Select **OK** to close the **Select the document** window.
26. Select **Submit**.
27. Navigate back to **All** > **Secrets Management** > **Secret Groups with Criteria**, and open the record you created in step 2.
28. Enable the **Active** field.
29. Select **Update** to save the record.

Upload the public/private keypair to the MID Server

Upload your public/private keypair to your MID Server. This keypair enables the MID Server to handle authentication requests from your instance.

Before you begin

Role required: none

Since ServiceNow lacks access to the private key, it can't pair it with the public key to decrypt the symmetric key, and then decrypt the credential. If the MID Server tries to use this encrypted credential, it's unable to decrypt the credential for authentication without access to the private key.

In these steps, you upload the private key to the MID Server to complete the Public/Private keychain. This upload grants the MID Server access without giving ServiceNow access.

To grant the MID Server access to the private key, you must construct a command to be run as administrator in Powershell. In this example, the command is for the Azure Windows virtual machine.

> **Important:**
> Ensure that the system you perform these steps on has access to both the MID Server and the keypair file.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. In your local environment, locate the folder where you created your key pair in the Create encryption keys and certificate steps.
2. Find and copy the full path to the `manage-certificates.bat` file.

   Note:
   This file is located on your MID Server folder. Depending on where you've stored your MID Server folder, your path may look like this example:

   ```
   C:
   \Users\<your_user_account>\Documents\SM_Implementation\mid.
   utah-07-08-2022__patch4b01-31-2023_02-07-2023_1702.windows.
   x86-64\sm_ig_MIDS\bin\scripts\manage-certificates.bat
   ```

3. Create a text file, and paste the path into the file.
4. In the text file, add the following after the path:
   `-a your_identity_key_alias`

   Replace `your_identity_key_alias` with the name of the identity key alias that you created when you uploaded your public certificate.
5. Find and copy the full path to your key pair file.

   Note:
   If you used the names in these steps that file is named `sm_keypair_bundle.pem`.

6. In your text file, add this path to the end of the line, adding a space between this path and the previous information.
   The text within your text file should look similar to this example:

   ```
   C:
   \Users\<your_user_account>\Documents\SM_Implementation\mid.utah
   -07-08-2022__patch4b01-31-2023_02-07-2023_1702.windows.x86-64\s
   m_ig_MIDS\bin\scripts\manage-certificates.bat -a
    your_identity_key_alias
    C:\Users\<your_user_account>\Desktop\sm_keypair_bundle.pem
   ```

   Note:
   In this example, the `sm_keypair_bundle.pem` file is on the desktop to make the path shorter.

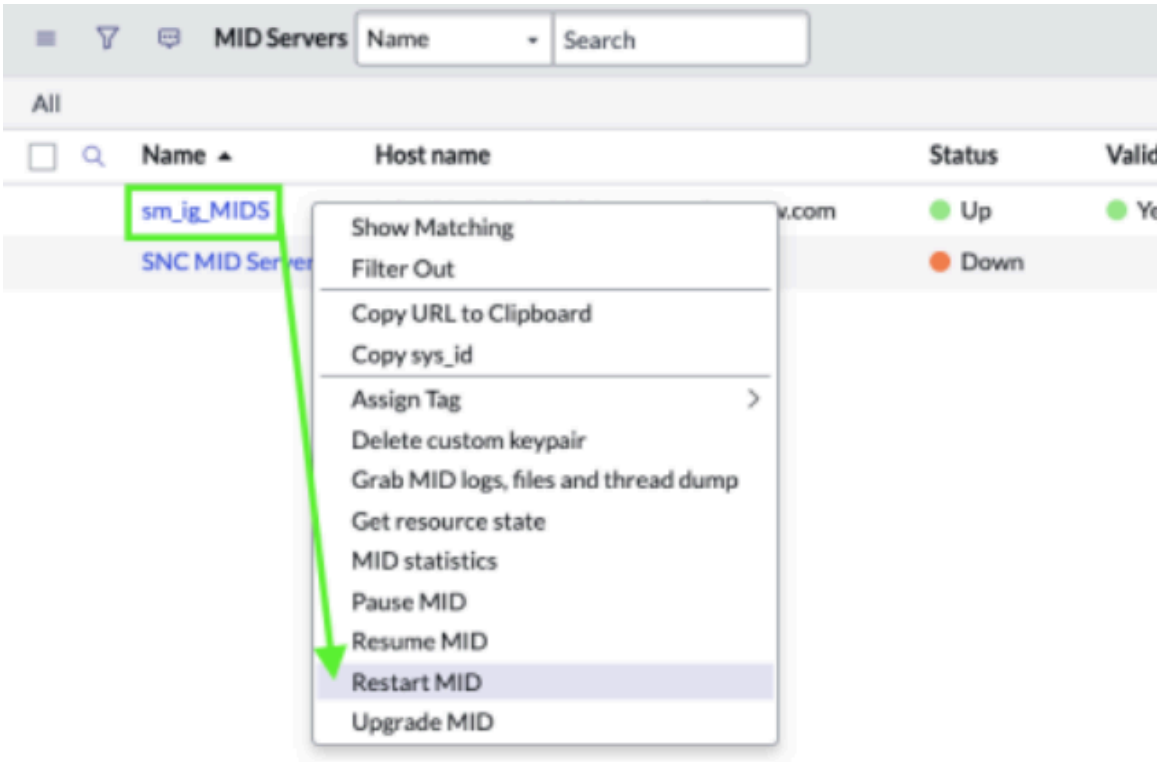
7. Copy the entire text of your text file to the clipboard.
8. Find Powershell on your system, and choose the **Run as Administrator** option.
9. Paste the text from your text file into Powershell, and press Enter.
   If successful, you can see the following message:

   ```
   Installed certificate with alias: <your_identity_key_alias>
    into the MID keystore.
   ```

   Tip:
   If you don't see this message, ensure that your command has no errors, spaces, or unnecessary quotes. Ensure that the full path is typed correctly.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

10. Restart your MID Server by navigating to your MID Server record, right-clicking the record, and selecting **Restart MID**.



Restarting the MID Server synchronizes the uploaded key pair in the MID keystore for use with operations. Wait for the MID Server to restart, with a status of **Up** and a validated value of **Yes** before continuing.

Create credentials and test credential encryption

Create a credential to authenticate into a third-party system.

Before you begin

Role required: admin, KMF_admin, sn_secrets.secret_manager, and sn_kmf.cryptographic_manager

> **Important:**
> The logged in user of the MID Server also is required to have the following roles: admin, KMF_admin, sn_secrets.secret_manager, and sn_kmf.cryptographic_manager.

Procedure

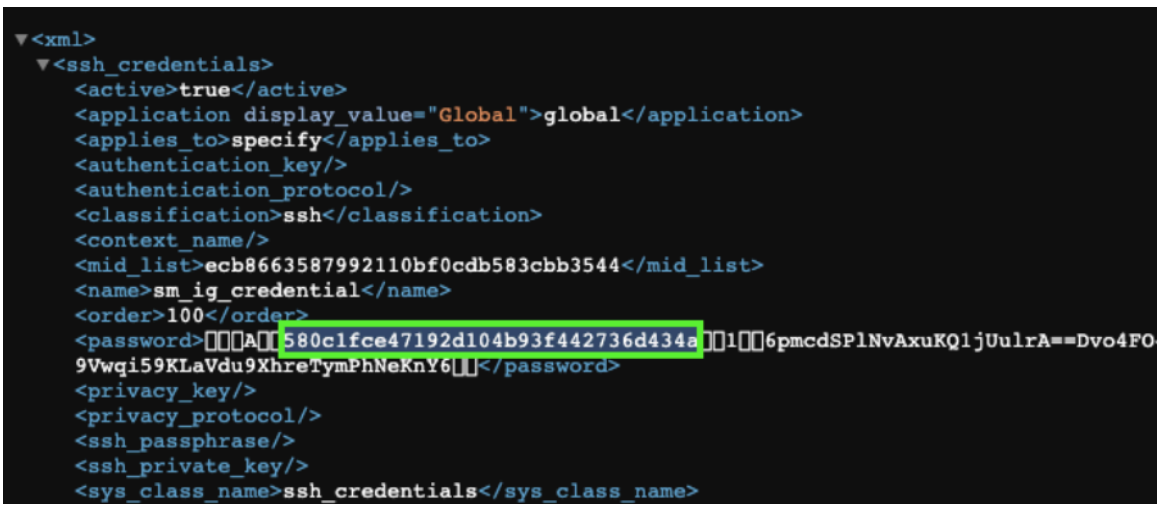
1. Navigate to the **SSH credentials** list by entering `ssh_credentials.list` in the navigation filter.
2. Select **New** to create an **SSH credential** record.
3. In the form, fill in the following fields.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

SSH credential form

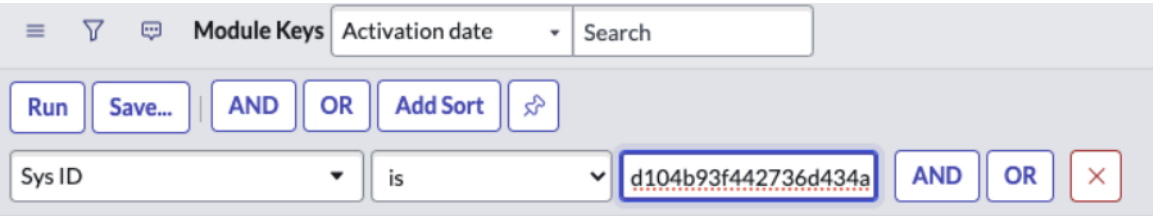
Field	Value
Name	Enter a name for your credentials record. This name can be any value you want.
Applies to	Select **Specific MID Servers**
MID Servers	Select your MID Server.
User name	Enter the user name.
Password	Enter the password related to the user in the **User name** field.

4. Select the lock icon ( ) next to the **Credential alias** field.
5. Select the reference icon ( ) to open the **Connection & credential aliases** list.
6. Select **New** to create a **Connection & credential alias** record.
7. Enter a name in the **Name** field.
8. Select **Credential** in the **Type** field.
9. Select **Submit**.
   You're returned to the **SSH Credentials** record. In the next steps, you test that the credential is encrypted.
10. Select and hold (or right-click) the form header and select **Show XML**.
11. Find the `<password>` XML tag within the XML.
12. Copy the sys_id within this `<password>` tag to your clipboard.
    The sys_id is a 32 character code representing the symmetric key that is being used to encrypt this credential. The encrypted password that you entered into the SSH Credentials table is to the right of the two sets of boxes on this same line.



13. Navigate to the **Module keys** list by entering `sys_kmf_module_key.list` in the navigation filter.
14. Filter the list for records where the **Sys ID** field matches the sys_id you copied in step 12, and select **Run**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Your search should return a single **Module key** record. This record shows you that you have successfully created, and are using, a symmetric key.

15. Navigate to the **Wrapped module keys** list by entering `sys_kmf_wrapped_module_key.list` in the navigation filter.
16. Filter the list for records where the **Crypto module** field matches the cryptographic module you created in the earlier steps, and select **Run**.
    Your search should return a single **Wrapped module key** record. From this list you can verify the following:
    - The **Wrapped key material** column shows that the symmetric key within the Crypto Module (that is being used to encrypt the SSH credential) is encrypted by the public key that you uploaded to the Identity Group.
    - The **Wrapped key sys id** field shows that it's the key (the Crypto Module symmetric key) that is being encrypted by the **Wrapping key sys id** (the Public Key uploaded to the Identity Group).

    If the preceding fields aren't on your list by default, you can add them to the list by selecting the **Personalize list** icon ( ).

    Note:
    Your instance executes a clean-up job every 10 minutes, which removes orphaned keys and helps prevent unassociated key proliferation after you update your credentials.

Configure Flow Designer to manage the integration

On your instance, use Workflow Studio to manage an integration between your local network and your instance.

Before you begin

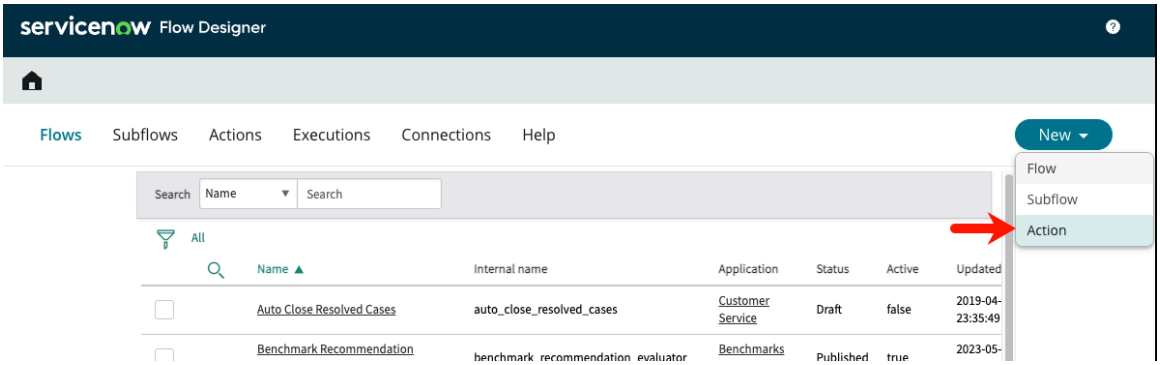
Role required: admin, KMF_admin, sn_secrets.secret_manager, and sn_kmf.cryptographic_manager

In these steps, you create a Workflow Studio workflow to create a text file on your local system.

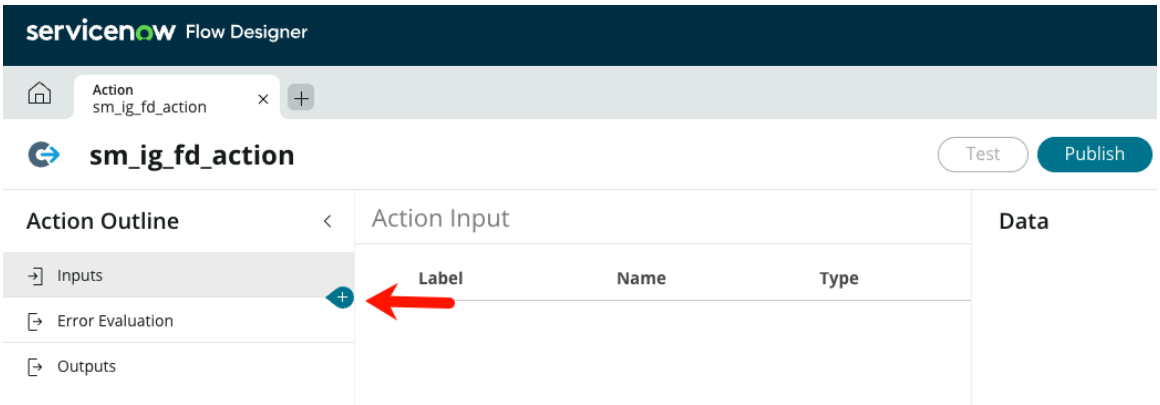
Procedure

1. On your instance, navigate to **All** > **Process Automation** > **Flow Designer**.
2. Create an action in ServiceNow by selecting **New** and selecting **Action**.

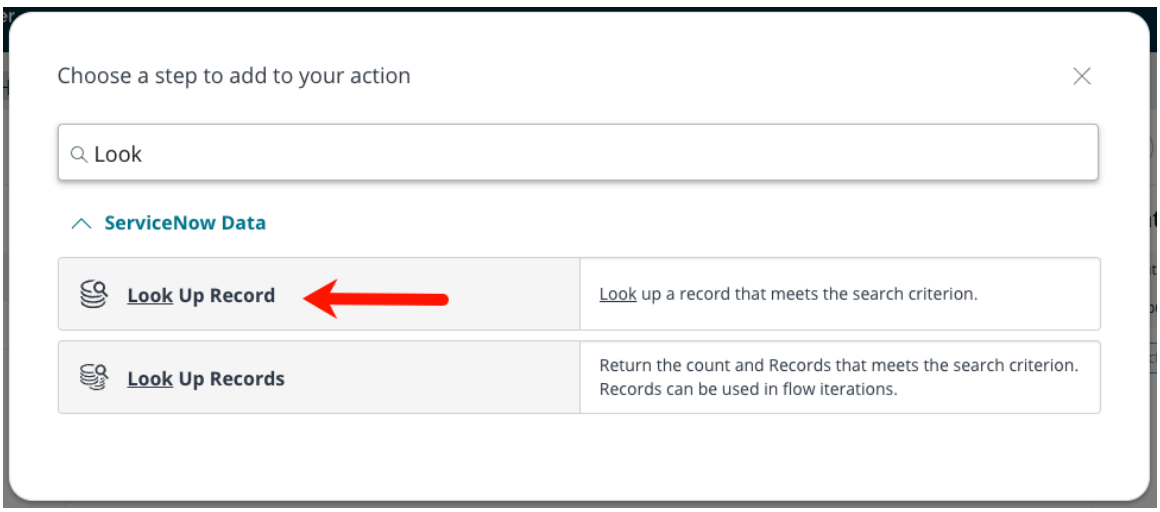
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



3. Enter a name in the **Action name** field, and select **Submit**.
4. Create a step by selecting the plus sign between **Inputs** and **Error Evaluation** in the **Action Outline**.



5. In the **Choose a step to add to your action** window, select **Look Up Record**.



6. In the **Look Up Record step** section, select **MID Server [ecc_agent]** in the **Table** field.
7. Create another step by selecting the plus sign under your **Look Up Record step**.
8. In the **Choose a step to add to your action** window, select **SSH**.

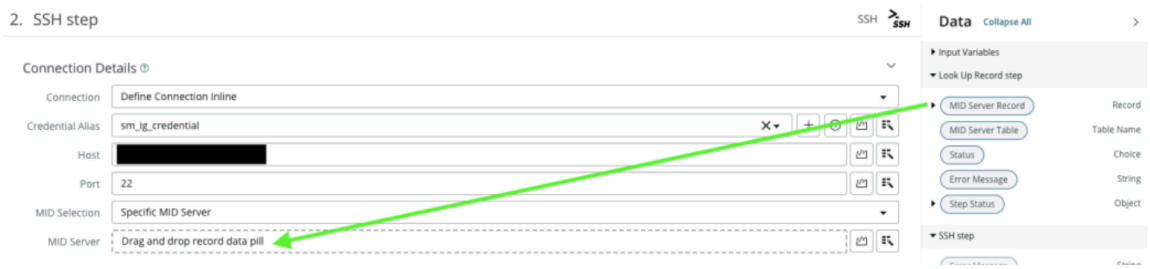
Note:
If you don't see the **SSH** option, you must activate the required plugin.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

9. In the **SSH Step** section, enter the following information:

Field	Value
Connection	Select **Define Connection Inline**
Credential Alias	Select the credential alias for the SSH credential that was created in earlier steps.
Host	Enter the IP address for the host that you're connecting to via SSH.
Port	Enter `22`.
MID Selection	Select **Specific MID Server**.

10. To fill the **MID Server** field, drag the **MID Server Record** pill from the **Data** section into the field.



> **Warning:**
> When dragging the pill into the field, select the pill and not the black arrow next to the pill.

11. In the **SSH Configuration** section, enter the following value into the **Command** field.

```
/bin/date > sm_ig_text_file.txt
```

This command creates a text file in your local system using the decrypted secrets from the MID Server. The MID Server grants access to the ServiceNow instance (through Workflow Studio) without ever giving the ServiceNow instance access to the decrypted secret.

> **Tip:**
> The `/bin/date` command is inserting the current date/time into the created text file. This command demonstrates that the integration is happening in real time based on the current date/time versus when the text file was created.

12. Select the **Save** button to save the workflow.

Test the end-to-end client-side encrypted secrets integration

Test your integration, and review the execution details to confirm your configuration is working.

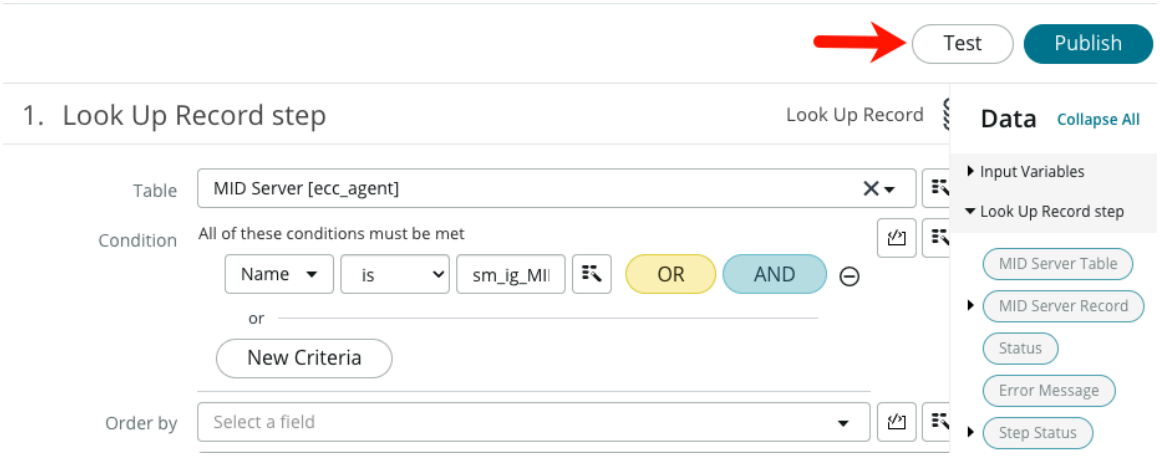
Before you begin

Role required: admin, KMF_admin, sn_secrets.secret_manager, and sn_kmf.cryptographic_manager

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. In Workflow Studio select the **Test** button in the top-right corner of the screen.



2. In the **Test Action** window, select **Run Test**.
3. Select **Your test has finished running. View the Action execution details.**
4. Refresh your screen until you see **Test Run – Completed** in the top-right side of the screen.
5. Select the **Steps** arrow at the bottom left of the screen.
6. Scroll down until you see a **Step Output Data** heading with the following success message:

```
{"Step Status";{"code";0,"message";"Success"}}
```

7. After seeing this message in Workflow Studio, verify that your text file has been created in your local system.

Test a Windows Management Instrumentation credential encrypted with Secrets Management

Verify that your Windows Management Instrumentation (WMI) credential is encrypted with Secrets Management and use an Integration Hub workflow to complete end-to-end testing.

Before you begin

Role required: admin, KMF_admin, sn_secrets.secret_manager, and sn_kmf.cryptographic_manager

- Integration Hub Enterprise must be active on your instance. For details, see Request an Integration Hub plugin.
- You must have a configured secrets group on your instance. See steps 1 through 3 listed in Configuring client accessible secrets.
- You must have a configured credential encrypted with Secrets Management. See steps 1 through 9 listed in Create credentials and test credential encryption.

Procedure

1. Confirm that the desired MID Server is associated with the Secret Group.
   Open the Secret Group with Criteria [sn_sm_criteria_secret_group] record, and look for your MID Server in the **Secret Group – Identity Group Members** list. If your MID Server isn't associated with a group see Create a secret group with criteria.
2. Confirm that the credential is encrypted with Secrets Management.

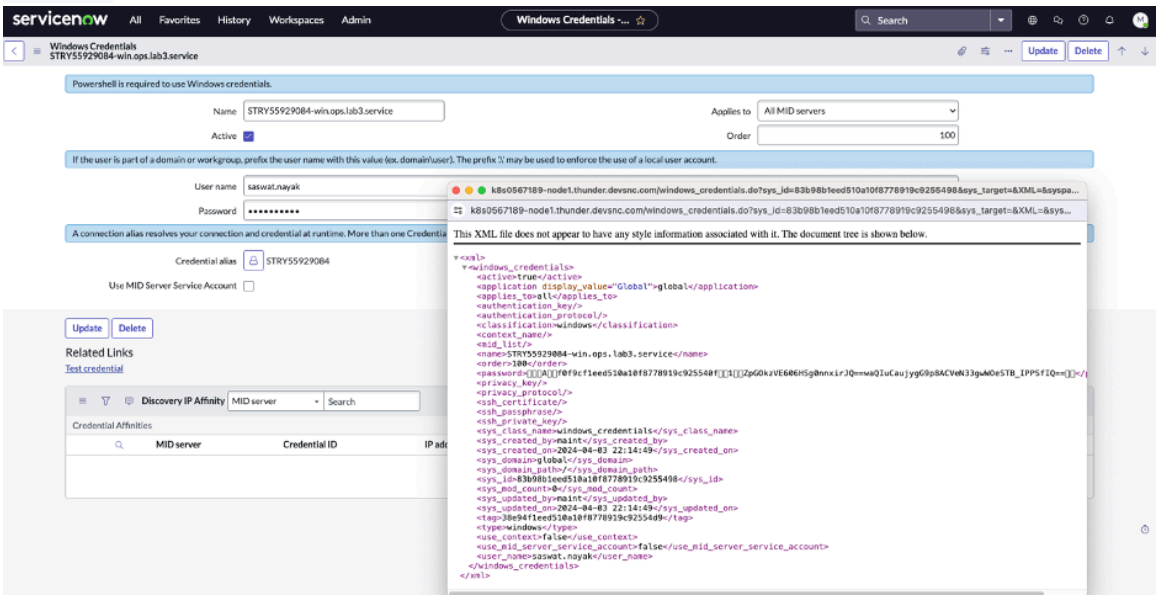
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

a. Navigate to **All** > **IntegrationHub** > **Connections & Credentials** > **Credentials**.

b. Open your credential record.
Verify that you have a credential alias listed in the **Credential alias** field. If you have not created one already, see Create a Connection & Credential alias.

c. Select and hold (or right-click) the header of your credentials record, and select **Show XML** from the list.

d. In the XML view of the record, find the password and confirm that the value starts with □□□A□□.



3. Create a testing workflow in Workflow Studio.

a. Navigate to **All** > **Process Automation** > **Workflow Studio**.

b. Select **New**, then select **Action** from the list.

c. Enter a name in the **Action name** field.
Leave the **Application** field set to Global.

d. Select the **Build action** button.

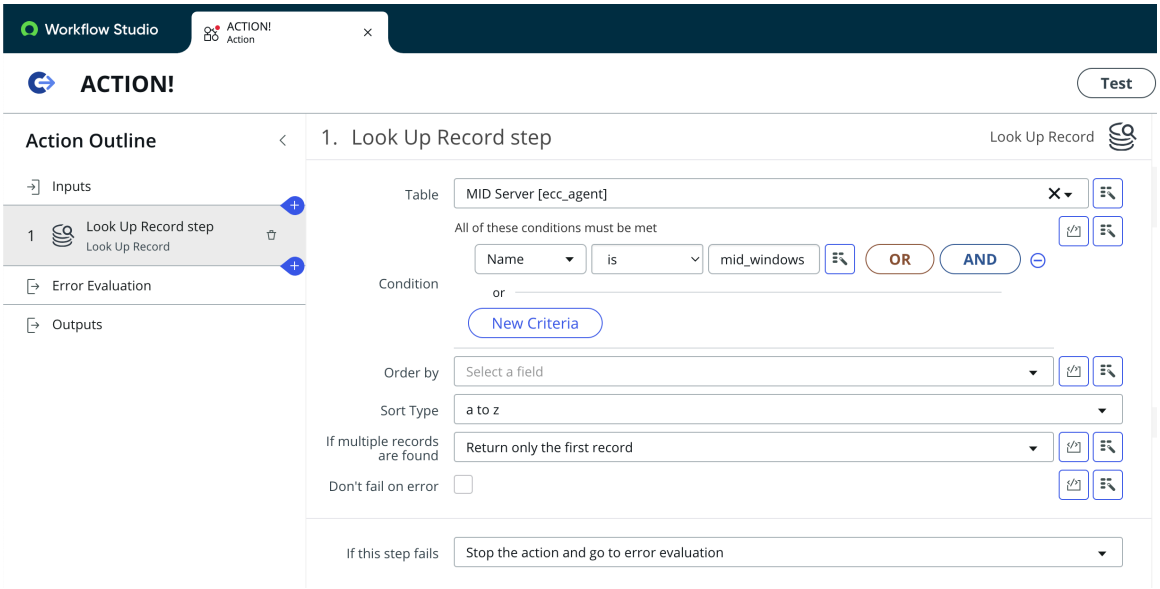
4. Configure a record lookup step in Workflow Studio.

a. In the **Action Outline**, select the plus button to add a new step.
Find and select the **Look Up Record** step type.

b. In the **Table** field, select **MID Server [ecc_agent]**.

c. For the condition, select **Name is**, followed by the name of your MID Server.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Important:
Make sure that the selected MID Server is the same as the one associated with the secret group.

5. Configure a record lookup step in Workflow Studio.

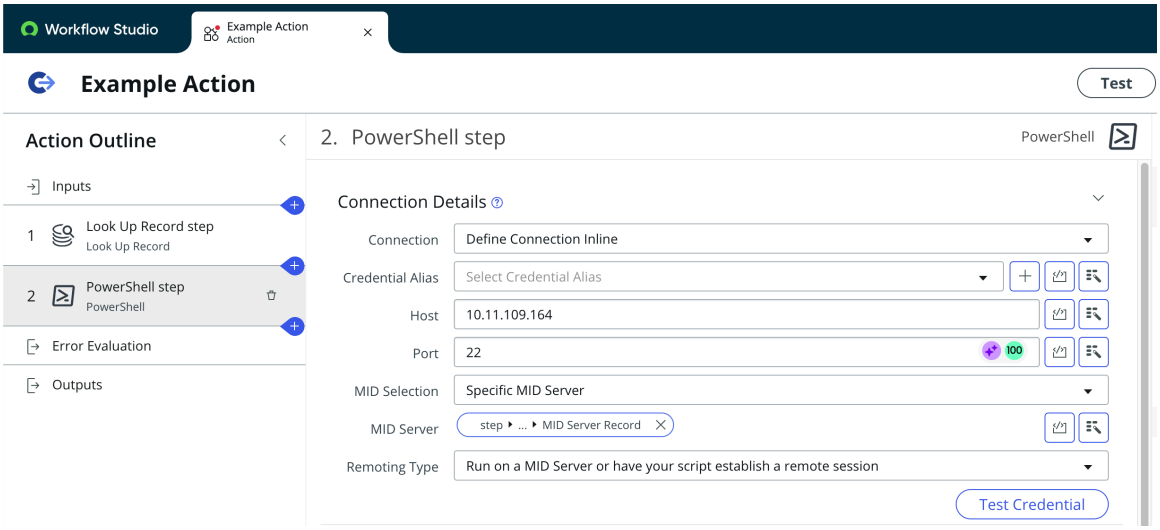
   a. In the **Action Outline**, select the plus button to add a new step below your Look Up Record step.
   Find and select the **PowerShell** step type.

   b. In the **PowerShell Step** form, fill in the fields as needed.

PowerShell step fields

Field	Value
Connection	Select **Define Connection Inline**
Credential Alias	Select your credential alias
Host	Enter the IP address of the target Windows server
Port	Enter 22 if it isn't already the default.
MID Selection	Select **Specific MID Server**
MID Server	Drag in the **MID Server Record** pill from the **Data** panel This data pill is visible in the **Data** panel on the right edge of the screen, under **Look Up Record step**.
Remoting Type	Select **Run on a MID Server or have your script establish a remote session**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



6. Create a script for your test action.

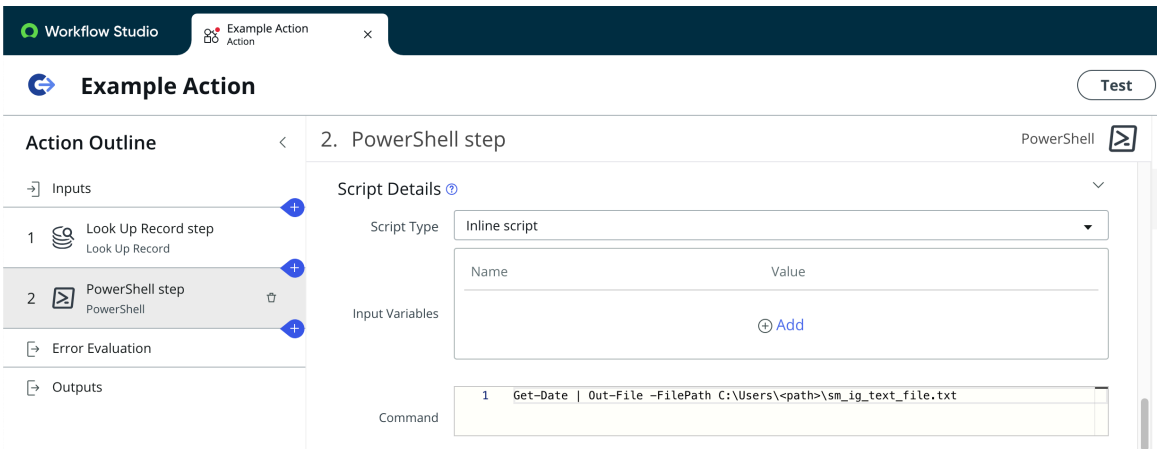
   a. In the **Script Type** field, select **Inline Script**.

   b. Use the following script, replacing the example path with the path from your test host.

```
Get-Date | Out-File -FilePath
 C:\Users\<path>\sm_ig_text_file.txt
```

> **Note:**
> You may also run your own script that suits your remote host configuration. It's important to confirm that a connection was established using the SM-encrypted value.

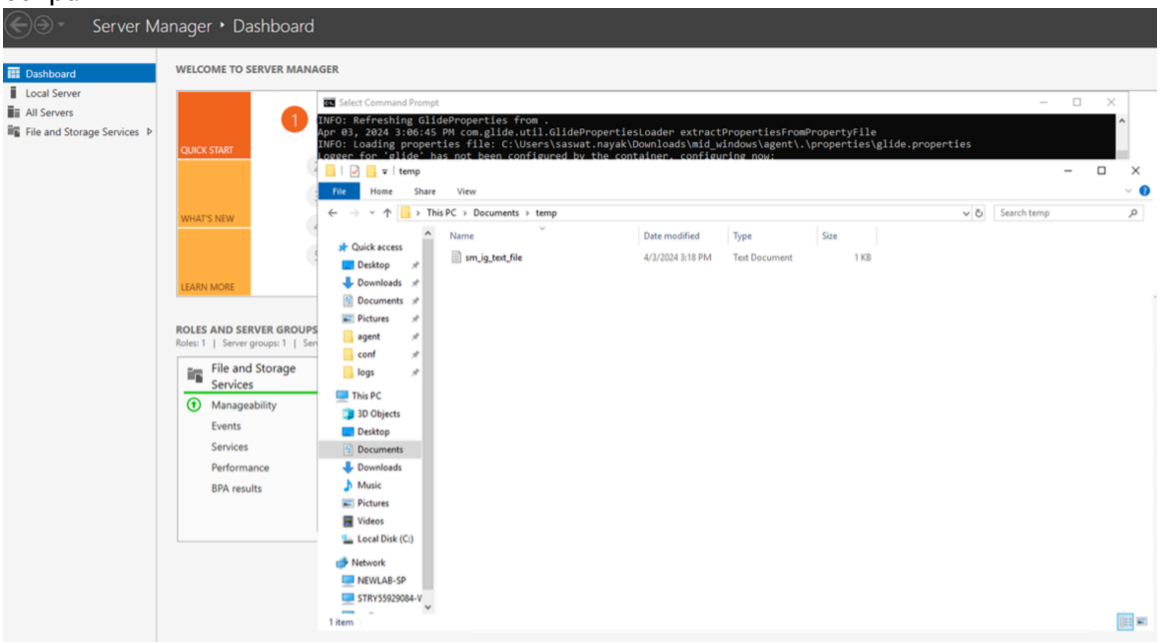
   c. Select the **Save** button to save your action.



7. Select the **Test** button to test your action.
8. Review the output logs for any error messages.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

9. Verify that a test file has been created on the host server in the file path you provided in the script.



Cloning and Secrets Management

Learn how to reconfigure secrets groups and client secrets groups after a clone.

After you clone an instance, your secrets groups and client secrets groups may need to be reconfigured to operate as expected.

Secrets group origin	Behavior after a clone
Original instance secrets groups from the target instance	Works as expected after manually importing the missing cryptographic module. See Exporting and importing data via XML.
Original client secrets groups from target instance	Works as expected after manually importing the missing cryptographic module. See Exporting and importing data via XML.
Cloned instance secrets groups from source instance	Doesn't work unless manually set up
Cloned client secrets groups from source instance	Work if manually config sg/identity group/ alias/mid

Secrets management dashboard

Use the secrets management dashboard to review the secret groups configured on your instance, and learn about any security issues.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Secret Group Overview

The **Secret Group Overview** tab displays information about your configured secret groups. Use this tab to see information about the secrets groups configured on your instance.

Secret Group by Type

Displays a pie chart showing secret groups installed on your instance, grouped by secret type (instance side of client side).

Secret Group by Criterion Type

Displays a pie chart showing secret groups with criteria configured on your instance by the type of criteria used.

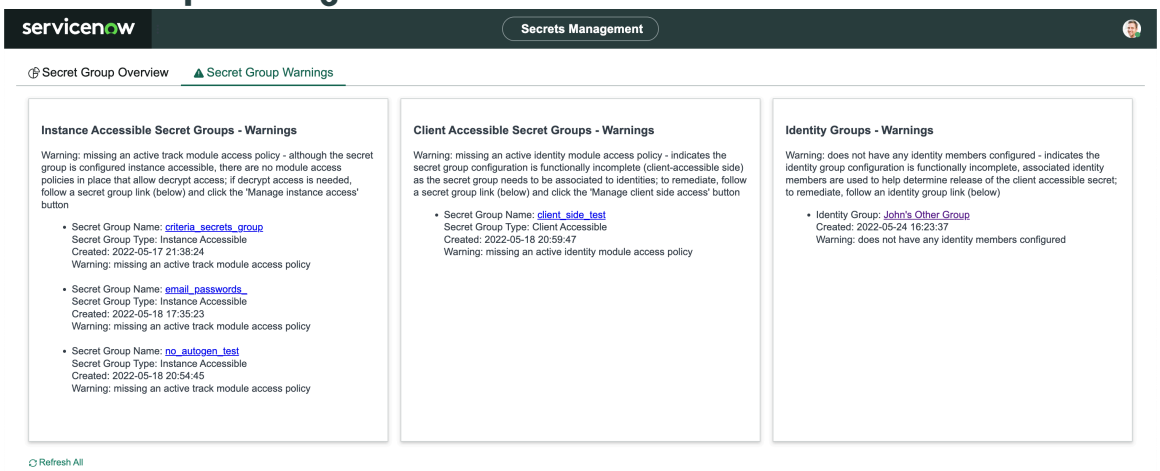
Number of Inactive Secrets Groups

Displays a count of the inactive secret groups configured on your instance.

Number of Dedicated Secrets

Displays a count of secrets within basic secret groups.

Secret Group Warnings



The **Secret Group Warnings** tab displays warnings related to your secret groups and identity groups.

Instance Accessible Secret Groups - Warnings

This card displays warnings if there are secret groups with no active access policies in place. Select a secret group name to view that record.

Client Accessible Secret Groups - Warnings

This card displays warnings if there are client accessible secret groups that don't have an active identity module access policy (MAP). Select a secret group name to view that record.

Identity Groups - Warnings

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

This card displays warnings if there are identity groups that don't have group members configured. Select the identity group name to view the record.

Note:
The Secrets Management Dashboard is a part of Secrets Management Enterprise. Secrets Management Enterprise is a paid plugin that ServiceNow personnel must activate on your production instance.

Secrets management roles

Secrets management adds these roles.

Secrets administrator [sn_secrets.admin]

Assign non-admin secrets roles to other users. Secrets administrators have the same privileges as secrets manager and viewer.

Contains Roles

List of roles contained within the role.

None.

Groups

List of groups this role is assigned to by default.

None.

Special considerations

Important:
Avoid granting an admin role when more specialized roles are available.

- A user must have both the admin and security_admin roles to be assigned the sn_secret.admin role.
- Avoid granting an admin role when more targeted roles are available.

Secrets manager [sn_secrets.secret_manager]

Grant this role to users who must be able to perform any of the following functions.

- View secret and secret group records
- View access history, and other usage activity info
- Create secret groups and filters
- Create secret providers
- Move secrets across secret groups
- Change secret group and secret provider settings

Contains Roles

List of roles contained within the role.

None.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Groups

List of groups this role is assigned to by default.

None.

Special considerations

Important:
Secrets managers can't see secrets in plain text.

Secrets viewer [sn_secrets.viewer]

Grant this role to users who must be able to view secret and secret group records.

Contains Roles

List of roles contained within the role.

None.

Groups

List of groups this role is assigned to by default.

None.

Special considerations

None.

Create a secret group cryptographic module

Create a secret group cryptographic module to perform encryption and decryption.

Before you begin

Role required:

- admin
- sn_secrets.admin
- sn_secrets.secret_manager
- sn_kmf.cryptographic_manager
- sn_kmf.admin

Procedure

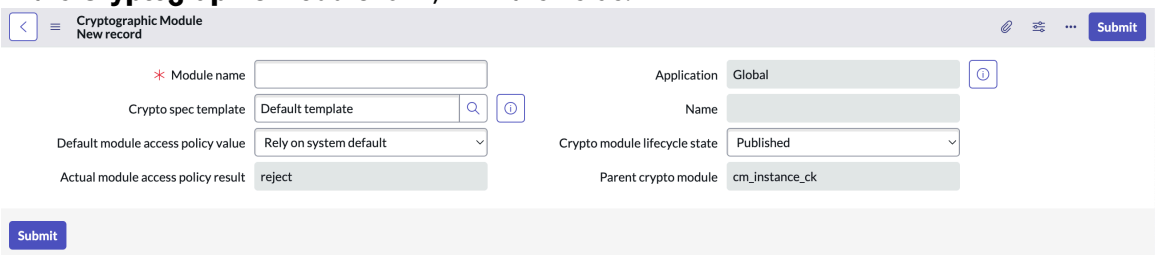
1. Navigate to **All** > **Secrets Management** > **Create Secret Group Crypto Module**.
2. Select the type of group crypto module would you like to create.

Cryptographic module type	Description
Create an instance accessible secret crypto module	Create instance accessible secrets that can be decrypted by your instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Cryptographic module type	Description
Createn a client accessible secret crypto module	Create client accessible secrets that are encrypted using your own key, which ServiceNow can't access.

3. In the **Cryptographic Module** form, fill in the fields.



Field	Description
Module name	Descriptive name for your module
Application	The application scope that contains your module. This field is automatically populated with the current module.
Crypto spec template	**Default Template** is selected by default.
Name	Name of the module. This name is automatically generated by based on the application and module name.
Default module access policy value	○ Rely on system default ○ Reject ○ Track
Crypto module lifecycle state	Whether the module is in a **Draft** or **Published** state.
Actual module access policy result	This field is for information purposes, and is read-only.
Parent crypto module	The parent cryptographic module, which is determined by the cryptographic module type you selected in the previous step. This field is read-only.

4. Select **Submit**.

Create a basic secret group

Create a basic secret group to group any secrets, regardless of their criteria.

Before you begin

Role required: admin

Basic secret groups can contain any secret you add to them, regardless of their table, scope, or application. After creating it, you manually add secrets to the group. To create a group specifically for all secrets that share a common attribute such as those, create a secret group with criteria using the instructions in Create a secret group with criteria.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Secrets Management** > **Secret Groups**.
2. Select **New**.
3. At the **What type of Secret Group would you like to create?** select **Basic Secret Group**.
4. In the **Secret Group** form, fill in the fields.

Secret group fields

Field	Description
Group Name	Name for the group **Note:** Secret group names can only contain lowercase characters, numbers, and underscores(_)
Secret Type	Whether the group is **Instance accessible** or **Client accessible**.
Autogen Module	Generates a new cryptographic module for this secret group. This module encrypts and decrypts your data. This field is enabled by default.
Application	Scoped application for this record. This read-only field is automatically populated with the current scope.
Short Description	Description of the group
Crypto Module	Select the cryptographic module to use with this group. This module encrypts and decrypts your data. This field is only visible when **Autogen Module** isn't selected. For details on module access policies, see Module access policy overview **Note:** You can review the module access policies related to your secret group using the **Manage instance access** button.

5. Click **Submit**.

Note: When created, a secret group is inactive by default. Return to the group record and select **Active** to activate the group.

Create a secret group with criteria

Create a secret group with criteria to organize secrets entered in Password2 fields automatically when they share a common criteria, such as table, scope, or application.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin

Role required: admin, KMF_admin, sn_secrets.secret_manager, and sn_kmf.cryptographic_manager

Secrets within this type of secret group must all share common criteria. For groups without this restriction, consider creating a basic secret group. Learn about creating a basic secret group in Create a basic secret group.

Procedure

1. Navigate to **All** > **Secrets Management** > **Secret Groups**.
2. Select **New**.
3. At the **What type of Secret Group would you like to create?** prompr, select **Secret Group with Criteria**.
4. In the **Secret Group** form, fill in the fields.

Secret group fields

Field	Description
Group Name	Name for the group **Note:** Secret group names can only contain lowercase characters, numbers, and underscores(_)
Secret Type	Whether the group is **Instance accessible** or **Client accessible.**
Autogen Module	Generates a new cryptographic module for this secret group. This module encrypts and decrypts your data. This field is enabled by default.
Application	Scoped application for this record. This read-only field is automatically populated with the current scope.
Short Description	Description of the group
Criterion Type	The criteria the secrets in this group shares. ○ Scope ○ Package ○ Target table ○ Secret column ○ Filter record
Crypto Module	Select the cryptographic module to use with this group. This module encrypts and decrypts your data. This field is only visible when **Autogen Module** isn't selected. For details on module access policies, see Module access policy overview

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Note: You can review the module access policies related to your secret group using the **Manage instance access** button.

Note:
Depending on your configuration, the **Crypto Module** might use an automatically selected value.

When the **Criterion Type** field is set to `Package`, and the **Autogen Module** field is selected:	The **Crypto Module** field is empty and read-only. An existing Password2 submodule is used. If a Password2 submodule isn't found, the instance level Glide Encrypter module is used.
When the **Criterion Type** field is set to `Package`, and the **Autogen Module** field is deselected: (The **Autogen Module** field can only be deselected by Enterprise users)	The **Crypto Module** field is editable, and admins can select a crypto module to use.

5. Select and hold (or right-click) the form header and select **Save**.

Note:
When created, a secret group is inactive by default.

6. After saving the record, additional fields might appear based on how you've configured your group.

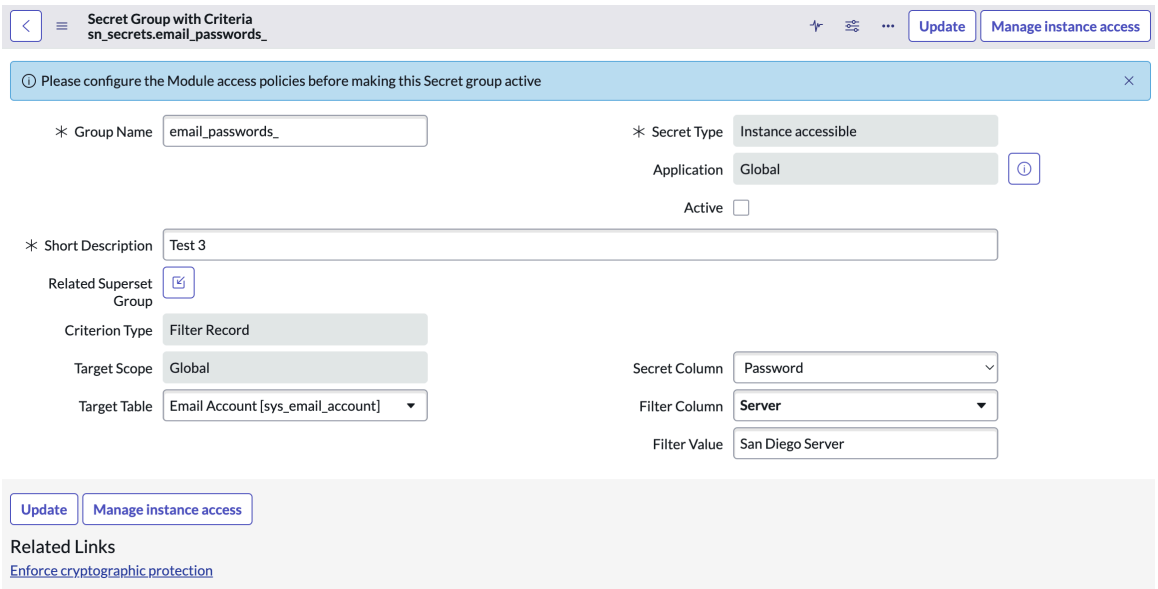
Additional secret group fields

Field	Description
Target Scope	Scope shared by the secrets to be assigned to this group. This field is only available when you select `Scope` in the **Criteria Type** field.
Target Package	Package shared by the secrets to be assigned to this group. This field is only available when you select `Package` in the **Criteria Type** field.
Target Table	Table shared by the secrets to be assigned to this group. This field is only available when you select `Table` or `Secret Column` in the **Criteria Type** field.
Target Scope	Application scope of the table selected in the **Target Table** field. This field is only visible when you select `Table`, `Filter Column`, or `Secret Column` in the **Criteria Type** field.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Secret Column	Table column that contains the pasword2 secrets you include in this group. The fields available in this list are determined by the table selected in the **Target Table** field. **Note:** If there are no columns on the select table that contain secrets, this field only displays – None -- as a selection.
Filter Column	The column on the table selected in **Target Table** you want to use as a filter. This field can't be a Password2 field.
Filter value	The value you want to use as a filter. This filter applies to the field select in the **Filter Column** field.

Example: An instance accessible group containing all email account passwords for an email server



What to do next

After creating your group, any new records matching the criteria will be encrypted. To encrypt existing records using this group's cryptographic module, you must run a security job. For details, see Run secrets management security jobs.

Client-accessible groups need a customer-provided public key to encrypt your secrets. For steps on uploading this key, see Upload a public key for Secrets Management.

Upload a public key for Secrets Management

Upload a public key for to encrypt your secrets.

Before you begin

Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Secrets Management** > **Secret Groups**, and open the secret group record.
2. In the record, select the **Manage Client Side Access** button.
   A new identity group record opens.
3. Select the **Upload Identity Key** button.
   A **Import identity public key certificate** window displays.
4. Enter an alias for your key in the **Identity Key alias** field.
5. Select the **Import** button, to upload the key from your local environment.
6. Select the **OK** button.
   The **Group module key** field uses the identity key alias name.
7. Select **Submit** to save the identity group record.

Run secrets management security jobs

Schedule a secrets management job to perform encryption tasks on secrets fields on your instance.

Before you begin

Role required: sn_kmf.admin, security_admin, and sn_secrets.admin

To perform these steps, you must elevate to the security_admin role. For details on this process see, Elevate to a privileged role

Procedure

1. Navigate to **All** > **System Security** > **Security Jobs** > **Create New**.
2. At the **What type of Security Job would you like to create?** prompt, select **Secrets Management Job**.
3. On the form, fill in the fields.

Secrets Management Job form

Field	Description
Name	Name of the security job
State	The initial job state is New. After the job has been executed as scheduled, the state will update accordingly
Time window start	Start time for the job in 24-hour format. The job begins execution at the chosen time.
Time window end	End time for the job in 24-hour format. If the job isn't finished by this time, it continues during the next specified processing window until the job is complete.
Enforcement Level	Whether the job affects all tables, or a selection of specific tables or fields. Select from ○ All Tables ○ Specific Tables

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	○ Specific Fields ○ Specific Packages **⚠ Warning:** Selecting the **All Tables** option may affect instance performance. Consider scheduling at non-peak hours.
Packages	The packages to include in this job. Encryption is applied to selected packages. This option displays only when the **Enforcement Level** field is set to **Specific Packages**
Tables	The tables to include in this job. Encryption is applied to all applicable fields within the selected tables. This option displays only when **Enforcement Level** is set to **Specific Tables**
Fields	The tables to include in this job. Encryption is applied to all selected fields. This option displays only when **Enforcement Level** is set to **Specific Fields**
Job Mode	Select from **Password2 to Secrets Management** Encrypt all password2 fields within your secrets groups using the cryptographic modules defined each group's module access policy. **Secrets Management to Password2** Re-Encrypt data in your secrets groups using password2 encryption. For details on this encryption type see Password2 encryption with KMF. **Secret Group Enforcement** Queries all data that should match the group selected in the **Secret Group** field. If all the data found by the query is already in the group, the job makes no changes. If the query finds data that is not yet in the group, the job re-encrypts this data within the Secret Group.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Note: If the data found in this query is already encrypted and your instances can't decrypt that data, it isn't encrypted and added to the secrets group.
Secret Group	Secret group containing the secrets to encrypt. This field is only available when **Secret Group** is selected in the **Job Mode** field.
Force rekeying data	
Summary	Displays information about the job progress. Summary also displays records that couldn't be encrypted by the job.

4. Select **Submit**.

What to do next

The job queries all data that should match the selected secret group. If all the data found by the query is already in the group, the job makes no changes. If the query finds data that is not yet in the group, the job re-encrypts this data within the Secret Group. (If the instance can decrypt it, which may not be the case for client side-encrypted secrets).

Code Signing

Code Signing creates digital signatures for the data which later are checked to confirm the authenticity and integrity of the data. Code Signing is a module licensed as a component of ServiceNow Vault.

Code signing and Circle of Trust

The Circle of Trust (COT) is a prerequisite for Code Signing that creates secure communication between your trusted and protected instances to ensure that only authorized users can access the Code Signing feature.

Multiple security measures help to prevent malicious actors from disabling or misusing code signing in the case a protected instance is compromised. As part of the defense-in-depth strategy, the COT uses the following components:

- Controls that restrict even the most powerful administrator accounts are established in the protected instance to help protect Code Signing processes and configuration.
- Trusted instances are required to work together with protected instances to establish the Circle of Trust relationship. At least one trusted instance is required, but multiple trusted instances may be configured to collaborate with the protected instance.

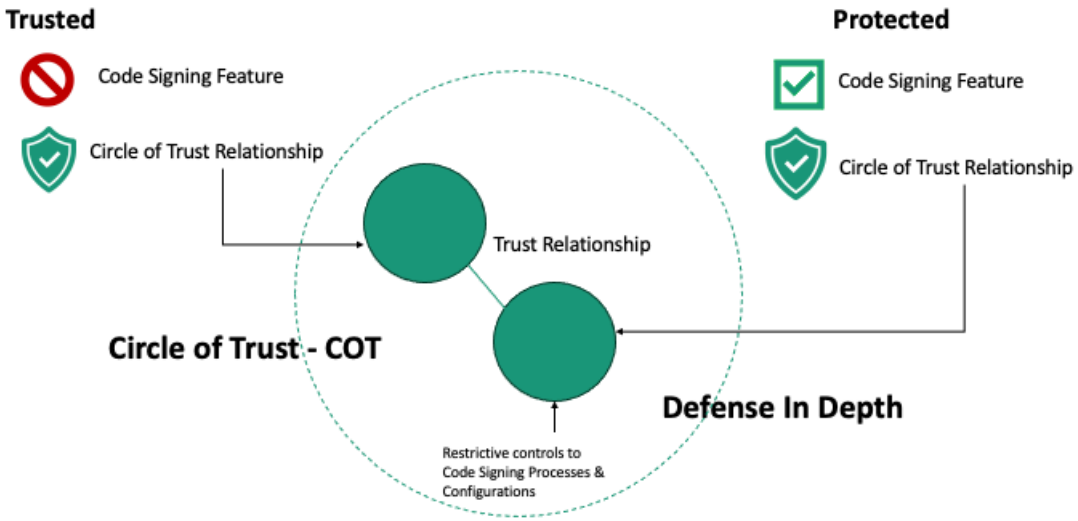
Circle of Trust overview



The Circle of Trust uses jobs, scripts, and business rules along with a key pair to generate signatures to sign update sets to the protected instance. When the job is called, the signature is verified along with the trusted certificate to execute protected instance updates.

Exploring Code Signing

Code Signing provides cryptographic verification to ensure that only authorized scripts can execute on MID Servers. Code Signing prevents unauthorized or tampered ECC queue records from being processed by MID Servers, maintaining the integrity of integrations between ServiceNow and external systems.

Code Signing creates digital signatures for your data, which are later checked to confirm the authenticity and integrity of the data. Code Signing is a module licensed as a component of ServiceNow Vault.

Note:
The Customer Service and Support team must grant access to Code Signing.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Code Signing declares the intent behind the operation being performed and validates whether the resource or record may be used for the intended purpose. To facilitate Code Signing, the Key Management Framework (KMF) uses digital certificates and industry standard asymmetric encryption for digital signatures.

Use Code Signing internally on the platform and infrastructure side. Code signing provides a way to sign the content of specific tables or of a subset of records in a given metadata table.

Code Signing uses a secure Circle of Trust (COT) between your trusted and protected instances to help ensure that only authorized, secure trusted instances can access the Code Signing feature.

Note:
Code Signing is enabled on the protected instance and not on the trusted instance.

How Code Signing protects your environment

Without Code Signing, an attacker who gains access to ServiceNow records can modify SQL statements in a protected instance. When the MID Server processes this data source request, it would execute the malicious SQL commands, potentially compromising system integrity and security.

When you implement a Circle of Trust architecture with Code Signing, transfer of data to the MID Server follows the following verification process. This process helps ensure that only authorized code originating from the trusted instance can execute on the MID Server. The processes reduces potential attack vectors that could otherwise compromise your systems.

1. Digital signatures are applied to data sources created or updated within the trusted instance.
2. Use the Code signing process to transfer the signed data from the trusted instance to the protected instance
3. The MID Server verifies the digital signature on all incoming requests, automatically rejecting any requests lacking valid signatures.
4. If the MID Server rejects a request, it logs this rejection and sends a notification to the protected instance.

Benefits of implementing Code Signing

Code Signing provides several key advantages:

Execution Control

Only cryptographically verified scripts can run on MID Servers

Tamper Detection

Any modifications to signed records are immediately identified and blocked.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Automated Protection

The system handles security enforcement without requiring manual intervention.

Comprehensive Logging

All signature verification failures generate detailed audit records.

Code Signing validation and jobs

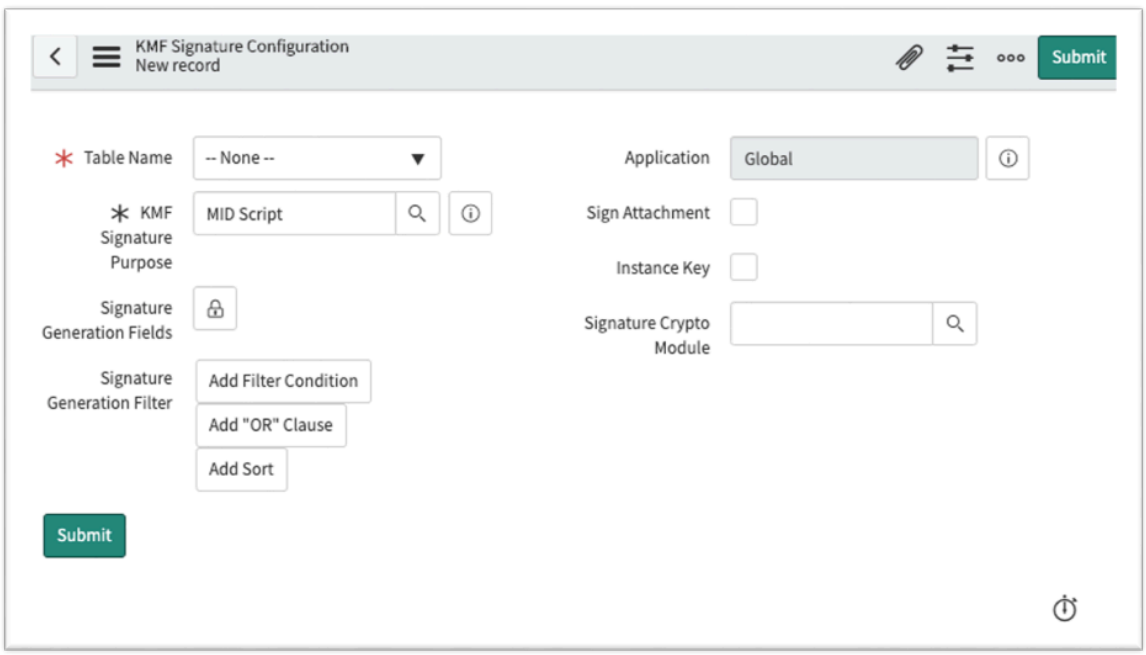
All the metadata tables with valid configurations are signed at build time using the Code Signing metadata plugin (*com.glide.code_signing*). Installing this plugin automatically installs the Code Signing OOB App Signatures plugin (*com.glide.code_signing.oob_apps_signatures*) which contains build time signatures for all relevant records in the trued-up ServiceNow® Store application versions. If you choose to sign tables, admin users with the Security administrator role have access to Code Signing jobs:

- Sign update sets.
- Mass sign records.
- Mass sign attachments.

Sign update set

This job signs records that match a signature configuration in the update set. The job also adds all the new signature records and the verification certificates to the update set.

KMF signature record for update set



Mass sign records

This job signs all the records that match the signature configuration applied on a specific metadata table.

Mass sign attachments

This job signs all the attachment records that are attached to a table that matches a specified signature configuration.

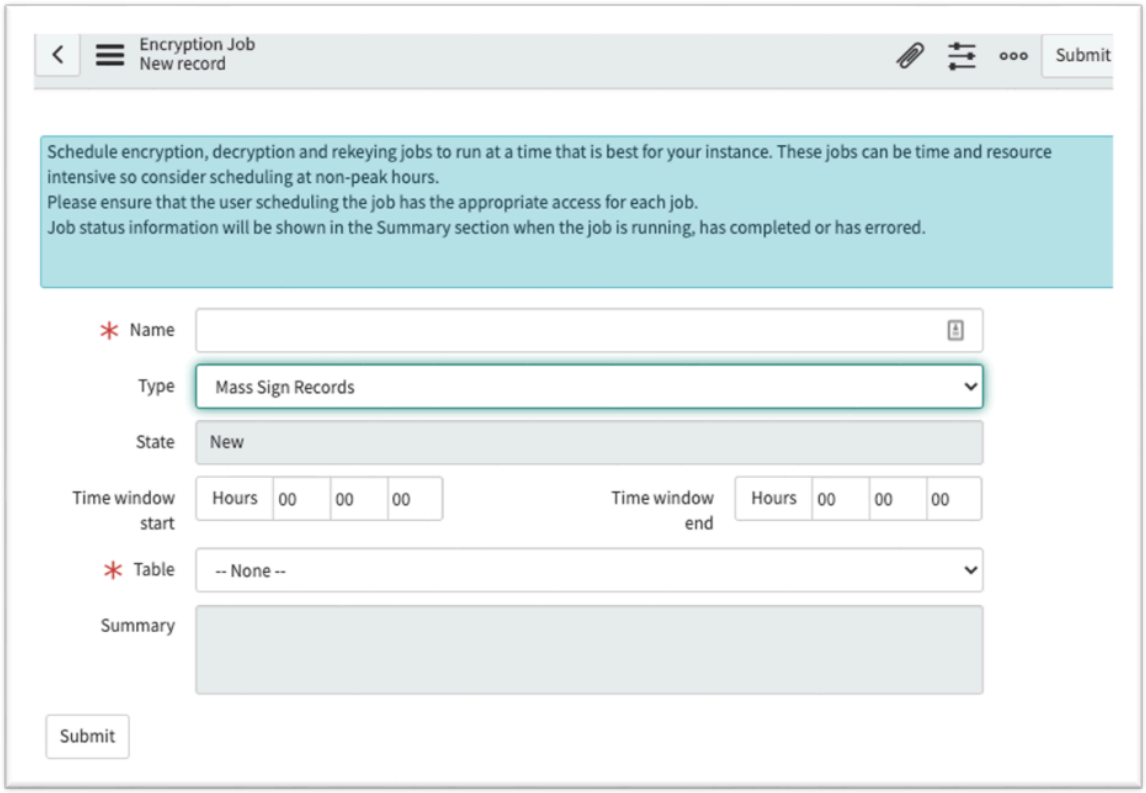
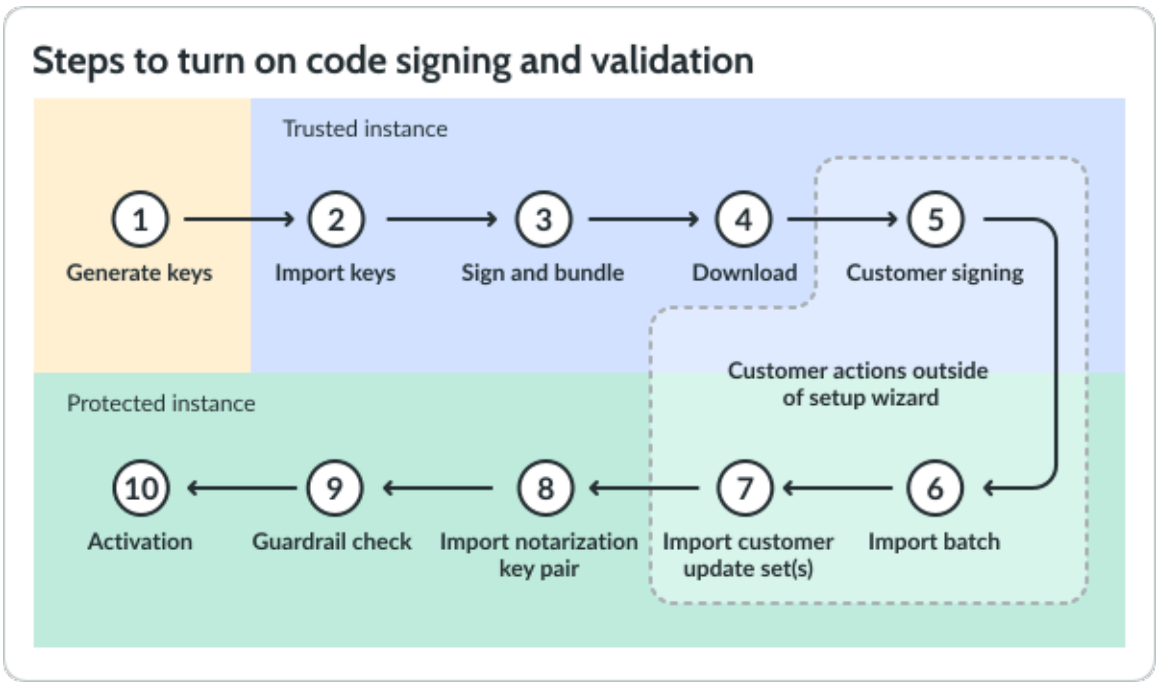
Encryption job to mass sign records



Configuring Code Signing

Activate and configure Code Signing to verify the authenticity and integrity of your data.



Code Signing Enterprise requires an initial trust relationship between trusted and protected instances that helps to prevent any unauthorized user with any authorization level from accessing unapproved activities.

Refer to each topic to complete the configuration steps to establish the Circle of Trust with Code Signing Enterprise:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Assign the Code Signing Administrator Role

Assign the Code Signing Administrator role to a user to access the Code Signing configuration experience.

Configure Code Signing Enterprise on your trusted instance

Turn on Code Signing on your trusted instance.

Upload your Code Signing configuration file to your protected instance

Upload the configuration file generated on your trusted instance.

Configure Code Signing Enterprise on your protected instance

Turn on and configure Code Signing on your protected instance.

Turn on certificate validation

Turn on certificate validation on your instance.

Turn off Code Signing

Disable code signing on your protected instance.

> **Note:**
> This optional step isn't part of the initial configuration for Code Signing

Assign the Code Signing Administrator Role

Assign the Code Signing Administrator role to a user to access the Code Signing configuration experience.

Before you begin

Roles required:

- admin
- security_admin

> **Important:**
> The user that is assigned the Code Signing Administrator role must be in the Global scope.

Procedure

1. Select a trusted instance to use.
   The trusted instance is used to create jobs, sign records, and perform other necessary tasks before enabling signature validation on your protected Instance.
2. Navigate to **All** > **Code Signing** > **Administration** > **Role Administration**.
3. Grant a user the Code Signing Administrator role by moving a user from the **Available Users** list to the **Selected User(s)** list.
4. Select **Save**.

> **Important:**
> The user assigned to the role must log out and lot in again to perform Code Signing tasks.

Result

The selected user has the Code Signing Admin role. A user with this role can access the Code Signing configuration experience, and assign other Code Signing roles to users.

To learn more about Code Signing roles, see Roles installed with Code Signing.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Configure Code Signing Enterprise on your trusted instance

Turn on and configure Code Signing on your trusted instance.

Before you begin

Roles required:

- admin
- security_admin
- codesigning_admin

> **Note:**
> The codesigning_admin role can be assigned using the process detailed in Assign the Code Signing Administrator Role.

- sn_kmf.cryptographic_manager

You must have at least one cryptographic key pair and certificate (p12 file extension) for customer signing and Circle of Trust (COT) administration. For improved security, consider using separate cryptographic key pairs for customer signing and COT administration.

> **Warning:**
> After completing this process, you will have downloaded a configuration file that must be installed on your protected instance within an hour. Verify that you have time available after this process to upload the configuration file to your protected instance. For details on that process, see Upload your Code Signing configuration file to your protected instance.

Procedure

1. On your trusted instance, navigate to **All** > **Code Signing** > **Configuration** > **Guided Setup** to open the Code Signing configuration page.
2. In the **Instance type** field, select **trusted instance**.
3. Select the **Next** button.
4. In the **Action** field under **Select the action you'd like to accomplish**, select **Turn on Code Signing**.
5. Next to **Attachments** in the **Customer signing key pair and certificate** section select **+Add File** to upload a cryptographic key pair (p12 file extension) to use for customer signing.

   > **Tip:**
   > If the **+Add File** option is not available, verify that you are in the Global scope, and that you have the sn_kmf.cryptographic_manager role.

6. In the **Password** field, enter the password for the uploaded key pair.
7. Select **Import**.
8. Select **Continue** to move to the next section.
9. Next to **Attachments** in the **COT administration key pair and certificate** section select **+Add File** to upload a cryptographic key pair (p12 file extension) to use for customer signing.
10. In the **Password** field, enter the password for the uploaded key pair.
11. Select **Import**.
12. Select **Continue** to move to the next section.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

13. On the **Export Configuration** file page, select **Export** to create and download a configuration file used to turn on Code Signing on your protected instance.
    The export process downloads an XML file to your local machine for use in the steps details in Configure Code Signing Enterprise on your protected instance.

    Note:
    Code Signing enforces limits on large update sets to improve the user experience. The maximum size for an update set is 10,000 records.

Upload your Code Signing configuration file to your protected instance

Upload the configuration file generated on your trusted instance.

Before you begin

Roles required:

- admin
- security_admin
- codesigning_admin

Note:
The codesigning_admin role can be assigned using the process detailed in Assign the Code Signing Administrator Role.

- sn_kmf.cryptographic_manager

You also need the configuration file generated in the steps detailed in Configure Code Signing Enterprise on your trusted instance.

Procedure

1. Navigate to **All** > **System Update Sets** > **Retrieved Update Sets**.
2. Select **Import Update Set from XML** at the bottom of the Retrieved **Update Sets** list.
3. Select **Choose File**, and select your configuration file (xml file extension).
4. Select **Upload**.
   You should see the **Codesigning configuration** update set in the **Retrieved Update Sets** list.
5. Select and open the **Codesigning configuration** update set.
6. Select **Preview Update Set Batch**.
   If any conflicts occur during the preview, resolve them by selecting **Accept remote update** or **Resolve known CS conflicts**.
7. After resolving any conflicts, select **Commit Update Set Batch**.

Configure Code Signing Enterprise on your protected instance

Turn on and configure Code Signing on your protected instance.

Before you begin

Roles required:

- admin
- security_admin
- codesigning_admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
The codesigning_admin role can be assigned using the process detailed in Assign the Code Signing Administrator Role.

- sn_kmf.cryptographic_manager

Procedure

1. On your PPI, navigate to **All** > **Code Signing** > **Configuration** > **Guided Setup** to open the Code Signing configuration page.
2. In the **Instance type** field, select **protected instance**.
3. Select the **Next** button.
4. Select the **Please confirm the Code Signing configuration update set was imported and committed** check box.
5. Select the **Next** button.
6. Wait for the certificate installation to complete.
   A blue alert message displays indicating that items from the configuration file are installing. The alert disappears in a few seconds when the installation finishes.
7. Next to **Attachments** in the **Runtime/notarization key pair and certificate** section select **+Add File** to upload a cryptographic key pair (p12 file extension) to use for runtime/notarization purposes.
   You can re-use a key pair from the trusted instance or upload a new one specifically for this use.

   Tip:
   If the **+Add File** option is not available, verify that you are in the Global scope, and that you have the sn_kmf.cryptographic_manager role.

8. In the **Password** field, enter the password for the uploaded key pair.
9. Select **Import**.
10. Select **Continue** to move to the next section.
11. Wait while your instance performs a guardrail check.
    This check scans your instance for any invalid signatures, and might take some time to complete. Don't exit or refresh the page until the scan completes.

    This workflow identifies signatures that were generated with expired or inactive certificates and re-signs the affected records. To improve performance, the workflow now divides the process into multiple events and runs them in parallel.

12. If the scan finds invalid signatures, select **Download Report**.

    Selecting **Download Report** downloads a report (`scan_report.txt`) that you can use to investigate and fix the invalid signatures.

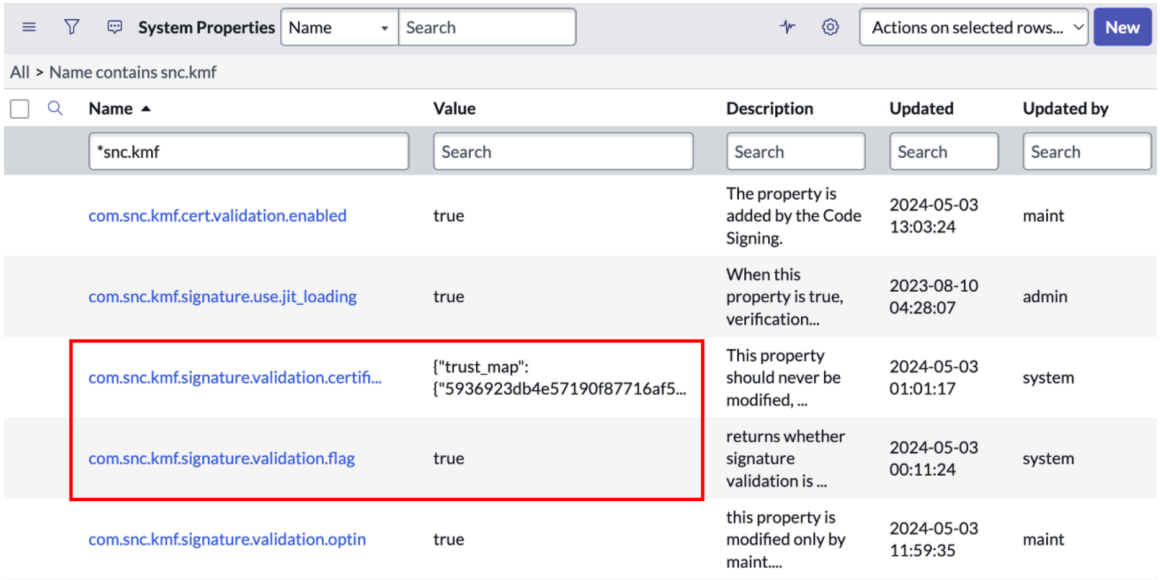
    After resolving errors, refresh the page to re-run the check.

13. If there are no errors, select **Complete setup**.
14. Wait for the configuration jobs to complete.
    Your instance runs one or more jobs to complete the configuration process. Don’t exit or refresh the page until the jobs have finished. When finished, you should see a **Code Signing configuration completed successfully** message.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Result

Signature validation is now being enforced on your production instance. You can verify successful completion by looking at your system properties. Look for the **com.snc.kmf.signature.validation.flag** property on the System Properties [sys_property] table, and verify that it has a value of **true**. Verify that the **com.snc.kmf.signature.validation.certificate_trust** property doesn't have an empty value.



Turn on certificate validation

Protect your instance with certificate based validation.

Before you begin

Role required:

- codesigning_admin
- security_admin
- sn_kmf.cryptographic_manager

Procedure

1. On your trusted instance, navigate to **All** > **Code Signing** > **Configuration** > **Guided Setup** to open the Code Signing configuration page.
2. In the **Instance type** field, select **trusted instance**.
3. Select the **Next** button.
4. In the **Action** field under **Select the action you'd like to accomplish**, select **Turn on Cert Validation**.
5. Select the **Next** button.
6. Next to **Attachments** in the **Customer signing key pair and certificate** section select **+Add File** to upload a cryptographic key pair (p12 file extension) to use for customer signing.

   Tip:
   If the **+Add File** option is not available, verify that you are in the Global scope, and that you have the sn_kmf.cryptographic_manager role.

7. In the **Password** field, enter the password for the uploaded key pair.
8. Select **Import**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

9. Select **Continue** to move to the next section.
10. Next to **Attachments** in the **COT administration key pair and certificate** section select **+Add File** to upload a cryptographic key pair (p12 file extension) to use for customer signing.
11. In the **Password** field, enter the password for the uploaded key pair.
12. Select **Import**.
13. Select **Continue** to move to the next section.
14. In the **Perform trusted instance tasks** section, wait for all tasks to be completed.

    Your instance generates and executes these tasks automatically. If you used Code Signing prior to the Vancouver release, tasks are created and executed to update your signatures.

    In some cases, no tasks are needed. **No tasks needed** displays on this page.
15. Select **Continue** to move to the next section.
16. On the **Export Configuration** file page, select **Export** to create and download a configuration file used to turn on Code Signing on your protected instance.
    The export process downloads an XML file to your local machine for use in the steps detailed in Configure Code Signing Enterprise on your protected instance.
17. On your protected instance, navigate to **All** > **System Update Sets** > **Retrieved Update Sets**.
18. Select **Import Update Set from XML** at the bottom of the Retrieved **Update Sets** list.
19. Select **Choose File**, and select your configuration file (xml file extension).
20. Select **Upload**.
21. Return to the code signing configuration page at **All** > **Code Signing** > **Code Signing Configuration**.
22. Use the wizard to complete your configuration, selecting the options for completing certificate validation activation.

Quorum Controlled Certificate Revocation

The quorum-controlled certificate revocation for Code Signing certificates provides a secure mechanism for a Code Signing admin to revoke Code Signing certificates. The revocation process involves submitting a request that requires approval from multiple stakeholders. This workflow helps to prevent accidental or unauthorized revocations.

This topic provides the high-level process overview for securely revoking certificates between a trusted instance and a protected instance using a quorum-based approval workflow.

- Request creation and export (Trusted instance): Initiate a quorum certificate revocation by creating a request with the required configuration properties. Export the update set, which includes the revocation request and related data. See Export Revocation Request Configuration
- Import and approval (Protected instance): Import the update set into the protected instance. Approvers receive notifications and must complete the approval workflow before the certificate is deleted. See Import the revocation request configuration
- Optional MID Server restart: If enabled in the configuration, MID Servers on the protected instance are restarted after the certificate revocation. This forces immediate certificate resynchronization but can result in data loss for unprocessed or cached events. See Approve certificate revocation

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:

Your *update set* expires after the time window defined by the `com.snc.kmf.signature.validity_window` property. If it expires, you can export a new signed update set from the trusted instance. This validity window applies to all update set operations, including export, import, and enabling Code Signing. This validity window is not related to the request time window that you specify when creating the request.

Export Revocation Request Configuration

Start the certificate revocation process by selecting the certificate that you want to revoke. Provide the required configuration properties. Export this transaction as part of an update set, which is imported into the protected instance for approval and execution.

Before you begin

Role required: sn_cse.codesigning_admin, sn_cse.quorum_requester, security_admin

Procedure

1. On your trusted instance, navigate to **All** > **Code Signing** > **Configuration** > **Guided Setup** and open the Code Signing configuration page.
2. In the **Instance type** field, select **trusted instance**.
3. Select the **Next** button.
4. In the **Action** field under **Select the action you'd like to accomplish**, select **Certificate Revocation**.
   The Certification Revocation Request page appears.
5. In the Select Certificate to Revoke page, select the certificate that you want to revoke and select **Initiate Revocation**.
6. Configure the approval requirements for certification revocation.

   a. In the Quorum Requirements menu, enter the appropriate information in the text fields.

   Quorum Requirements Properties

Property	Description
Minimum approvals	Minimum number of approvers required to approve the certificate revocation request.
Time window	Expiration time for the revocation request.
Approvers	Email address of the users who are authorized to approve the revocation request.

   b. In the **Request description** field, enter the reason for initiating the certificate revocation.

   c. Select **Save**.
   The Export configuration file menu appears.

   d. On the Export Configuration file page, select **Export** to create and download a configuration file used to run certificate revocation workflow on your protected instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Result

The export process downloads an XML file to your local machine for use in the steps detailed in Configure Code Signing Enterprise on your protected instance.

Import the revocation request configuration

Import the update set into the protected instance to initiate the certificate revocation process. Approvers receive email notifications and they should complete the approval workflow before the certificate is revoked. The approval means that the revocations are confirmed, authorized, and traceable for security and compliance purposes.

Before you begin

Role required: sn_cse.codesigning_admin, sn_cse.quorum_requester, security_admin

Procedure

1. Log in to your protected instance and navigate to **All** > **System Update Sets** > **Retrieved Update Sets** > **Import XML**.
   The Import XML page appears.
2. Select **Choose file** and select the configuration XML file from your local system.
3. Select **Upload**.
4. Return to the code signing configuration page at **All** > **Code Signing** > **Code Signing Configuration**.

   a. Review the following configuration files in the **Customer Updates in Batch** tab.
      - Code Signing Configuration Property (`time_window`)
      - Code Signing Configuration Property (`approver_email_ids`)
      - Code Signing Configuration Property (`minimum_approvals`)
      - Code Signing Configuration Property(`restart_mid_servers`)
      - Code Signing Quorum Request (CSEQCxxxxxxx)
      - Code Signing Transaction (CSETRANSxxxxxxx)
      - KMF Signature Records

   b. Select **Batch Update Set Preview** > **Commit Update Set Batch**.

5. Return to the code signing configuration page at **All** > **Code Signing** > **Configuration** > **Guided Setup**.
6. In the **Instance type** field, select **Protected instance** and select **Next**.
   The **Start or continue your configuration** page appears.
7. Select the **Confirm that the Code Signing configuration update set was imported and committed.** check box and select **Next**.
   In the Quorum Control Configuration page, review the information that you entered and select **Trigger Quorum Approval**.
8. In the Protected instance, select **Certification Revocation Status** in the Trigger Quorum Approval page to review updates on the quorum control request approvals.
9. Select **Approver details** and review the status of the quorum requests.

Approve certificate revocation

Review and approve certificate revocation requests from the email approval notifications that are sent to your registered email address. Review the approval notification and select the **Click here**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

to approve or **Click here to reject** link to access the protected instance and act. You can also access the approval request and the code-signing quorum request directly from the email.

Before you begin
Role required: sn_cse.codesigning_admin, approver_user

Procedure

1. Access the protected instance by following the links provided in the notification email.
2. Review the transaction requests under the Approvals menu.
3. Approve the task by selecting **Approve**.
4. In the approval confirmation page, select **Yes** to access the specific code signing quorum request.
5. Review the Code Signing quorum request and add any additional notes in the **Comments** menu, if necessary.
6. Select **Update**.

Result
The Code Signing quorum request is approved. If you have enabled the MID Server restart while exporting the revocation request, the MID Server restarts for the request to be activated.

Turn off Code Signing

Disable code signing on your protected instance.

Before you begin
Role required: admin, codesigning_admin

Procedure

1. On your trusted instance, navigate to **All** > **Code Signing** > **Configuration** > **Guided Setup** to open the Code Signing configuration page.
2. In the **Instance type** field, select **trusted instance**.
3. Select the **Next** button.
4. In the **Action** field under **Select the action you'd like to accomplish**, select **Turn off Code Signing**.
5. In the **Export configuration file** panel, select **Export** to download the update set.
   The export process downloads an XML file to your local machine for use in the next steps.
6. Select **Done**.
7. Log in to your protected instance.
8. Upload your configuration files using the steps in Upload your Code Signing configuration file to your protected instance.
9. Navigate to **All** > **Code Signing** > **Configuration** > **Guided Setup** to open the Code Signing configuration page.
10. In the **Instance type** field, select **protected instance**.
11. Select the **Next** button.
12. Select the **Please confirm the Code Signing configuration update set was imported and committed** check box.
13. Select the **Next** button.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

14. Wait for the certificate installation to complete.
    After completion, a **Code Signing configuration completed successfully** message displays.

Result
You can verify successful completion by looking at your system properties. Look for the **com.snc.kmf.signature.validation.flag** property on the System Properties [sys_property] table, and verify that it has a value of **false**.

Create Code Signing key pairs and certificates

Create two key pairs to signed certificates to establish trust between your protected and trusted instances.

To establish trust between your instances, you must create a key pair and certificate for each of the `cm_code_attest` and `cm_code_signing` cryptographic modules.

Creating key pairs and certificates is done using a cryptographic tool installed on your local device, such as the OpenSSL tool. For more information on this tool, see https://www.openssl.org. If your organization uses other cryptographic tools, such as LibreSSL or GnuTLS, refer to the documentation for those products for similar steps.

Key pair specifications

The key pairs you create must meet these requirements.

Type	RSA
Key length	4096
Signing algorithm	RSASSA_PKCS1_V1_5_SHA_512

Certificate specifications

Certificates must be signed by a public certificate authority.

Specify custom rules in ECC firewall

Configure the External Communication Channel (ECC) firewall in your MID Server by specifying the custom rules to selectively allow or reject the incoming message and override the Code Signing configuration.

Security administrators can use the ECC firewall tags to override the Code Signing configuration and allow or reject specific operations on MID Server. These custom rules must be specified in the YAML file of the located at: `agent/boot-config.yaml`.

These tags are specific to a protocol. The configuration specified for the parent tag is applicable to the child tag. For example, if `Http` protocol is allowed, `rest` and `soap` protocols are also allowed. This table outlines the available parents and child tags.

Parent tag	Child tag
DNS	
HTTP	• REST • SOAP

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Parent tag	Child tag
DIRECTORY_SERVICES	LDAP
SNMP	
SSH	• SCP • SFTP
SYSLOG	
WINDOWS	• CIM • POWERSHELL • WMI • WINRM
JAVASCRIPT	
GROOVY	
VCS	GIT
DATABASES	JDBC
DATA_SOURCES	
INTEGRATION_HUB	
ITOM	• CLOUD_PROVISIONING_GOVERNANCE • DISCOVERY • EVENT_MANAGEMENT • HEALTH_LOG_ANALYTICS • SERVICE_MAPPING
ORCHESTRATION	

To configure the custom rules:

1. In the MID Server, identify the file `boot-config-sample.yaml`.
2. Rename the YAML file to `boot-config.yaml` and move the file to the location: `agent/boot-config.yaml`.
3. In the YAML file, specify the custom rules and save the changes. An example of the YAML file:

```
security:
  eccFirewall:
    mode: enforcing
    rules:
      - tags: [rest]
        action: accept
      - tags: [soap]
        action: accept
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
      - tags: [jdbc]
        action: reject
```

4. Restart the MID Server.

Change your Root of Trust configuration

Trust and use your own certificates instead of relying on ServiceNow build certificates (default) by changing to use your Root of Trust (ROT). ServiceNow components like script includes, business rules, etc., are signed at build time using a ServiceNow build time key (verification certificate is the ServiceNow build certificate).

Changing the root of trust

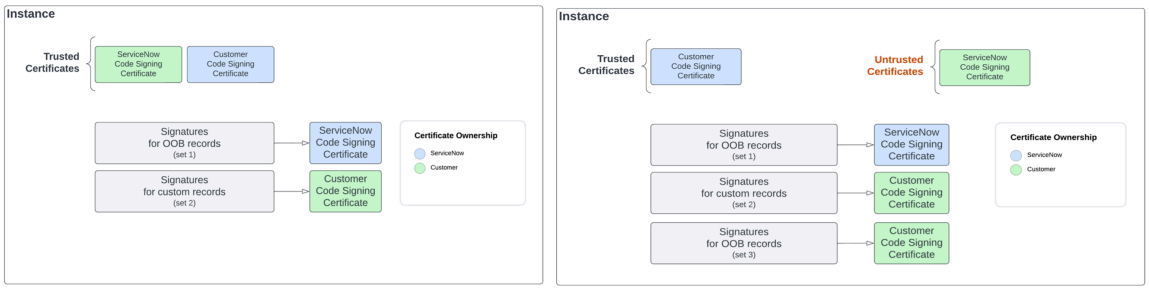
To change the Root of Trust for these records signatures, you must follow the change of Root of Trust process.

- Generate and migrate a new set of signatures for all provided components, using your provided certificate.
- Disable the Root of Trust property using a scheduled job.

Learn more about these steps in Migrate signatures to use a customer certificate and Disable ServiceNow Root of Trust.

Impact on the signature generation and verification process

By default, Code Signing build certificates are trusted during the signature verification process. After making this change, your instance accepts signatures only from your own Code Signing certificate.



ROT property set to false (default)	ROT property set to true
• When verifying, signatures with build certificates are trusted. • When signing, if you don't provide keys, the instance signing key is used as a backup key. • The signature REST end point *api/sn_kmf/signature/certificates* returns ServiceNow Code Signing build certificates along with other certificates present on the instance.	• When verifying, signatures with build certificates aren't trusted. • When signing, if you don't provide keys, signing isn't performed. • The signature REST end point *api/sn_kmf/signature/certificates* excludes ServiceNow build certificates (San Diego, Vancouver PKI, W PKI).

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Impact on your MID Server

When the ROT property is set to false

If you choose to leave your ROT property at its default value (false), there's no impact on your MID Server.

When Code Signing is enabled and the ROT property is set to true

- The `isTrusted()` API returns `false` for signatures with a build certificate.
- The `isTrusted()` API returns `true` for signatures with your certificate.
- The REST API call for certificates excludes build certificates.
- You may see MID Server issues, such as `signature validation failed` messages in the logs.

Migrate signatures to use a customer certificate

Run a signing job to migrate your signatures to a customer Root of Trust (ROT).

Before you begin

Role required: admin, security_admin, and sn_kmf.cryptographic_manager

Code Signing must be enabled on your protected and trusted instances. You can verify by checking that the **com.snc.kmf.signature.validation.flag** system property is set to `true`.

This procedure is part of a series of procedures to change a customer Root of Trust (ROT) on your instances. For an overview of this process, see Change your Root of Trust configuration.

Procedure

1. Log in to your protected instance.
2. Navigate to **All** > **System Definition** > **Scheduled Jobs**.
3. Find and open the **ROT - Generate Updateset of records to migrate signatures using customer certificate** scheduled job.
4. At the bottom of the form, select **Execute Now**.
5. Navigate to **All** > **System Security** > **Security Jobs** > **Create New**.
6. At the prompt, select **Signing Job**.
7. In the **Signing Job** form, fill in the fields as needed.

Field	Value
Name	Create a unique name for your job.
Type	Select **Sign Update Set**.
Table	Select the update set created in the previous steps. The update set has a name beginning with `change_root_of_trust_updateSet`.

8. Right-click the form header and select **Save** to save this record.
9. Right-click the form header and select **Export** > **XML (This Record)** to export this record as an XML file.
10. Log in to your trusted instance.
11. Navigate to **All** > **System Security** > **Security Jobs** > **All**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

12. Right-click the list header and select **Import XML**.
13. In the **Import XML** form, select **Choose File** and select the XML file you downloaded in the previous steps.
14. Select **Upload**.
15. From the list, open the imported security job.
16. Select **Export Code Signing job to production**.
    This action signs the job and places it in a new update set you can import into your protected instance.

    Important:
    After signing the job, you must perform the next steps within 10 minutes. If you exceed this time period, you can re-sign the job using these steps, which creates another signed update set.

17. Navigate to **All** > **System Update Sets** > **Local Update Sets**.
18. Find the update set created in the previous steps.
    The name starts with `SIGN_UPDATE_SET_updateSet`.
19. Select **Export XML** to export your update set as an XML file.
20. Log in to your protected instance.
21. Navigate to **All** > **System Update Sets** > **Retrieved Update Sets**.
22. At the bottom of the list, select **Import Update Set from XML**.
23. In the **Import XML** form, select **Choose File** and select the XML file you downloaded in the previous steps.
24. Select **Upload**.
25. Navigate to **All** > **System Update Sets** > **Retrieved Update Sets**, and open the update set starting with `SIGN_UPDATE_SET_updateSet`.
26. Select **Preview Update Set**.
27. After the preview is completed, select **Commit Update Set**.
28. Navigate to **All** > **System Security** > **Security Jobs** > **All**.
29. Open the imported security job.
30. Select **Start** to run the security job.

    After the security job is completed, information regarding the status of the job appears in the **Summary** field.

    When the job is in Done state, all signatures of update set records must use the customer provided certificate as verification certificate. You can verify this on the KMF Signature Records [sn_kmf_record_signature] table.

What to do next

To continue the Root of Trust configuration process, see Disable ServiceNow Root of Trust.

Disable ServiceNow Root of Trust

Run a scheduled job on your trusted instance to disable Root of Trust.

Before you begin

Role required: admin, security_admin, and sn_kmf.cryptographic_manager

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Code Signing must be enabled on your protected and trusted instances. You can verify by checking that the **com.snc.kmf.signature.validation.flag** system property is set to `true`.

This procedure is part of a series of procedures to change to a customer Root of Trust (ROT) on your instances. For an overview of this process, see Change your Root of Trust configuration.

Procedure

1. Log into your trusted instance.
2. Navigate to **All** > **System Definition** > **Scheduled Jobs**.
3. Open the **Disable ServiceNow Root of Trust** scheduled job.
4. Select the **Export signed job to production**.
5. Navigate to **All** > **System Update Sets** > **Local Update Sets**.
6. Find and open the **Disable ServiceNow Root of Trust** update set.
7. Select **Export XML** to export your update set as an XML file.
8. Log in to your protected instance.
9. Navigate to **All** > **System Update Sets** > **Retrieved Update Sets**.
10. At the bottom of the list, select **Import Update Set from XML**.
11. In the **Import XML** form, select **Choose File** and select the XML file you downloaded in the previous steps.
12. Select **Upload**.
13. Navigate to **All** > **System Update Sets** > **Retrieved Update Sets**, and open the **Disable ServiceNow Root of Trust** update set.
14. Select **Preview Update Set**.
15. After the preview is completed, select **Commit Update Set**.
16. Navigate to **All** > **System Definition** > **Scheduled Jobs**.
17. Open the scheduled job imported in the update set.
18. Select the **Execute Now** button to run the job.

Result

Executing the scheduled job sets the ROT property to true. Your instance is configured to use the customer root of trust.

Using Code Signing

Learn how to sign records, messages, and attachments to help verify the authenticity and integrity of your data.

Sign the JDBC data source records in the protected instance

Use update sets to sign and validate the JDBC data sources by enabling the code signing in protected and trusted instances.

Sign the REST and SOAP messages in the production instance

Use update sets to sign and validate the REST and SOAP messages by enabling the code signing in protected and trusted instances.

Sign the flows, subflows, and actions in the protected instance

Use update sets to sign and validate the flows, subflows, and actions by enabling the Code Signing in protected and trusted instances.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Sign specific records or attachments

Create a security job to sign specific records or attachments rather than all records or attachments on a table.

Standalone signing tool

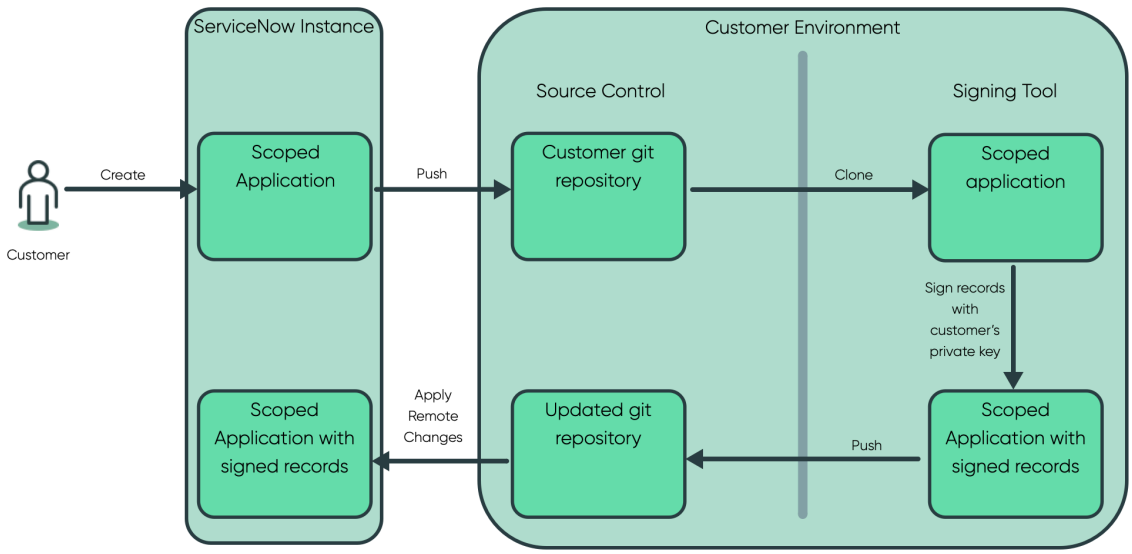
Use the standalone Signing Tool to sign supported records in ServiceNow applications using your own private key.

Standalone signing tool

Use the standalone Signing Tool to sign supported records in ServiceNow applications using your own private key.

Use the Signing Tool to sign records in ServiceNow apps. The tool generates signatures for records in your local environment using your own private key.

Signing tool workflow



1. Create or select an existing ServiceNow application with records to be signed, such as business rules or script includes.
2. Push the application into your Git repository, which resides in your environment.

   Note:
   Applications can be synced between a Git repository and your instance using the Source Control Integration. For details on configuring and using this integration, see Legacy - Source Control integration.

3. Clone the application in your local environment.
4. Use the Signing Tool (also in your local environment) to sign the supported records from the cloned ServiceNow application using your private key. The Signing Tool creates signature records and X.509 Certificate [sys_certificate] records. For details on using the Signing Tool, see Using the Signing Tool.
5. Push the updated application to your Git repository.
6. In your instance, import the updated application by applying remote changes.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Using the Signing Tool

Learn how to use the Signing Tool to sign supported records in ServiceNow applications.

Before you begin

Role required: admin

To perform these steps, you must have the following:

- A ServiceNow application that has records to be signed.
- A private key for signing records.
- The *signRecords.sh* script in your local environment, with execute permission.

> **Important:**
> The *signRecords.sh* script is included as part of the signing-tool jar file, which you must request from ServiceNow customer support.

Procedure

1. In your local environment, navigate to the directory containing the *signRecords.sh* script.
2. Use the following command format to sign your records:

```
./signRecords.sh -d [Path to the root directory of the
 ServiceNow Application to Sign] -f [Path to the Keystore file]
```

   For example:

```
./signRecords.sh -d /users/abc/ServiceNow-App-1
 -f /users/abc/codesigning.p12
```

3. If prompted, enter the password for the keystore.
   Press Enter if there's no password.
4. Review the output to confirm a successful signing.

```
Sep 26, 2022 2:41:09 PM com.snc.java.commands.ACommand start
INFO: CODESIGN: executing codesigning...
Sep 26, 2022 2:41:09 PM
 com.snc.core.codesigning.CodeSignerSupplier get
INFO: CODESIGN: signing record for documentId:
 65e8113277021110574l6efe7c5a994f
Sep 26, 2022 2:41:11 PM com.snc.java.commands.ACommand start
INFO: CODESIGN: codesigning successfully completed!
```

   In the preceding output example, the Signing Tool used the provided keystore file to sign the record. You can also see that:

   - The script found a supported record `65e8113277021110574l6efe7c5a994f` and signed it.
   - In the ServiceNow-App-1 directory, two records created: `sys_certificate.xml` and `sn_kmf_record_signature.xml`.

5. Import the updated application back into your instance by applying remote changes in Studio. For more information, see Legacy - Apply remote changes.

Signing Tool arguments

Learn about the available arguments for the Signing Tool.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Command line arguments

Argument	Required	Description
-d	Yes	Root directory of project to sign. Should contain project directory (random 32 alphanumeric), sn_source_control.properties file, and a <project_name>.iml file
-f	Yes	The file path of the keystore.
-a	No	Alias used to access a specific entry within the keystore.
-c	No	Concatenate record signatures into one file.
-k	No	Password to access the key stored within the keystore. You can also enter this password when prompted instead of within the argument.
-o	No	Sign with a new certificate in place of any existing sys_cert files.
-p	No	Password to access the keystore if it has a password. You can also enter this password when prompted instead of within the argument.
-w	No	Wipe all existing signature record files.
-h	No	Show this help message and exit.

Sign the JDBC data source records in the protected instance

Use update sets to sign and validate the JDBC data sources by enabling the code signing in protected and trusted instances.

- Establish Circle of Trust between the protected and trusted instances.
- Role required: security_admin

Note:

- MID Server doesn't handle the file data sources and hence, these data sources are not code signed.
- LDAP data sources can't be code signed.

Sign existing data sources of the JDBC type

Use update sets to bring mass signing jobs to the protected instance.

Before you begin

Role required: security_admin

Procedure

1. In the trusted instance, configure the KMF signing job to sign the data sources.

   a. Navigate to **System Security** > **Security Jobs** > **All**.

   b. Click **New**.

   c. On the form, fill these values.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Name	Name to identify the record.
Type	Type of the encryption job. Select **Mass Sign Records**.
Table	Table from which the records should be signed. Select **Data Source**.

d. Click **Export Code Signing job to production**.
A confirmation message is displayed that the update set is signed.

e. Export the generated update set to an XML file.

2. In the protected instance, import and commit the update set to retrieve the mass signed jobs from trusted instance.

a. Navigate to **System Security** > **Security Jobs** > **All**.

b. Open the update set exported from the trusted instance.

c. Click **Start**.
A confirmation message is displayed that the records are signed.

Sign new data sources of the JDBC type

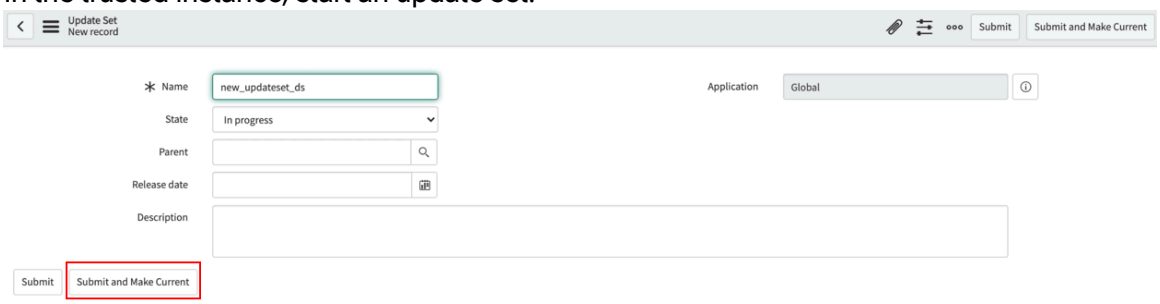
Use update sets to bring the signed update set to the protected instance.

Before you begin

Role required: sn_kmf.cryptographic_manager

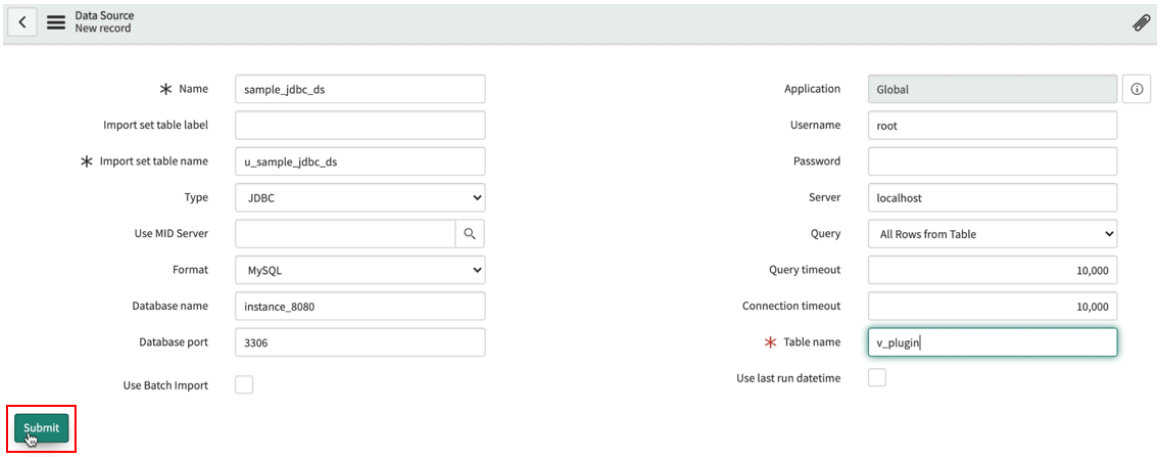
Procedure

1. In the trusted instance, start an update set.



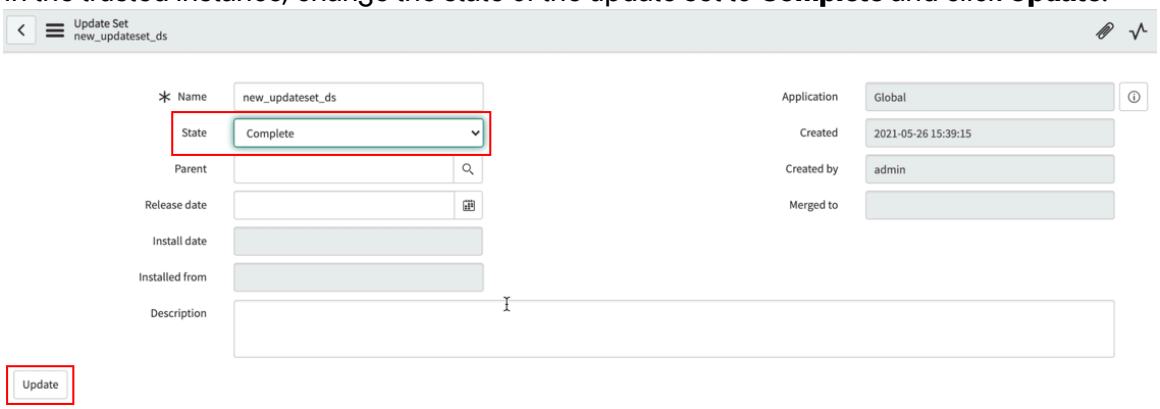
2. In the trusted instance, create the required data sources.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



The data sources are added to the update set.

3. In the trusted instance, change the state of the update set to **Complete** and click **Update**.



4. In the trusted instance, sign the update set by creating an encryption job.

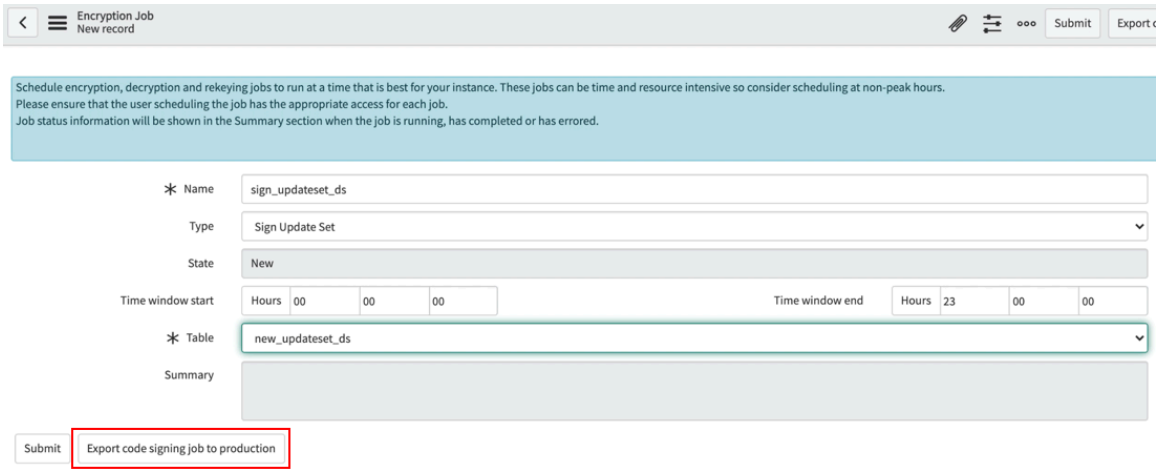
   a. Navigate to **System Security** > **Security Jobs** > **All**.

   b. Click **New**.

   c. On the form, fill these values.

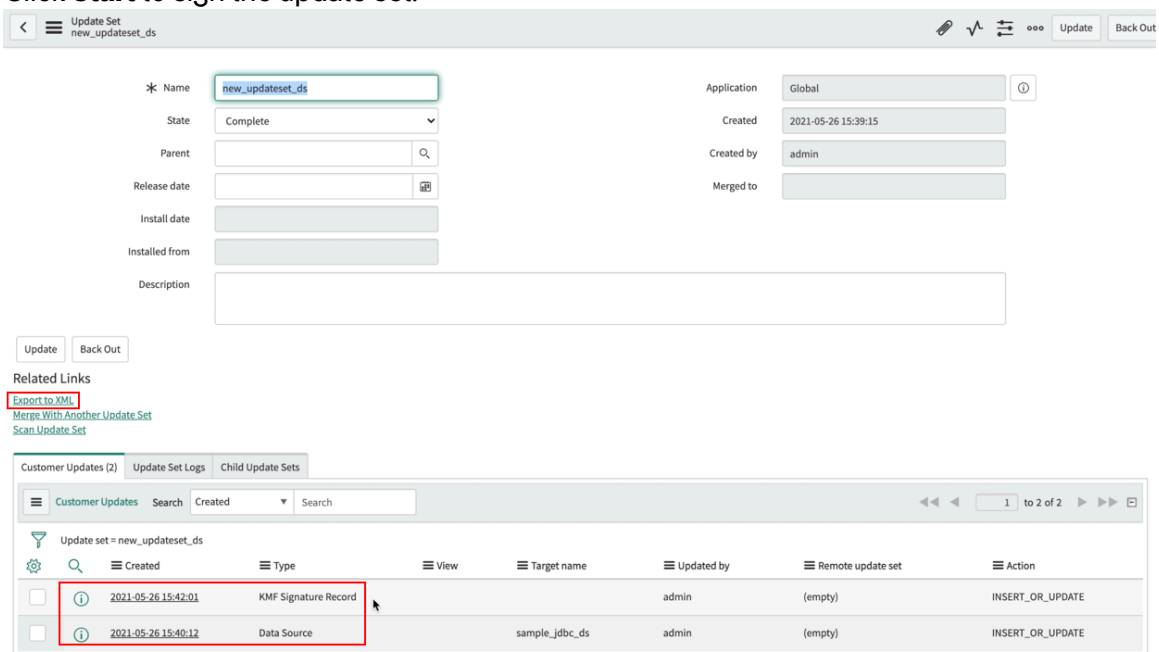
Field	Description
Name	Name to identify the record.
Type	Type of the encryption job. Select **Sign Update Set**.
Table	Update set from which the records should be signed.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



d. Click **Submit**.

e. Click **Start** to sign the update set.



- **Summary** is updated that the records are signed.
- The update set is updated and includes the signature.

5. In the trusted instance, open the signed update set record and export it to an XML.

6. In the protected instance, import the signed update set.

a. Navigate to **System Update Sets** > **Retrieved Update Sets**.

b. Click the **Import Update Set from XML** related link to import the update set that is exported from the trusted instance.
For more information, see Import and commit the quick-start update set.
The update set is committed successfully.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Sign the REST and SOAP messages in the production instance

Use update sets to sign and validate the REST and SOAP messages by enabling the code signing in protected and trusted instances.

Before you begin

- Establish Circle of Trust between the protected and trusted instances.
- Role required: security_admin

Sign the existing REST and SOAP messages

Sign and validate the existing REST and SOAP messages by enabling the Code Signing in protected and trusted instances.

Before you begin

Role required: sn_kmf.cryptographic_manager

Procedure

1. In the trusted instance, configure the KMF signing job to sign the UI actions.

   a. Navigate to KMF Signature Configuration.

   b. On the form, fill these values.

   KMF Signature Configuration form

Field	Description
Table Name	Glide table name. For example, select **UI Actions [sys_ui_action]**.
KMF Signature Purpose	Purpose of signing the records. Select **ECC Queue**.
Signature Generation Fields	Fields in the data source that you want to sign. If any changes are made to the values in one or more of these fields, the previously generated signature becomes invalid. Select **Name** and **Script**.
Signature Generation Filter	Filter criteria that must be met to sign the records.
Sign Attachment	Option to sign the attachment in the glide record.
Instance Key	Option to use the instance key.

   c. Right-click the form header and click **Save**.

2. In the trusted instance, sign the required records.

   a. Navigate to **System Security** > **Security Jobs** > **All**.

   b. Click **New**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

c. On the form, fill these values.

Field	Description
Name	Name to identify the record.
Type	Type of the encryption job. Select **Mass Sign Records**.
Table	Table from which the records should be signed. Select **UI Action**.

d. Click **Export Code Signing job to production**.
Two locally signed update sets are created.
- One update set for the UI action configuration.
- Another update set from the encryption job to export the code signing job.

3. In the trusted instance, export the local update set to an XML file.
   a. Navigate to **System Update Sets** > **Local Update Sets**.
   b. Open the update set you had created for mass signing the records.
   c. Click the **Export to XML** related link and save the XML file.
4. In the protected instance, import the update sets.
   a. Navigate to **System Update Sets** > **Retrieved Update Sets**.
   b. Click the **Import Update Set from XML** related link to import the update set that is exported from the trusted instance.
   For more information, see Import and commit the quick-start update set.
   The update set is committed successfully.
5. In the protected instance, run the encryption job you had earlier created in the trusted instance by selecting **Start**.
   A confirmation message is displayed mentioning that the records are signed.

Sign new REST and SOAP messages

Sign and validate the new REST and SOAP messages from the trusted instance by enabling the Code Signing in protected and trusted instances.

Before you begin

Role required: security_admin

Procedure

1. In the trusted instance, start an update set.
2. In the trusted instance, create the required REST or SOAP messages.
   The messages are added to the update set.
3. In the trusted instance, change the state of the update set to **Complete** and click **Update**.
4. In the trusted instance, sign the update set by creating an encryption job.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

a. Navigate to **System Security** > **Security Jobs** > **All**.

b. Click **New**.

c. On the form, fill these values.

Field	Description
Name	Name to identify the record.
Type	Type of the encryption job. Select **Sign Update Set**.
Table	Update set from which the records should be signed. Select **Sign new Rest V2 update set - 1**.

d. Click **Submit**.

e. Click **Start** to sign the update set.
   - **Summary** is updated that the records are signed.
   - The update set is updated and includes the signature.

5. In the trusted instance, open the signed update set record and export it to an XML.
6. In the protected instance, import the update set.

a. Navigate to **System Update Sets** > **Retrieved Update Sets**.

b. Select the **Import Update Set from XML** related link to import the update set that is exported from the trusted instance.
For more information, see Import and commit the quick-start update set.
The update set is committed successfully.

Sign specific records or attachments

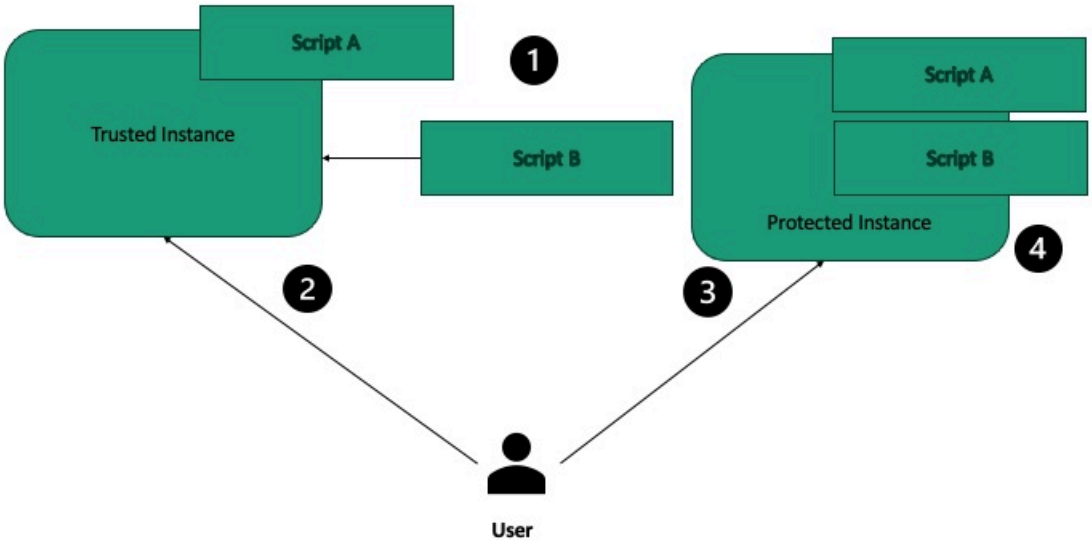
Create a security job to sign specific records or attachments rather than all records or attachments on a table.

Beginning in the Vancouver release, security administrators can use security jobs to sign specific records on a table rather than all records on a table. Sign specific records to avoid accidentally signing any unreviewed code.

These jobs include an attached log file, which is generated at the end of the signing job. This log file contains information about signed records and the signature configuration used.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Signing process



This diagram shows an example of how you can use the signing process. In this example, a script, labeled `Script B` exists only on the protected instance, and must be imported to a trusted instance to be signed. `Script A` exists on both instances already, doesn't need to be signed. It has either already been reviewed and signed, or hasn't been reviewed yet and shouldn't be signed.

1. Import the record to your trusted environment.
2. In the trusted instance, create a signing job to sign the record. This process is detailed in Create a job to sign specific records or attachments on a trusted instance.
3. Import the signed signing job to your protected instance using an update set.
4. In the protected instance, run the imported signing job.

Create a job to sign specific records or attachments on a trusted instance

Sign a specific record, or group of records you define on a trusted instance.

Before you begin

Role required: security_admin or sn_kmf.cryptographic_manager

Procedure

1. Navigate to **All** > **System Security** > **Security Jobs** > **Create New**.
2. At the **What type of Security Job would you like to create?** prompt, select **Signing Job**. A new **Signing Job** record displays.
3. In the form, fill in the fields as needed:

Signing job fields

Field	Description
Name	Descriptive name for this job.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Type	Type of security job. To sign specific records, select the **Sign Specific Records** option. To sign specific attachments, select **Sign Specific Attachments**.
State	State of this job. This field begins with the value of **New**. This field is read only.
Table	Table containing the records or attachments you want to sign. If signing attachments, select the table with records that the attachments are associated with, not the Attachment [sys_attachment] table. **Tip:** Check the Key Management Framework (KMF) Signature Record [sn_kmf_record_signature] table to ensure that there aren't already signatures for the table you've selected.
Filter Records	Filter conditions used to limit which records appear in the **Select records for signing** table.
Select records for signing	List of records on the table selected in the **Table** field, limited by filter created in the **Filter Records** field. Move records from the **Available** window to the **Selected** window to include them in the signing job.
Time window start	The start of the time window to run this job. The job will run after the time entered in this field. A valid time value is in Coordinated Universal Time based on a 24-hour time notation.
Time window end	The end of the time window to run this job. The job runs before the time entered in this field. If the job hasn't yet completed, the job will pause and resume at the next time window start. The end time must be after the start time. A valid time value is in Coordinated Universal Time based on a 24-hour time notation.
Summary	Summary of the execution of this job. This field is read only.

4. Right-click the form header, and select **Save**.
5. Open the job that you saved, and click **Start**.
   This action signs the signing job, and it's ready for export.
6. Navigate to **All** > **System Update Sets** > **Local Update Sets**
7. Find and open the update set for your signing job.
   In the customer updates tab, you can see that this update set includes the signing job and the signature record.
8. Select **Export to XML**.
   This action creates an XML file containing your update set on your local device.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

9. On your protected instance, navigate to **All** > **System Update Sets** > **Retrieved Update Sets** > **.**
10. At the bottom of the page, select **Import Update Set from XML**.
11. Select the **Choose File** button, and select the XML file created in previous steps.
12. Select **Upload**.
    Your update set is loaded, and appears in the **Retrieved Update Sets** list.
13. In the **Retrieved Update Sets** list, open the record for your imported update set.
14. Select the **Preview Update Set** button.
    After the preview completes successfully, you'll see the **Commit Update Set** button appear.
15. Select **Commit Update Set**.

Sign the flows, subflows, and actions in the protected instance

Use update sets to sign and validate the flows, subflows, and actions by enabling the Code Signing in protected and trusted instances.

- Establish Circle of Trust between the protected and trusted instances.
- Role required: security_admin

Sign the existing flow, subflows, and actions

Sign and validate the existing flow, subflows, and actions by enabling the code signing in production and trusted instances.

Before you begin

Role required: sn_kmf.cryptographic_manager

Procedure

1. In the trusted instance, sign the records in the Step Instance table.

   a. Navigate to **System Security** > **Security Jobs** > **All**.

   b. Click **New**.

   c. On the form, fill these values.

Field	Description
Name	Name to identify the record.
Type	Type of the encryption job. Select **Mass Sign Records**.
Table	Table from which the records should be signed. Select **Step Instance**.

   d. Click **Export Code Signing job to production**.
   Two locally signed update sets are created.
   - One update set for the KMF signature.
   - Another update set from the encryption job to export the code signing job.

2. In the trusted instance, export the local update set to an XML file.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

a. Navigate to **System Update Sets** > **Local Update Sets**.

b. Open the update set you had created for mass signing the records.

c. Click the **Export to XML** related link and save the XML file.

3. In the protected instance, import the XML file.

a. Navigate to **System Update Sets** > **Retrieved Update Sets**.

b. Click the **Import Update Set from XML** related link to import the update set that is exported from the trusted instance.
For more information, see .
The update set is committed successfully.

4. In the protected instance, run the encryption job you had earlier created in the trusted instance.

a. Navigate to **System Security** > **Security Jobs** > **All**.

b. Open the encryption job you had earlier created in the trusted instance.

c. Click **Start** to start the job.
A confirmation message is displayed mentioning that the records are signed.

Sign new flow, subflows, and actions

Sign and validate new flow, subflows, and actions by enabling the Code Signing in protected and trusted instances.

Before you begin

Role required: sn_kmf.cryptographic_manager

Procedure

1. In the trusted instance, start an update set.
2. In the trusted instance, create the required flows, subflows, or actions, and publish them.
The flows, subflows, or actions are added to the update set.
3. In the trusted instance, change the state of the update set to **Complete** and click **Update**.
4. In the trusted instance, sign the update set by creating an encryption job.

a. Navigate to **System Security** > **Security Jobs** > **All**.

b. Click **New**.

c. On the form, fill these values.

Field	Description
Name	Name to identify the record.
Type	Type of the encryption job. Select **Sign Update Set**.
Table	Update set from which the records should be signed.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

d. Click **Submit**.

e. Click **Start** to sign the update set.

- **Summary** is updated that the records are signed.
- The update set is updated and includes the signature.

5. In the trusted instance, open the signed update set record and export it to an XML.
6. In the protected instance, import the signed update set.

a. Navigate to **System Update Sets** > **Retrieved Update Sets**.

b. Select the **Import Update Set from XML** related link to import the update set that is exported from the trusted instance.
For more information, see Import and commit the quick-start update set.
The update set is committed successfully.

Code Signing Health and Status Dashboard

The Code Signing Health and Status dashboard provides a centralized, user-friendly view of your Code Signing environment's health and configuration. Use it to identify issues, verify configuration accuracy, and support secure, uninterrupted code-signing operations.

The Code Signing Health and Status dashboard highlights configuration issues and includes intuitive guidance to help you resolve them quickly, reducing the need for escalation. You can use the dashboard to verify that Code Signing configurations are set up correctly and performing securely. It helps you identify potential issues that could lead to failures and enables you to provide accurate guidance to the stakeholders involved.

The dashboard lets you search, filter, and rescan the following parameters:

- Configurations
- Certificate status
- Plugin details
- Signature verification certificate
- MID Server setup

To access the Code Signing Health and Status Dashboard, go to **All** > **Code Signing** > **System Health** > **Dashboard**.

Overview Dashboard

The Overview dashboard provides a centralized view of your Code Signing environment, offering real-time insights into key components and their status.

The Overview dashboard displays the following reports:

Overview Dashboard

Title	Type	Description
Enterprise plugin	Text field	Status of essential plug-ins and system properties

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Overview Dashboard (continued)

Title	Type	Description
		required for Code Signing functionality. **Enterprise plugin** displays the core plugin needed for signing operations.
Opt-in property	Text field	Configuration flag that enables Code Signing capabilities. **Note:** This setting must be **Active** to confirm that code signing functions according to the specific requirement.
Signature validation status	Text field	Indicates whether signature validation is enforced during code execution to verify that only the trusted scripts are executed.
Signature states	Pie chart	Comprehensive overview of all the script signatures, including their current validation status. The signatures are categorized into: • **Trusted** signatures are valid and associated with trusted code signing certificate. • **Untrusted** signatures fail validation or are linked to untrusted verification certificate. • **Orphan** signatures are present but no longer linked to a known or active certificate. **Note:** Use this information to assess script integrity and take corrective action as needed.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Overview Dashboard (continued)

Title	Type	Description
MID Server configuration state	Pie chart	Status and trust relationship of all the MID Servers in your instance. Use this section to view the total number of MID Servers and check their status. • **Active MID Servers**: The number of servers that are currently running and successfully connected. • **Inactive MID Servers**: The number of servers that aren't running or are disconnected.
Signed records by type	Pie chart	Distribution of signed records by record type, showing the percentage coverage across the following categories: • **Business Rules**: The percentage of signed business rule records. • **Script Includes**: The percentage of signed script include records. • **Others**: The percentage of signed records in other supported categories.
Signed records by application	Pie chart	Distribution of signed records across different application modules, showing the percentage of code signing coverage. • **User Management**: Percentage of signed records in the User Management module. • **Form Validation**: Percentage of signed

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Overview Dashboard (continued)

Title	Type	Description
		records related to form validation. • **Others**: Percentage of signed records in all other application modules.

Signature Verification Status

View the status of valid, invalid, and missing signatures across different applications to assess code signing coverage. Use this information to identify areas that may require additional attention or action.

The Signature Verification Status dashboard displays the following reports:

Signature Verification Status Dashboard

Title	Type	Description
Script name	Text field	Identifier or title assigned to a specific script within the system.
Type	Text field	Category of the script within the system. It helps define the role and functionality of the script. Example: • Business rule • Script include • Client script • Flow action
Application	Text field	Module or area within the system where the script is applied. Example: • User management • Reporting • Form validation • Workflow • Notifications
Status	Text field	Indicates the current verification status of the script signature.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Signature Verification Status Dashboard (continued)

Title	Type	Description
		• **Valid**: The script signature is verified and is trusted. • **Invalid**: The script signature isn't verified or is deemed untrusted. • **Missing**: The source document is eligible for signing but doesn't have a signature yet. Use this status to identify eligible records that remain unsigned and require code signing.
Last scanned	Text field	Date and time when the script was last scanned for signature verification in the format: `DD/MM/YY/H:S (Day/Month/Year/Hour:Minute)`

Code Signing MID Server Configuration

Manage and configure the trust relationships and certificate settings for MID Servers.

The Code Signing MID Server Configuration dashboard displays the following reports:

Code Signing MID Server Configuration

Title	Type	Description
MID Server	Text field	Name of the specific MID Server instance.
Status	Text field	Current operational state of the MID Server. • **Active** • **Inactive**
Version	Text field	Software version of the MID Server currently in use. Use this information to: • Ensure compatibility with your instance. • Ensure that the server is running the latest supported features and security updates.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Code Signing MID Server Configuration (continued)

Title	Type	Description
Last check-in	Text field	Most recent date and time that the MID Server successfully communicated with the instance in the following format: `DD/MM/YY/H:S (Day/Month/Year/ Hour:Minute)`

Key Pair and Certificates

The Key Pair and Certificates dashboard displays details about the cryptographic keys and digital certificates used for Code Signing. It includes information such as key type, certificate issuer, expiration date, and validity status. Use this dashboard to manage code signing certificate credentials, verify their validity, and help ensure secure and trusted Code Signing operations.

The Key Pair and Certificates Configuration dashboard displays the following reports:

Key Pair and Certificates Configuration

Title	Type	Description
Certificate Name	Text field	The unique identifier (name) assigned to a digital certificate used for Code Signing.
Crypto Module	Text field	The cryptographic component used to generate, store, and manage private keys for Code Signing. It ensures secure key operations and helps protect sensitive cryptographic material from unauthorized access.
Type	Text field	The classification of the cryptographic key or certificate used for Code Signing. Example: • ServiceNow • Third party
Expires	Text field	Date when the digital certificate expires and is no longer valid for use.
Status	Text field	Current validity of the digital certificate.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Key Pair and Certificates Configuration (continued)

Title	Type	Description
		• **Valid**: The certificate is active and can be used for Code Signing. • **Expired**: The certificate has passed its expiration date and is no longer valid. • **Expiring Soon**: The certificate is nearing its expiration date. Use this status to take proactive steps for renewal to avoid disruptions in code signing operations.
Chain	Text field	The certificate chain, which includes the digital certificate along with the intermediate and root certificates that establish a trust path. Select **View Chain** to view the certificate chain.

Code Signing Configuration

The Code Signing Configuration dashboard displays the system properties and key settings that control Code Signing in your environment, including flags and enforcement policies. These settings enable features, enforce signature validation, and define trusted sources.

The Code Signing Configuration dashboard displays the following reports:

Code Signing Configuration

Title	Type	Description
Setting	Text field	Name of a specific configuration property that controls a feature or behavior related to code signing. Each setting defines how the system should handle aspects like signature validation, enforcement, or trusted sources.
Value	Text field	Current state or input assigned to a specific setting. It determines how the setting behaves. For example, whether Code Signing is enabled (true) or disabled

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Code Signing Configuration (continued)

Title	Type	Description
		(false). The value directly affects the system's Code Signing operations and enforcement.
Last Updated	Text field	Most recent date and time when the setting was modified in the following format: `DD/MM/YY/H:S (Day/Month/Year/Hour:Minute)`

Code Signing reference

Reference topics provide additional information to administer and troubleshoot Code Signing.

Properties installed with Code Signing

Code Signing adds the following properties.

Roles installed with Code Signing

Code Signing includes the following roles.

Troubleshooting and accessing logs

Access various logs to troubleshoot and identify the failure reasons.

Properties installed with Code Signing

Code Signing adds the following properties.

Property	Type	Description
com.glide.codesigning.expanded.tracking.enabled	true|false	When true, the validation length for the meta stack is increased for ecc_queue topics listed in the **com.glide.codesigning.expanded_tracking.topic.list** property. **Important:** Elevated Security is needed to modify this property.
com.glide.codesigning.expanded.tracking.length	Integer	Levels of Code Signing validation to occur when Code Signing is enabled. The default value is 3. **Important:** Elevated Security is needed to modify this property.
com.glide.codesigning.expanded_tracking.topic.list	String	Comma-separated list of topics to be subject to increased meta-stack tracking.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property	Type	Description
		Important: Elevated Security is needed to modify this property.
com.glide.codesigning.tracking.agent.validation.exclusion.list	String	Comma-separated list of ecc_queue agents for which Code Signing should be skipped
com.glide.codesigning.tracking.debug	true|false	When true, debug logging for the Code Signing tracker is enabled.
com.glide.codesigning.tracking.enabled	true|false	When true, enables Code Signing caller tracking. **Important:** Elevated Security is needed to modify this property.
com.glide.codesigning.tracking.logging.enabled	true|false	When true, enables logging for Code Signing tracking.
com.glide.codesigning.tracking.unsupported_script_tracking.enabled	true|false	When true, ecc_queue records inserted via unsupported scripts (if detected) aren't notarized. **Important:** Elevated Security is needed to modify this property.
com.glide.codesigning.tracking.validation.fail_fast	true|false	When true, Code Signing verification fails at the first script validation failure instead of verifying all scripts. **Important:** Elevated Security is needed to modify this property.
com.glide.event_handler.code_signing.tracking	String	Defines the Event Handler that helps ensure that customers newly enabling Code Signing are configured to be as secure as possible. **Important:** Elevated Security is needed to modify this property.
com.glide.web_service_outbound.impl.codesigning.tracking	true|false	When true, enables SOAPMessageV2 Code Signing tracking **Important:** Elevated Security is needed to modify this property.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property	Type	Description
com.snc.csf.maximum_update_size	Integer	The maximum number of records allowed in a Code Signing update set. This value should be limited to a value between 6000 to 10000. If this value is exceeded, multiple update sets are generated and are linked to the same parent update set to enable batch processing. This limitation prevents UI issues described in KB0557104.
com.snc.csf.servicenow_root_of_trust.disabled	true|false	Whether the Root of Trust feature is active. The default value is `false`, meaning that ServiceNow build certificates are trusted. **Important:** This property can only be changed using a signed scheduled job from a user with the admin, security admin and KMF manager roles. For details on changing your Root of Trust, see Change your Root of Trust configuration.
com.snc.kmf.signature.validation.optin	true|false	When true, enables Code Signing on your instance. **Important:** This property can only be changed via a request to Customer Service and Support.
glide.jdbcprobeloader.tracking	true|false	Toggles Code Signing on or off for JDBC data sources. **Important:** Elevated Security is needed to modify this property.
glide.rest.codesigning.tracking	true|false	When true, enables RESTMessageV2 Code Signing tracking. **Important:** Elevated Security is needed to modify this property.

Roles installed with Code Signing

Code Signing includes the following roles.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Code signing admin [codesigning_admin]

Use the code signing admin role to assign codesigning_manager and codesigning_auditor roles to other users.

Contains Roles

List of roles contained within the role.

None.

Groups

List of groups this role is assigned to by default.

None.

Special considerations

Avoid granting an admin role when more specialized roles are available.

Code signing manager [codesigning_manager]

Use the code signing manager role to create and update signature configuration, and create and run code signing jobs.

Contains Roles

List of roles contained within the role.

None.

Groups

List of groups this role is assigned to by default.

None.

Special considerations

None.

Code signing auditor [codesigning_auditor]

Use the code signing auditor role to view signature configurations and signing jobs. The auditor role does not have create or write access to code signing assets.

Contains Roles

List of roles contained within the role.

None.

Groups

List of groups this role is assigned to by default.

None.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Special considerations

None.

Troubleshooting and accessing logs

Access various logs to troubleshoot and identify the failure reasons.

Code Signing logs

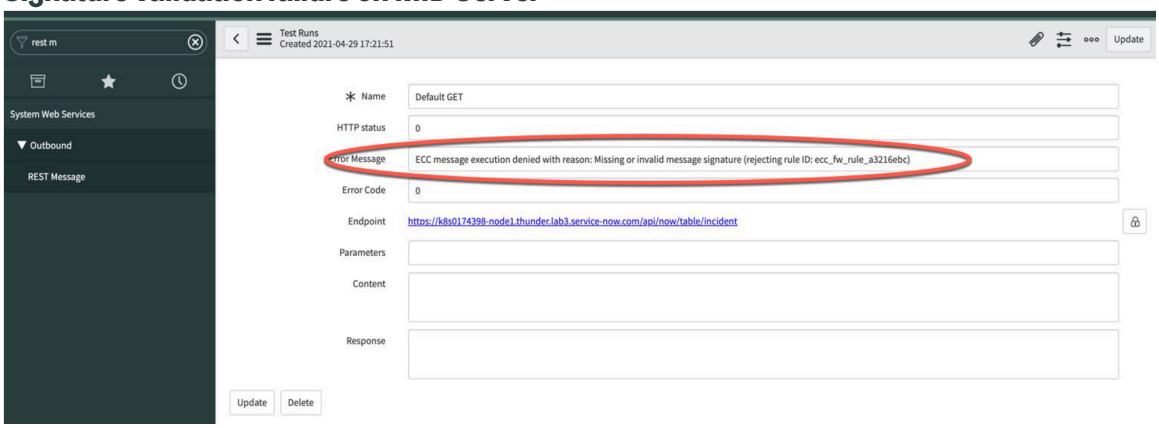
If any of the ECC queue records is not signed by the Code Signing Tracker API, the unsigned messages and the required details are displayed in the Code Signing module. Navigate to **System Logs** > **System Log** > **Code Signing** to access the list of records that are not trusted.

For additional debug node logs, enable *com.glide.codesigning.tracking.debug* and set its value to `true`.

REST message signature validation failure on MID Server

Access the error message regarding to the signature validation failure, by navigating to **System Web Services** > **Outbound** > **REST Message** and opening the required REST message record.

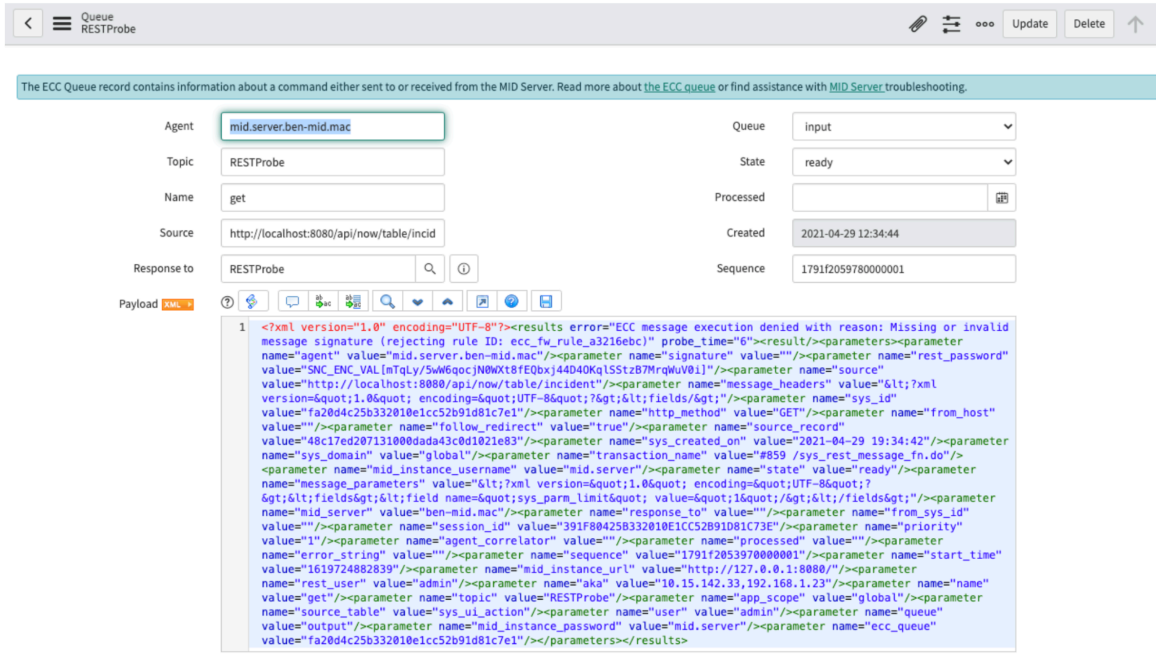
Signature validation failure on MID Server



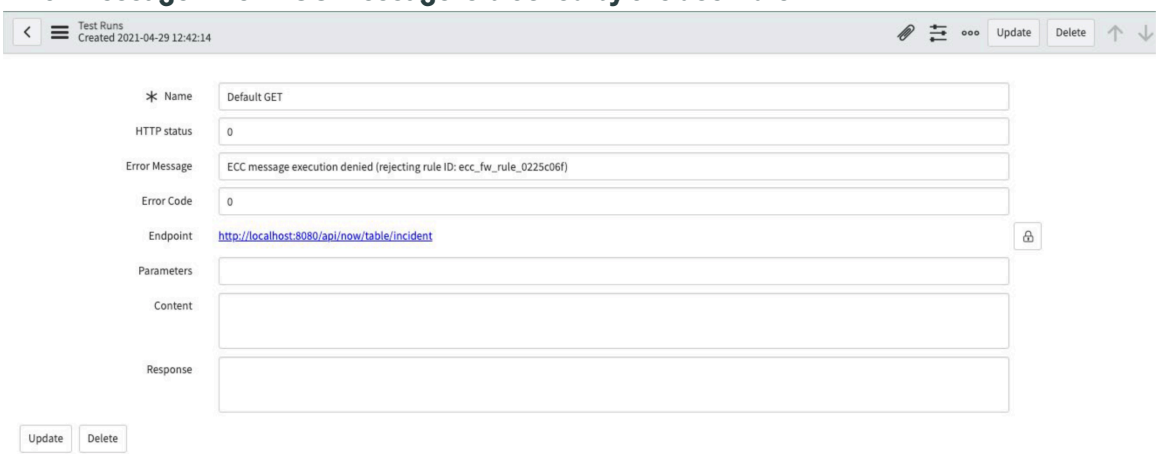
Note:
Error messages related to the ECC firewall rejections start with `ECC message execution denied`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

ECC queue when signature validation fails on MID Server



Error message when ECC message is blocked by the user rule

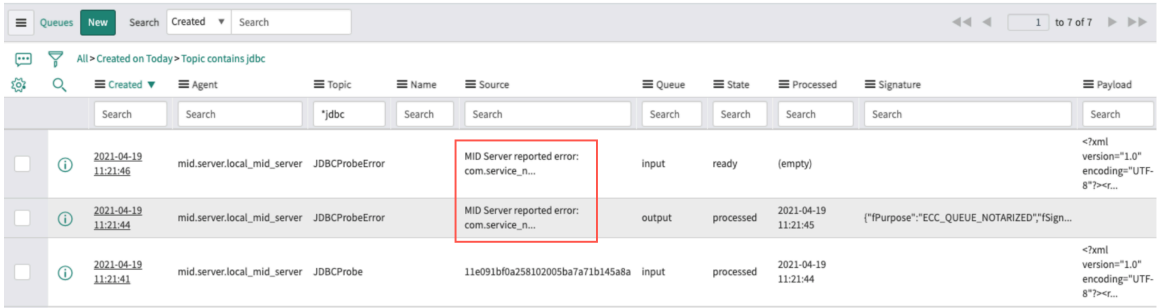


JDBC probe

When a JDBC data source with an invalid or missing signature is executed on a MID Server, an error message with the required details is displayed.

Source also displays the details of the error message.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



MID Server logs

To enable the detailed ECC firewall logging, increase the log level by setting the value of the MID Server configuration parameter, *`mid.log.level`*, to TRACE. The detailed logs provide information about:

- Rules that the MID Server loaded from the boot configuration file.
- Granular execution trace of rules.
- Specific rule due to which an ECC message is to be accepted or rejected.

Note:
If `boot-config.xml` is invalid, the MID Server fails to start and the failure details are logged in the MID agent logs.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Antivirus Scanning

Use Antivirus Scanning to help protect your instance against virus infections that can be introduced by file attachments to your system records, such as incidents, problems, and stories.

Explore Antivirus scanning

Learn the value of Antivirus Scanning.

Configure Antivirus protection

Understand how to configure Antivirus protection.

Resolve Infected Files

Learn what to do with infected files.

Reference for Antivirus scanning

Know about the Dictionary Attributes for Antivirus Scanning.

Exploring Antivirus Scanning

Use Antivirus Scanning to help protect your instance against virus infections that can be introduced by file attachments to your system records, such as incidents, problems, and stories.

Antivirus Scanning scans file attachments stored in your attachment [sys_attachment] table to help protect users from uploading and downloading infected files. All the document types supported by the Platform are scanned by Antivirus Scanning.

If Antivirus Scanning is enabled, all file attachments in the Attachments table [sys_attachment.do] are scanned by default.

The Antivirus Protection plugin (com.glide.snap) is activated and enabled by default on your instance. As an administrator, you can deactivate and reactivate the Antivirus Scanning feature across your instance at the switch of a toggle, set configuration options, and review antivirus activity on the instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:

- Antivirus Scanning is also available for customers in the Government Community Cloud (GCC) and commercial environment.

  GCC Users must set the (com.glide.snap.fed_enable_scan) property to `true` to start using the feature.

  Commercial users must set *com.glide.snap.enable_scan* to `true`.

- HTTP and HTTPS communication protocols are supported.
- Edge-encrypted files are excluded from this scan.
- Antivirus definitions are updated everyday.
- Any file above 100-MB file size isn't scanned.

Email scanning

Inbound emails are scanned for viruses by the system email filters, not by Antivirus Scanning.

File Attachment field in a table

The addition of a **File Attachment** field in a table generates zz_yy tables. These tables are dynamic and virtual. They are automatically generated when the column type **file_attachment** is added to parent tables.

Consider adding a user photo to the Users table and incorporating it into the form view. When a photo is uploaded to a record, it automatically uploads the attachment to the sys_attachment table. The sys_attachment table maps the photo to the zz_yyUsers table.

By default only attachments attached to zz_yylive_profile tables are scanned. To scan other tables that have column type **file_attachment** create the system property *com.glide.snap.scan.zz_yytables* and insert the table name.

Example

The "zz_yyincident" and "zz_yycase" tables are dynamic tables created when the column is added to the parent tables: Incident and Case, then the property value should be *zz_yyincident,zz_yycase*.

After this property is set, attachments for the zz_yyincident and zz_yycase tables are scanned.

Scanning scenarios

Review these upload and download scenarios to understand how the system identifies potential security threats from files attached to your records.

Scenario 1 - Upload a file

1. The user unknowingly uploads an infected file to a record.
2. The system scans the file and moves it to quarantine.
3. The file appears in the Attachments window, where it's marked as unavailable.
4. The user selects the file and this error message appears: `The file Infected_testing.txt did not pass the security scan. Please remove the file from record INC0000059 and try again.`

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

5. The system sends an email notification to the user and the antivirus administrator.
6. The user closes the Attachments window and is returned to the record. The infected file is displays in the header as unavailable. Example, `infected_testing123.txtZ [unavailable]`.

Scenario 2 - Download a file

1. The user opens a record to download a file that is attached to it.
2. Unaware that the file is infected, the user selects it for download.
3. The system scans the file, moves it to quarantine, and displays a message similar to `The file infected_testing123.txt did not pass security scan and cannot be downloaded.`
4. The user closes the message and the screen refreshes showing that the file is unavailable.
5. The system sends an email notification to the user and the antivirus administrator.

Scenario 3 - Download a ZIP file

1. A user opens a record and downloads a ZIP file that is attached to it.
2. The system scans the ZIP files individually.
3. One file doesn't pass the security scan and is marked as unavailable. The remaining files are zipped and downloaded successfully.
4. The user opens the ZIP file and sees an "error.txt" file in addition to the successfully downloaded file. This file contains an error message specifying which file didn't pass scanning and was therefore not included in the ZIP.
5. The user opens the record again, and sees that the unavailable file has been moved into the **Potential security risks** section in the Attachments window and can't be downloaded.

Configuring Antivirus Scanning

Configure Antivirus Scanning across your instance and at the table level.

Before you begin

Role required: antivirus_admin or admin

About this task

Antivirus Scanning is active by default in your instance, where it automatically scans attachments to identify any files that are infected by viruses. Configure the feature by ensuring the scan is enabled across your instance, and by identifying any tables that you want to exclude from the scan.

Procedure

1. Navigate to **All** > **Antivirus** > **Configuration**.
2. As you configure the feature, consider the following.
3. Select **Save**.
4. Exclude tables from the Antivirus scan by adding them to the **List of Tables Excluded**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

a. Navigate to **System Definition** → **Dictionary**

b. Search for the table you want to exclude from the scan and select the table with Type set to collection.

c. In the **Attributes** tab, select **New**.

d. Add `Exclude_from_antivirus_scan` in the Attributes field and enter `True` in the **Value** field.

e. Select **Submit**.

Result

Antivirus Scanning is enabled in your instance, and the **List of Tables Excluded** on the Antivirus Configuration page is populated with all the tables that you excluded from the scan.

Reviewing quarantined files

Review quarantined file attachments and take further action as needed.

Before you begin

Role required: antivirus_admin or admin

About this task

Monitor your quarantined file entries in the Antivirus Quarantine page at regular intervals to perform any of the following actions.

Procedure

1. Navigate to **All** > **Antivirus** > **Quarantine**.
2. Select the check box next to each quarantined entry on which you want to perform an available action.
3. Select the **Actions on selected rows** drop-down in the banner to choose the action to be performed on the selected row quarantined entry.

Result

The system asks for confirmation and performs the selected action per your input.

Related topics

Antivirus metrics

Review antivirus activity

Review the Antivirus Activities log that tracks all activities that occur on potentially-infected files from the point that they are discovered and placed into quarantine.

Before you begin

Role required: antivirus_admin or admin

About this task

This log functions as a report that captures antivirus activity, such as discovery, deletion, and other possible quarantined file events.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Antivirus** > **Activity**.
2. Review the log of quarantined files.
   You can view the actions performed in the Event column for each quarantined file.

What to do next

Determine which records you want to delete, restore, download, or keep in the log. See Review quarantined files

Understanding Dictionary attributes for Antivirus Scanning

Dictionary attributes alter the behavior of the table or element that the dictionary record describes. As an administrator, you can set the values of dictionary attributes to modify the behavior of the default Antivirus Scanning configuration.

Dictionary attributes for Antivirus Scanning

Name	Value	Target element	Description
Exclude_from_antivirus_scan	true/false	any table	If true, file attachments on the table are excluded from the antivirus scan. See Configuring Antivirus Scanning
Supress_antivirus_email_notification	true/false	any table	If true, stops sending Platform-generated email notifications when a potentiality-infected file is identified.
Suppress_antivirus_ui_notification	true/false	any table	If true, stops Platform-generated UI notifications when a potentially-infected file is identified.

Exploring HTML sanitizer

Remove unwanted code and protect against security concerns such as cross-site scripting attacks by sanitizing HTML markup in HTML fields and translated HTML fields.

Use HTML sanitization to ensure HTML content within your instance doesn't contain potentially harmful content. HTML sanitization works by removing HTML tags that could be used to compromise your instance, such as `<script>`, `<link>`, or `<embed>` tags that can be used to run unwanted scripts on your instance or direct your users to unwanted content. Safe tags that control the formatting of your content are preserved. As an administrator, you're able to customize what content is removed or preserved. You're also able to control whether sanitization applies to all content, or just fields you specify.

The HTML sanitizer works by checking the built-in inclusion list for markup that you always want to preserve. The sanitizer provides the *HTMLSanitizerConfig* script include that administrators can use to modify the built-in inclusion list. Items can also be added to the exclusion list to remove HTML markup. Contents of the exclusion list override the inclusion list.

The following types of items can be added to the inclusion and exclusion lists:

- Global attributes
- Any HTML elements

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
By default, URL attributes like `href` and `src` support only these protocols:

- `http`
- `https`
- `mailto`
- `data`

For example:

```
<a href="https://community.servicenow.com/community">ServiceNow
Community</a>
```

Note:
To learn more about the *`glide.html.sanitize_all_fields`* property that controls use of the HTML sanitizer, see Enable HTML Sanitizer [Updated in Security Center 1.3] in Instance Security Hardening Settings.

Configure urlAttributes and the protocols

You can configure urlAttributes and their protocols in the **HTMLSanitizer** script include. For example:

```
HTML_WHITELIST : {
urlAttributes: { "protocols" : [ "file", "notes" ] },
                 -   -
                 -   -
        }
```

Because `notes` is in the inclusion list in this example, this URL isn't sanitized:

```
<a title="Lotus"
 href="Notes://
ABC/X575C90019DE33/ABC594DCB76D86EB4925653E0011C4C1/ZZ90B7E2D339
64749257EEA003456FD">Lotus</a></p>
```

Default Inclusion List

Note:
The Default Inclusion List is a system list and is not accessible by users in the Instance.

```
BUILTIN_HTML_WHITELIST :{

 globalAttributes:{ attribute:["id","class","lang","title","styl
e"],
                                  attributeValuePattern:{}},
    label:{ attribute:["for"]},
    font:{ attribute:["color","face","size"]},
    a:{ attribute:["href","nohref","name","shape"]},
```

    body:{},   caption:{},   head:{},   title:{},  shape:{},},
```

Using variables and templates in HTML fields

HTML/Translated HTML fields undergo HTML sanitization by default. This process sanitizes the input HTML to protect it from cross-site scripting (XSS) and related security attacks. Storing

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

templates or variables such as ${description} or {{description}} or similar and replacing them with a true description post sanitization will reduce the effectiveness of the sanitization process. This is due to the sanitization being called solely on the placeholder template and not the HTML content. Storing only HTML content in the HTML/Translated HTML fields helps ensure an effective sanitization process.

Configuring HTML sanitizer

You must modify a script include to make configuration changes to the HTML sanitizer.

Before you begin
Role required: admin

Procedure

1. Navigate to **All** > **System Definition** > **Script Includes**.
2. Open **HTMLSanitizerConfig**.
3. To add items to the exclusion list, use the HTML_BLACKLIST class.

   To add items to the inclusion list, use the HTML_WHITELIST class.

   Use this format:

```
HTML_XXXXLIST :{
        globalAttributes :{

            attribute:[attribute-name1,...],

 attributeValuePattern:{ attribute-name2:attribute-value-regex-
pattern,...}

        },<html-element-name>:{// Same as Above},----}
```

   - *globalAttributes* contains attribute or attributeValuePattern items that are applicable globally for all the HTML elements.
   - *attribute* is a comma-separated list of attributes.
   - *attributeValuePattern* is a dictionary of attribute to attribute-value-regex-pattern pairs. The attribute-value-regex-pattern is a regular expression which has to match the attribute value.

Example:
Consider the following example:

```
HTML_WHITELIST:{
        globalAttributes:{
            attribute:["id","name"],},
        img:{
            attribute:["style","align"],
            attributeValuePattern:{src:".*jpeg"}},
        iframe:{},}
```

It adds the following items to the inclusion list:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- The global attributes id and name. This is a list of strings that can be applied globally to all the elements.
- The img element where the attributes are style and align.
- The img element where the source attribute of the image is a file with the .jpeg extension. This is an example of a regular expression pattern that matches an attribute value.
- The iframe element.

Enabling HTML sanitizer

The HTML sanitizer provides a property to enable or disable the sanitizer for all HTML fields in the system.

Before you begin
Role required: admin

About this task
By default, the property is set to true for new instances.

Procedure

1. In the navigation filter, enter `sys_properties.list`.
2. Set the properties *`glide.html.sanitize_all_fields`* and *`glide.translated_html.sanitize_all_fields`* to **true**.

> **Note:**
> To learn more about this property, see Enable HTML Sanitizer [Updated in Security Center 1.3] in Instance Security Hardening Settings.

Trouble?

If the properties do not exist in the System Properties table, you can add them.

Enable sanitization on individual fields

You can use field attributes to enable or disable the sanitizer on individual fields.

Before you begin
Role required: admin

About this task
You need to first set the sanitizer property to false, and then enable the sanitizer on a per-field basis for any form.

Procedure

1. Navigate to the sys_properties table and set the *`glide.html.sanitize_all_fields`* to **false**.
   This disables the sanitizer for all HTML fields in the system.
2. Navigate to the form that contains the HTML field.
3. Right-click the HTML field label, and select **Configure Dictionary**.
   The Dictionary Entry form opens for the HTML field.
4. Enter one of the following in the Attributes field:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- To disable sanitization enter `html_sanitize=false`
- To enable sanitization enter `html_sanitize=true`

5. Click **Update**.
6. To enable the HTML sanitizer for translated HTML fields, set the *`glide.translated_html.sanitize_all_fields`* property is **true**.

Enable HTML Sanitizer logging

When the HTML sanitizer removes elements or attributes, they are added to the system log.

Before you begin

Role required: admin

About this task

You can review these sanitized elements by adding /syslog_list.do?sysparm_query=source %3DHTMLSanitizer to your instance URL.

Procedure

1. To review these sanitized elements add `/syslog_list.do?sysparm_query=source %3DHTMLSanitizer` to your instance URL.
2. To enable or disable logging, add the `glide.html_sanitize.discarded_log.enable` property to the system properties and set the value to **true** (enabled) or **false** (disabled).
   This property is **true** by default.

Reference

Know about the History sets.

Exploring Auditing

Track record changes on auditing-enabled tables. By default, the system tracks changes to the incident, change, and problem tables, among others.

Auditing overview

Enabling auditing tracks the creation, update, and deletion of all records in the table. If you want to audit individual fields in a table, you can hide fields you don't want to track using a dictionary attribute.

Auditing information is kept in the following tables:

- Audit
- Knowing about History sets

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Warning:
Auditing system tables that receive a large amount of traffic, such as workflow Contexts [wf_context] or Event Management Alerts [em_alert], can impact performance. For this reason, you can't audit the em_alert table as a whole. Instead, audit selected fields of interest. Set *audit=true* on both the em_alert table and the selected fields. Try to audit as few fields as possible.

Auditing users

Auditing has the following users.

- admin
- security_admin

Auditing benefits

Benefit	Feature	Users
Enable table auditing to track changes to all or some of the table's fields	Configuring auditing for a table	admin
Experience a more enhanced way of defining and configuring the audit capability	Configure auditing using Audit Management Console	admin
Automate and simplify the deletion of audit data	Setup your audit retention	security_admin

What to explore next

To learn more about using Auditing, see:

- Configuring auditing for a table
- Configure auditing using Audit Management Console
- Viewing Sys Audit and Audit Relationship Change tables
- Knowing about History sets

Auditing components

Explore the following auditing components for a better understanding of auditing tables, deletions, and exemptions.

Auditing parent and child tables

Tables don't derive the audit flags from parent or child audited tables.

- For example, if you enable auditing for the Configuration Items [cmdb_ci] table, only CIs stored in that base table are audited.
- Likewise, if you enable auditing for the Computers [cmdb_ci_computer] table, only the computer CI records are audited, including any fields on the Computers [cmdb_ci_computer] table that is derived from the Configuration Items [cmdb_ci] table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Auditing system tables

By default, the system doesn't audit the deletion of a record from system tables. To audit a system table, add it to the list of tables in the *glide.ui.audit_deleted_tables* property list.

Auditing deletions from a form or list

By default, the system audits deletions of individual records from a form. To prevent auditing, set the table's dictionary attribute *no_audit_delete*.

The system audits deletions from a list when it **audit** is selected on the table dictionary, and the table isn't listed in the *glide.db.audit.ignore.delete* property.

Note:
By default, the *glide.db.audit.ignore.delete* property isn't present in the System Property [sys_properties] table. To change the property, and its associated values, you must first manually add it. However, when manually added, it overwrites the following default values:

```
glide.db.audit.ignore.delete =
sys_mutex,sys_db_cache,sys_lucene_block,sys_lucene_file,sys_lucene_directo
cmdb_ci_windows_service, cmdb_sam_sw_install,
cmdb_software_instance, cmdb_sam_sw_usage,
sam_sw_counter_detail
```

To learn more about adding system properties, see Add a system property

It is to be noted that by default, the audit deletes are enabled whether the record is deleted from the form view, list view, or through a script/scheduled job.

Information audited

Auditing tracks the following record changes:

- Unique Record Identifier (sys_id) of the record that changed
- Field that changed
- New field value
- Old field value
- Number of times this record and field have been updated
- Date and time when the change occurred
- User who made the change
- Reason for the change (if any reason is associated with the change)
- Internal checkpoint ID for the record, if the record has multiple versions.

Information exempted from auditing

Some updates aren't audited despite enabling auditing on a table. For example, you may see 132 updates in a record's history, but only seven audited ones.

Auditing excludes the following information:

- Updates made by an upgrade.
- Updates are made through import sets.
- Records in parent or child tables.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Fields with the no_audit dictionary attribute.
- System tables are not listed in the *glide.ui.audit_deleted_tables* property list.
- Fields that begin with the sys_ prefix (system fields), except the sys_class_name and sys_domain_id columns.
- UI Pages can sometimes trigger updates to a record without creating an audit log.
- Anytime an inactivity monitor touches a record. It prevents you seeing possibly hundreds of updates listed against an incident, with the noise drowning out the useful data.
- Manual changes to Performance Analytics scores.
- Applying Update Set
- Import XML

Auditing a table

For instructions on how to audit a table, see Configuring auditing for a table.

By default, the system tracks all fields in an audited table. You can audit a subset of fields in a table in one of two ways:

- You can enable auditing for the entire table, then exclude those fields you don't want to include. It's appropriate when you want to audit most, but not all, fields, and is referred to as an exclusion listing. For more information, see Exclude a field from being audited (exclusion listing).
- You can enable auditing for the table, but only for specified fields. It's appropriate when you want to audit only a small number of the table's fields and is referred to as an inclusion listing. For information on how to include a field using an inclusion listing, see Include a table field in auditing (inclusion listing).

Non-cancellable audit records

Reduce the chances of audit records not being recorded when a transaction is canceled with the new default setting.

Audits have been set to create a record immediately in the same transaction with the target record write operations. If the target record gets deleted, the audit still gets created and retained under **NCA Test Audit Delete** module.

Note:
The enhanced audit process is enabled by default. If the `glide.db.audit.lazy` property is set to `True`, the enhanced audit process is disabled.

Prior to Zurich release, if a transaction is cancelled, certain auditable operations were missed being recorded. This is because the platform executes some operations between the record change and is cancelled before audit creation. But, now audits are created immediately after the record is changed, reducing the chances of a cancelled transaction aborting the operation before the audit is recorded.

Audits are now recorded in the same thread as the transaction. Earlier audits were created in a background thread. This change redefines the default value of the `glide.db.audit.lazy` property from True to False. This property is not usually defined in the Properties table because the majority of instances start using the new default value and behavior. On some instances, this property might be already present and set as True, which means that these instances won't be able to use this change to audit behavior.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
It is recommended to delete this property to leverage the update.

Configuring auditing for a table

You can enable table auditing to track changes to all or some of the table's fields.

Before you begin

Note:
Encrypted fields aren't audited by design. This behavior isn't configurable.

Role required: admin.

Procedure

1. Navigate to **All** > **System Definition** > **Dictionary**.
   The system displays the list of dictionary entries. The list includes a row for each table as well as a row for each column (field) in the table.
2. In the list of dictionary entries, find the row corresponding to the table you want to audit, for example `cmdb_ci_computer`.
   You can distinguish the row for the table itself – versus a row for a column in the table – by finding the row with the correct table name, an empty entry for the **Column** name, and a **Type** of **Collection**.
3. Select the dictionary entry for the table.
   The system displays the dictionary entry form.
4. Check the **Audit** check box.
5. Select **Update**.

What to do next

If you want to audit only a few fields in the table Enable inclusion list auditing for a table. If you want to audit most – but exclude some – fields, see Exclude a field from being audited (exclusion listing).

Enable inclusion list auditing for a table

Enable a table to audit only those fields you explicitly designate. This is useful when you want to audit only a small number of fields in an audited table.

Before you begin

The table must be enabled for auditing.

Role required: admin

Procedure

1. Navigate to **All** > **System Definition** > **Dictionary**.
   The system displays the list of dictionary entries. The list includes a row for each table as well as a row for each column (field) in the table.
2. If necessary, customize the list view to show the **Attributes** column.
3. In the list of dictionary entries, find the row corresponding to the table you want to audit, for example `cmdb_ci_computer`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

You can distinguish the row for the table itself – versus a row for a column in the table – by finding the row with the correct table name, an empty entry for Column name, and a type of *collection*.

4. In the **Attributes** field for that row, enter *audit_type=whitelist*.

What to do next
Designate which fields you want to audit in this table.

Exclude a field from being audited (exclusion listing)

Prevent the ServiceNow AI Platform from tracking a subset of fields in an audited table by excluding those fields from an audit.

Before you begin
To exclude a field in a table from being audited, you must have first enable auditing for that table.

Role required: admin

About this task
Add a set of fields to an exclusion list when you want to audit most of the fields in an auditable table. If you want to audit only a few fields, follow the inclusion listing procedure instead.

Note:
Disabling auditing on journal-based fields can impact the functionality of features, such as the Activity Formatter. For more information, see KB0743142.

Procedure
1. Navigate to **All** > **System Definition** > **Dictionary**.
2. If necessary, customize the list view to show the **Attributes** column.
3. Navigate to the row corresponding to the table and field (column) you want to exclude from auditing.
4. In the **Attributes** column for that row, enter `no_audit`.

Include a table field in auditing (inclusion listing)

Track a subset of fields in an audited table by add those fields to an inclusion listing.

Before you begin
To add fields in a table to an inclusion list, you must have first enabled auditing for that table and enabled inclusion list auditing for that table.

Role required: admin

About this task
Add a set of fields to an inclusion list when you want to audit only a small number of an audited table's fields. If you need to audit most fields, and exclude only a few, follow the exclusion list procedure instead.

Procedure
1. Navigate to **All** > **System Definition** > **Dictionary**.
2. If necessary, customize the list view to include showing the **Attributes** column.
3. Navigate to the table and field (column) you want to the inclusion list.
4. In the **Attributes** field, enter *audit=true*.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Enable auditing for a system table

Deletions from tables with a sys_ prefix are not audited by default. To track deletions from these tables, add the table name to the *glide.ui.audit_deleted_tables* property. Enabling the Restore Deleted Records plugin adds several default values to this property.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Properties** > **UI Properties**.
2. Locate the **List of system tables (beginning with "sys_", comma separated) that will have the delete audited** property.
3. Add or remove table names.
   Table names should be separated by commas, without any spaces.
4. Select **Save**.

> **Note:**
> For more information about auditing, see Understanding the sys audit Table.

Configure auditing using Audit Management Console

Use Audit Management Console module to experience a more enhanced way of defining and configuring the audit capability within your instance.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **Audit Management Console**.
   A list of all tables in your instance shows up.

   > **Note:**
   > By default, the list of tables that has set Audit enabled shows up.

   You can select **Disabled** tab to see the list of tables that has set Audit disabled. You can also select the All tab to see all the tables in your instance with either enabled or disabled Audit option.

2. Select the table from the list you want to update the auditing configurations.
   The table with its respective columns show up. You can also see the total number of columns in the selected table.

   > **Note:**
   > **Columns** and **Retention** are the tabs that show up on the table.

3. Modify the Audit toggle depending on if you want to enable or disable audit for the selected table.

   > **Note:**
   > When Audit is enabled in a table, all the columns and fields within the table are enabled by default.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. **Optional:** Select **Edit Audit Status** if you don't want all the columns to be enabled within an audit enabled table.
   The Select Columns to be Edited modal shows up.
5. **Optional:** Unselect the columns that you don't want to be enabled.
   You can also add any column by checking the column from the Available columns list.
6. Select **Save** to save the latest modifications.
   Select **Clear All** to remove all the columns being enabled. See Setup your audit retention for more information about audit data retention.

Setup your audit retention

Use the Retention option to automate and simplify the deletion of audit data as per your requirement.

Before you begin

Role required: security_admin

Procedure

1. Navigate to **All** > **Audit Management Console**.
2. Select the table from the list you want to update the retention policy.

   Note:
   By default, you land on the Columns tab at the end of this step.

3. Select the Retention tab to update the retention policy for the selected table audit data.
   A modal showing the retention option shows up.
4. Enable the Automatically Purge Audit Records toggle.
5. Select the duration from the Duration dropdown menu.
   Select **Yes** if you want to proceed with the selected duration. You can also select **Cancel** if you want to select a different duration.

   Note:
   Logs older than your set duration will be purged and can't be restored.

   The Retention Policy modal shows up confirming the selected duration.
6. Select **Save** to update the retention policy for the selected table.
7. **Optional:** To disable deletion of Audit records of a table, disable the Automatically Purge Audit Records toggle and select **Save**.

   Note:
   The audit records that were previously deleted due to the selected retention duration are permanently unavailable.

Viewing Sys Audit and Audit Relationship Change tables

The ServiceNow AI Platform tracks inserts and updates to audited records in the Sys Audit (sys_audit) and Audit Relationship Change (sys_audit_relation) tables.

The ServiceNow AI Platform tracks audit tables. To track tables, select the **Audit** check box in the dictionary record to set the value to true. By default, it does not audit records from system tables, such as update sets tables.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
To prevent performance issues and infinite loops, the system skips any business rule or workflow triggered by inserts to the Sys Audit table.

Sys audit table columns

Access the Sys Audit table on your instance by entering `sys_audit.list` in the navigation filter.

The following columns appear in the sys_audit table records:

Field	Description
Table name	Table that the audit record is for (for example, "`incident`")
Field name	Column in the table that the audit record is for (for example, "`assigned_to`")
Document key	Sys_id (Unique Record Identifier) for the originating record associated with the audit record.
User	Name of the user who created the change. **Note:** Some automated processes use the system or guest user to apply and track changes to records. For more information, see System and guest users.
Old value	Old value of the field change represented by this sys_audit record. • Reference fields: Unique sys_id value of the changed record. • Date and time fields: Value in Coordinated Universal Time (UTC) as stored in the database.
New value	New value of the field change represented by this sys_audit record. • Reference fields: Unique sys_id value of the changed record. • Date and time fields: Value in Coordinated Universal Time (UTC) as stored in the database.

How the Audit Relationship Change (sys_audit_relation) table works

The Sys Audit [sys_audit] table tracks changes to reference fields in tables that are flagged for auditing. This activity includes journal field entries and history sets. The Audit Relationship Change [sys_audit_relation] table tracks relationship changes between sys_audit table records and the source tables that the audited records originate from. It also tracks when a record might have been deleted.

-
- Whenever you audit any record in a table, a relationship is created between the various originating tables to the store that records data. This relationship information is saved in the sys_history_set, sys_history_line, and sys_journal tables.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- If you delete a field that is related to an audited table record, the sys_audit_relation table records the deletion. In other words, anytime you change an audited record, it first deletes past elements, and then creates a relationship in the sys_audit_relation table with new document IDs.

Knowing about History sets

The system automatically generates History Set records as needed from the Audit table when a user either creates a record or views its history.

If a record is in an audited table, its history set is generated when the record is inserted or when a user views the record.

Note:
Don't use history sets to generate reports.

Several fields of information are captured in the History Set record, displayed in the list view.

List View Record Fields

Field	Input Value
ID	Document ID for the record whose history is being recorded.
Table	Audited table for the record whose history is being recorded.
Load Time	Amount of time it took to generate the history set.

Audit History Record Fields

Field	Input Value
Label	The label of the field that was changed.
Old	Value before the change.
New	Value after the change.
Type	Indicates if the entry is for a normal field, an email record, or a relationship change record.
Update Number	The number of times this field has been changed. A value of -1 indicates when the record was created or deleted.
Update Time	Date and time of the change. **Note:** The Update time for auto-generated history lines doesn't match the Created or the Updated time for a record in a specific processing situation. When you view a history set of a record for the first time, an initial set of history line records is auto-generated. Since file changes in an upgrade aren't audited, this date mismatch occurs when: • You view a history set after a change is made to a record, but • Before another change is made to it in a future upgrade.
User Name	Name of the user who created the change.

History Sets in a Calendar View

After History Sets are active, the History context menu choice populates using information from the history set, rather than from the `sys_audit` table. From the user's perspective, the same historical data is available in the same user interface, but how the information is stored is different.

Since the History view includes a calendar view, but doesn't use the normal list interface to filter and interact with the history records, it enables:

- Searching and filtering historic data.
- Exporting historic data.

Viewing history sets

There are two ways of viewing the history set, accessible through the Context Menu action **History**.

Differences Between Audit and History Sets

The Audit [sys_audit], History Sets [sys_history_set], and History [sys_history_line] tables store the same data, but they serve different purposes and manage data differently.

Audit [sys_audit] table

The Audit [sys_audit] table is where the system stores historical information for all records. These records are intended to be kept forever so that administrators can always track the history of audited records. As the number of auditing records grows over time, it becomes more inefficient to directly query the Audit table for historical information. It is much more efficient to run queries only on the smaller subset records you actually want to view historical information for.

History Set [sys_history_set] table

The History Set [sys_history_set] table identifies which particular records from an audited table have historical information. The History [sys_history_line] table stores the actual changes to field values that occurred.

- The system automatically generates History Set and History records as needed from the Audit table when a user either creates a record or requests its history.
- Rather than containing a complete history of all changes in the system, History Set and History records only contain a recent subset of historical information for records where users have created or requested such information.
- In addition to audit data, history sets also include the information that is set during record insert, including journal field entries. Journal field entries you create before creating a record are handled in the same manner as journal entries created at the time of record creation. These journal entries appear in history sets with the same creation time and created by data as the associated record itself.

The system limits History Set and History records by:

- Having the table cleaner delete History Set records that have not been updated in 30 days.
- Using table rotation to rotate between four History tables every seven days. The system drops History records that are older than 28 days.

Should someone need historical information again at a later date, the system can regenerate it from auditing source records.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

After the system generates History Set records, the context menu choice **History** uses the History Set rather than Audit records. From the user's perspective, the same historical data is available in the same user interface, but the way the information is stored is different.

Control access to history

You can give a role access to view audit history by setting a system property.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Properties** > **System**.
2. Select the *glide.history.role* property from the table.
3. In the *List of roles (comma-separated) that can access the history of a record*, select the user roles you want to access history.
4. Select **Save**.

Result

Any changes to a field are omitted if a user without read-access views the history of a record.

Change the number of history entries

By default, the history displays a maximum of 250 history entries, but you can change this value.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Properties** > **System**.
2. Select the *glide.history.max_entries* property.
3. Set the *Maximum number of field entries displayed in record history, default is 250* value with a new maximum number of entries to be displayed.

History List

The history list displays each change as its own row in the change list.

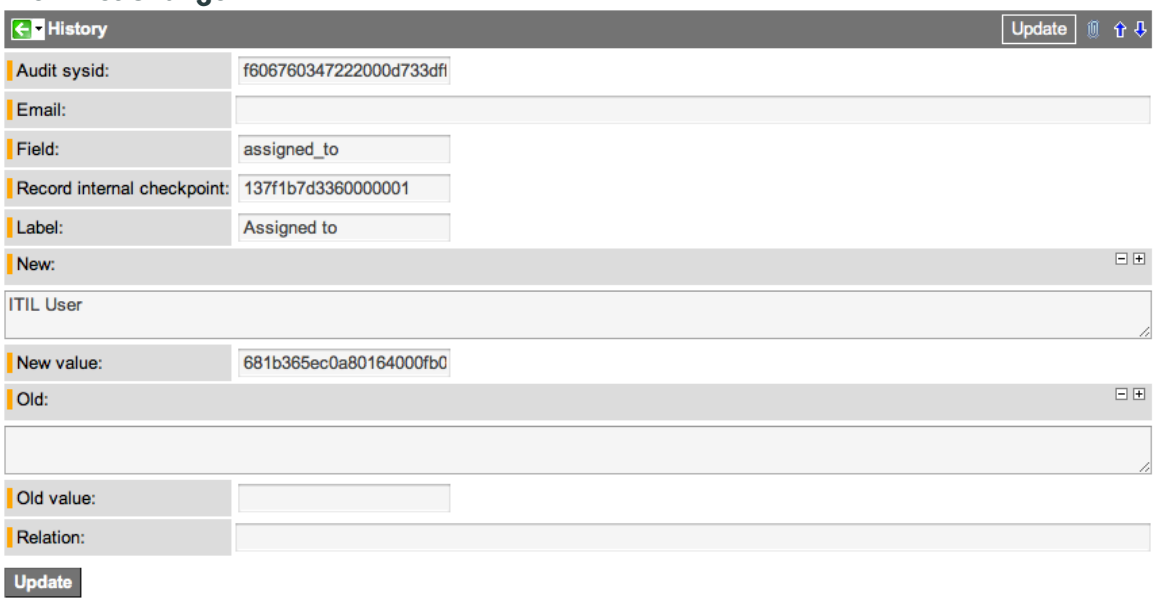
Click on a row item to view additional details about the change.

View List Change



Requirements

To view a history list, the following requirements must be met.

Auditing

Auditing for the table must be enabled to view a history list.

ACLs

By default, the *List* history option is only available to users with the admin user role. To enable this option to non-admins, create a custom ACL rule granting read access to the Record History [sys_history_set] table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Roles

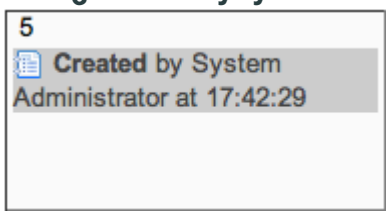
At least one of the roles that the user has must be included in the *glide.history.role* property, which includes the itil role by default.

History Calendar

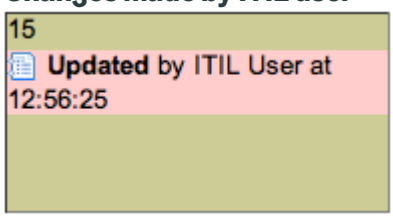
The history calendar shows you the days where the record was changed, who made the change, and when.

The History Calendar is sorted by update number. Each user is assigned a color so you can tell at a glance how many times a record was changed by a specific user. For example:

Changes made by system administrator



Changes made by ITIL user



To highlight changes to a particular field, select the field from the **Highlight changes to field** selection box. Picking a field from this selection box changes the calendar to highlight the times that field was changed. Hover over the text of one of a highlighted change to see the change in value.

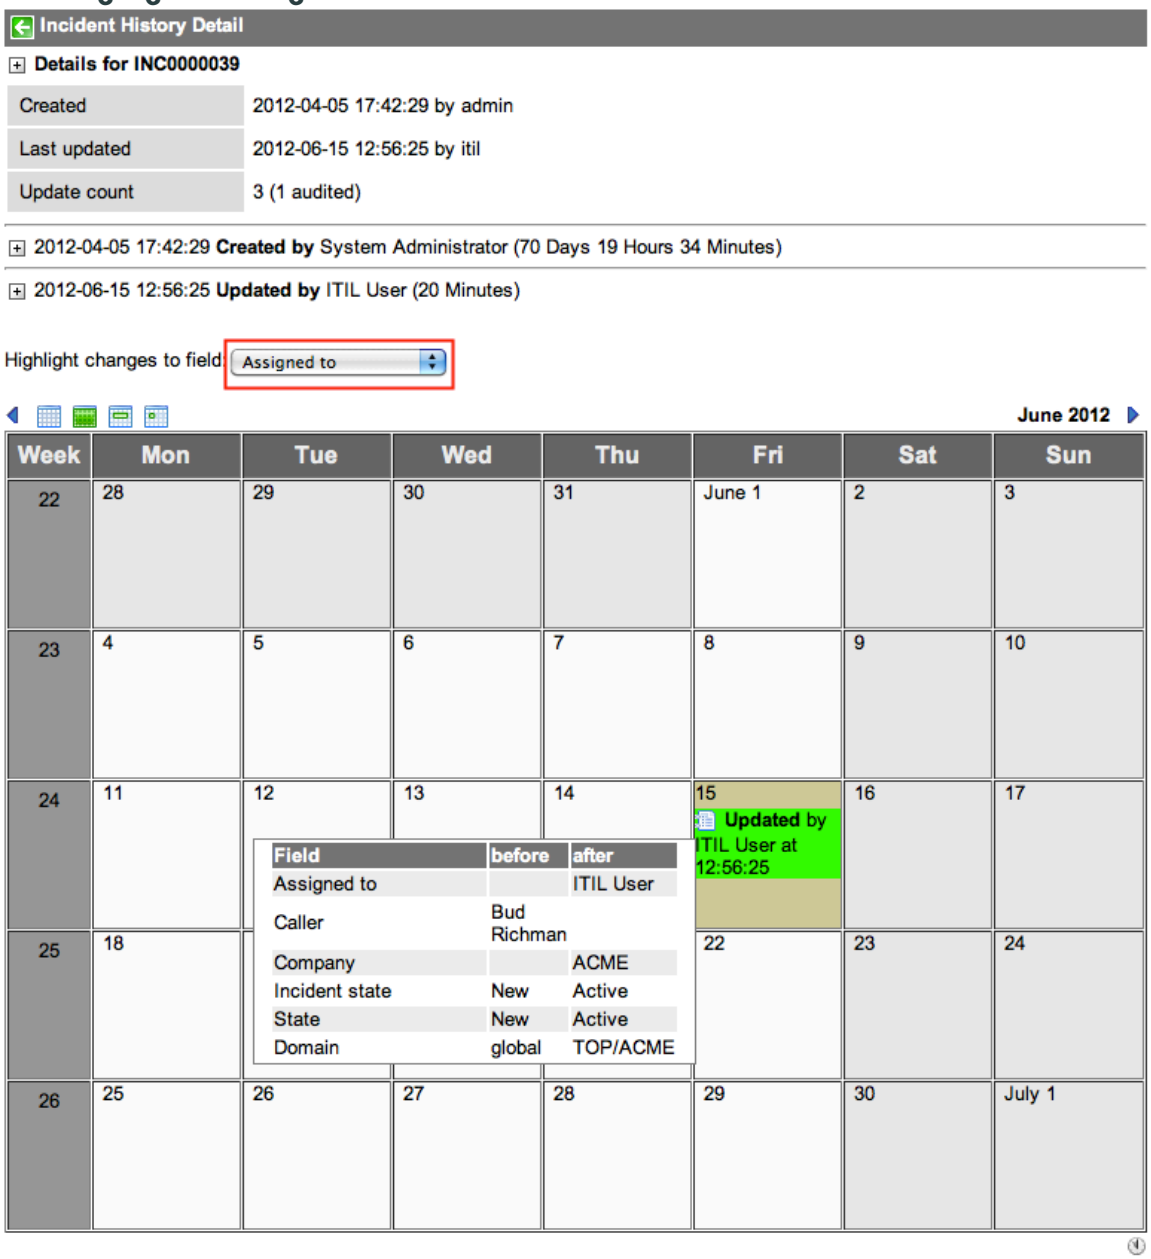
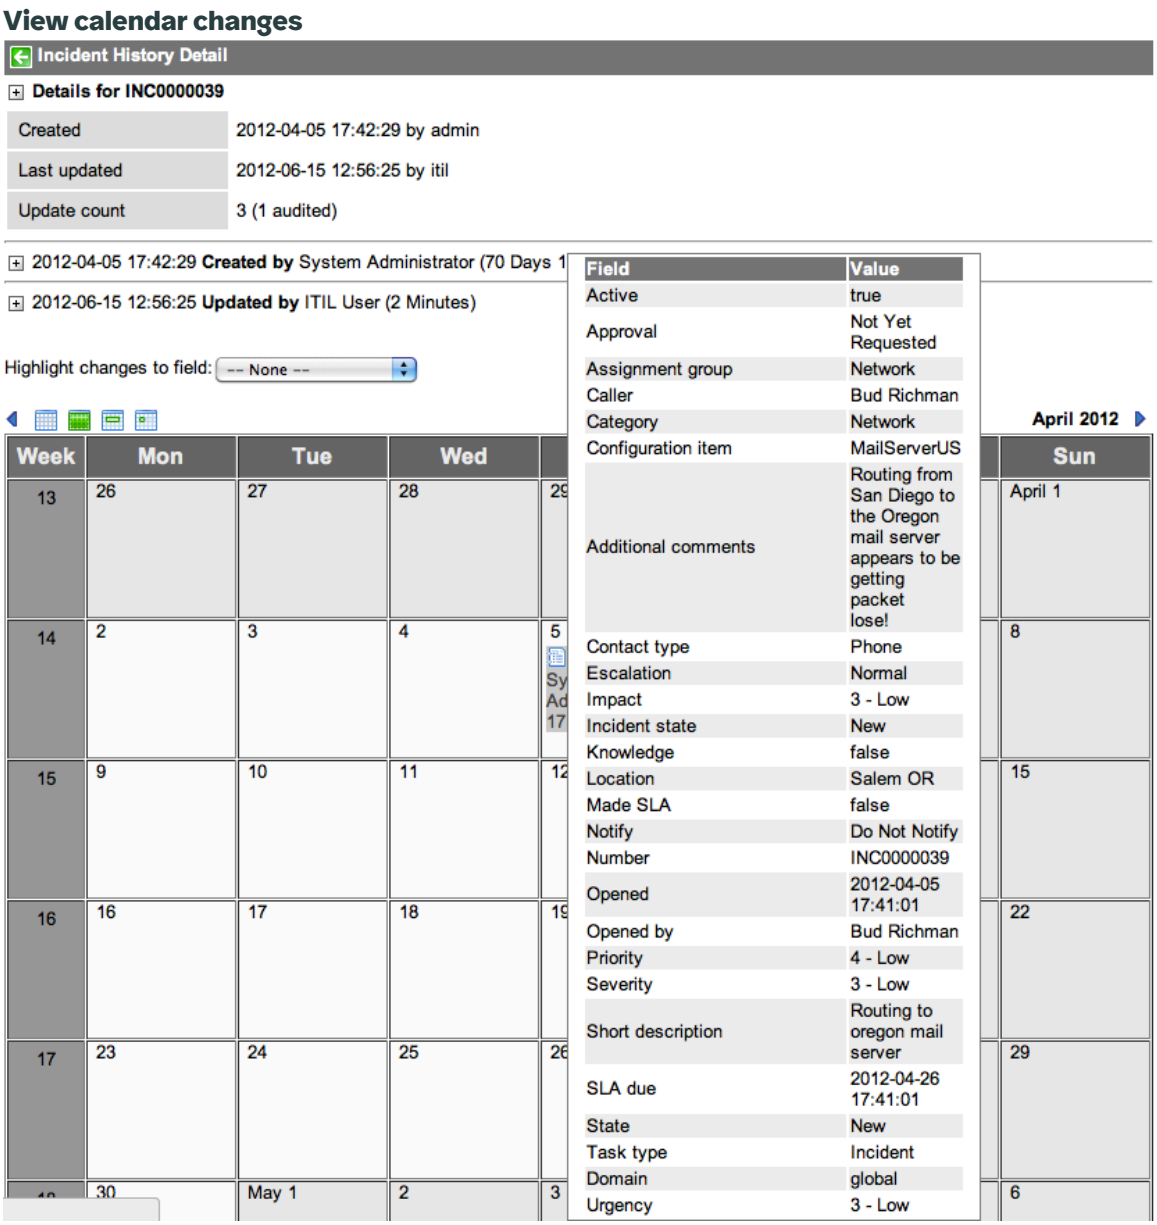
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

View highlighted changes



If you hover over the icon within an entry, a popup displays all the value changes. This is the same information that is displayed in the top part of the form.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



You can click on the day number to get a view of the changes for that day. You can also click on the week number to the left to get a the week view. You can scroll to and from month to month to see changes.

History Timeline

You can view a timeline of changes for a CI and for its related records, relationships, baselines, and proposed changes for the CI. Timelines are available for CIs in the Configuration Item [cmdb_ci] table or a descendant of this table, if auditing is enabled for the tables.

Role required: The ACL for this view is based on the roles defined in the *`glide.history.role`* system property, which by default is set to `itil`. Also, the user must have read access to the History Set [sys_history_set] table, which by default is granted to admin.

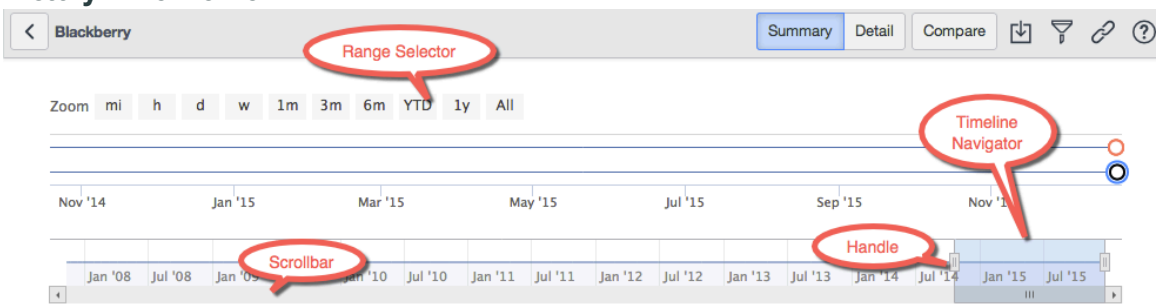
You can open a timeline when you view the history of a CI. You can specify the time period, time range, and properties that are displayed in the timeline. You can view either what has changed in a particular change set, or view the entire CI to better troubleshoot any issues. You can also display a timeline of changes to the CI's related records, and export and compare snapshots of the CI at any point in time.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

CI changes are represented by bubbles in different shapes and colors along the timeline. The shape of each bubble represents a different type of change and the color of each bubble specifies whether the change is valid or invalid. CI baselines are represented by black circles that you can hover over to display more details. Click the **?** icon to display bubble shape and color definitions, and point to a bubble to display details about the change set.

A change to a relationship is considered valid only if it was applied through change management. If the change was applied via the Proposed Changes framework, it is valid. For additional validation steps, see Create or edit a planned validation script .

History Timeline view



Timeline bubbles

Note:
Proposed changes that do not have a planned start date are placed at future points of time.

Timeline navigator

Use the handles on both ends of the timeline navigator to extend or to shorten the time period that is shown.

You can scroll to a different period of time by clicking on the bottom part of the timeline navigator and then dragging the navigator to the left or right.

Zoom

By default, the timeline for the last month is shown. Next to the **Zoom** label above the timeline, you can select another time interval. You can select intervals from a minute to the entire period of data.

If there are many changes of the CI during the time period, the bubbles displayed might get too crowded. You can zoom in or out to spread the bubbles in either method:

- Change the time interval on the timeline. As you shorten the time interval, you zoom in, and as you lengthen the time interval, you zoom out.
- Select the section of the timeline that you want to zoom into.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property filter

You can filter the bubbles that are displayed. By default, all bubbles are displayed, representing changes to all of the CI's properties. You can limit the view to display only the bubbles in which selected properties have changed and exclude bubbles in which only unselected properties changed.

The **Detail** and **Summary** views highlight properties within your filter scope that have changed. The changed properties are highlighted in light blue.

In the **Summary** view, you can choose to include all the properties of the CI, or only properties that have changed. If you choose to display all properties in the summary view, then changed properties are listed before unchanged properties.

Summary view

The **Summary** view displays snapshots of the CI's represented by each bubble. Each snapshot displays the changes to the CI's fields and relationships according to the change set. It displays old and new values before and after the change, and any relationships that were added or deleted.

Use the **>** and **<** buttons on both sides of the snapshot display to scroll through the next and previous change set records in a chronological order.

Detail view

The **Detail** view displays snapshots of the CI that correspond with the bubbles. Each snapshot includes the fields that are within the property filter scope, displaying the properties that have changed with a light blue background. Click on a bubble to display its corresponding snapshot of the CI. The data that is displayed is read-only.

Use the **>** and **<** buttons on both sides to scroll through the next and previous change set records in a chronological order.

View timeline of changes to related records

On the time line of changes for a CI record, you can also view a timeline of changes for the CI's related records.

Before you begin

Role required: admin

- Target table: the CI record must be in the Configuration Item [cmdb_ci] table or a descendant of this table.
- Auditing: must be enabled for the table containing the CI.

Procedure

1. Open the timeline for the CI.
2. Select the **Related Records** icon and select related records from the **List of Related Records** to view.
   Click the Related Records icon again to display the related records timeline.

Result

The timeline of changes to the CI's related records is displayed right above the CI's timeline. If you uncheck all related records, the related records timeline is hidden.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

What to do next
Hover over a change bubble on the related records timeline to display details about the change, such as date and number of changed properties. As you change the time interval in focus, or zoom in or out, it affects both the CI timeline and the related records timeline simultaneously.

Export a snapshot of a configuration item

You can export a snapshot of a configuration item from its timeline.

Before you begin
The configuration item must be in the Configuration Item [cmdb_ci] table or a descendant of this table. Auditing must be enabled for the table containing the CI.
Role required: admin.

About this task
You can export a snapshot of the CI to an XML, PDF (Portal), or PDF (Landscape) format.

Procedure
1. Navigate to **All** > **Configuration** > **Base Items** > **All** to open the configuration item list.
2. Open a configuration item record.
3. Open the timeline for the record.
4. Select the bubble representing the time for which you want to export a snapshot of the CI.
5. Click the export icon ( ).
6. Select the file format to use for the export.
   You can download the file to your system for viewing.

Compare CI snapshots

You can compare the properties and relationships of a CI at two different points in its timeline.

Before you begin
The CI must be in the Configuration Item [cmdb_ci] table or a descendant of this table. Auditing must be enabled for the table containing the CI.
Role required: admin.

Procedure
1. Open the timeline for the CI.
2. Click **Compare**.
3. Select a **Start** date and an **End** date.
4. Click **Compare**.

Tracking changes to reference fields

Administrators can track changes to reference field display values.

Since reference fields only store an ID value, the system can normally only audit changes when the ID value changes. By default, the system does not audit changes when a reference field display value changes.

Consider the following situation. A user changes their name from Jane Smith to Jane Miller. Since the user name is the display value for the User table, any previous reference to Jane Smith instead refers to Jane Miller. If the administrator just updates the name of the existing

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

user record, audit and history records will only display the new name Jane Miller. By default, the system does not provide a way to distinguish between changes made under the original user name versus those made with the new user name.

If your auditing policy requires tracking user name changes, you can:

- Create a new user record for the new name and deactivate the previous user record. The system preserves audit records for the old user name and creates future audit records with the new user name.
- Create custom fields and a business rule to save the previous name and the date of the name change. The system can use this information to construct the proper names in audit and history records.

Tracking inserts

By default, the system does not create Audit records for inserts because in a typical instance, inserts can account for over 80% of the size of the Audit table.

Not tracking inserts allows for better performance and a much smaller Audit table. Administrators can enable auditing of inserts by setting the `glide.sys.audit_inserts` property to *true*.

Tracking CI Relationships

Changes to a CI relationship (CI Relations, CI/User Relations, or CI/Group Relations) appear in the history of the items on both sides of the changed relationship regardless of whether the change was manual or a result of Discovery.

For example, if the computer alpha has a used by CI Relation with the computer beta, then the history for alpha has a record of when the relationship with beta was established, and likewise, the history for beta has a record of when the relationship with alpha was established. This example illustrates the history displayed when some CI Relations are established, and then one of the relations is removed:

High Security Settings

High Security Settings refer to several security options available in your instance.

Explore High Security setting	Activate High Security Settings
Learn the features and business values of High Security Settings.	Activate the High Security Settings.

Exploring High Security Settings

High Security Settings refer to several security options available in your instance.

The High Security Settings module is activated with the High Security Settings plugin, which is active by default on new instances. If High Security Settings are not active on your instance, see Requesting High Security Settings activation. To learn more about this plugin, see Enable High Security Plugin [Updated in Security Center 1.3] in Instance Security Hardening Settings. Properties for these types of high security settings are available:

- Default property values: To harden security on your platform by centralizing all critical security settings to one location for management and auditing.
- Default deny property: Provides a security manager property to control the default security behavior for table access.
- Security Administrator role: Provides a role to prevent modification of key security settings and resources. The Security Administrator role is not inherited by the admin role and must be explicitly assigned.
- Elevated privileges: Allows users with the security admin role to operate in the context of a normal user and elevate to higher security role when needed.
- Property access controls: Allows security administrators to set the roles required to read and write properties.
- System logs: Are read only.
- Access control rules: Control what data users can access and how they can access it.

Note:

- High Security Settings also automatically activates the Contextual Security plugin, if it is not already active. In addition, Platform Security Settings - High delivers settings and features in the context of increasing the security of your instance.
- The Instance Security Hardening Settings content contains detailed descriptions, and compliance values, for the security-related system properties and plugins in the ServiceNow AI Platform.
- To learn more about each of these properties, see Hardening settings.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

There are two ways to set or change High Security Settings properties.

- Navigate to **System Security** > **High Security Settings**.

  Options on the High Security Properties page are **Yes** or **No**.

- Navigate to the **sys_properties.list** and search for the property you want to set or change.

  Options in the System Properties table [sys_properties.list] are **true** or **false**.

Property access control

Two additional columns are created in the Properties [sys_properties] table when High Security Settings are active:

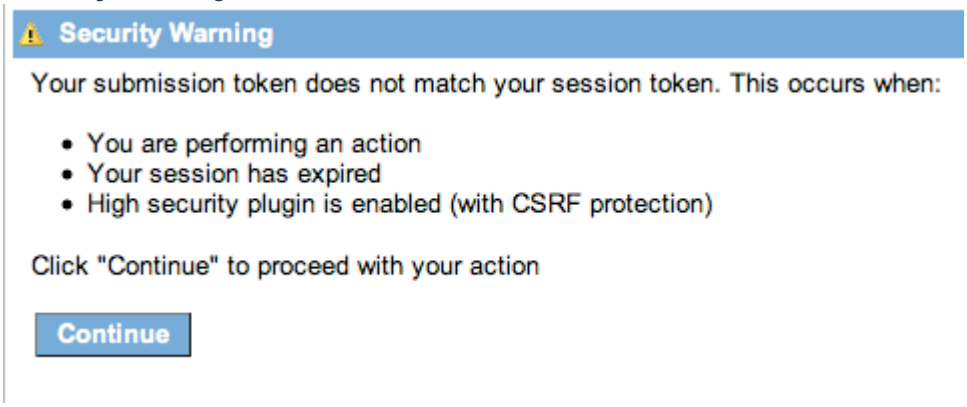
- **read_roles**: A comma-separated list of role names that are allowed to read all fields of this property.
- **write_roles**: A comma-separated list of role names that are allowed to write/modify all fields of this property.

Properties listed in the Properties table have **read_roles** of admin, and **write_roles** of security_admin. Users with the admin role can view and read the property values, but must elevate to the security_admin role to modify them.

Notifications

Activation of high security settings also activates security warning messages. The following is an example of a message that appears after an approval.

Security Warning notification



High Security Settings properties

Property	Description	Default Value	Instance Security Hardening Settings
glide.ui.escape_text	Escape XML values at the parser level for the user interface. Prevents reflected and stored cross-site scripting attacks. This property is not	Yes	Escape XML markup [Updated in Security Center 1.3]

Property	Description	Default Value	Instance Security Hardening Settings
	linking to external unauthorized content.		
glide.set_x_frame_options	Enable this property to set the X-Frame-Options response header to SAMEORIGIN for all UI pages. The X-Frame-Options HTTP response header can be used to indicate whether a browser should be allowed to render a page in a <frame> or <iframe>. Sites can use this property to avoid clickjacking attacks by ensuring that their content is not embedded into other sites. https://developer.mozilla.org/en/the_x-frame-options_response_header	Yes	Implement the x-frame-options: SAMEORIGIN security header [Updated in Security Center 1.3]
glide.ui.attachment.download_mime_types	A list of comma-separated attachment mime types that do not render inline in the browser. Prevents cross-site scripting attacks. For example, `text/html` forces HTML files to be downloaded to the client as attachments rather than viewed inline in the browser.	`text/html,image/svg,image/svg+xml`	Restrict downloadable MIME types [Updated in Security Center 1.3 and 2.0]
glide.security.groupby_acl_check	When this property is enabled, ACL checks for GroupBy operations are performed for the group names based on the actual data from the groups.	Yes	None
glide.security.diag_txns_admin	If **Yes**, only the admin user or	No	Restrict performance monitoring access

Property	Description	Default value	Instance Security Hardening Settings
com.glide.security.check_unsanitized_html	Enforces sanitization behavior of translated_html fields on a global level for field assignments.	enforce	None

Activating High Security Settings

The High Security Settings plugin is active by default on all new instances. If it is not active on your instance, you can request the plugin.

Before you begin

Role required: None

Before activating High Security Settings on an existing instance:

1. Review the following information to understand the new behavior:
   - Access Control List Rules
   - High Security Settings
   - Default deny property
2. Enable the plugin on a non-production instance. A recent clone of production is preferable.
3. Test the revised functionality, especially the added ACLs and default-deny functionality. Continue testing until the system performs as expected. If users cannot access expected resources, ensure they have appropriate roles and ACL rules to grant them the access.
4. Create update sets of any needed changes so you can apply them to production.

Note:
To learn more about this plugin, see Enable High Security Plugin [Updated in Security Center 1.3] in Instance Security Hardening Settings.

Role required: admin

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Select **Request plugin** to open the **Activate Plugin** form on Now Support.
3. On the **Activate Plugin** form, provide the following information.

Activate Plugin form

Field	Description
What is your target instance	Select the instance that you want to activate the plugin on.
Which plugin would you like to activate	Select the name of the plugin to activate.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Note: If the system doesn't list the plugin you want or if you're activating the plugin on an OEM or on-premise instance, select the **Plugin I'm looking for is not listed** check box and then enter the name of the plugin.
Select Maintenance Date and Time	Select the date and time to activate the plugin.

Example

For example, see the following form to activate the Event Management plugin on an instance named SNC Instance.

4. Select **Submit**.
   After the maintenance window, the system installs the plugin on your instance. To confirm the installation, go to the Installed tab in the Application Manager.

Virtual Private Network (VPN)

Use a virtual private network (VPN) to integrate your instance with external data sources over the Internet.

Explore

Learn the features and business values of virtual private network.

Activate

Active the virtual private network.

Configure

Understand how to configure virtual private network.

Exploring Virtual Private Network (VPN)

Use a virtual private network (VPN) to integrate your instance with external data sources over the Internet.

My IP Information

When configuring an integration that uses an encrypted protocol, such as Lightweight Directory Access Protocol (LDAP) or HTTPS, it is good practice to use the Internet as a transport mechanism.

However, there may be security or network architecture requirements that dictate the use of a site-to-site Internet Protocol Security (IPSEC) Virtual Private Network (VPN) connection between the datacenters and your business networks. The VPN supports the necessary encrypted communication between the instance and your network.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Warning:

When a VPN tunnel is initiated, it operates as site-to-site connection. This means that the endpoint on your infrastructure receives an IP address, referred to as an encryption domain. This public IP can be accessed by any instance within the same data center.

For example, if you have an internal web service and establishes a VPN tunnel, your instance is able to reach the internal endpoint as well as all your other instances in the same data center.

VPN connections

The ServiceNow VPN infrastructure uses pairs of Cisco adaptive security appliance (ASA) devices that serve as VPN termination points.

The VPN between the instance and your network utilizes your existing networking hardware to support communications. It is not necessary to install a piece of hardware. Because each customer has a unique configuration, the instance has a flexible VPN solution. the instance has built tunnels to Checkpoint, Juniper, Nortel, and other IPSEC VPN-capable devices.

The VPN connections between the instance and your network are created to support the encrypted flow of traffic into your network. Frequently, integrations that use the VPN do not have encryption as part of the underlying protocol. For example, LDAP over the VPN versus LDAPS over the Internet and HTTP over the VPN versus HTTPS over the Internet.

The network does not allow any inbound-to-ServiceNow integration or end-user-to-ServiceNow traffic to traverse a VPN connection. This restricted communication includes end-user access to the platform, administration of the platform, web services integrations, and other integrations that are configured to use a MID Server. All such inbound communication to the instance must be performed over the Internet using HTTPS. This configuration provides an encrypted communication channel. The encryption channel, along with IP access control, meets the security requirements for this traffic flow.

Addresses for VPN communication

To prevent conflict or overlap with internal ServiceNow networks or with another internal IP address schemes in your network, all tunneled traffic in the encryption domain must use non-RFC-1918 addresses on both sides of the tunnel.

ServiceNow provides a single IP address for the source of queries into your network. You must provide Network Address Translation (NAT), non-RFC-1918 addresses for each host that is integrating with your instance. These public addresses need to be owned by your organization. Third-party addresses cannot be used inside tunnels. Additionally, the encryption domain must not contain the IP address of the VPN peer.

Redundant tunnels

There are two ways to build redundancy for your tunnels:

- Using the same encryption domain behind both of your peers. This is the preferred method.
- Using a different encryption domain behind each peer.

With the first method, you need to provide the same NAT address behind each of your peers to create a connection path using that address to your server. The path to your server could be the same physical machine or a mirror which provides identical services. With this method, your instance would use the same IP address to connect to your servers regardless of whether your primary or secondary tunnel is active. If you have more than one server, follow this same scheme

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

for your additional servers. This method provides the most transparency to your users and is recommended.

The second method requires configuration in your instance to provide the redundancy. When the tunnel is used for LDAP, for example, you could provide redundant LDAP servers in your instance. Note that this method requires the connection to the first configured LDAP server to timeout before the instance attempts to connect to the secondary server. Because of this additional time delay, this solution should only be implemented if the first option is unattainable. Also note that not all services can be configured for redundantly in your instance. If you are using a VPN tunnel for something other than LDAP and redundancy is required, check that your configuration can support multiple addresses, or see the first option above.

Alternatives to using a VPN

These alternatives provide a simpler way to connect your instance to the resources in the ServiceNow data centers and provide better encryption. Additionally, you can avoid any issues that VPN downtime might cause, such as making your instance unavailable to users if there is an issue with the VPN tunnel.

Single sign-on and MID server

Consider using a combination of Single Sign-On (SSO) for authentication and the MID Server for user data synchronization, rather than using a VPN to connect your LDAP server to your instance. For integrations other than LDAP, consider using certificate-based encryption.

You can use the LDAP listener on a MID server to synchronize your user table in near real time.

The advantage of this approach is that there are no firewall holes, routes, VPN tunnels, or other special network settings to configure and maintain. The SSO/MID-Server solution is the most flexible, secure, and cost-effective method to achieve the complete LDAP integration.

LDAP over SSL

Another alternative to using a VPN tunnel is to configure LDAP Over SSL (LDAPS) directly over the Internet. You can configure a read-only domain controller and lock the instance down in your DMZ using only the instance's source addresses and the destination ports of your choice. Since the ports for LDAP are configurable in your instance, you can perform a port address translation (PAT) if desired. With LDAPS, you control the certificate that is uploaded over an encrypted channel to the instance, (see Uploading a certificate to an instance). The packets cannot be encrypted or decrypted without the certificate.

The advantage of this approach is that it provides a stronger encryption and decryption mechanism. A VPN can only encrypt and decrypt the traffic between the two peers sitting on the Internet with a coordinated pre-shared key, similar to a password. LDAPS provides a longer encrypted path, end-to-end, at the application layer and with a certificate that is far more complicated than a pre-shared key that the IPSec tunnel uses.

VPN setup

From the time that a VPN request is submitted, it typically takes one week or less to complete the VPN build. To support the redundancy requirements of your instance and your organization, a minimum of two and a maximum of four VPNs are provisioned (from the active site to your active site or the active site to your DR site, and so on).

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

It is good practice for the encryption domain to be as specific as possible. Ideally, the encryption domain would include only the specific hosts that are required for the integrations. A large encryption domain can create opportunities for routing discrepancies (VPN versus Internet).

To create the VPN, the instance does the following:

1. Provides the VPN peer and host addresses from each data center.
2. Builds the necessary VPN connectivity from two data centers into your network. To support redundancy and disaster recovery (DR) requirements, the VPNs can be provisioned from two data centers into two networks.

The instance does not support building multiple VPN tunnels into a customer network for the purpose of connecting to multiple geographic regions or subsidiaries. You should perform any inter-site routing, traffic distribution, or traffic shaping within your own internal network, rather than having multiple VPN tunnels.

Activating a VPN service

For all VPN requests, including provisioning, modifications, or general questions, use the Service Catalog VPN Request form.

Before you begin

Role required: admin

Procedure

1. Navigate to https://support.servicenow.com/now?draw=case.
2. Select the **Automation Store** tab.
3. Use tree on the left to navigate to **All automations** > **Service catalog** > **Cloud Infrastructure**.
4. Select **VPN Requests**
5. Select the appropriate VPN request type.
6. Answer the questions.
   Questions vary depending on the request type selected.
7. Click **Submit**.

Result

Once your request is submitted, ServiceNow will work with your network engineer(s) to test and validate that the VPN is successfully passing traffic. To ensure that your questions are answered in a timely manner, please address VPN-related questions during this process.

Configuring an address for VPN communication

To prevent conflict or overlap with internal ServiceNow networks or with another customer's internal IP address schemes, the instance requires that all tunneled traffic in the encryption domain use non-RFC-1918 addresses on both sides of the tunnel.

Before you begin

Role required: admin

About this task

The instance provides a single IP address for the source of queries into your network.

Platform Privacy

Privacy enables you to mask sensitive data on your instance.

Store Applications

Data Privacy	Data Discovery
	Use Data Privacy to classify sensitive data and to remove personally identifiable information (PII) from user data in a production instance and anonymize data in non-production instances.	Use Data Discovery to identify sensitive data within an instance to classify, protect, or report.

Plugins

Data Privacy (Classic)	Data Anonymization	Data Classification
		Use the legacy Data Privacy(Classic) plugin.	Data anonymization provides a way to easily transform data so that it is unidentifiable and more compliant with data privacy regulations.	Group data by type, using pre-defined or user-defined data classifications. If you have an assigned data classification administrator or auditor role, you can administer different data classes or visually analyze the current state of different types of data within the instance.

Exploring Data Privacy

Use Data Privacy to classify sensitive data and to remove personally identifiable information (PII) from user data in a production instance and anonymize data in non-production instances. Once anonymized, the user data is no longer considered regulated private information.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Explains the importance of data privacy and the steps businesses can take to protect sensitive information through classification and anonymization. Using the Data Privacy store application, we give an overview of the main dashboard and capabilities.

Developers must work with data on non-production instances to ensure that their implementations are working as expected. While importing data from your production instance is a useful way to simulate production, it presents a security risk. Administrators can use data privacy to provide developers with data that does not contain private information to work safely in a non-production environment.

Data classification

Identify and classify your sensitive data according to pre-defined criteria determined by the level of sensitivity of the data types in your instance. Data sensitivity levels help determine how each type of classified data should be handled. There are several pre-defined classes provided with base level data privacy. Use the classification section of Data Privacy to label and group data within your instance. Add classes, view data class structure and classify data. Group data by type, using pre-defined or user-defined data classifications.

Explains how to classify data using the Data Privacy store application.

User data anonymization

As an administrator, you define whether to anonymize all information for all users or for a subset of users. When anonymized, data for the selected user records is replaced with randomized values or values you define. When replacing values, the data structure can be preserved using various techniques.

Explains how to anonymize data using the Data Privacy store application.

Data Privacy

Use Data privacy to classify sensitive data and to remove personally identifiable information (PII) from user data in a production instance and anonymize data in non-production instances.

Note:
You can also use the legacy plugin Data privacy (Classic).

Installation details

You must have the following applications installed on your instance:

- Data Privacy (Classic) [com.glide.data_privacy]
- Data Privacy [sn_dp_store_app]
- Data Discovery [sn_data_discovery]
- Data Discovery APIs[com.glide.data_discovery]

Here is the how the installation works:

- Installing the Data Privacy Store App will auto install the Data Discovery Store App, Data Privacy (Classic) plug-in, and the Data Classification plugin.
- Installing the Data Discovery Store App will auto install the Data Discovery APIs plugin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Considerations

- Only classified data can be anonymized. For information on data classes and classification, see Data classification (Classic) or Data classification Store App.
- PII in logs and other auditing data are not anonymized.
- Only structured data can be anonymized. Unstructured data, such as Journal fields, comments, attachments, and other fields where partial text may represent PII is not anonymized. See Supported field types for anonymization for more information.
- Integrations with single sign-on (SSO) systems may resynchronize user information from their source of truth systems. There is no mechanism in place to ensure the permanency of the de-identification of sys_user data. For information on user administration and sys_users see User Administration.

Data Privacy

Use Data Privacy to classify sensitive data and to remove personally identifiable information (PII) from user data in a production instance and anonymize data in non-production instances.

Get started

Explore	Configure
Learn more about Data Privacy for Now Assist	Configure Data Privacy for Now Assist

Note:
Data Privacy for Now Assist detects and masks sensitive data based on Regex patterns and does not support contextual(model-type) data patterns.

Important:

- Not all model providers are available for customers with in-country SKUs, and some Now Assist products/features are currently unavailable for in-country customers. For more information, see the KB1584492 article in the Now Support Knowledge Base. Be sure to check for model provider availability updates in future releases.
- Some Now Assist products/features are currently unavailable for customers in the FedRAMP, NSC DOD IL5, or Australia IRAP-Protected data centers, self-hosted customers, or in other restricted environments. For more information, see the KB0743854 article in the Now Support Knowledge Base . Be sure to check for availability updates in future releases.
- Some Now Assist products/features are currently available only for customers in some regions. Be sure to check for availability updates in future releases.
- Some AI products and skills are not available in Regulated Markets. For more information, see KB2593939: Regulated Markets AI Products/Skills Not Available. Be sure to check for availability updates in future releases.

Exploring Data Privacy for Now Assist

Learn more how Data Privacy for Now Assist enhances your ability to protect sensitive data.

Data Privacy for Now Assist overview

Sensitive data such as age, phone number, and other personally identifiable information(PII) can be masked so that it does not get processed from generative AI prompts. Placeholder text and anonymized data are sent with the prompt instead, and these values are replaced with the original text after the large language learning module(LLM) response has been received. This two-way masking ensures that end users receive accurate responses, but sensitive data is not exposed to the LLM.

There are some considerations for configuring Data Privacy for Now Assist. See Configuring Data Privacy for Now Assist for configuration details.

Important:

Data Privacy for Now Assist detects and masks sensitive data based on Regex patterns and does not support contextual(model-type) data patterns

© 2026 ServiceNow, Inc. All rights reserved.

Configuring Data Privacy for Now Assist

Configure a data privacy advanced configuration to de-identify personally identifiable information (PII) in generative AI applications.

Before you begin

You must have the following applications installed on your instance:

- Data Privacy (Classic) [com.glide.data_privacy]
- Data Privacy [sn_dp_store_app]
- Data Discovery [sn_data_discovery]
- Data Discovery APIs[com.glide.data_discovery]

Installing the latest version of the Generative AI controller will auto install the Data Privacy Store App(sn_dp_store_app). The Data Privacy Store App will auto install the Data Discovery store app[sn_data_discovery], Data Privacy (Classic)(com.glide.data_privacy) plug-in, and the Data Discovery APIs[com.glide.data_discovery].

Role required: now_assist_data_privacy_admin

Important:
You do not need a full active license to configure Data Privacy for Now Assist.

Procedure

1. Navigate to **All** > **Data Privacy (Classic)** > **Privacy Policy Advanced Configuration**.
   If you previously used the Sensitive Data Handler to help de-identify data for generative AI, you may already see a privacy policy configured. Your previously configured regular expressions have been migrated as part of your upgrade. If you already have a data policy for Now Assist, skip to step 6.
2. Select **New**.
3. Enter a name for the privacy policy.
4. In the **Data Channel** field, select the data channel to be used.
5. Set **Active** to `true`, then select **Submit** to create the policy advanced configuration.
   Only one policy configuration for each data channel can be active at a time. To activate a new policy advanced configuration, you must set **Active** to `false` for all other policy configurations on that data channel.
6. After you're redirected to the list of policy advanced configurations, open the record you created.
   Open the existing record with the Now Assist data channel if one is already present.
7. To add a data pattern to de-identify, select **Select Data Patterns**.
8. **Optional:** To create your own data pattern, see Configure Data Discovery patterns.
9. Select your data patterns, then select **Save**.

Result

Data caught by the regular expressions selected in the data patterns is de-identified for generative AI applications. In this example policy, it is configured to catch a series of active data patterns and then use the data extraction data channel.

Data privacy

The data privacy store app is a Next Experience refresh for data classification and data privacy with modern look, feel, and usability. Data privacy store app is supported in Utah and above.

Data privacy is comprised of several components, Overview, Classification, and Anonymization.

Overview

Use the Overview section as a starting point to manage your data and data privacy compliance. See Data privacy overview for details.

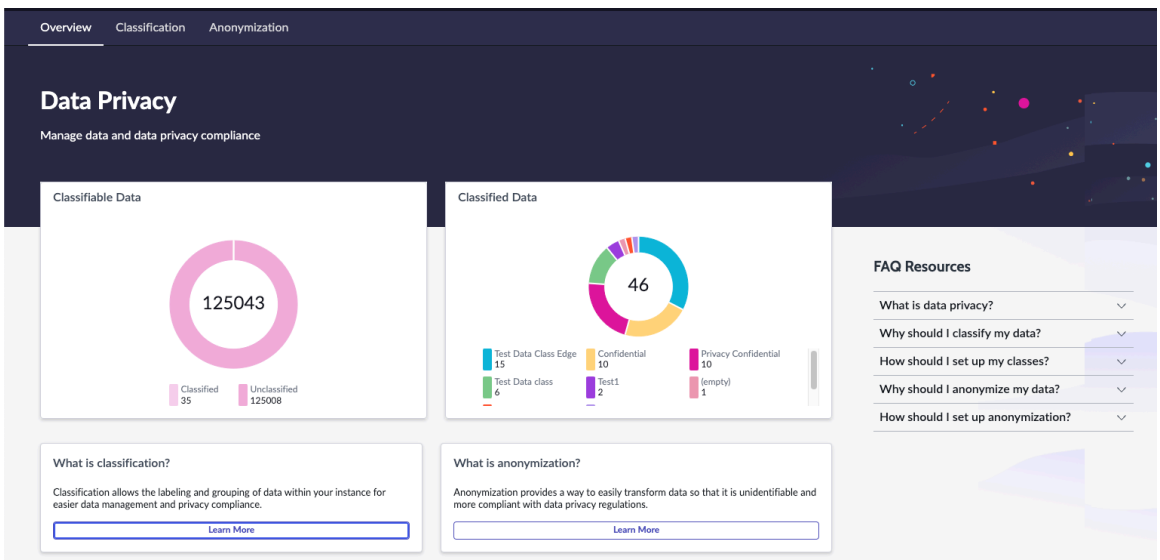
Classification

Data classification is the process of organizing data into categories that make it easy to retrieve, sort, and store for future use. Using a classification system helps to focus on confidentiality and security policy requirements. Classify data to be used for anonymization. For information on data classes and classification, see Data classification.

Data privacy overview

The Overview homepage is a starting point to manage your data and data privacy compliance.

The Overview dashboard reports the current state of data classifications and anonymization jobs within your instance. You can view your data with the Overview dashboard to see how much data can be classified, the data classes available, the amount of data in each class, and an overall status of the anonymization jobs. The classified data is broken into different categories. Selecting a sub-category in either chart will add or remove the category from the overall chart and adjust the counts.



Classifiable Data

Displays the total number of data records in the instance that can be classified. The number is broken down into the total number of classified data and the total of unclassified data. This gives administrators a quick view of potential classification opportunities.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Classified Data

Displays the total number of data records in the instance that have been classified. The number is broken down into the total number of classified data for each assigned data class. This provides a quick understanding how much data has been classified in each area.

Anonymization Jobs

Displays data privacy jobs that are currently in process of jobs that have completed on your non-production instance for user and data class jobs.

Learn More

The **Learn More** sections provide a quick view into understanding classification and anonymization, as well as an easy way to get started in the process.

FAQ Resources

Access in product learning resources about classification or anonymization for additional information on how to get started securing your instance with data privacy.

Data classification

Group data by type, using pre-defined or user-defined data classifications. If you have an assigned data classification administrator or auditor role, you can administer different data classes or visually analyze the current state of different types of data within the instance.

Data Classification enables support for:

- Visibility into the types of data hosted on a ServiceNow AI Platform instances.
- Compliance with privacy laws, and meeting regulation requirements for industries such as financial services and medical device manufacturing.

Data classifications

Data classification is a standalone process in which you manually apply data classifications to existing dictionary entries in any table. See Data dictionary tables for additional information.

- You classify data as you find appropriate for your business and you can alter the available data classes as necessary.
- When you classify data, you can use the pre-defined data classifications, or create your own. Although use of pre-defined data classifications is optional, it is advisable do so as a starting point. These pre-defined data classifications are included in demo data that you can install in your instance.
- If you create your own data classifications, you can also design a tiered hierarchical system with parent and child data classifications.

Note:
Data Classification supports domain separation, and the data_classification table itself is process separated. See Domain separation and Data Classification for additional information.

Use cases

General Data Protection Regulation (GDPR) is a European Union regulation whose purpose is to provide individuals with control over their own personal data. You can use data classifications, such as Personally Identifiable Information, to identify where personal data is being stored in

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

your instance. By applying the appropriate security mechanisms to protect that personal data from leaking out, your organization satisfies GDPR requirements.

If you store customer information in the ServiceNow AI Platform, use the Personally Identifiable Information (PII) classification code where needed to track data subject to regulation by local privacy laws.

You can apply a Restricted data classification to Employee table columns that store sensitive employee information such as Social Security Numbers (SSN). Administrators and auditors can then use the Overview dashboard to confirm that you have assigned data classifications to the correct columns. They can also view the classification details for restricted types of information.

Create data classifications

Create your own user-defined data classifications in the [data_classification] table that you can then assign to specific columns in specific tables. Create new data classes to start the classification process.

Before you begin

Role required: data_classification_admin, admin

Procedure

1. Navigate to **All** > **System Security** > **Data privacy** > **Classification**.
2. Select **+Add data class**.

   Note:
   There are several data classes included with the base system.

3. Fill in the fields on the form.

Field	Description
Class Name	Name of the data classification.
Parent Class	Name of the parent data classification that this data classification is subordinate to. Leave the field empty if this data classification isn't a child to a parent data classification.
Description	Description of the data classification.

4. Click **Submit**.
   The new data class is added. If the data class is a child, it will be listed under the parent in the left-hand navigation bar.

Classify data

Group data by type, using pre-defined or user-defined data classifications. Assign data classifications to specific table columns in the Dictionary [sys_dictionary] table. When you assign data classifications, it creates entries in the Dictionary-Data Class [m2m_dictionary_dataclass] table, which you can then review in the Overview dashboard.

Before you begin

Role required: data_classification_admin, admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Select **New** to assign data from a table to be classified.
2. Select the data class from the drop-down.
3. Select the records reflecting the tables and columns to be classified.
   Choose additional rows to display per page in the table to simplify locating a particular table.
4. Select **Classify data**.
   The data is classified under the Classification Name in the Classified Data table.
5. View or export the data to Excel, CSV, JSON, or PDF.
   Choose to download the data in the chosen format or receive it via email.

Data anonymization

Anonymization provides a way to easily transform data so that it is unidentifiable and more compliant with data privacy regulations.

Administrators can perform the anonymization process in both production and non-production instances. Data privacy can be used in production instances to de-identify users. Anonymization of data classes should only be used with non-production instances. This preservation ensures that data like email addresses or physical addresses are replaced with similarly formatted, but anonymized versions.

Administrators can also use anonymization as part of their General Data Protection Regulation (GDPR) Right to be forgotten (RTBF) processes to anonymize user information. See https://gdpr-info.eu/art-17-gdpr/ for more information.

Use the anonymization section of data privacy to create and view privacy policies and techniques,and to perform privacy bulk assignment. View all of the jobs, with the description, private policy used, and status. In order to access the anonymization section, an admin must first elevate to the data_privacy_admin and data_privacy_processor roles.

Anonymization techniques

Anonymization techniques are options you select to determine how your data is anonymized. You must create an anonymization technique to reference in the anonymization job. See Create anonymization techniques to associate a privacy technique to an associated **Anonymization technique configuration**.

Anonymization policies

Configure an anonymization policy to specify which data privacy techniques are used when anonymizing your data. See for Create anonymization policies details.

Anonymization jobs

Anonymization jobs use all of these components to anonymize your data. For more information on these jobs, see Create anonymization job.

Create anonymization techniques

Create a data privacy technique configuration to customize how data privacy anonymizes your data.

Before you begin

Role required: data_privacy_admin and admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Elevate to the **data_privacy_admin** role.
   For details on role elevation, see Elevate to a privileged role.
2. Navigate to **System Security** > **Data Privacy** > **Anonymization**.
3. Select **View techniques**.
   There are several pre-defined techniques available for selection.

Technique	Description
Selective Replace	This technique does a selective replace of String data. All characters between the input's start and end indices are replaced with the character you choose. You can specify characters to exclude from masking: ○ start_index: Technique masks data starting at the specified character. If left blank, masking begins with the first character. ○ end_index: Technique masks data from the start of the string to the specified character. If left blank, masking ends with the last character. ○ exclude_char: Define a character to exclude from masking. ○ replacement_char: Define a character used for masking. If none is provided, asterisks(*) are used by default.
Static Replace	This technique swaps values with static values. String, Number, and Date data can use this technique: ○ date_time_value: Replace Date values with this date. Use the yyyy-MM-dd HH:mm:ss format. ○ date_value: Replace Date values with this date. Use the yyyy-MM-dd format. ○ number_value: Replace Number values with this number. ○ string_value: Replace String values with this text. ○ number_type: Accepts an integer number
Random Replace	This technique swaps values with randomly generated values. String and Number data can use this technique.
Remove	This technique removes values, replacing them with empty (null) values.
No Action	This technique is a placeholder. It does not modify fields when selected.
Selective Replace with X	Transforms String data and selectively replaces sensitive characters with the letter X. **Note:** Default technique for data patterns in Exploring Data Discovery (Classic).
Data pattern anonymization	Only anonymizes discovered data patterns within unstructured data fields while keeping underlying context intact. **Note:** Settings for this technique reference data pattern anonymization technique settings in Exploring Data Discovery (Classic).

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Select **Add custom technique**, if not using a pre-defined technique.
5. Fill in the fields in the **Customize technique** form.

Field1	Description
Base technique	Select a pre-defined technique, as custom techniques are based on the pre-defined techniques.
Technique name	Enter a name for the technique.
Technique description	Enter a description for the technique.

6. Select **Next**.
7. Enter the technique parameters.
   The available parameterized values depend on which privacy technique you have selected. There are no parameterized values for the **No Action** and **Remove** techniques.

Privacy parameterized values for the Base techniques

Base Technique	Privacy Technique Parameter value	Description	Default value
Selective Replace	end_index	Technique masks data from the start of the string to the specified character. If left empty, masking ends with the last character.	(Empty)
Selective Replace	exclude_char	Character to skip masking. Only a single character can be used in this value. If more than one is entered, the first character is used.	(Empty)
Selective Replace	replacement_char	Character to use when replacing values using a selective replace.	An asterisk (*) is used if no other value is entered.
Selective Replace	start_index	Technique masks data starting at the specified character.	If left blank, masking starts at the first character.
Static Replace	date_time_value	Replace date and time values with this date. Use the yyyy-MM-dd HH:mm:ss format.	1988-11-11 10:10:10
Static Replace	date_value	Replace date values with this date. Use the yyyy-MM-dd format.	1988-11-11

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Base Technique	Privacy Technique Parameter value	Description	Default value
Static Replace	number_value	Replace Number values with this number.	1234567
Static Replace	string_value	Replace String values with this text.	TEXT123
Random Replace	preserve_data_length	Set to **true** to preserve data length. De-identified data will have the same length as the original data.	True

8. Select **Create Custom Technique**.
   Your custom technique is added to the Anonymization techniques.

What to do next
See Create anonymization policies to configure an anonymization policy to specify which techniques are used when anonymizing your data.

Create anonymization policies

Configure an anonymization policy to specify which techniques are used when anonymizing your data.

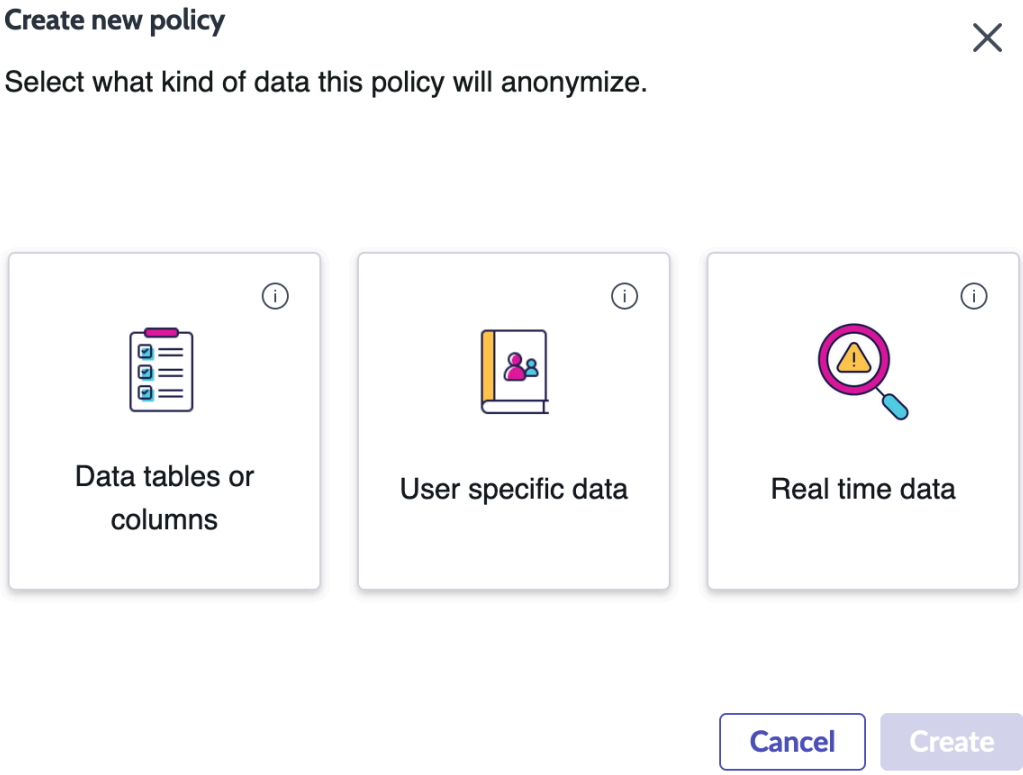
Before you begin
The data privacy configuration defines tables, sys_user and other, and columns to the de-identified, depending on the use case and specifies parameterized types of the techniques to be used while de-identifying data.

> **Note:**
> To complete a privacy configuration, you must first configure a data privacy technique configuration. See Create anonymization techniquesfor more information.

Role required: data_privacy_admin and admin

Procedure
1. Elevate to the **data_privacy_admin** role.
   For details on role elevation, see Elevate to a privileged role.
2. Navigate to **System Security** > **Data Privacy** > **Anonymization**.
   All anonymization policies display. Published policies are available to schedule the anonymization job.
3. Select **Create new policy**.
4. Select to either anonymize **Data tables or columns**, **User specific data**, or **Real time data**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Data Type	Description
Data tables or columns	Records that match the data policy will be anonymized.
User specific data	Select a set of users or user groups to be anonymized.
Real time data	Anonymize real time entries for a set of columns.

Data privacy policies can only apply to classified data, for more information on data classification, see Data classification.

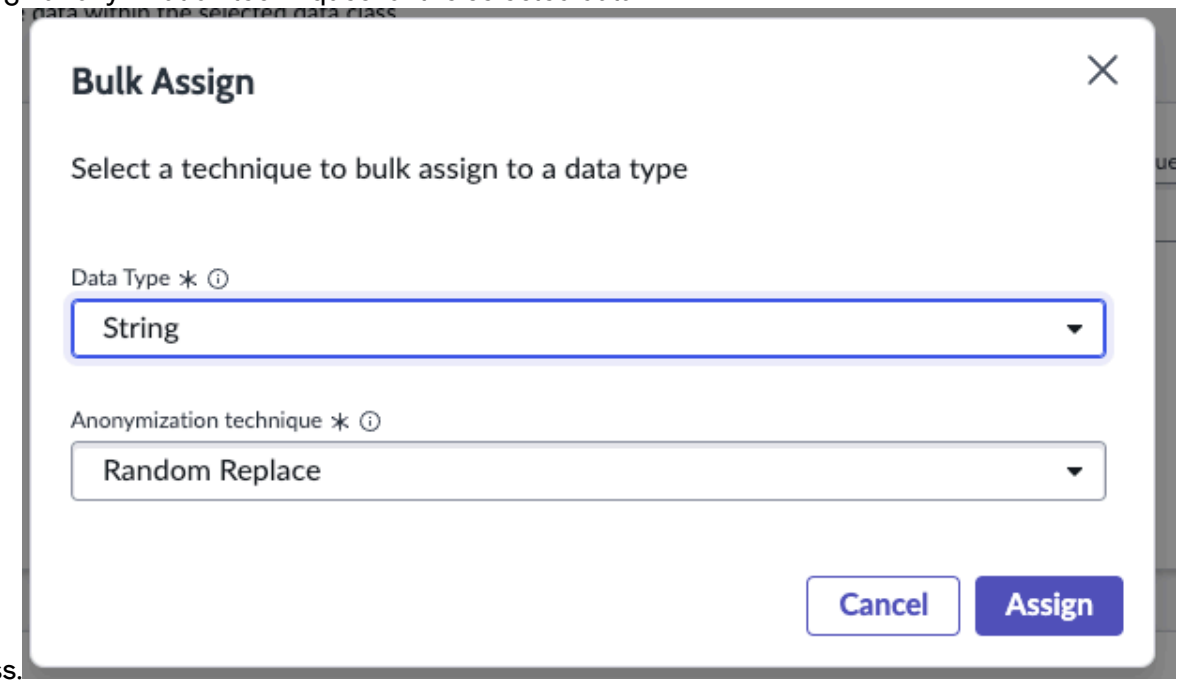
5. Select **Create**.
   There are sequential steps required to complete the policy, **Define details**and **Assign techniques**. **Select user reference** is also required when defining the policy for user specific data.
6. Define the details for the new anonymization policy.
   - Enter the policy name in the **Name** field, and the policy description in the **Description** field.
   - Define what channels automatically activate the policy and the channel priority in **Activation Channels**
   - In the **Data Class** field, select the data class to use with this policy.
   - Turn on or off real time data anonymization. See Step 8 if real time data anonymization is on

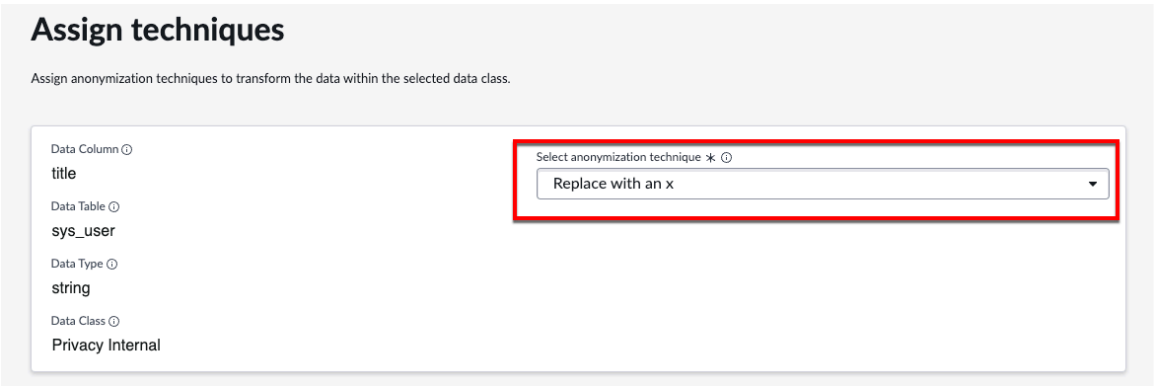
Note:
If you are not anonymizing an entry, select the **DoNothing** technique rather than leaving the entry empty. Policies with empty values in the Privacy Technique Configuration field cannot execute when used in data privacy jobs.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

After selecting a data class, the Assign techniques form displays for each record returned for the defined data class.

7. Assign anonymization techniques for the selected data class.





8. **Optional:** Enter child tables to be scanned.
Child tables of the parent will be anonymized, if a table has no children this option will not be available.

> **Warning:**
> A parent job will fail if a child job fails.

9. **Optional:** If Data Pattern Anonymization is selected, select the anonymization technique to be used.
10. **Optional:** Set the ordering for data patterns.
11. **Optional:**

> **Tip:**
> Use the **Test** feature to test sample inputs. You can review metrics from the result like scan time, result, and discovered patterns.

Select the **Test** button to test the policy.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

12. **Important:**
    All tables must have a correct sys_dictionary entry.

    Select **Save**.

13. Select **Publish** to update the anonymization policy for scheduling and be returned to Anonymization policies.

    Note:
    Only published policies can be used for anonymization job scheduling.

What to do next

Create anonymization job.

Configure data anonymization clone request

Data privacy clone integration is configured using a PostClone script to create and execute data privacy jobs for configured policies on the target. After running the script, users will see de-identified data and will not have access to the original data.

Before you begin

The data privacy PostClone script is installed with the activation of the data privacy plugin (sn_dp_store_app). See Activate data privacy for details.

Role required: data_privacy_clone_processor, data_privacy_admin, and admin

Procedure

1. Activate the data privacy plugin (sn_dp_store_app) on the source instance.
   The data privacy PostClone script is installed.
2. Elevate to the **data_privacy_admin** role.
   For details on role elevation, see Elevate to a privileged role.
3. Navigate to **System Security** > **Data Privacy** > **Anonymization**.
4. Select **Create new policy**.
   See Create anonymization policies for details.
5. Select **Data tables or columns**.
6. Select **Create**.
7. Enter a name and select a data class.
8. Select to **Activate the policy during cloning**.
9. Select the policy order to run if there are multiple clone policies.
   A data privacy job for Postclone configuration with a higher Application Order might start before another job of lower order, if the job with the higher order does not involve any table related to other lower order job.
10. Select **Continue**.
11. Complete the policy configuration and publish the policy.
12. Back up data privacy configurations.
13. Schedule the anonymization job.
    See Create anonymization jobfor details.
14. As the data privacy admin, submit a clone request.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Result

The data privacy PostClone script executes on the target Instance and The PostClone script creates a data privacy federated job record on the target instance. The federated job creates and executes a data privacy job for each post-clone policy, in Application Order, on the target instance.The backup source is cloned to the target Instance. Data privacy PostClone script creates and executes data privacy jobs for configured policies on the target instance.

The elevated data privacy clone processor can log on to the target instance and monitor the post-clone federated job state on the dp_federated_job.list and dp_job.list.

Create anonymization job

Configure a data privacy job on your production instance to use anonymized data on your non-production instance for user and data class jobs.

Before you begin

The data privacy job supports two de-identification use cases:

- Sensitive data of specific sys_users
- Sensitive data of particular data class.

Role required: data_privacy_processor and admin

Procedure

1. Elevate to the **data_privacy_processor** role.
   For details on role elevation, see Elevate to a privileged role.
2. Navigate to **System Security** > **Data Privacy** > **Anonymization**.
3. In an Anonymization policy, select **Schedule job** for the policy to be used in the job.
   A policy must be in a published state in order to schedule an anonymization job.

> **Warning:**
> Anonymization jobs are highly destructive and can only be reversed on rollback. Double check all information, such as records and table processed, before scheduling a job.

4. In the form, fill in the fields.

Data privacy job fields

Field	Description
Policy used	Read only name of the selected privacy policy configuration to use for this job. Edit the policy to view additional information about the policy. For detail on privacy policy configurations, see Create anonymization policies.
Job description	Description of the job.
Start time	The start of the time to run this job in **HH:MM:SS**.
End time	The end of the time window to run this job in **HH:MM:SS**. The end time must be after the start time.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	The job runs before the time entered in this field. If the job has not yet completed, the job will pause and resume at the next time window start.
Dry Run	Run the job as a test. No records are affected when running this job. Results are displayed in the **Jobs** list, as though the job had executed. **Note:** **Dry Run** must be turned off when configuring a data privacy job with rollback. See Data privacy job rollback for details.
Type of user selection	Select either users or groups to be anonymized.
Select users/groups	Select a the specific set of users or groups to be anonymized in this job. Supports up to a maximum of 1000 users. **Note:** This required field displays only when the selected privacy policy condition requires a selection of user records.

5. **Important:**
   All tables must have a correct sys_dictionary entry before scheduling and during its job.

   Select **Schedule job** on the form to place the anonymization in the job queue.

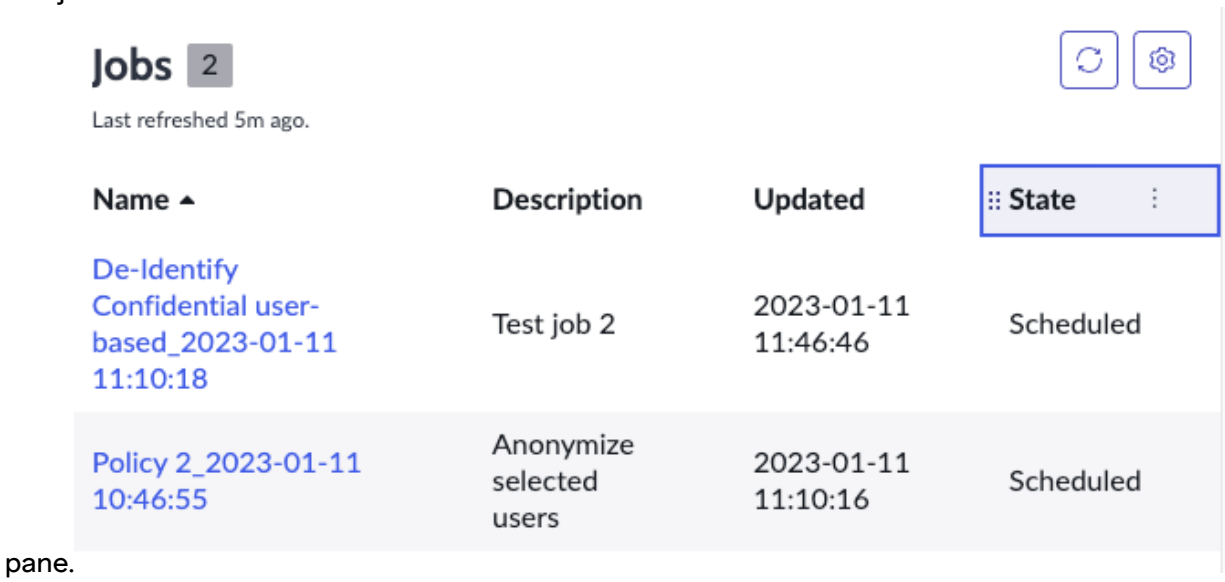
   The job runs between the times selected in the **Start time** and **End time** fields. If the job has not completed during the start and end time window, the job will continue at the next time window start.

   A job can only be executed once, even if **Dry Run** is selected. To run a job again based on the same policy, select **Schedule job** and complete the form using the same field values.

   Warning:
   Anonymization jobs on encrypted columns will you to decrypt and re-encrypt any encrypted columns targeted by the job. To prevent this, select **No Action** as the policy technique.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The job is listed in the **Jobs**



pane.

Field	Description
Name	Name of the anonymization job.
Description	Description of the anonymization job.
Updated	The date and time that the job was last updated.
State	State of the data privacy job: ○ **Scheduled**: Default state for new jobs. ○ **Completed**: The job has successfully anonymized the selected data. ○ **Cancelled**: The job was manually cancelled. ○ **Error**: There was a problem saving the job. Re-schedule the job or create a new job. There may be issues with the configuration if the error continues. ○ **Rollback in progress**: The job has been set to roll back anonymization. ○ **Rollback complete**: The anonymization job rollback has successfully completed. A read-only field.

6. Select a job from the **Jobs** pane to open the Job summary.
After a job is scheduled, the **Cancel Job** and **Pause** buttons appear in the Job summary.

Additional fields for scheduled jobs

Field	Description
Estimated record count	The estimated number of records this dry-run job affects before being executed. A read-only field
Total data records processed	The total number of individual data records affected by this job. A read-only field.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Total data tables processed	The total number of data tables processed by this job. A read-only field.
Time remaining to rollback	The remaining time that a completed data anonymization job can be rolled back and de-anonymize the data. A read-only field.
Total users processed	The total number of individual user records this job affects. A read-only field.
Cancel job	Select to cancel the anonymization job. This must be selected prior to the job start time. When selected, the job status updates to *Cancelled*.
Pause	Select to pause the job and rollback recording, if rollback was selected. A warning message will display after a three-day expiry period for rollback contexts. This must be selected after the job start time and before the job end time. When selected, the job status updates to *Paused*.
Resume	Restarts a paused job. Rollback is not supported for resumed jobs if paused. Cancel the job and create a data privacy job. The recording uses an unexpired rollback context. When selected, the job status updates to *Scheduled*.
Export	Downloads a .PDF file of the data privacy job details.

Activate parallel jobs for data anonymization

Use parallel jobs to reduce your anonymization job execution time.

Before you begin

Role required: admin

Procedure

By default data class and user based anonymization jobs run using a single thread. Multiple threads may be activated for data class and user based jobs. In addition, federated jobs used during cloning uses parallel jobs with 3 workers by default.

1. In the navigation filter enter `sys_properties.list`.
2. Create the property `com.glide.data_privacy.max_parallel_workers`
3. **Optional:** To adjust the number of federated job parallel workers, edit the `dp.max_concurrent_clone_item_workers` property.
4. Verify the **Type** is `integer`.
5. **Important:**
   It is recommended to start with a small number of workers per node(2 or 3).

   Enter the number of parallel job workers in the **Value** field up to 5.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Real time anonymization

Use the real time anonymization(RTA) policy to anonymize data entries in real time.

Real time anonymization Overview

Users create an RTA policy by selecting real time anonymization in the Anonymization Policies page, and then selecting the appropriate data channel. For example you can use Virtual Agent with real time anonymization: create an anonymization policy with the Virtual Agent selected as its **Data Channel**.

Columns from the target tables may be selected for RTA, whereupon active data patterns are used and their policies applied to any valid record entries to the columns targeted for RTA. If an entry matches an active data pattern its associated anonymization technique will be used for anonymization.

Tip:
If you need to change the anonymization technique see Configure Data Discovery patterns.

Real time anonymization failures

If an RTA policy fails, you can review its status with the Real time anonymization failures table.

Real time anonymization failures

Review real time anonymization(RTA) failures.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Security** > **Data Privacy(Classic)**.
2. Review the RTA failures in the table.

Field title	Description
Table Column	The table column the failure occurred in.
Failure Reason	Category of the failures cause.
Failure Reason Details	Short description summarizing the cause of the failure.
Privacy Configuration	The RTA privacy configuration that failed.
Record	The specific record that failed.
Table Name	Table the failure occurred in.
Timestamp	Time of the failure.

Activate data privacy

Data Privacy includes data classification and anonymization and is installed from the ServiceNow Store.

Before you begin

To use data anonymization, Data Privacy (Classic) must first be activated with the ServiceNow Vault entitlement. See Activate data privacy (Classic) for additional information.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
Installing the Data Privacy Store App will auto install the Data Discovery Store App, Data Privacy (Classic) plug-in, and the Data Classification plugin.

Role required: admin

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All** > **Data Privacy**.
2. Find the application using the filter criteria and search bar.

   You can search for the application by its name or ID. If you cannot find an application, you may have to request it from the ServiceNow Store.

   Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store. For cumulative release notes information for all released apps, see the ServiceNow Store version history release notes.
3. Select a version from the list and select **Install**.

   In the Install dialog that is displayed, any dependencies that are installed along with your application are listed.
4. If you are prompted, follow the links to the ServiceNow Store to get any additional entitlements for dependencies.
5. **Optional:** If demo data is available and you want to install it, select the **Load demo data** check box.

   (Optional) Demo data comprises sample records that describe application features for common use cases. Load demo data when you first install the application on a development or test instance.

   Important:
   If you don't load the demo data during installation, it's unavailable to load later.
6. Select **Install**.

Data Privacy for Virtual Agent

You can use Data Privacy to detect and mask the sensitive data and PII during a Virtual Agent conversation.

Before you begin

Role required: virtual_agent_data_privacy_admin

About this task

Use Data Privacy to detect and mask the sensitive data and PII during a Virtual Agent conversation. Data Privacy is replacing the depreciated Sensitive Data Handler, see Deprecation Process [KB0867184] for more information. The setup process may vary depending on if Sensitive Data Handler was previously installed and configured.

Note:
If you have previously configured Sensitive Data Handler your settings will be migrated to Data Privacy as a policy. See Create anonymization policies for more information.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Conversational Interfaces** > **Settings**.
2. Under **Sensitive data detection**, select **View all**.
   If the button reads **Get data privacy**, you will need to install the Data Privacy plugin to continue. See Activate data privacy (Classic) for more information
3. Set the slider to **Active**.
4. **Optional:** If Data Privacy is not yet installed you will be prompted to install the Data Privacy plugin to continue, see Activate data privacy (Classic) for more information.
5. Select the appropriate conversation flow:
   a. Requester to agent - detect and mask sensitive data entered by the requester in an Agent Chat conversation.
   b. Agent to requester - detect and mask sensitive data entered by the agent in an Agent Chat conversation.
   c. Requester to Virtual Agent - detect and mask sensitive data entered by the requester during a Virtual Agent conversation.

   Note:
   You must select at least one conversation flow.

6. Select **Manage in Data Privacy**.
   If you have configured Sensitive Data Handler before, your settings will be migrated as a policy to Data Privacy
7. Create a new Data Privacy policy for Virtual Agent, see Create anonymization policies for more information on Data Privacy policies.

Domain separation and data privacy

Domain separation is unsupported for data privacy. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: No support

- The domain field may exist on data tables but there is no business logic to manage the data.
- This level is not considered domain-separated.

For more information on support levels, see Application support for domain separation.

Related topics

Domain separation for service providers

Supported field types for anonymization

Check which field types are supported when anonymizing data.

Note:
Not all field types that have been classified are available for anonymization.

Some high risk field types are turned off by default, as detailed in the table. For more information about fields, see Field Types.

Data privacy (Classic)

Data Privacy (Classic)is a legacy application that provides data classification, techniques, and jobs to anonymize PII.

Data Privacy Classic

Note:
This section is for Data Privacy(Classic). See Data privacy for the latest up to date store version.

Activate data privacy (Classic)

You can activate the data privacy plugin (com.glide.data_privacy) for Platform Security if you have the admin role. The application includes demo data and installs related ServiceNow® Store applications and plugins if they aren't already installed.

Before you begin

Important:
This section is for Data Privacy(Classic). See Data privacy for the latest up to date store version.

Data privacy requires a separate subscription from the rest of the ServiceNow AI Platform®.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

To purchase a subscription, contact your ServiceNow account manager. When you purchase a subscription, certain plugins are activated automatically. If a paid plugin isn't activated automatically, you can manually activate it from the All Applications list in your instance.

Note:
Before purchasing a subscription, you can evaluate Data Privacy(Classic) and Data Discovery with a 30 day trial period. After your trial expires you will no longer be able to discover data or run anonymization jobs in without a license.

Role required: admin

About this task

The following items are installed with data privacy:

- Plugins
- Roles
- Tables

For more information, see Installed with data privacy (Classic).

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the Data Privacy plugin (com.glide.data_privacy) using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

   Note:
   When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

   You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Installed with data privacy (Classic)

Learn about the components installed with the data privacy plugin (com.glide.data_privacy).

Tables installed

Table	Description
Data Privacy Federated Job [dp_federated_job]	Federated jobs for data privacy
Data Privacy Job [dp_job]	Data privacy jobs

Table	Description
Data Privacy Job [dp_job_summary]	Data privacy job summaries
Data Privacy Technique [dp_technique]	Data privacy techniques
Primary Reference Link [dp_primary_reference]	Primary reference links
Privacy Classified Field Technique [dp_field_technique]	Data privacy classified field techniques
Privacy Configuration [dp_configuration]	Data privacy configurations
Privacy Technique Configuration [dp_technique_with_params]	Data privacy techniques
Privacy Technique Parameter [dp_technique_with_parameter]	Data privacy techniques with parameters
Privacy Technique Parameter Value [dp_technique_with_parameter_value]	Parameter values used in Data privacy techniques with parameters.

Data privacy (Classic) configuration

Learn how to create data privacy techniques and policies, and how to create and execute data privacy jobs.

Important:
This section is for Data Privacy(Classic). See Data privacy for the latest up to date store version.

Data privacy techniques

Data privacy techniques are options you select to determine how your data is anonymized. You must create a data privacy technique to reference in the data privacy job. See Create a data privacy technique configuration to associate a privacy technique to an associated **Privacy technique configuration**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Data privacy policies

Configure a data privacy policy to specify which data privacy techniques are used when anonymizing your data. See Create a data privacy policy for details.

Data privacy jobs

Data privacy jobs use all of these components to anonymize your data. For more information on these jobs, see Configure a data privacy job.

Create a data privacy technique configuration

Create a data privacy technique configuration to customize how data privacy anonymizes your data.

Before you begin

Role required: data_privacy_admin and admin

Procedure

1. Elevate to the **data_privacy_admin** role.
   For details on role elevation, see Elevate to a privileged role.
2. Navigate to **System Security** > **Data Privacy** > **Privacy Technique Configuration**.
3. Click **New**.
4. In the **Name** field, enter a name for your privacy technique configuration.
5. In the **Privacy Technique** field, select a privacy technique.

Data privacy techniques

Technique	Description
No Action	This technique is a placeholder. It does not modify fields when selected.
Random Replace	This technique swaps values with randomly generated values. String and Number data can use this technique.
Selective Replace	This technique does a selective replace of String data. All characters between the input's start and end indices are replaced with the character you choose. You can specify characters to exclude from masking: ○ start_index: Technique masks data starting at the specified character. If left blank, masking begins with the first character. ○ end_index: Technique masks data from the start of the string to the specified character. If left blank, masking ends with the last character. ○ exclude_char: Define a character to exclude from masking. ○ replacement_char: Define a character used for masking. If none is provided, asterisks(*) are used by default.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Technique	Description
Static Replace	This technique swaps values with static values. String, Number, and Date data can use this technique: ○ date_time_value: Replace Date values with this date. Use the yyyy-MM-dd HH:mm:ss format. ○ date_value: Replace Date values with this date. Use the yyyy-MM-dd format. ○ number_value: Replace Number values with this number. ○ string_value: Replace String values with this text.
Remove	This technique removes values, replacing them with empty (null) values.

Note:
Previously supported value **Replace** is deprecated and renamed **Replace-Deprecated** and should not be used.

6. Right-click the header and click **Save** in the context menu.
   After the record is saved, the **Privacy Parameterized Values** list appears.
7. Use the records in the **Privacy Parameterized Values** list to customize your data privacy technique configuration.
   The available parameterized values depend on which privacy technique you have selected. There are no parameterized values for the **No Action** and **Remove** techniques.

Privacy parameterized values for Selective Replace

Privacy Technique Parameter value	Description	Default value
char_to_replace	Character to use when replacing values using a selective replace.	*
end_index	Technique masks data from the start of the string to the specified character. If left empty, masking ends with the last character.	(Empty)
exclude_char	Character to skip masking. Only a single character can be used in this value. If more than one is entered, the first character is used.	(Empty)
start_index	Technique masks data starting at the specified character.	1

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Privacy parameterized values for Replace

Privacy Technique Parameter value	Description	Default value
date_time_value	Replace date and time values with this date. Use the yyyy-MM-dd HH:mm:ss format.	1988-11-11 10:10:10
date_value	Replace date values with this date. Use the yyyy-MM-dd format.	1988-11-11
number_value	Replace Number values with this number.	1234567
preserve_data_length	Set to **true** to preserve data length. De-identified data will have the same length as the original data.	true
string_value	Replace String values with this text.	TEXT123
use_random_generated_value	Set to **true** to replace data with randomly generated values. Only String and Number data can be replaced with random values. This option overrides static values.	false

8. Click **Save**.

Create a data privacy policy

Configure a data privacy policy to specify which data privacy techniques are used when anonymizing your data.

Before you begin

The data privacy configuration defines tables, sys_user and other, and columns to the de-identified, depending on the use case and specifies parameterized types of the techniques to be used while de-identifying data.

Note:
To complete a privacy configuration, you must first configure a data privacy technique configuration. See Create a data privacy technique configuration for more information.

Role required: data_privacy_admin and admin

Procedure

1. Elevate to the **data_privacy_admin** role.
   For details on role elevation, see Elevate to a privileged role.
2. Navigate to **System Security** > **Data Privacy (Classic)** > **Privacy Policy Configuration**.
3. Select **New**.
4. In the **Name** field, enter a name for your privacy policy configuration.
5. In the **Data Class** field, select the data class to use with this policy.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Data privacy policies can only apply to classified data, for more information on data classification, see Data classification.
After selecting a data class, the **Privacy Classified Field Techniques** and **Privacy Primary Reference Links** lists display on the form.

6. **Optional:** Select **Apply to All Data in Class** to apply anonymization to all data in the chosen data class.
   If you don't select this field, your data privacy processor users can choose which users to anonymize when creating data privacy jobs. If you select this field, that option is not available.
   - **Apply when Cloning**: This option becomes available. When selected, the privacy configuration executes during data privacy clone.
   - **Application Order**: A data privacy job for Postclone configuration with a higher Application Order might start before another job with lower order.

   Important:
   Avoid creating multiple data privacy policies with the same Application Order, as the resultant processing order for those with the same order will be inconsistent.

7. **Optional:** Select **Supports Rollback** to enable the ability to de-anonymize the data from a data privacy job.
   See Roll back a data privacy job for more information.
   After selecting **Supports Rollback** when creating a data privacy job, the option to roll back the job becomes available.
8. Select the **Privacy Classified Field Techniques** tab to display the **Privacy Classified Field Techniques** list.
9. Select an entry in the **Table** field to open the **Privacy Technique Configuration** field for each list entry.
   The **Privacy Classified Field Techniques** list displays all the data to be anonymized in your selected data class. For each of these entries, you must select a privacy technique to apply.
10. Select a **Privacy Technique Configuration** to apply.

    Important:
    If you aren't anonymizing an entry, select the **DoNothing** technique rather than leaving the entry empty. Policies with empty values in the **Privacy Technique Configuration** field can't execute when used in data privacy jobs.

11. Select **Submit** or **Save** to save the record.

What to do next
Configure a data privacy job.

Configure a data privacy job

Configure a data privacy job on your production instance to use anonymized data on your non-production instance for user and data class jobs.

Before you begin
The data privacy job supports two de-identification use cases:

- Sensitive data of specific sys_users
- Sensitive data of particular data class.

Role required: data_privacy_processor and admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Elevate to the **data_privacy_processor** role.
   For details on role elevation, see Elevate to a privileged role.
2. Navigate to **System Security** > **Data Privacy** > **Data Privacy Job**.
3. In the Data Privacy Jobs list, click **New**.
4. In the form, fill in the fields.

Data privacy job fields

Field	Description
Name	Name of the job.
Description	Description of the job.
Privacy Configuration	The privacy policy configuration to use for this job. For detail on Privacy policy configurations, see Create a data privacy policy.
Frequency	○ **Run Once**: The job will run once in the specified time window. ○ **Weekly**: The job will run each day of the **Day of the week** field in the specified time window. ○ **Monthly**: The job will run each day of month as entered in the **Day of the month** field in the specified time window.
Users	Select the users or group of users to be anonymized in this job. Up to 1000 users of a group can be processed. **Note:** This field displays only when the selected privacy policy condition requires a selection of user records.
Dry Run	Run the job as a test. No records are affected when running this job. Results are displayed in the **Summary** field as though the job had executed. **Note:** **Dry Run** must be turned off when configuring a data privacy job with rollback. See Roll back a data privacy job for details.
State	State of the data privacy job: ○ **Completed**: Job completed successfully. ○ **Ready to Schedule**: Default state for new jobs.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	○ **Rollback in progress**: The job has been set to roll back anonymization. ○ **Rollback complete**: The anonymization job rollback has successfully completed. ○ **Completed with Errors**: The job completed but has errors. See Data Privacy Job Logs for more information. ○ **Error**: Job did not complete and had an error. See Data Privacy Job Logs for more information A read-only field.
Estimated record count	The estimated number of records this job affects. A read-only field.
Summary	A read-only field that displays the results of the job when you execute it.
Time window start	The start of the time window to run this job. The job will run after the time entered in this field. A valid time value is in Coordinated Universal Time based on a 24 hour time notation.
Time window end	The end of the time window to run this job. The job runs before the time entered in this field. If the job has not yet completed, the job will pause and resume at the next time window start. The end time must be after the start time. A valid time value is in Coordinated Universal Time based on a 24 hour time notation.

5. Right-click the form header and select **Save** from the context menu.
   After saving the record, the **Schedule Job** and **Delete Job** buttons appear.
6. Click **Schedule Job** to run your job.
   The job runs between the times selected in the **Time window start** and **Time window end** fields. If the job has not completed during the start and end time window, the job will continue at the next time window start.

   Note:
   A job can only be executed once, even if **Dry Run** is selected. To run the same job again, create a data privacy job using the same field values.

7. **Optional:** Choose one of the following functions:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **Cancel Job**: Cancels the data privacy job.
- **Pause**: Pauses job and rollback recording, if rollback has been selected. A warning message will display after a three-day expiry period for rollback contexts. See Roll back a data privacy job for details.
- **Resume**: Restarts a paused job. Rollback is not supported for resumed jobs if paused. Cancel the job and create a data privacy job. The recording uses an unexpired rollback context.

Data privacy job rollback

Database changes are captured for actions like jobs and scripts so that the changes can be rolled back. Roll back a data privacy job for when human error inadvertently anonymizes incorrect user information. The rollback de-anonymizes the data from the data privacy job.

Overview

- Rollback is limited to a few days, per the configured expiry duration of the RollbackContext of the new RollbackType *REDACT*. After expiration of the RollbackContext associated with a data privacy job, the rollback function is no longer available for that job.
  - A rollback context from de-anonymization is saved for three days by default.
  - The default expiry time can be set to a value greater than one by the data privacy administrator in the **RollbackContext** of the new **RollbackType** *REDACT*. Set the value in the Glide system property *glide.rollback.expiration_days_redact*. See Roll back and delete recovery.

    To learn more about adding or creating a system property, see Add a system property.

    for additional information.
- Rollback is available for data privacy jobs that are in a Completed, Canceled, or Error state.
- For every successful sys_user de-anonymization job which is configured with a data privacy policy with rollback support turned on, a rollback context is created. There can be at most one rollback context per data privacy job.

Roll back a data privacy job

Roll back a data privacy job on your non-production instance that uses anonymized data from your production instance to a state prior to de-identification of a data class or user job.

Before you begin

Role required: data_privacy_admin or data_privacy_processor, and admin

Procedure

1. Elevate to the **data_privacy_processor** or **data_privacy_admin** role.
   For details on role elevation, see Elevate to a privileged role.
2. Navigate to **All** > **System Security** > **Data Privacy** > **Data Privacy Job**.

   Note:
   In advance, a data privacy policy configuration that supports rollback must be created. Create a data privacy policy.

3. Create a data privacy job and select a Privacy Configuration that supports Rollback.
   See Configure a data privacy job.
4. Schedule the job for data anonymization.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- After the job has run, the data will be anonymized for the selected configuration.
- A message displays in the job informing of the expiration time.
  Within the expiry period you have the ability to roll back the job.

5. Elevate to the **data_privacy_processor** role.
6. Open the data privacy job to be rolled back.
7. Select **Rollback** to de-anonymize the data.

Data privacy clone

As customer data are cloned from a source to a target instance, typically from production to non-production, sensitive data are de-identified on the target instance.

Important:
This section is for Data Privacy(Classic). See Data privacy for the latest up to date store version.

A data privacy administrator configures post-clone policies. After the post-clone script completes on the target instance, the users will see de-identified data and will not have access to the original data. Data privacy administrators can configure de-identification policies to apply on the target instance when cloning to ensure that the target instance will not have original sensitive data. An order is specified for the policy relative to other policies to be executed.

Note:
Data privacy cloning is not available on self-hosted instances.

Data privacy clone has the following additional attributes:

- The data privacy plugin creates the post clone script to be executed on the target instance.
- Data privacy jobs created for PostClone configuration can run in parallel if they don't involve the same tables.
- A data privacy job for Postclone configuration with a higher Application Order might start before another job of lower order, if the job with the higher order does not involve any table related to other lower order job.
- With the data privacy plugin, data privacy tables are by default in the Clone Data Preservers table set.
- An attempt to add a data privacy table (dp_[table]) to Clone Exclude Tables will get a warning, that table should not be excluded.

Configure data privacy clone request

Data privacy clone integration is configured using a PostClone script to create and execute data privacy jobs for configured policies on the target. After running the script, users will see de-identified data and will not have access to the original data.

Before you begin

Role required: data_privacy_clone_processor, data_privacy_admin, and admin

Procedure

1. Activate the data privacy plugin (sn_dp_store_app) on the source instance.
   The plugin can only be installed by Customer Service and Support.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The data privacy PostClone script is installed.

2. Elevate to the **data_privacy_admin** role.
   For details on role elevation, see Elevate to a privileged role.
3. Navigate to **System Security** > **Data Privacy** > **Privacy Policy Configuration**.
4. Create a Privacy Policy configuration.
   Select **Apply to All in Data Class** and **Apply when Cloning**. See Create a data privacy policy for more information.
5. Back up data privacy configurations.
6. As the data privacy admin, submit a clone request.

Result

The data privacy PostClone script executes on the target Instance and The PostClone script creates a data privacy federated job record on the target instance. The federated job creates and executes a data privacy job for each post-clone policy, in Application Order, on the target instance.The backup source is cloned to the target Instance. Data privacy PostClone script creates and executes data privacy jobs for configured policies on the target instance.

The elevated data privacy clone processor can log on to the target instance and monitor the post-clone federated job state on the dp_federated_job.list and dp_job.list.

Data Privacy Job Logs

Review errors from Data Privacy jobs.

Before you begin

Important:
This section is for Data Privacy(Classic). See Data privacy for the latest up to date store version.

Role required: data_privacy_admin, data_privacy_clone_processor, data_privacy_processor, data_privacy_auditor

About this task

Use the **Data Privacy Job Logs** to review failed discovery, classification, and anonymization jobs.

Procedure

1. Navigate to **System Security** > **Data Privacy(Classic)** > **Data Privacy Job Logs**.
2. Review the table

Data Privacy Job Logs table

Label	Description
Created	Who or what created the log entry
Level	The severity of the error
Message	Description of the cause of the error
Source	Plugin source of the error
Type	The type of error that occurred
Code	Error code that occurred
Job Table Name	The table the job is located in

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Label	Description
Job Id	The job ID
Target Table Name	Table the job executed on
Target Table Column	Column the job executed on
Target Table Record	Record the job executed on

Data Discovery

Use Data Discovery to identify sensitive data within an instance, such as credit card information, emails, or social security numbers.

Explore Data Discovery

Learn about Data Discovery.

Configure Data Discovery

Get help configuring Data Discovery.

Roles in Data Discovery

Learn about roles in Data Discovery.

Data Discovery Findings

Review Data Discovery Findings.

Exploring Data Discovery (Classic)

Use Data Discovery to identify sensitive data within an instance, such as credit card information, emails, or social security numbers.

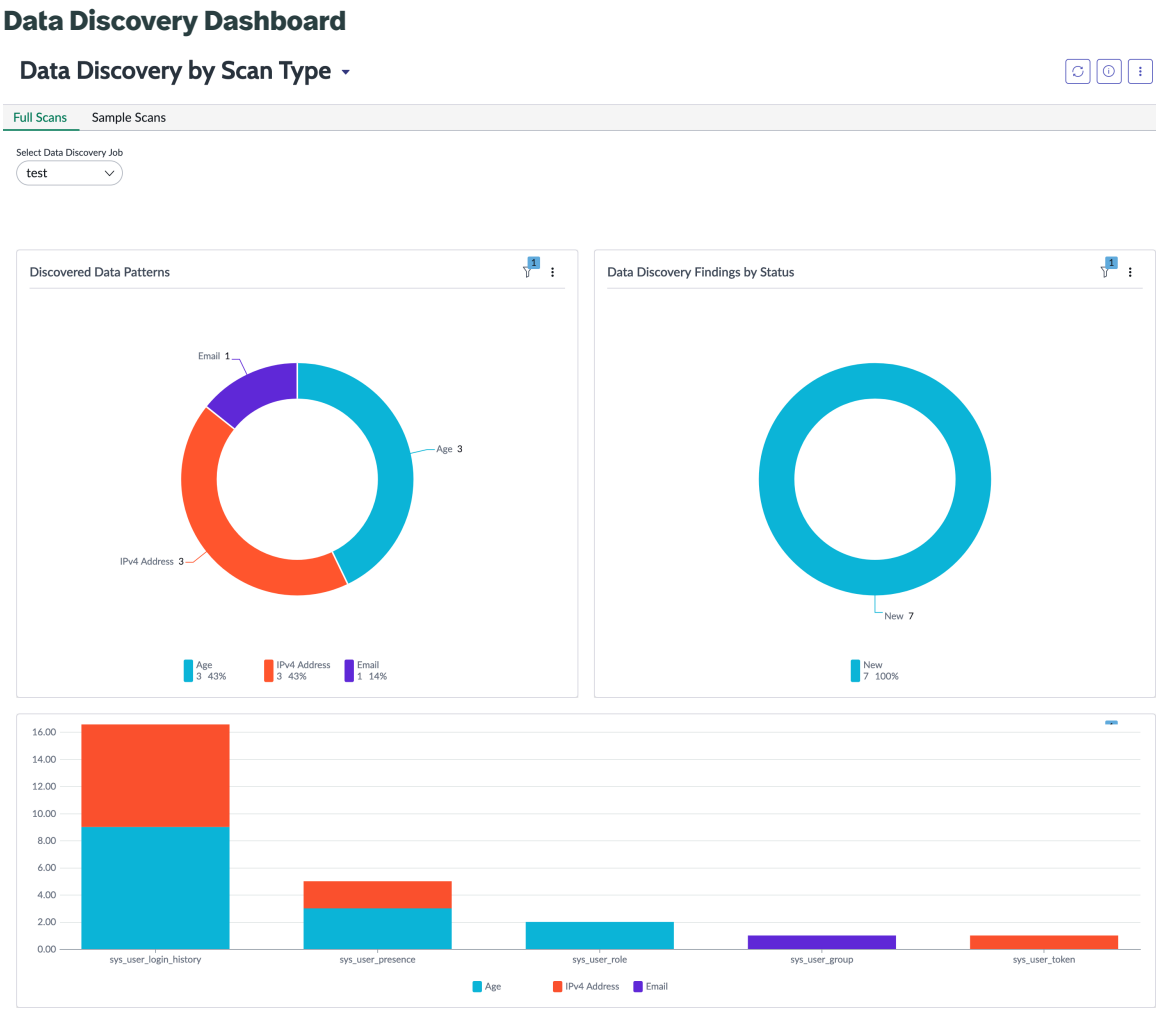
Data Discovery runs a user-defined set of jobs on a set of tables. The jobs search for and report sensitive information for review on the Data Discovery dashboard. A scheduled job automatically uses all active data patterns and target tables when it runs.

Data Discovery also includes pre-allocated roles with varying levels of access to data.

Access the Data Discovery dashboard

Navigate to **All** > **System Security** > **Data Discovery (Classic)** > **Dashboard** to view the Data Discovery Dashboard and to review your current job findings.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Discovered Data Patterns

Tip:
Select a record to view more information and take further action with the findings. See Data Discovery job results for more.

The Discovered Data Patterns chart displays the number and percentage of currently discovered data patterns. Select a section to take further action.

Data Discovery Findings by Status

The Data Discovery Findings chart reviews the number and percentage of currently discovered data patterns by their status.

Discovered Tables

The Discovered tables highlight which tables currently discovered data is in, and their data pattern.

Columns with Discovered Data

The Columns with Discovered Data section reviews currently discovered data by their column.

Activating Data Discovery

The application installs Data Discovery and related ServiceNow® Store applications and plugins if they aren't already installed.

Before you begin

Data discovery requires a separate subscription from the rest of the ServiceNow AI Platform.

To purchase a subscription, contact your ServiceNow account manager. When you purchase a subscription, certain plugins are activated automatically. If a paid plugin isn't activated automatically, you can manually activate it from the All Applications list in your instance.

Note:

Before purchasing a subscription, you can evaluate this feature on a non-production instance without charge by requesting it from the Now Support Service Catalog.

Installing the Data Discovery Store App will auto install the Data Discovery APIs plugin

Role required: admin

About this task

The following items are installed with data discovery:

- Roles
- Tables

For more information on the roles and tables installed, see Data Discovery roles and Default data patterns.

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the Data Discovery plugin (sn_data_discovery) using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

   Note:
   When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

   You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Classify data in Data Discovery Findings page

Classify sensitive data found by all successful jobs through Data Discovery Findings.

Before you begin

Roles required: data_discovery_admin

A job must complete a successful run before any result data can appear to be classified.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

About this task

The Data Discovery Findings page shows all data entries that have been found by a job. The Findings page enables you to review the entries and associate them with a classification.

Procedure

1. Navigate to **System Security** > **Data Discovery(Classic)** > **Data Discovery Findings**.
2. Select the entry that you want to classify.
3. In the Data Discovery Findings list, select **Classify**.
4. Select the data classes that you want to associate with the table entries.
5. Select **Classify**.

Data Discovery jobs

Data Discovery reviews your targeted information using user-defined data patterns and target tables.

Data Discovery works by first scheduling a job in the **Data Discovery Job** section. When a scheduled job runs, all active data patterns are searched for on the current target tables. For more information on creating and configuring a Data Discovery job, see Configure a Data Discovery job.

Note:
Sample Scan jobs scan up to 10,000 records are scanned per table per pattern.

Warning:
If a job is executed twice in a small amount of time, the number of scanned rows may return 0 for second run.

Data Discovery data patterns

The **Data Patterns** section shows all current data patterns, both active and inactive. A data pattern is a regular expression used to match sensitive data. For more information on how to access and configure data patterns, see Configure Data Discovery patterns. The **Active Data Patterns** section shows only active patterns. Inactive patterns don't appear.

Target tables

The **Target Tables** section lists all tables that can be processed for a job. To access the target tables, select **Target Tables**.

The following tables aren't supported:

- sr
- sysx
- v
- sh$
- syslog
- ua
- usageanalytics
- ecc
- clone

Granular Configuration

The Granular Configuration tool enables more specific and fine tuned controls for discovering sensitive data in a table. However there are key differences in its operation compared to a traditional data discovery job. A granular configuration scans only specified columns of a table for discovery, reporting its findings by the record. Findings from the scan of Granular Configurations, called Granular Findings have their actions specified per record, and require the data_privacy_admin role to be anonymized.

Configure a Data Discovery job

Configure a Data Discovery job and review the status of ongoing jobs. A Data Discovery job defines when a pattern is executed on a target table.

Before you begin

Role required: data_discovery_admin

Procedure

1. Navigate to **System Security** > **Data Discovery(Classic)** > **Data Discovery Job**.
2. In the Data Discovery Jobs list, select **New**.
3. On the Data Discovery job fields form, fill in the fields.

Data Discovery job fields

Field	Description
Name	Name of the job.
Description	Description of the job.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Scan Type	Number of entries to be scanned. Possible states are as follows: ○ **Sample**: Scans 10,000 entries. ○ **Incremental**:Scans for sensitive data patterns in new or modified records. This scan type is recurring. ○ **Full**: Scans all entries.
Policy	The Data Discovery policy to be used in this job. See Data Discovery policies for more information.
Scan Attachments	Scans attachments for any sensitive data patterns. Images embedded under .pdf or .doc files will not be scanned for sensitive data. **⚠ Warning:** This feature requires sending your data to a controlled ServiceNow environment. Before enabling, please confirm you have agreed to the additional terms and conditions required to use this feature.
Context	Job details about patterns scanned, target tables entries hit, and time elapsed.
State	State of the Data Discovery job. The possible states are as follows: ○ **Ready to Schedule**: Default state for new jobs. ○ **Scheduled**: The job is scheduled to run. ○ **In Progress**: Job is actively running. ○ **Completed**: Job has finished running successfully. ○ **Error**: The job has stopped running due to an error. ○ **Canceled**: The job has been canceled. ○ **Paused**: The job is paused.
Summary	Displays the results of the job after you execute it.
Start Date	Sets the start date for the job.
Time window start	The start of the time window to run this job. The job will run after the time entered in this field. The time entered in the **Time window start** field must happen before the time entered in the **Time window end** field.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Note: A valid time value is in Coordinated Universal Time based on a 24-hour time notation.
Time window end	The end of the time window to run this job. The job runs until the time entered in this field. If the job hasn't complete this time, the job pauses and resumes at the next time window start. The time entered in the **Time window end** field must happen after the time entered in the **Time window start** field. **Note:** A valid time value is in Coordinated Universal Time based on a 24-hour time notation.

4. Select **Submit**.
   The **Schedule Job** and **Update** buttons appear.
5. Select **Schedule Job** to run your job.
   The job runs between the times selected in the **Time window start** and **Time window end** fields. If the job hasn't completed during the start and end time window, the job will continue at the next time window start.
6. **Optional:** Choose one of the following functions:
   - **Cancel Job**: Cancels the job.
   - **Pause**: Pauses the job.
   - **Resume**: Restarts a paused job.

Attachment scanning in Data Discovery jobs

Attachment scanning in Data Discovery enables you to scan, discover, and report on sensitive data in file attachments.

Sensitive data such as social security Numbers (SSN), credit card numbers, and other personally identifiable information (PII) are often contained in file attachments. Data Discovery jobs attachment scanning, enables you to discover and report sensitive data in certain attachments.The attachment scanning feature is only available for scheduled scans.

Warning:
This feature requires sending your data to a controlled ServiceNow environment. Contact your account and support teams for enabling the attachment scanning feature

Limitations

- Embedded images and attachments in PDF and DOC files will not be scanned for sensitive data.
- Files must be less than 10MB.
- Support is available for the following file types:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- PDF
- DOC(X)
- TXT
- XLS
- CSV

Configure Data Discovery patterns

Configure a Data Discovery pattern and review current patterns. A Data Discovery pattern defines the regular expression used to match data against a target table.

Before you begin

Role required: data_discovery_admin

Procedure

1. Navigate to **System Security** > **Data Discovery** > **All Data Patterns**.
2. In the Data Discovery Pattern list, select **New**.
3. In the Data Discovery job fields form, fill in the fields.

Data Discovery job fields

Field	Description
Internal Scope	Scope of the pattern.
Description	Description of the job.
Name	Name of the data pattern.
Application	Application scope of pattern.
Expression	Regular expression used to discover the data pattern. **Note:** Expression length must be less than 1000 characters.
Keyword(Optional)	A specific word(or words separated by comma) to be searched for around a expression. Must be used with **Keyword Proximity** **Note:** A keyword can be used to search for additional context for a pattern. For example, using keyword can help differentiate between a date of birth or a date of hire given they have the same MM/DD/YY formatting.
Keyword Proximity(Optional)	How far from the expression to search for keywords. Must be used with **Keyword**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Note: Default is 30, upper bound of 64
Privacy technique configuration	Privacy technique used for the pattern
Synthetic Value	List of values substituted for the patterns
Type	Type of pattern ○ **Local**: The pattern is regex-based ○ **Model**: Uses AI/ML service

4. Select **Submit**.
   - The **Test** button enables you to test your regular expression before submitting the data pattern list.

The data pattern must be set as active to be used with scheduled jobs.

5. Navigate to **System Security** > **Data Discovery** > **Active Data Patterns**.
6. In the Data Discovery Active Pattern list, select **Edit**.
7. Select the pattern list from **Available Lists** and move it to **Selected Lists**.

Default data patterns

Review the default data pattern regular expressions included in Data Discovery. These default data patterns can be used to filter table entries for further classification.

The following are available default patterns for data discovery.

Name	Description	Regular Expression	Keywords	Examples
Age	A person's age between 0-99	\b([0-9]|[1-9][0-9]|1[012][0-9])\b	age	**Matching** 24 **Non matching** • 103 • -2
Date of birth	Date of birth using the DD/MM/YYYY format	\b[0-3]?[0-9]/[0-3]?[0-9]/(?:[0-9]{2})?[0-9]{2}\b	dob, birthday, date of birth	**Matching** • 06/18/2012 • 1/1/19
Email	Standard email address	\b[\w!#$%&'*+/=?`{\|}~^-]+(?:\.[\w!#$%&'*+/=?`{|}~^-]+)*@(?:[a-zA-Z0-9-]+\.)+[a-zA-Z]{2,6}\b		**Matching** • johndoe@emailserver.com • historyprofessor@college **Non matching**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Name	Description	Regular Expression	Keywords	Examples
				• notanemail.com • bademail@.org
Vehicle identification number	A vehicle identification number (VIN)	\b[A-HJ-NPR-Z0-9]{17}\b		**Matching** AHUYA31581L000000
IP Address	Standard IP address	**4 digit IP** \b(?:(?:25[0-5]|2[0-4][0-9]|[01]?[0-9][0-9]?)\.){3}(?:25[0-5]|2[0-4][0-9]|[01]?[0-9][0-9]?)\b **6 digit IP** \b(((?:[0-9A-Fa-f]{1,4}(?::[0-9A-Fa-f]{1,4})*)?)::((?:[0-9A-Fa-f]{1,4}(?::[0-9A-Fa-f]{1,4})*)?))|((?:[0-9a-fA-F]{1,4}:){7}[0-9a-fA-F]{1,4})\b		**Matching 4 digit IP** 102.28.46.103 **Matching 6 digit IP** 914b:d45a:61ea:6346:59bc:
Credit Card- Visa	Visa credit card number	\b4[0-9]{12}(?:[0-9]{3})?\b		**Matching** 4444434342424242

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Name	Description	Regular Expression	Keywords	Examples
Credit Card- American Express	American Express credit card number	\b3[47][0-9]{13}\b		**Matching** 378225246366005
Credit Card- Mastercard	Mastercard credit card number	\b(?:5[1-5][0-9]{2}|222[1-9]|22[3-9][0-9]|2[3-6][0-9]{2}|27[01][0-9]|2720)[0-9]{12}\b		**Matching** 5555444455554444
Credit Card- Diners Club	Diners Club credit card number	\b3(?:0[0-5]|[68][0-9])[0-9]{11}\b		**Matching** 3056930009020004
Credit Card- Discover	Discovery credit card number	\b6(?:011|5[0-9]{2})[0-9]{12}\b		**Matching** 6011025690875424
Credit Card- CCV	Credit card security number	\b[0-9]{3,4}\b	cvv,verification code,security code	**Matching** 124
Credit Card- Expire Date	Credit card expiration in MM/YYYY format	\b(([1-9])|(0[1-9]|1[0-2]))\/?([0-9]{4}|[0-9]{2})\b	expire,exp	**Matching** • 02/2027 • 04/23 **Non matching** 03/9
USA- Social security number	USA citizen social security number	\b(?!666|000|9\d{2})\d{3}-(?!00)\d{2}-(?!0{4})\d{4}\b		**Matching** 001-22-111
USA- Phone Number	USA phone number ⚠ **Warning:** Does not use the USA calling code.	\b\(?([0-9]{3})\)?[-.]?([0-9]{3})[-.]?([0-9]{4})\b		**Matching** 2065550199 **Non matching** 1 555 238 0199
USA- Passport Number	9 digit USA passport number	\b[a-zA-Z0-9]\\d{8}\b		**Matching** 770022122
USA- Taxpayer ID	USA taxpayer ID number	\b(9\d{2})([\-]?)([7]\d|8[0-8])([\-]?)(\d{4})\b		**Matching** 927 70 5828

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Name	Description	Regular Expression	Keywords	Examples
USA- California State Driver License number	State of California, USA driver license number	\b[a-zA-Z]\d{7}\b		**Matching** A0002144
USA - Bank Routing number	US Bank Routing (ABA) number	\b((0[0-9])|(1[0-2])|(2[1-9])|(3[0-2])|(6[1-9])|(7[0-2])|80)([0-9]{7})\b		**Matching** 125210305

Configure Data Discovery target table

Add a target tables to be used in Data Discovery jobs. Only target tables will be scanned for data patterns.

Before you begin
Role required: data_discovery_admin

About this task
When a Data Discovery job is run it will run against all target tables with all active patterns.

Procedure
1. Select **System Security** > **Data Discovery (Classic)** > **Target Tables**.
2. Select **New**.
3. Select your target table in the **Table Name** field.
4. Select **Submit**.

Activate parallel jobs for Data Discovery

Use parallel jobs to reduce your Data Discovery job execution time.

Before you begin
Role required: admin

Procedure
By default Data Discovery runs jobs using a single thread. Multiple threads may be activated for Data Discovery full scans.

1. In the navigation filter enter `sys_properties.list`.
2. Create the property `com.glide.data_discovery.max_concurrent_item_workers`
3. Verify the **Type** is `integer`.
4. **Important:**
   It is recommended to start with a small number of workers per node(2 or 3).

   Enter the number of parallel job workers in the **Value** field up to 5.

Data Discovery roles

You can assign Data Discovery roles to limit user access to certain data types.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Data discovery administrator [sn_data_discovery.data_discovery_admin]

View, create, and modify, data patterns and related jobs.

- Data patterns:
  - Create
  - Read
  - Update
  - Delete
- Active data patterns:
  - Delete
  - Read
- Jobs:
  - Create
  - Read
  - Update
  - Delete
  - Schedule
  - Pause
  - Resume
  - Cancel
- Target tables:
  - Create
  - Read
  - Write
- Granular configuration:
  - Create
  - Read
  - Update
  - Delete
- Granular findings:
  - Create
  - Read
  - Actions

> **Note:**
> Users with this role may only take the ignore action

Contains Roles

List of roles contained within the role.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- data_classification_auditor
- data_classification_admin
- sn_data_discovery.data_discovery_api_processor

Groups

List of groups this role is assigned to by default.

None.

Special considerations

Admins are automatically assigned this role on product installation.

Note:
Avoid granting an admin role when more specialized roles are available.

Data discovery auditor [sn_data_discovery.data_discovery_auditor]

Read data patterns and target tables.

- Read data patterns
- Read active data patterns
- Read Data Discovery jobs
- Read target tables
- Review granular configuration
- Review granular findings

Contains Roles

List of roles contained within the role.

None.

Groups

List of groups this role is assigned to by default.

None.

Special considerations

None.

Data classification administrator [data_classification_admin]

Read data patterns, discovery jobs, and the data_classification table when an enabled specific pattern finding is classified.

Contains Roles

The Data classification role contains the List of roles contained within the data_classification_auditor role.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Groups

List of groups this role is assigned to by default.

None.

Special considerations

Note:
For more information about the Data Classification admin role, see Installing Data Classification plugin demo data.

Data Discovery job results

The Data Discovery Findings page shows details on the data found by a job. You can use the Findings page to review the results of a job and begin classifying data.

The Data Discovery Findings page displays the following details after a completed job.

Column	Description
Dictionary Entry	Column of the target table where the data was
Table	Target table where the data was found
Data Pattern	Data pattern used to find the data
Data Pattern Match Count	Number of data entries that match the data pattern
Total Row Scan Count	Number of rows scanned during the job
Percentage of Matching Rows	Percentage of rows in the target table that match the data pattern
Data Discovery Job	Job used on the target table
Status	Status of the entry

After you run a Data Discovery job, the results have a status of New. If no action is necessary, you can leave the data alone, which automatically sets the status to Ignored. Otherwise, you can classify the data, such as by creating user-defined data classifications, to prepare for data anonymization using the Data Classification tool.

Granular Findings

Users may select the **Track Granular Findings** action to use the Granular Findings page to take action on specific discovered records. See Granular Findings for more information.

Available Protections

Select the **Available Protections** button to review an entries control service, status, notes, and last check in. As of Xanadu this feature supports only Field Encryption.

Protecton services can also be accessed from the Dashboard. For more information on the dashboard see, Data Discovery.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Consolidate findings

Job results can be consolidated using the **Consolidate Findings** button. Job results shared between two separate jobs will then be consolidated under the most recently run job.

Note:
Only finished full scan jobs may be consolidated

Classify data in the Data Discovery job results page

Classify data in Data Discovery directly from a job's results page.

Before you begin
Role required: data_discovery_admin and admin

A job must complete a successful run before any result data can appear to be classified.

Procedure

1. Go to **System Security** > **Data Discovery** > **Data Discovery Job**.
2. Select the entry that you want to classify.
3. In the Data Discovery Findings list, select **Classify**.
4. Select the data classifications that you want to associate with the table entries.
5. Select **Classify**.

Data Discovery supported data types

Check which field types are supported when using Data Discovery.

Note:
Not all field types that have been classified are available for Data Discovery.

Some high risk field types are turned off by default, as detailed in the table. For more information about fields, see Field Types.

Supported field types for data discovery

Field type	Available by default
audio	No
condition	No
condition_string	No
currency	Yes
decimal	Yes
due_date	Yes
float	Yes
glide_date	Yes
glide_date_time	Yes
glide_duration	No
glide_time	Yes

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field type	Available by default
html	No
icon	No
integer	Yes
ip_addr	No
ip_address	No
journal	Yes
journal_input	Yes
journal_list	Yes
longint	Yes
name_values	No
percent_complete	No
phone_number_e164	Yes
price	Yes
string	Yes
string_full_utf8	Yes
translated_html	No
translated_text	No
url	No
user_image	No
video	No
wiki_text	No

Scanning with Granular Configuration

Granular scan can be used to scan specific table columns for discovery. Traditional Data Discovery jobs scan the entire table to discover data, whereas granular scan targets specific columns of the table thereby offers more control over the discovery process

Before you begin

Role required: admin, sn_data_discovery_admin, data_privacy_admin

Procedure

1. Navigate to **All** > **System Security** > **Data Discovery(Classic)** > **Granular configuration**.
2. In the **Granular Configurations** list, select **New**.
3. In the **Granular Configuration** fields form, fill in the fields.

Granular Configuration fields

Field	Description
Dictionary Entry	Column to be scanned.
Table	Table to be scanned.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Column label	Label of column to be scanned
Scan start point	Sensitive data will only be discovered for the day of and after the scan start point. **Note:** If the scan start point is left empty, all entries in the column will be scanned. If scan start point is changed, the scanning will be reset to start from the newly configured timestamp.
Active	Check to activate the granular configuration.

4. Select **Submit**.
   Children of extensible tables may be selected for configuration.
5. **Optional:** Select the Granular Configuration for the parent table, select **Select Child Tables** and select child tables for scanning.

Result

The specific column of the target table will be scanned for discovery. Granular Scan makes use of Data patterns from **Active Data Patterns**. You can review the findings and take action at **All** > **System Security** > **Data Discovery(Classic)** > **Granular findings**. See Granular Findings for more information.

Granular Findings

Granular findings may be reviewed using the Granular Findings tool.

Reviewing Granular Findings

Granular Findings is used to review up to 500 findings from Granular Configurations. When there are 500 findings, scanning of Granular Configurations is paused until action is taken.

Column label	Description
Record	Discovered record.
Table	Parent table of record.
Column	Column of the record where sensitive information was discovered.
Data Patterns	Pattern used to discover record.
Action	Action to take on findings. Select to change **Important:** The data_privacy_admin role is required to take the Anonymize action on a record. **Review** Record is pending review. This is assigned to new granular discoveries.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Column label	Description
	Ignore No action will be taken on the record **Anonymize** Record will be anonymized.
Status	Status of record. **New** Status assigned to finding when it is first reported **Processed** When user chosen action has been successfully applied on the finding **Note:** Processed findings are store for 3 days in the Granular Findings table before deletion **Manual Review** When applying user chosen action has failed. **Warning:** Findings in Manual Review should be deleted by users after taking appropriate actions.

Warning: Rollback is not supported for anonymization triggered from Granular Findings.

Contextual based discovery

Use contextual based discovery to help discover sensitive data that does not follow fixed patterns.

Data Discovery supports using a Named Entity Recognition (NER) model to discover data such as names, organizations, nationalities, and political affiliations. Data patterns with the type **Model** use this feature, see pattern type in Configure Data Discovery patterns for more details.

Warning: This feature requires a license check from the customer before it is enabled.

AI model-based discovery supports 5 patterns by default.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Contextual discovery patterns

Pattern	Description	Example text	Matching text
Person	The name of individual(s)	John Doe came by for a coffee.	John Doe
Nationality, religious or political groups (NRPs)	National, religious and political affiliations.	He was an American.	American
Location	Addresses or location information	He was in New York	New York
Date_Time	Dates and time information	He came at 9:30 today.	9:30 today
Organization	Organization names	He works at ServiceNow.	ServiceNow

Note:
AI Model-based discovery is only supports English for use with Real time anonymization(RTA) for tables and the Data Kit channel.

Data Discovery policies

Use Data Discovery policies to scan specific tables and enable column based jobs.

Data Discovery policies allow you to have fine-grained control over defining specific data patterns, tables and columns that should be included in a job. Additionally, using policies enables you to create multiple discovery job settings at the same time, instead of one global configuration. You can review your Data Discovery policies by navigating to **All** > **System Security** > **Data Discovery (Classic)** > **Data Discovery Policies**.

Note:
If no columns are selected for a policy, all columns of the target table will be scanned

See Create a Data Discovery policy to learn how to create a Data Discovery policy.

Create a Data Discovery policy

Create a Data Discovery Policy for granular control over your Data Discovery jobs.

Before you begin
Role required: admin, sn_data_discovery_admin, data_privacy_admin

Procedure

1. Navigate to **All** > **System Security** > **Data Discovery (Classic)** > **Data Discovery Policies**.
2. Select the **New** button.
3. Fill in the form.

Data Discovery Policy

Label	Description
Name	Name of the policy
Target Column(s)	Select the target columns to use in the policy

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Label	Description
	Note: If no columns are selected, all columns of the target table will be scanned
Target Table	Select the target table to use in the policy
Active	Determines if the policy is active or inactive **Note:** Defaults to active
Data Pattern	The data pattern the policy will use.

4. Select **Submit**.

Result
Select the policy when creating a Data Discovery jobs.

Data Discovery Store

Discover and track sensitive data within a ServiceNow instance

Data Discovery Store

Use Data Discovery to discover sensitive data within your instance. Scan for structured sensitive data such as, credit card numbers, phone numbers, social security numbers (SSN), etc. Get started quickly by using out-of-the- box common data patterns or create their own for a more granular experience. For unstructured and often context-based sensitive data such as names, addresses, etc. you can use AI and machine learning to aid with identification

Data Discovery Store overview

Get an overview of your Data Discovery metrics, and a starting point for using its tools.

Data Discovery policy

Review current Data Discovery policies and configure them.

Data Discovery sources

See the data patterns and target tables currently used by your discovery jobs

Data Discovery scheduled discovery

Schedule and review discovery jobs, including granular column discovery jobs.

Data Discovery Store overview

Get visibility into sensitive data on your instance and work towards implementing security measures to prevent loss or exposure of sensitive data.

The **Overview** tab provides an easy starting point for using Data Discovery, alongside showing important discovery metrics and findings. Navigate to **All** > **Data Discovery** > **Overview** to begin using the tab.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Create discovery policy and schedule discovery job

You can begin using Data Discovery with the recommended action items. Select **Create Policy** to define what sensitive data patterns should be identified and how they should be handled. See Data Discovery policy for more information on creating a new policy. Select **Schedule Job** to schedule a data discovery jobs that will scan your instance for sensitive information. See Data Discovery scheduled discovery for more information on scheduling a new discovery job.

Data discovery summary

You can review at a glance important Data Discovery metrics. Additionally, you can select the charts to drill-down further. For more information on reviewing discovery findings see Review discovery findings.

Discovered data

A bar chart overlaying the classifications and amount of discovered data. It summarizes where and how many instances of PII were discovered across different tables in your instance, categorized by data pattern types.

Discovery status

A donut chart displaying the proportions of the current state of all discovered patterns- whether they are new findings pending review, have been classified, or marked as ignored

Discovered data and recent jobs

You can review newly discovered data and recent discovery jobs in this section. For a more detailed review of these tables and their contents see Data Discovery scheduled discovery

.

Data Discovery policy

Use Data Discovery policies to define what sensitive data patterns should be identified and how they should be handled.

The **Policy** tab of Data Discovery reviews current discovery policies. View additional details of a policy by selecting the **View details** button. Edit, delete, and switch the state of current policies by selecting the three dots ⋮. To create a new policy see Create new policy.

Create new policy

Create a Data Discovery policy to begin scanning tables for data patterns.

Before you begin

Role required: discovery.admin

Procedure

1. Navigate to **All** > **Data Discovery** > **Policy**.
2. Select the **Create new policy** button.

   Edit or delete an existing policy by selecting the three dots ⋮ icon.
3. Fill in the fields of the pop-up window.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

New Discovery Policy form

Field	Description
Name	Enter a unique name for the policy
Data patterns	Select which sensitive data patterns to scan for. You can select multiple data patterns **Note:** AI/ML model based data patterns require an additional license and are subject to additional terms and conditions.
Select user tables and columns	Check the table(s) to be scanned **Note:** All selected table columns will be scanned by default. See the step below to narrow your selection to specific columns
Selected tables and columns	Displays a list of currently selected tables and columns for the policy

4. **Optional:** Select the arrow icon to view and select specific columns of the table.
5. Select **Save**.

Result

By default the new policy will be set to **Active**. Select the three dots icon and select **Deactivate policy**/**Activate policy** to switch its state.

Data Discovery sources

Create, and select the data patterns to be used in Data Discovery, and what tables to scan.

The **Sources** tab of Data Discovery helps you review your all your data patterns, set which pattern to use for scans, and select the tables to scan.

All Patterns

The **All Patterns** table lists all current patterns. Note that inactive patterns will show up in this list.See Create new data pattern to create a new data pattern.

Note:
Patterns musts be active to be used in discovery jobs.

All Patterns table

Label	Description
Name	Name of the data pattern.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

All Patterns table (continued)

Label	Description
Expression	Regular expression used to discover the data pattern.
Keyword	A specific word(or words separated by comma) to be searched for around a expression.
Keyword Proximity	How far from the expression to search for keywords.
Privacy Technique Configuration	Privacy technique used for the pattern

Active Patterns

The **Active Patterns** table lists all of the current active data patterns. See Select active data patterns to learn how set a pattern to active and used by discovery jobs.

Active Patterns table

Label	Description
Name	Name of the data pattern.
Expression	Regular expression used to discover the data pattern.
Keyword	A specific word(or words separated by comma) to be searched for around a expression.
Keyword Proximity	How far from the expression to search for keywords.
Privacy Technique Configuration	Privacy technique used for the pattern

Target Tables

The **Target Tables** table lists all tables currently selected for discovery jobs. See Select target tables to select tables for use in discovery jobs.

Target Tables table

Label	Description
Table Name	The name of the table
Display name	The display name of the table (Used in reporting)
Application	The application scope of the table.

Create new data pattern

Create a new Data Discovery store pattern.

Before you begin

Role required: discovery.admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Data Discovery** > **Sources**.
2. Select **All Patterns** in the navigation pane.
3. Select the **Create new** button.
4. Fill in the form.

New data pattern form

Field	Description
Description	Description of the pattern.
Name	Name of the data pattern.
Expression	Regular expression used to discover the data pattern. **Note:** Expression length must be less than 1000 characters.
Keyword	A specific word(or words separated by comma) to be searched for around a expression. Must be used with **Keyword Proximity** **Note:** A keyword can be used to search for additional context for a pattern. For example, using keyword can help differentiate between a date of birth or a date of hire given they have the same MM/DD/YY formatting.
Keyword Proximity	How far from the expression to search for keywords. Must be used with **Keyword** **Note:** Default is 30, upper bound of 64
Privacy Technique Configuration	Privacy technique used for the pattern
Synthetic Value	List of values substituted for the patterns
Type	Type of pattern
Application	Application scope of pattern.
Scope	Scope of the pattern.

5. **Optional:** Select the **Test** button to test your regular expressions if necessary.
6. Select **Submit**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Result
The new data pattern must be set as active to be used in discovery jobs. See Select active data patterns for more information.

Select active data patterns

Select the active data patterns to be used for Data Discovery jobs.

Before you begin
Role required: discovery.admin

Procedure
1. Navigate to **All** > **Data Discovery** > **Sources**.
2. Select **Active Patterns** in the navigation pane.
3. Select the **Edit** button.
4. Check the patterns to activate, they will show in the right side of the popup.
5. **Optional:** Select and drag patterns to re-order them.

   Note:

   (Optional) The order of the data patterns will also determine the order of anonymization techniques applied for data pattern anonymization.

6. Select the **Save** button.

Select target tables

Select target tables to be used in discovery jobs.

Before you begin
Role required: discovery.admin

Procedure
1. Navigate to **All** > **Data Discovery** > **Sources**.
2. Select **Target Tables** in the navigation pane.
3. Select the **Edit** button.
4. Check the tables to target, they will show in the right side of the pop-up.

   Note:
   Target tables will scan all columns, unless specified otherwise in policy.

5. Select the **Save** button.

Result
Selected tables will now be targeted by scheduled discovery jobs.

Data Discovery scheduled discovery

Set up and schedule data discovery jobs to scan your instance for sensitive information.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Discovery Jobs

The **Discovery Jobs** table lists all discovery jobs. See Create discovery job to create a new discovery job.

Discovery jobs table

Name	Name of the job
Description	The job description
Percent Complete	The percentage completion of the job
Scan Type	Scan type of the job. Possible states are as follows: • **Sample**: Scans 10,000 entries. • **Full**: Scans all entries.
Start Date	The start date of the job
Updated	When the job was last updated.
State	State of the Data Discovery job. The possible states are as follows: • **Ready to Schedule**: Default state for new jobs. • **Scheduled**: The job is scheduled to run. • **In Progress**: Job is actively running. • **Completed**: Job has finished running successfully. • **Error**: The job has stopped running due to an error. • **Canceled**: The job has been canceled. • **Paused**: The job is paused.
Run	How often the job is scheduled to run.

Discovery Findings

The **Discovery Findings** table lists all the discovered findings from discovery jobs. See Review discovery findings to review and classify findings from discovery jobs.

Discovery Findings table

Label	Description
Dictionary Entry	Column of the target table where the data was in
Table	Target table where the data was found
Data Pattern	Data pattern used to find the data

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Discovery Findings table (continued)

Label	Description
Data Pattern Match Count	Number of data entries that match the data pattern
Total Row Scan Count	Number of rows scanned during the job
Percentage of Matching Rows	Percentage of rows in the target table that match the data pattern
Data Discovery Job	Job used on the target table
Status	Status of the entry

Granular Configuration

The **Granular Configuration** table lists all granular discovery jobs. See Create granular job to learn how to create a granular discovery job.

Granular Configuration table

Label	Description
Table	Table of the granular discovery job
Column label	Column label of the granular discovery job
Scan Start Point	Sensitive data will only be discovered for the day of and after the scan start point. **Note:** If the scan start point is left empty, all entries in the column are scanned.
Active	The state of the granular discovery job.

Granular Findings

The **Granular Findings** table lists all the granular findings from granular discovery jobs. See Review granular findings to review the findings from granular discovery jobs.

Granular Findings table

Label	Description
Record	Discovered record
Table	Parent table of the record
Data Pattern	Pattern used to discover the record
Action	Action to be taken on the record **Review** Record is pending review. This is assigned to new granular discoveries **Ignore**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Granular Findings table (continued)

Label	Description
	No action will be taken on the record **Anonymize** Record will be anonymized
Status	The status of the record **New** Status assigned to finding when it is first reported **Processed** When user chosen action has been successfully applied on the finding **Note:** Processed findings are store for 3 days in the Granular Findings table before deletion **Manual Review** When applying user chosen action has failed **Warning:** Findings in Manual Review should be deleted by users after taking appropriate actions.

Create discovery job

Create and schedule a new Data Discovery Store job.

Before you begin

Role required: discovery.admin

Procedure

1. Navigate to **All** > **Data Discovery** > **Scheduled Discovery**.
2. Select **Discovery Jobs** in the right side navigation pane.
3. Fill in the form.

Schedule new discovery form

Field	Description
Name	Name of the job.
Description	Description of the job.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Scan Type	Number of entries to be scanned. Possible states are as follows: ○ **Sample**: Scans 10,000 entries. ○ **Full**: Scans all entries.
Select policy	The policy to use for the scheduled job.
Start Date	Sets the start date for the job.
Time window start	The start of the time window to run this job. The job will run after the time entered in this field. The time entered in the **Time window start** field must happen before the time entered in the **Time window end** field. **Note:** A valid time value is in Coordinated Universal Time based on a 24-hour time notation.
Time window end	The end of the time window to run this job. The job runs until the time entered in this field. If the job hasn't complete this time, the job pauses and resumes at the next time window start. The time entered in the **Time window end** field must happen after the time entered in the **Time window start** field. **Note:** A valid time value is in Coordinated Universal Time based on a 24-hour time notation.

4. Select the **Schedule** button.

Review discovery findings

Classify data in Data Discovery Store

Before you begin
Role required: discovery.admin

Procedure

1. Go to **All** > **Data Discovery** > **Scheduled Discovery**.
2. Select **Discovery Findings** in the right-side navigation pane.
3. Check the entries to be classified.
   Select the **Edit** button to edit the classification of selected entries.
4. Select the **Classify** button.

Note:
Select the **Available Protections** button to review protection options for classified data.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

5. Select the data classifications that you want to associate with the table entries.
6. Select **Classify**.

Result
The selected data is now classified.

Create granular job

Scan specific table columns in Data Discovery Store.

Before you begin
Role required: discovery.admin

Procedure
1. Navigate to **All** > **Data Discovery** > **Scheduled Discovery**.
2. Select **Granular Configuration** in the right side navigation pane.
3. Select **Create new**.
4. Fill in the form.

Create new granular configuration form

Field	Description
Table	The table to be scanned
Column label	The column to be scanned
Scan start point	Sensitive data will only be discovered for the day of and after the scan start point. **Note:** If the scan start point is left empty, all entries in the column will be scanned. If scan start point is changed, the scanning will be reset to start from the newly configured timestamp.

5. Set **Active** slider.
6. Select **Save**.

Result
A granular scan is scheduled to run on the target table and column, after it executes you can review the scan findings.

Review granular findings

Review granular findings in Data Discovery Store

Before you begin
Role required: discovery.admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Data Discovery** > **Scheduled Discovery**.
2. Select **Granular Findings** in the right side navigation pane.
3. Review the table entries.

Column label	Description
Record	Discovered record.
Table	Parent table of record.
Data Patterns	Pattern used to discover record.
Action	Action to take on findings. Select to change **Important:** The data_privacy_admin role is required to take the Anonymize action on a record. **Review** Record is pending review. This is assigned to new granular discoveries. **Ignore** No action will be taken on the record **Anonymize** Record will be anonymized.
Status	Status of record. **New** Status assigned to finding when it is first reported **Processed** When user chosen action has been successfully applied on the finding **Note:** Processed findings are store for 3 days in the Granular Findings table before deletion **Manual Review** When applying user chosen action has failed.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Column label	Description
	Warning: Findings in Manual Review should be deleted by users after taking appropriate actions.

Warning:

Rollback is not supported for anonymization triggered from Granular Findings.

Data Classification

Group data by type, using pre-defined or user-defined data classifications. If you have an assigned data classification administrator or auditor role, you can administer different data classes or visually analyze the current state of different types of data within the instance.

Explore Data Classification

Learn about Data Classification.

Configure Data Classification

Create and configure your own data classes.

Reference for Data Classification

Learn how Data Classification works with demo data.

Analyze Data Classifications

Learn how to analyze Data Classifications.

Exploring Data Classification

Explore about data classification.

Data Classification enables support for:

- Visibility into the types of data hosted on a ServiceNow AI Platform instances.
- Compliance with privacy laws, and meeting regulation requirements for industries such as financial services and medical device manufacturing.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Data classifications

Data classification is a standalone process in which you manually apply data classifications to existing dictionary entries in any table. See Data dictionary tables for additional information.

- You classify data as you find appropriate for your business and you can alter the available data classes as necessary.
- When you classify data, you can use the pre-defined data classifications, or create your own. Although use of pre-defined data classifications is optional, it is advisable do so as a starting point. These pre-defined data classifications are included in demo data that you can install in your instance. To learn more, see Installing Data Classification plugin demo data and Components installed with Data Classification demo data.
- If you create your own data classifications, you can also design a tiered hierarchical system with parent and child data classifications.
- When creating manual data classifications on an extended or child table, base fields inherited from the parent table are not available for selection.

  Classification is supported only for dictionary entries. You can't assign different classifications to inherited columns because they share the same dictionary entry. For example, you can't classify task.description as PII while classifying incident.description as Public.

Overview dashboard

Use the Overview dashboard to understand how your current data tables map to different data classifications. You can also analyze how your global, regional, international users may require different approaches to data classification, regarding the use or access to data. You can also customize the Overview dashboard content and layout to fit your needs.

To learn how to use the available scripted and REST APIs to apply the classification metadata within existing processes, workflows, and applications, see the following:

- Data Classification - REST API
- DCManager - Global
- ScopedDCManager - Scoped

Note:
Data Classification supports domain separation, and the data_classification table itself is process separated.

Use cases

General Data Protection Regulation (GDPR) is a European Union regulation whose purpose is to provide individuals with control over their own personal data. You can use data classifications, such as Personally Identifiable Information, to identify where personal data is being stored in your instance. By applying the appropriate security mechanisms to protect that personal data from leaking out, your organization satisfies GDPR requirements.

If you store customer information in the ServiceNow AI Platform, use the Personally Identifiable Information (PII) classification code where needed to track data subject to regulation by local privacy laws. When you install demo data, it automatically applies this classification code to certain security-sensitive fields in the User [sys_user] table. To learn more, see:

- Components installed with Data Classification demo data
- Assigning data classifications to dictionary entries

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

You can apply a Restricted data classification to Employee table columns that store sensitive employee information such as Social Security Numbers (SSN). Administrators and auditors can then use the Overview dashboard to confirm that you have assigned data classifications to the correct columns. They can also view the classification details for restricted types of information.

Installing Data Classification plugin demo data

When you upgrade to or install Zurich (and above), the Data Classification (com.glide.data_classification) plugin is automatically activated. However, you should manually install the demo data that comes with the plugin. It includes several important pre-defined data classifications, and it also assigns one of them to specific User [sys_user] table columns in your instance.

Before you begin

Role required: admin

About this task

Regardless of whether you install demo data, the activated Data Classification plugin adds the following user roles in your instance:

- data_classification_admin: Can administer all aspects of the Data Classification application, including data classification setup and assignment.
- data_classification_auditor: Can audit Data Classification code assignments made to user tables and columns.

Important:
Notice regarding use by Customers:

All decisions in connection with the implementation of this application are at the sole decision of the Customer. Customers acknowledge and agree that use of the application is not a representation by ServiceNow of compliance with any law or regulation and any suggested language, field or classification provided out of the box with the application does not constitute legal advice by ServiceNow.

Customers remain solely responsible for complying with their legal obligations under applicable law, including (but not limited to) data protection, security requirements, and privacy laws, and are responsible for configuring and making any necessary modifications to this application, including (but not limited to) templates, to meet the Customers' requirements.

Procedure

1. Navigate to **System Applications** > **All Available Applications** > **All**.
2. Find the Data Classification plugin using the filter criteria and search bar.
   An `Installed` message appears after you locate the plugin.
3. Click the icon with three vertical dots, then select **Repair** to access the Activate Plugin dialog.
4. Select **Load demo data**, and then click **Repair**.

Components installed with Data Classification demo data

When you install the demo data included in the Data Classification (com.glide.data_classification) plugin, several types of components are installed in your instance. These components include pre-defined data classifications and code assignments for specific User [sys_user} columns.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Data Classifications installed

data classification	Description
Confidential	Sensitive data that if compromised could negatively affect operations.
Internal	Internal data not meant for public disclosure.
Personally Identifiable Information	Also known as PII. Data that could potentially be used to identify a particular person.
Public	Data that may be freely disclosed to the public.
Restricted	Highly sensitive corporate data that if compromised could put the organization at financial or legal risk.

Data Classification assignments

Table	Assigned Column	Assigned data classification
sys_user	zip	Personally identifiable information
sys_user	first_name	Personally identifiable information
sys_user	email	Personally identifiable information
sys_user	city	Personally identifiable information
sys_user	middle_name	Personally identifiable information
sys_user	street	Personally identifiable information
sys_user	mobile_phone	Personally identifiable information
sys_user	last_name	Personally identifiable information
sys_user	country	Personally identifiable information
sys_user	gender	Personally identifiable information
sys_user	name	Personally identifiable information
sys_user	photo	Personally identifiable information
sys_user	state	Personally identifiable information
sys_user	home_phone	Personally identifiable information

Creating data classifications

Create your own user-defined data classifications in the Data Classification [data_classification] table that you can then assign to specific columns in specific tables.

Before you begin
Role required: data_classification_admin, admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **System Security** > **Data classification** > **Data classes**.
2. Select **New**.
3. Fill in the fields on the form.

Field	Description
Classification Name	Name of the data classification.
Description	Description of the data classification.
Parent	Name of the parent data classification that this data classification is subordinate to. Leave the field empty if this data classification is not a parent to child data classifications.
Application	Application scope for this data classification.

4. If this data classification should be a parent to child data classifications, click **New**.
   If you do not want to create child data classifications, skip this step.
5. Fill in the fields on the form.

Title

Field	Description
Classification Name	Name of the child data classification.
Description	Description of the child data classification.
Parent	Name of the parent data classification that this data classification is subordinate to. Leave the field empty if this data classification is not a parent to child data classifications.
Application	Application scope for this child data classification.

6. Click **Submit**.

Assigning data classifications to dictionary entries

Assign data classifications to specific table columns in the Dictionary [sys_dictionary] table. When you assign data classifications, it creates entries in the Dictionary-Data Class [m2m_dictionary_dataclass] table, which you can then review in the Overview dashboard.

Before you begin

Role required: data_classification_admin and admin

Procedure

1. In the Navigator pane, type `sys_dictionary.list`.
2. In Dictionary Entries, select each of the elements you want to assign specific data classifications to.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. After selecting the elements, click **Actions on selected rows**, and then select **Classify**.

   Note:
   To clear previously assigned data classifications for selected dictionary elements, you can select **Clear classification**.

4. When the Assign to data class dialog appears, select the data classifications you want to assign to your selected dictionary elements, then click **Classify**.

   Warning:
   This will overwrite any existing classifications for the selected dictionary items.

   You can select multiple data classifications as needed.

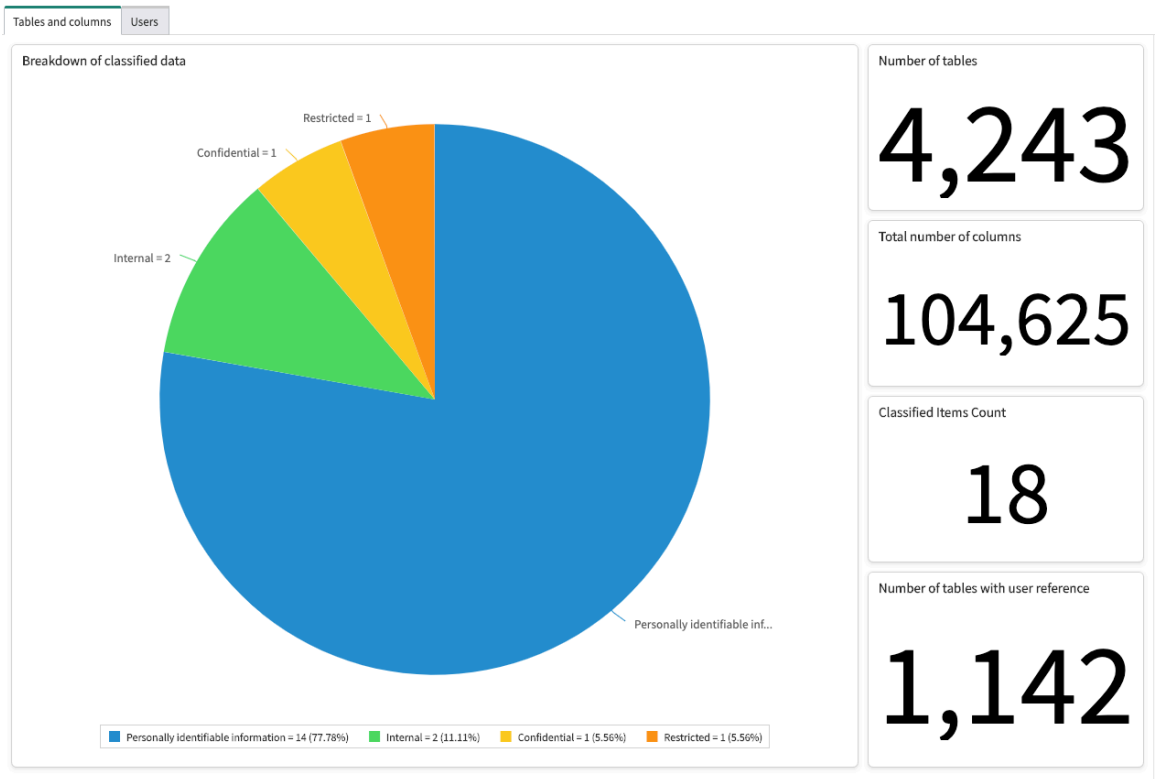
   See Data dictionary tables for additional information.

Analyzing data classifications using the Overview dashboard

The Overview dashboard reports the current state of data classifications within your instance and how your users are distributed by location.

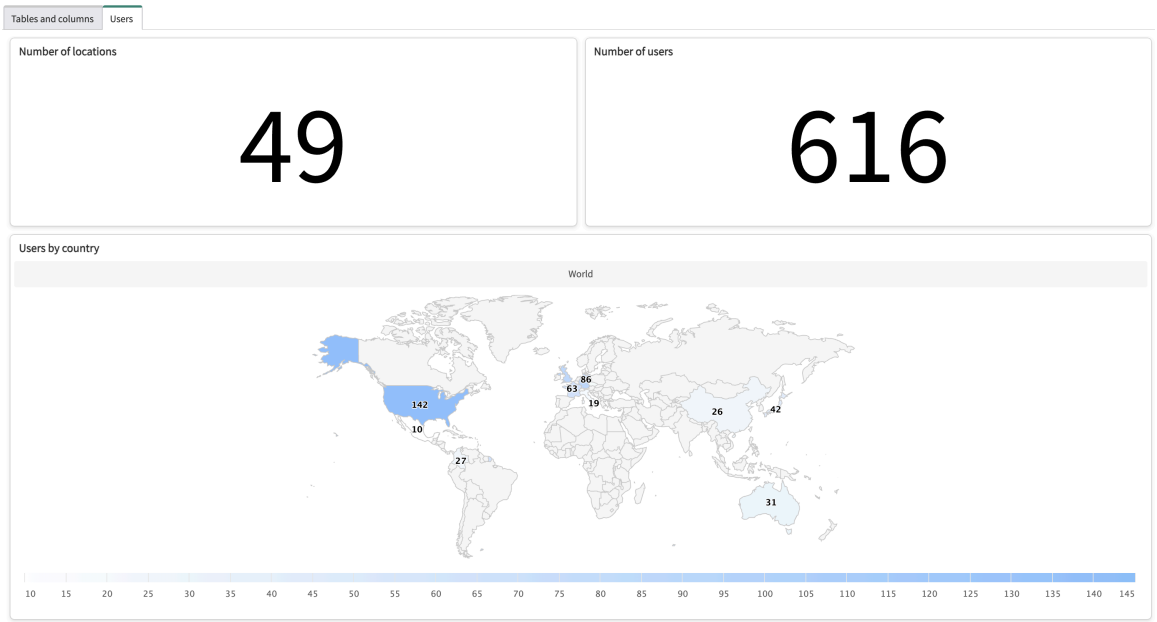
If you have a data classification administrator or auditor role, you can visualize the current sensitivity of instance data, which helps increase security and compliance with privacy laws. By using the Location field in user records, administrators map users across different regions that have differing privacy regulations.

Tables and columns tab



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Users tab



Required ServiceNow AI Platform roles

- data_classification_admin: Administers all aspects of the Data Classification application, including data classification setup, and assignment.
- data_classification_auditor: Audits Data Classification code assignments.

Use cases

For additional examples of how different people in your organization would use this dashboard, see Use Cases in Data Classification.

User	Dashboard use
data_classification_admin	Confirm that you have assigned data classifications to the correct fields in your instance.
data_classification_auditor	Audit the senility and security of data in your instance.

Reports

Title	Type	Source table	Description
Breakdown of classified data	Donut chart	m2m_dictionary_dataclass	Provides a breakdown of instance data classifications, by data class, total displayed in center.
Total tables	Single Score	sys_dictionary	Total number of data tables in the entire dictionary.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Title	Type	Source table	Description
Total columns	Single Score	sys_dictionary	Total number of classified data columns in the entire dictionary.
User reference columns	Single Score	sys_dictionary	Total number of user reference columns in the dictionary.
User location count	Single Score	sys_user	Total number of distinct locations found for users
User count	Single Score	sys_user	Total number of user records in your instance.
Users by country	Map	sys_user	Breakdown of user records by country.

Domain separation and Data Classification

Domain separation is supported for Data Classification . Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: Enhanced

- Includes all aspects of **Basic** and **Standard** levels of support.
- Data-driven process enables service provider customers to modify business logic that is based on defined use cases. These configurations are UI-based and fail-safe so that configurations by one customer cannot affect another.
- Tenants of the instance must be able to configure minimum viable product (MVP) business logic and data parameters for themselves. This logic and parameters would be expected for the application's normal function.

Sample use case: Tenant-customers of a shared environment must be able to modify the impact, urgency, or priority matrix to set priority within their domain.

For more information on support levels, see Application support for domain separation.

How domain separation works in Data Classification

For domain separation, the application uses process separation for the Data Classification [sys_data_classification] table. For the Dictionary-Data Class [m2m_dictionary_dataclass] table, it uses data separation. For learn more about data and process separation, see Domain separation explained.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Encrypts sensitive data on your company premises before sending data over the internet to your ServiceNow instance. Data remains encrypted at rest on the instance.	Use certificates to establish secure connections and validate signatures.	Encrypt all stored data in real-time, providing protection for data online and offline with no loss of functionality.

Key Management Framework

Use the Key Management Framework (KMF) to generate, exchange, store, use, and replace the cryptographic keys used to encrypt and decrypt sensitive data on your ServiceNow instance.

Key Management refers to the activities involved in handling your cryptographic keys and related security parameters during the key's life cycle. Key Management Framework is based on National Institute of Standards and Technology (NIST) 800-57 guidelines. In accordance with these guidelines, you can use KMF to:

- Assign dedicated roles for cryptographic management and operations, auditing, and integration.
- Create cryptographic modules to configure of cryptographic specifications for unique cryptographic purposes and key types.
  - Symmetric key: encryption and decryption, key wrapping and unwrapping, and authentication
  - Asymmetric key: digital signature generation and verification, encryption and decryption, key wrapping and unwrapping
- Manage your key life cycle to generate, rotate, revoke, and suspend keys, including support of several key life cycle states
- Create module access policies (MAPs) to enforce access controls, to grant access only to users and scripts that you choose.
- Protect your cryptographic keys with the Federal Information Processing Standard (FIPS) 140-2-L3 hardware Root of Trust (RoT), Public Key Infrastructure (PKI), key hierarchy, and envelope encryption.
- Assign the auditing role to users to can then view auditing information such as key usage statistics.

	Key Management Framework actions One of the core features of KMF is to provide the capability#to manage #keys, such as revoking or rotating keys.#KMF properly secures sensitive data with the most up-to-date encryption materials and life cycle operations.	

Activation information

The ServiceNow Platform Encryption subscription bundle is a group commercial entitlement that includes Key Management Framework, Field Encryption Enterprise, Cloud Encryption, and Database Encryption.

Field Encryption Enterprise is the unlimited license of Field Encryption. The Field Encryption Enterprise plugin is available with the activation of the com.glide.now.platform.encryption plugin. For details, see Encryption and Key Management subscription bundle.

Note:
KMF doesn't support domain separation, but can be used with on-premise instances.

Exploring the Key Management Framework

Learn about the components of the Key Management Framework (KMF), and how to use them to manage how cryptographic operations are performed on your instance.

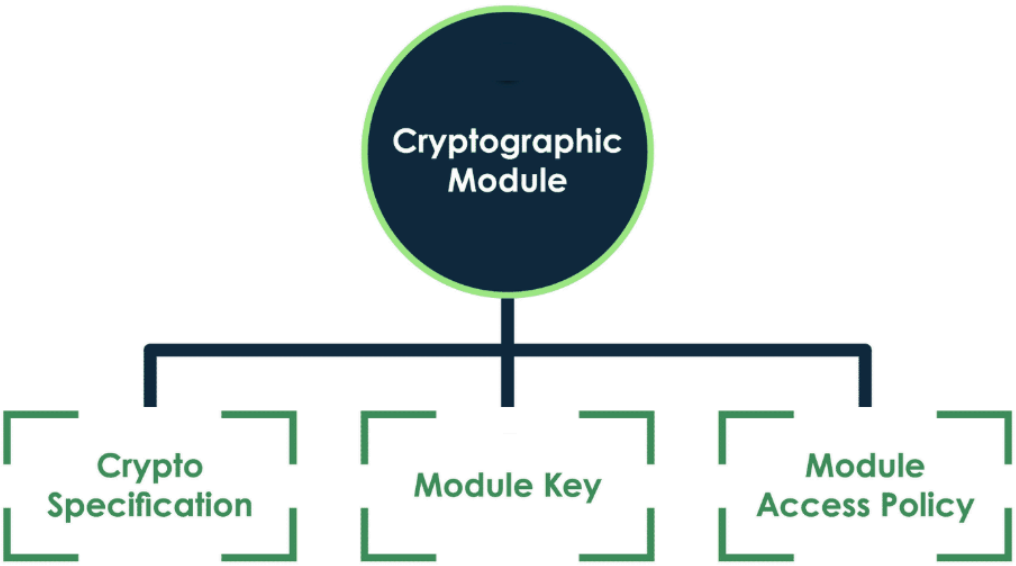
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Components of the Key Management Framework



Key Management Framework consists of the following components.

Cryptographic modules

KMF is centered around managing cryptographic modules. These modules act as the parent record for the other components. They define what data on your instance is encrypted, and what method of encryption to use. Using multiple modules, you can encrypt different areas of your instance with different specifications.

For example, you can create a module to secure the data in your Human Resources application to users with a specific role. You could then create another module to encrypt Incident descriptions which are visible to certain users based on a script you create.

Module access policies are found by navigating to **All** > **Key Management** > **Cryptographic Modules** > **All**. For more information on these modules, see Cryptographic module overview.

Module keys

Cryptographic keys are strings of characters used in cryptography. When used together with a cryptographic algorithm, they can encode or decode your data. These keys are used by the cryptographic specifications assigned to your modules. You can choose to use a key generated by ServiceNow, or upload your own key.

You can access the module keys for a cryptographic module in the **Module Keys** related list in cryptographic module records. For more information on module keys, see Instance level keys in the Key Management Framework.

Cryptographic specifications

A cryptographic specification defines algorithms used to encrypt your data. These algorithms use a cryptographic key to encode or decode your data. Assigning a cryptographic specification to the module determines how the data assigned to that module is encrypted.

You can access the module keys for a cryptographic module in the **Crypto Specifications** related list in cryptographic module records. For more information on module keys, see Cryptographic specification overview.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Module access policies

Module access policies (MAPs) are the access controls you apply to your cryptographic modules. Use these policies to determine which users and scripts can access data encrypted by a cryptographic module.

Find module access policies by selecting the **View access policies** link in cryptographic module records. For more information, see Module access policy overview.

Key Management Framework workflow

1. Assign KMF roles

Administrators must begin by assigning themselves the sn_kmf.admin role. This role enables you to use KMF features and assign KMF roles to other users.

2. Configure KMF settings

Configure your field encryption settings to select either supplied keys or your own customer-supplied keys (CSK) for encryption.

3.Create cryptographic modules

Use cryptographic modules to select a set of data on your instance to be encrypted. In later steps, you assign a cryptographic specification to determine how to encrypt this data, and a module access policy to determine who can decrypt the data.

4. Create a cryptographic specification

The cryptographic specification defines a method of encryption. Once assigned to a module, it defines how the data assigned to that module is encrypted.

5. Create module access policies

After creating modules to secure your data, create module access policies to control which users and scripts are able to access the encrypted data.

6. Create a cryptographic module life-cycle policy

These policies place limits on cryptographic modules, such as how long a cryptographic key is valid. These policies can safeguard your cryptographic modules by limiting their exposure.

Key Management Framework benefits

Benefit	Feature	Users
Protect your sensitive and proprietary data.	Encryption and key Management	All
Maintain compliance with NIST 800-57 guidelines. These guidelines are provided by the National Institute of Standards and Technology to reduce cybersecurity risk to your networks and data.	Encryption and key Management	Security administrators
Use the Key Management Framework to generate, upload, view, and manage your cryptographic keys. Use key rotation for manual or scheduled rotation of your keys for increased security.	Key Management Framework	Security administrators

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Cryptographic module overview

The Key Management Framework (KMF) is centered around managing Cryptographic modules. Use these modules to select a cryptographic mechanism and define where they're applied on your instance.

Cryptographic modules are the centerpiece of KMF. They define the specific cryptographic mechanisms used for cryptographic operations for a given use case.

For example, you want to secure the data in your Human Resources application with an AES-CBC with a 256-bit symmetric key. You can create a module for that purpose.

Cryptographic modules also support key life-cycle management. You can create and rotate your cryptographic keys, and define your encryption method. Cryptographic modules are composed of the following components:

Cryptographic specification

Defines which algorithm to use for encryption, and where the key will come from. All keys use the Advanced Encryption Standard with Cipher Block Chaining (AES CBC), but you can select either 128 or 256 bit. This specification covers both asymmetric and symmetric key-based cryptographic operations.

Note:
Symmetric encryption uses a single key for both encryption and decryption. Asymmetric encryption uses a pair of keys, a public key for encryption and a private key for decryption.

Cryptographic keys

The key your module uses to encode or decode cryptographic data. This key can be generated by your instance, or a customer-supplied key you create and upload.

Module access policies

Module access policies are the access control mechanisms that place limits on whether data can be encrypted or decrypted.

Module policy exceptions

A control mechanism to define exceptions to a module access policy.

The following screen shows these high-level components in a cryptographic module:

© 2026 ServiceNow, Inc. All rights reserved.

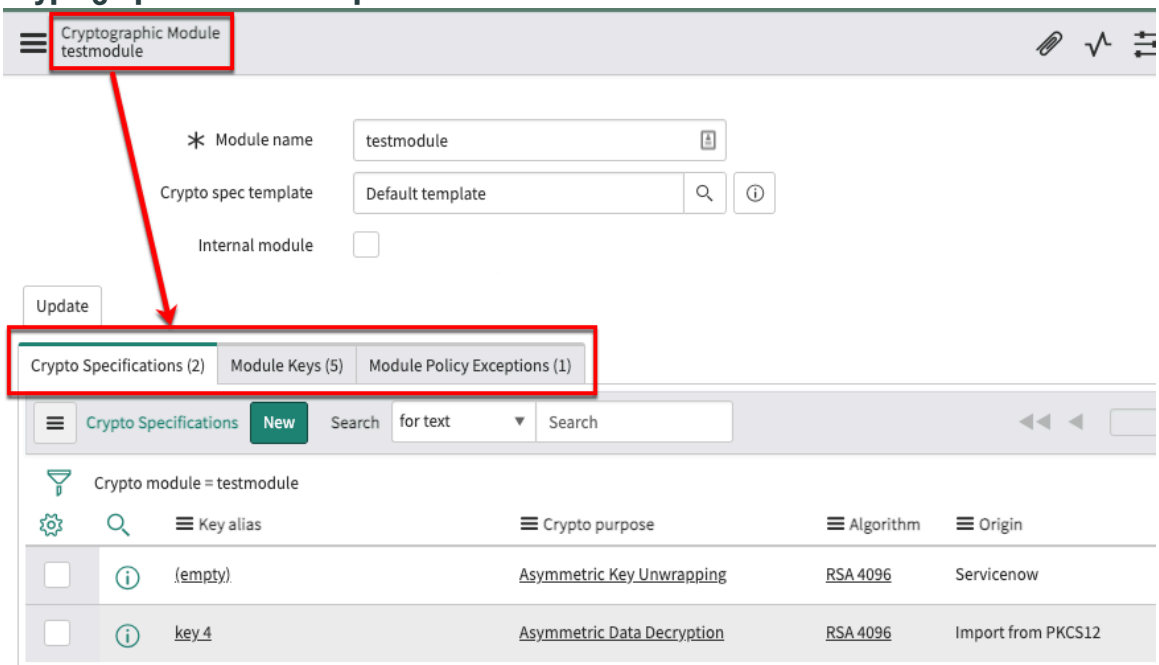
Cryptographic module components



For details on creating cryptographic modules, see Create a cryptographic module.

Cryptographic specification overview

The Cryptographic specification is the component that defines aspects of your cryptographic module, including its cryptographic purpose and which encryption algorithm to use.

Cryptographic specifications can be tailored to a specified cryptographic purpose, covering both asymmetric and symmetric key-based cryptographic operations. Selection of a cryptographic purpose offers further choices, namely to a set of supported algorithms and key length configurations.

Cryptographic purposes, algorithms, and key information

Cryptographic Purpose	Algorithm	Key Information
Asymmetric Data Decryption	RSA	Asymmetric – 2048-bit, 3072-bit, and 4096-bit key
Asymmetric Data Encryption	RSA	Asymmetric – 2048-bit, 3072-bit, and 4096-bit key
Asymmetric Key Unwrapping	RSA	Asymmetric – 2048-bit, 3072-bit, and 4096-bit key
Asymmetric Key Wrapping	RSA	Asymmetric – 2048-bit, 3072-bit, and 4096-bit key
Signature Generation	RSA	Asymmetric – 2048-bit, 3072-bit, and 4096-bit key
Signature Verification	RSA	Asymmetric – 2048-bit, 3072-bit, and 4096-bit key
Symmetric Authenticity	HMAC	Symmetric – 256-bit, 384-bit, and 512-bit key
Symmetric Data Encryption/ Decryption*	AES-CBC *	Symmetric – 128-bit, 192-bit, 256-bit key
	AES-CFB	

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Cryptographic purposes, algorithms, and key information (continued)

Cryptographic Purpose	Algorithm	Key Information
	AES-OFB	
	AES-CTR	
	AES-GCM **	
Symmetric Key Wrapping/ Unwrapping*	AES-CBC *	Symmetric – 128-bit, 192-bit, 256-bit key
	AES-CFB	
	AES-OFB	
	AES-CTR	
	AES-GCM **	

* AES-CBC supports equality-preserving options.#Field Encryption Enterprise utilizes AES-CBC.

** AES-GCM has built-in data integrity.

The configuration of these parameters is covered in Create a cryptographic module.

Module access policy overview

Module access policies (MAPs) are access controls that you apply to your cryptographic modules. Use these access policies to decide which users and scripts can access data encrypted by a cryptographic module.

Module access policies

Note:
A subscription is required to utilize the Field Encryption Enterprise functionality. See Activate Field Encryption for more information on Field Encryption Enterprise.

Module access policies are introduced with the Key Management Framework (KMF) in the base system.

Module access policies expand on the role-based designations that were provided with the encryption modules. Module access policies can be based on the following:

- Basic (scope)
- Role
- System user
- Script
- Resource Exchange

Note:
See Key Management Framework Resource Exchange for details.

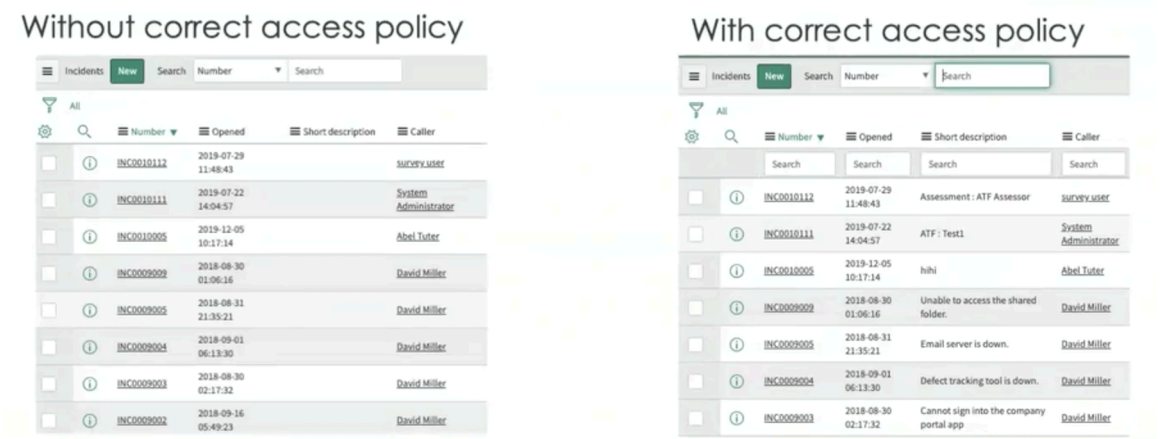
In a cryptographic module, you must configure the correct module access policies to permit access to encrypted data. Without a module access policy associated with a cryptographic

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

module, encrypted data isn't visible to users and associated fields and columns in lists display as empty.

In this example, the absence of a module access policy on the encrypted Short Description field hides the content from all users accessing the Incident table. With a module access policy in place, only users with a specific role are able to see the encrypted data.

Encrypted short descriptions with and without module access policies



Note:
The data in the column also appears empty to users without the correct role specified in the module access policy.

Refer to Create a module access policy for setup.

Autogen policies

Autogen policies are automatically system generated based on the default module access policy defined for the given cryptographic module. If there are no granular level policies defined when the system or a script tries to access the given cryptographic module, these global policies are generated and applied.

Important:

Autogen policy rules aren't applied for scheduled jobs types, or field encryption modules (modules where the parent module is Field Encryption).

Instance level keys in the Key Management Framework

Learn about the Key Management Framework (KMF) key structure, which uses envelope encryption to ensure that all platform keys under KMF management are protected through a chain of keys. Customer Data Encryption Keys (CDEKs) created by KMF are also included in this structure

.

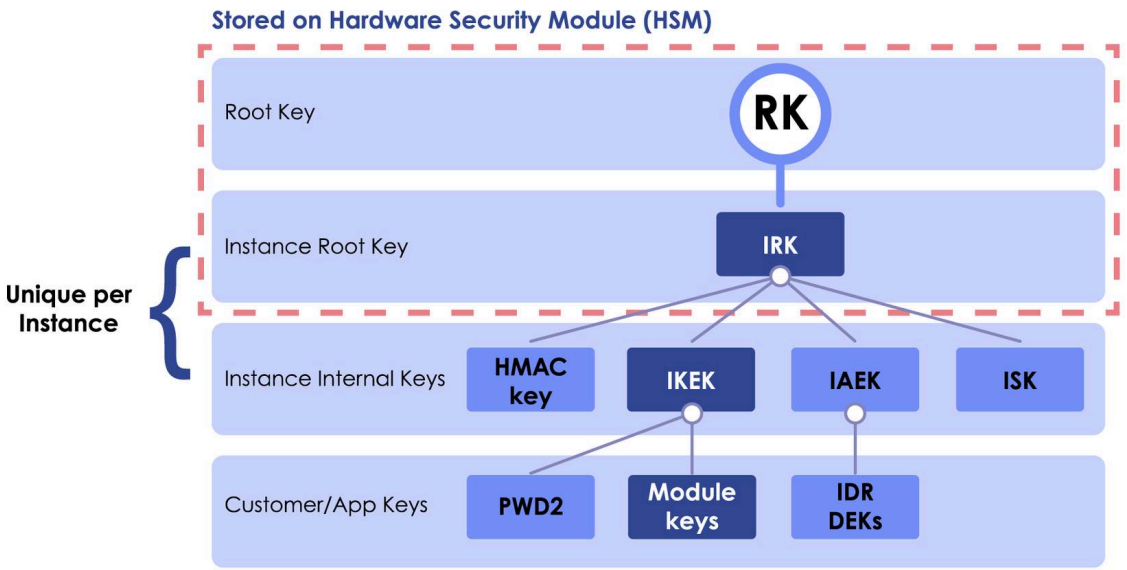
KMF key storage architecture

The KMF key structure uses the SafeNet KeySecure Hardware Security Module (HSM). The HSM is designed to be physically and electronically tamper-proofed to meet the FIPS 140-2-L3 security standard. KMF uses envelope encryption to ensure that all platform keys under KMF management are protected through a chain of keys, including the module keys that can be generated by KMF.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Envelope encryption

Envelope encryption is the practice of encrypting a key with another key, also referred to as wrapping. Module keys are envelope encrypted by the Instance Key Encryption Key (IKEK), which in turn is envelope encrypted by the Instance Root Key (IRK), which is finally envelope encrypted by the Root Key (RK). Since the IRK can only be accessed by the HSM, the IKEK must be uploaded for decryption.



At the instance level, KMF defines several keys that are used internally for varying cryptographic purposes throughout the ServiceNow AI Platform.

This table provides examples of a subset of available keys that are managed and protected by KMF.

Key	Location	Description
Root Key (RK)	Hardware Security Model (HSM)	Root key used to decrypt the IRK.
Instance Root Key (IRK)	HSM	A key unique to your instance that is used to envelope-encrypt several instance internal keys.
Instance HMAC Key (IHK)	Instance	Unique per instance, the IHK is used internally for Hash-Based Message Authentication Code (HMAC) purposes. The IHK helps to verify the authenticity and integrity of module keys and is wrapped on either KeySecure or the File Key Store.
Instance Key Encryption Key (IKEK)	Instance	The IKEK wraps the module keys and is wrapped on either KeySecure or the File Key Store.
Instance Asymmetric Encryption Key (IAEK)	Instance	A key unique to your instance that is used internally for asymmetric encryption purposes.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Key	Location	Description
		The IAEK is used to transmit confidential messages between an instance during Key Exchange or Instance Data Replication consumer approval.
Instance Signature Key (ISK)	Instance	A key unique to your instance that is used internally for signing purposes.
Password2 (PW2)	Instance	With KMF, the key for PW2 fields is fully managed by KMF.
Customer Data Encryption Key (CDEK)	Instance	Encryption keys created through KMF are envelope-encrypted by the IKEK.
Instance Data Replication (IDR) Data Encryption Key (DEK)	Instance	Specific encryption keys used for the IDR process.

Configuring the Key Management Framework

Create and maintain Key Management components to customize and manage how cryptographic operations are performed on your ServiceNow instance.

Assign Key Management Framework roles

Administrators with the security_admin role can assign Key Management Framework (KMF) admins, who in turn can assign other Key Management Framework roles.

Before you begin

Role required: admin and security_admin

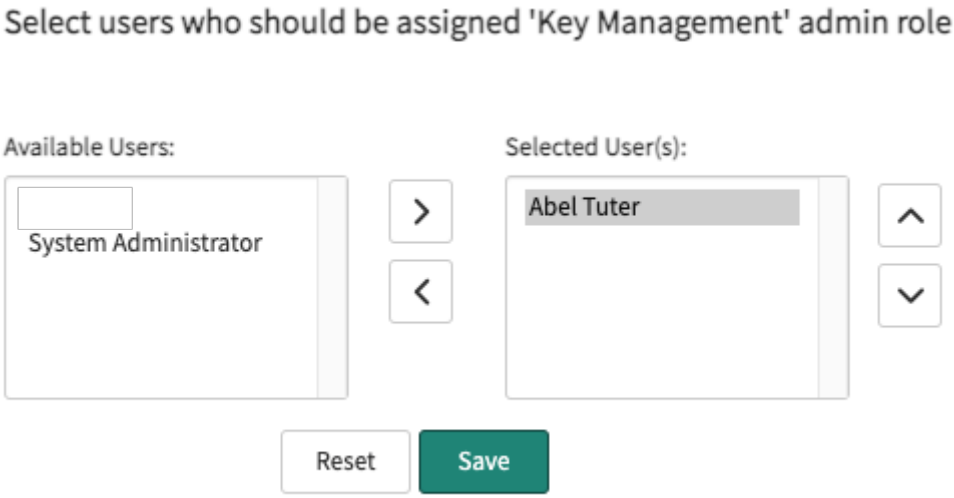
You must elevate to the security_admin role before assigning the KMF admin role. For instructions, see Elevate to a privileged role.

Important:
KMF roles are required to use the Key Management Framework. Users without KMF roles aren't be able to access lists, tables, and modules used to configure key management.

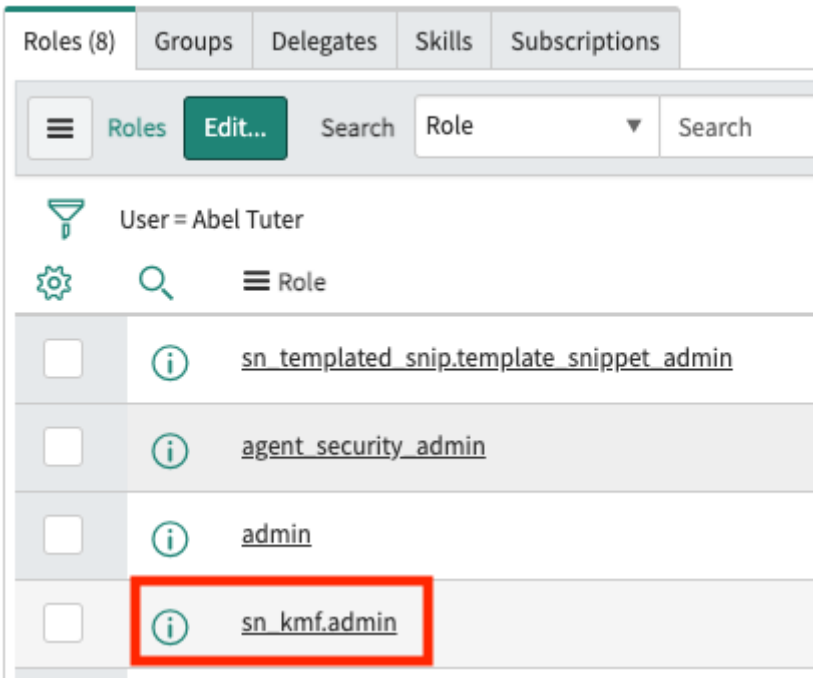
Procedure

1. Elevate to the security admin role.
2. Navigate to **User Administration** > **Users** and select the user you want to be the KMF admin.
3. If the user doesn't already have the admin and security_admin roles, select **Edit** under the Roles related list and add **admin** and **security _admin**.
4. Navigate to **System Security** > **Key Management Administration**.
5. Select the user that you want to be KMF admin in the **Available Users** column and move them to the **Selected User(s)** column.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



6. Select **Save**.
7. Navigate to **User Administration** > **Users** and select the user you just gave the KMF admin role to.
   That user now has the sn_kmf.admin role in the Roles related list. That user can now assign other KMF roles.

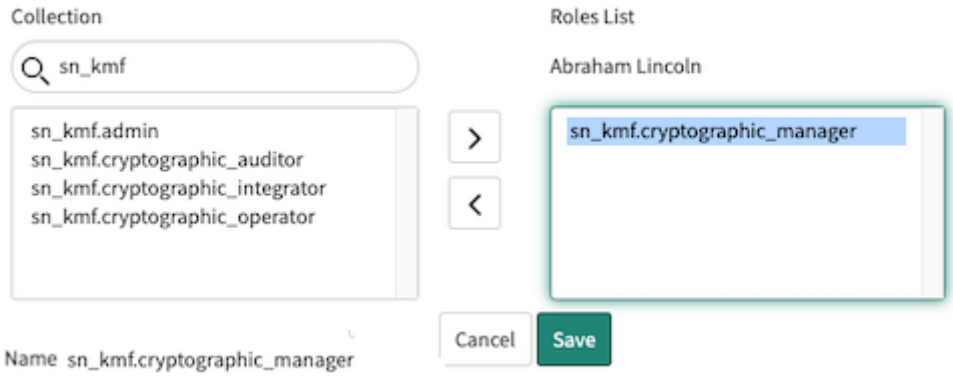


What to do next

If you have the KMF admin role, follow these steps for assigning other KMF roles:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

1. Navigate to **User Administration** > **Users** and select the user you want to have another KMF role, such as KMF Cryptographic Manager.
2. In the Roles related list, click **Edit** and select the KMF roles you want to assign the users. All KMF roles start with `sn_kmf`.



What to do next

To learn more about the available KMF roles, see Roles installed with Key Management Framework.

Configure field encryption settings to select key type

Configure your field encryption settings to use ServiceNow supplied keys or your own customer-supplied keys (CSK) for encryption on the ServiceNow AI Platform.

Before you begin

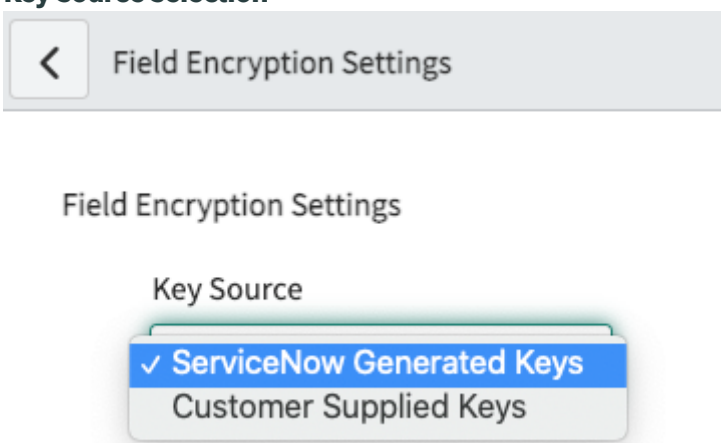
Customer-supplied keys are only supported with Field Encryption Enterprise.

Role required: sn_kmf.cryptographic_manager and security_admin

Procedure

1. Navigate to **All** > **System Security** > **Field Encryption Settings**.
2. From the Field Encryption Settings, select either **ServiceNow Generated Keys** or **Customer Supplied Keys** from the **Key Source** list.

Key source selection



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

This option changes the `com.glide.encryption.cle_kmf.key_source` property to either **ServiceNow Generated Keys** or **Customer Supplied Keys**.

3. Select **Save**.

What to do next

- If you're using your own customer-supplied keys, see Using customer supplied keys with Field Encryption Enterprise.
- If you're using ServiceNow supplied keys, start creating your cryptographic module. See Create a cryptographic module.

Create a cryptographic module

Create a cryptographic module to define the mechanisms used for cryptographic operations. After you create the module, you create a cryptographic specification, where you define an algorithm for encryption and generates a key.

Before you begin

If you're supplying your own keys, go to Configure and upload your customer supplied key.

Role required: sn_kmf.cryptographic_manager

About this task

This procedure describes options that are available with KMF in the ServiceNow platform base system. Field Encryption Enterprise functionality is available only when the *com.glide.now.platform.encryption* plugin is active. See Activate Field Encryption for more information on obtaining Field Encryption Enterprise. See Create cryptographic module for Field Encryption.

Note:
Cryptographic module [sys_kmf_crypto_module] records can't be deleted.

Procedure

1. Navigate to **All** > **Key Management** > **Cryptographic Modules** > **Create New**.
2. On the form, fill in the fields:

Cryptographic Module fields

Field	Description
Module name	Alphanumeric string to be referenced when running scripts.
Crypto spec template	Select the **Default** template to use to create the cryptographic module, as it contains mappings of supported algorithms for crypto specifications.
Default module access policy value	○ Rely on system default: ○ Reject ○ Track
Actual module access policy result	Reject or track, based on the default policy value or the value selected during the creation of the module access policy.
Name	Crypto module name prepended with application scope name.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Crypto module life-cycle state	Life cycle refers to the creation, use, and deactivation of a cryptographic module. Set to **Draft** initially during configuration. When using the module, set this field to **Published**. The Default template is automatically set to Published.

3. Select **Submit**.

> **Warning:**
>
> **For legacy encryption support users:**
>
> If you're using the non-enterprise version of Field Encryption, you're limited to five modules. If you've exceeded this limit, you receive the following warning:
>
> This insertion exceeds the number of published modules limit for Field Encryption entitled with the Subscription Product. The Enterprise subscription for Field Encryption is required for additional modules. Please reach out to your Account team.

After submitting successfully, your cryptographic module is listed in the Cryptographic Modules table. The system prepends the name with the scope to avoid conflict with other scoped applications. For example, if you created a module with the name `my_crypto_module` in the global application scope, the name is saved as `global.my_crypto_module`.

What to do next

Create a cryptographic specification

.

Create a cryptographic specification

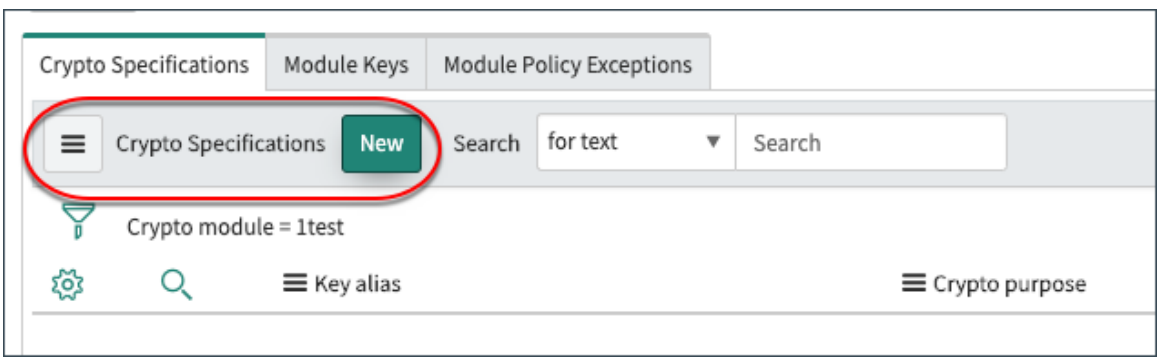
After you create a cryptographic module, create a cryptographic specification to define the module algorithms.

Before you begin

Role required: sn_kmf.cryptographic_manager

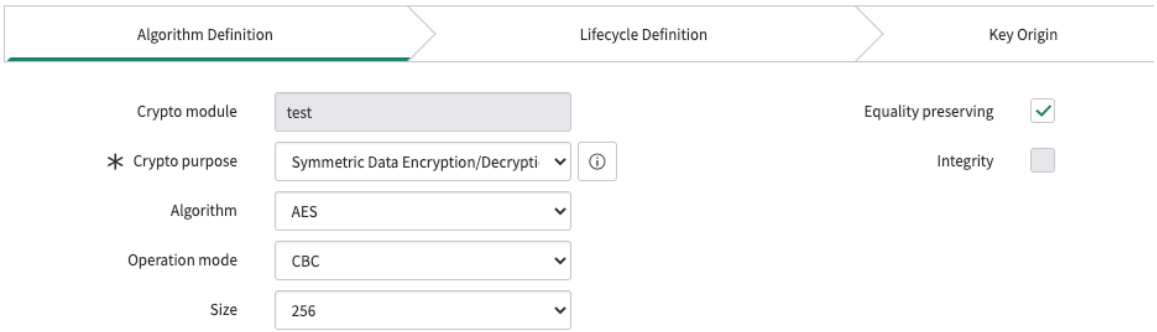
Procedure

1. Navigate to **Key Management** > **Cryptographic Modules** > **All**.
2. Select the cryptographic module for definition to open the configuration options.
3. On the **Crypto Specifications** tab, select **New**.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Complete the Algorithm Definition form.
   See Cryptographic specification overview for details.



The algorithm definition screen opens. Select options for the key generation. Repeat this step to generate multiple keys for the selected crypto module.

Algorithm Definition fields

Field	
Crypto module	Read only. Name of the selected cryptographic module displays.
Crypto purpose	Select the purpose of this module. For example, you might use it for data encryption, signature generation, or key wrapping. The available algorithms adjust based on the selected crypto purpose. See Cryptographic specification overview for details.
Algorithm	Type of algorithm used to accomplish the crypto purpose. The algorithm also controls the key origin. Adjusts automatically based on the selected crypto purpose. Cryptographic specification overview for details.
Operation mode	This field may display based on the selected crypto purpose.
Size	Select the bit size.
Hash	This field becomes available based on the algorithm selected.
Equality preserving	Enables non-deterministic encryption. This option appears when you select **Symmetric Data Encryption/Decryption** with **AES** and in **Cipher Block Chaining (CBC)** mode. Selecting this option means that if the same data is encrypted again the encoded data is the same each time. Non-deterministic encryption doesn't support filtering a list of

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	
	encrypted data using equality comparison operators.
Integrity	GCM operation mode provides Integrity.

5. Select **Next**.
   The crypto specification is listed on the Key Lifecycle table based on the algorithms selected.

What to do next
Perform one of the following operations:

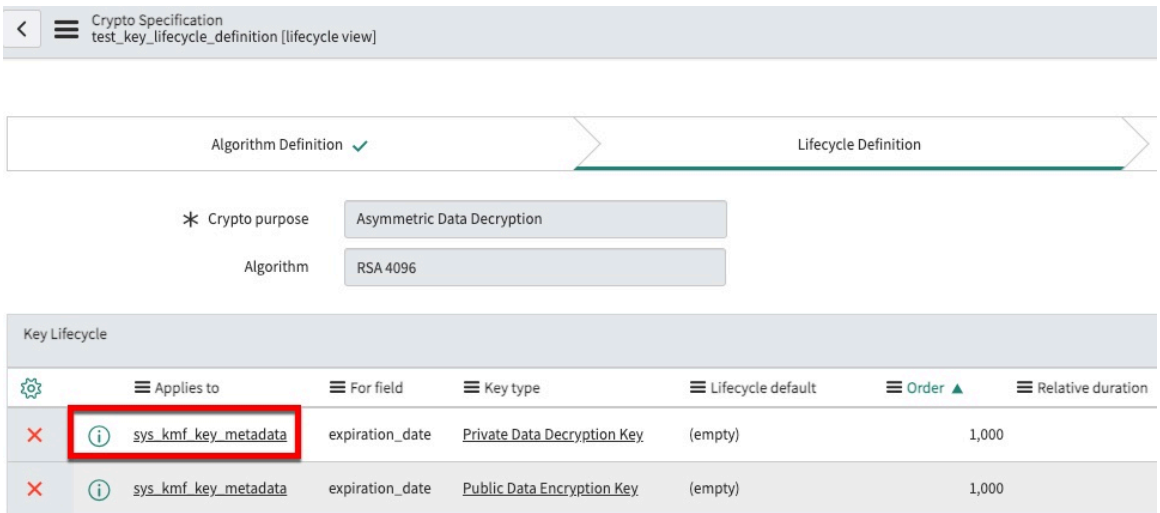
- Select an entry in the Key Lifecycle table to define key lifecycle behavior. See Configure key lifecycle states for details to complete the lifecycle definition for the key.
- Select **Next** to create a cryptographic key. See one of the following tasks for key generation:
  - Generate a ServiceNow cryptographic key.
  - Configure properties for customer-supplied keys.
  - Import the wrapping / unwrapping key pair.

Configure key lifecycle states

After you have created a cryptographic specification, you can configure the lifecycle actions for the keys in your instance.

Before you begin
Role required: sn_kmf.admin

Procedure
1. Navigate to **Key Management** > **Cryptographic Modules** > **All**.
2. Select the cryptographic module to configure the lifecycle of a key.
3. Select a key alias on the Crypto Specifications tab.



4. Select **Next**.
   The Field Lifecycle Template loads. Default Key Lifecycle values are created based on the selected algorithms for the defined cryptographic specification.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

5. Select a Key Lifecycle from the **Applies to** column on the Lifecycle Definition step for the crypto specification.

Key Lifecycle fields

Field	Description
Applies to	Selected key that the lifecycle applies to.
For field	Select the type of control for the key that the lifecycle applies to. **Key lifecycle management "For field" values** Type	Select if the valuation for the key lifecycle is a relative value or an absolute value: ○ **Relative**: Enter a value that depends on other data entries in the system, such as key generation, activation, and deactivation. ○ **Absolute**: Enter an exact value, such as a date.
Lifecycle default	Read only. Displays a value if set.
Order	Enter the sequence in which to process the key lifecycle state for the crypto specification.
Relative duration type	Duration of the lifecycle: **Years**, **Months**, or **Days**.
Relative duration	Number of years, months, or days the key is valid.
Relative operation	**Before**or **After**.
Relative to	Field the duration is relative to. Displays if a relative duration or operation is selected. 
Generate a ServiceNow cryptographic key

Follow this procedure to upload and configure a ServiceNow cryptographic key to encrypt sensitive data.

Before you begin

Role required: sn_kmf.cryptographic_manager

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

About this task

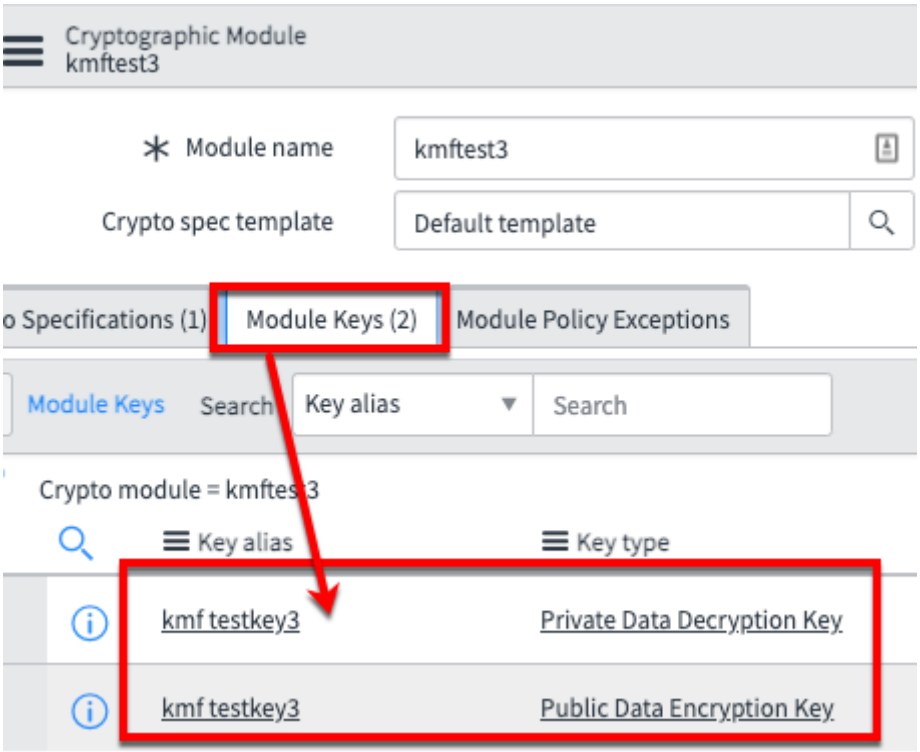
Cryptographic managers have the choice to use ServiceNow supplied keys or their own customer-supplied keys (CSK) for encryption on the ServiceNow AI Platform with Field Encryption Enterprise. For information on CSK, see Configure properties for customer-supplied keys.

Procedure

1. Set field encryption settings to use ServiceNow Generated Keys.
   See Configure field encryption settings to select key type for details.
2. Navigate to **Key Management** > **Cryptographic Modules** > **All**.
3. Select the corresponding cryptographic module to open the Cryptographic Module details page.
4. Select the row for the key alias entry on the Crypto Specifications tab.
   If a key hasn't yet been generated, the key alias field is empty.
5. Select **Next** to navigate to the Key Origin tab of the Crypto Specification components.
   The Lifecycle Definition tab displays along with the Key Lifecycle table and can be reviewed or edited. See Configure key lifecycle states for details.
6. Select **Servicenow** in the Origin

   field.
   This field varies based on the field encryption settings from Step 1 and the algorithm selected. To use an imported key, see Import the wrapping / unwrapping key pair. See Configure properties for customer-supplied keys if you're using your own key.
7. Enter a friendly name for the Key alias.
8. Select **Next** to move to the Key Creation tab.
9. Select **Generate Key**.
   After you generate the key, the Cryptographic Module form reloads displaying the cryptographic specification.
10. Select the **Module Keys** tab to view the keys.
    Secure information for the key is stored on the Module Keys tab along with the number of keys that exist for the cryptographic specification.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



11. Select a key to perform key management actions.
    See Key management actions for details.

Create a module access policy

Create module access policies to decide which users and scripts can access data encrypted by a cryptographic module.

Before you begin

Role required: sn_kmf.cryptographic_manager or sn_kmf.admin

About this task

Field Encryption supports role-based module access policies and additional configuration options become available with (CLE_Ent) functionality.

- Configure the specific cryptographic operation in module access policies for cryptographic modules that support symmetric operations. For instance, a user can be enabled to encrypt data but not decrypt data.
- Set a default module access policy value or according to a cryptographic module.
- Associate script versions where changes to the script are tracked and invalidate the script policy providing better security for script-type module access policies.

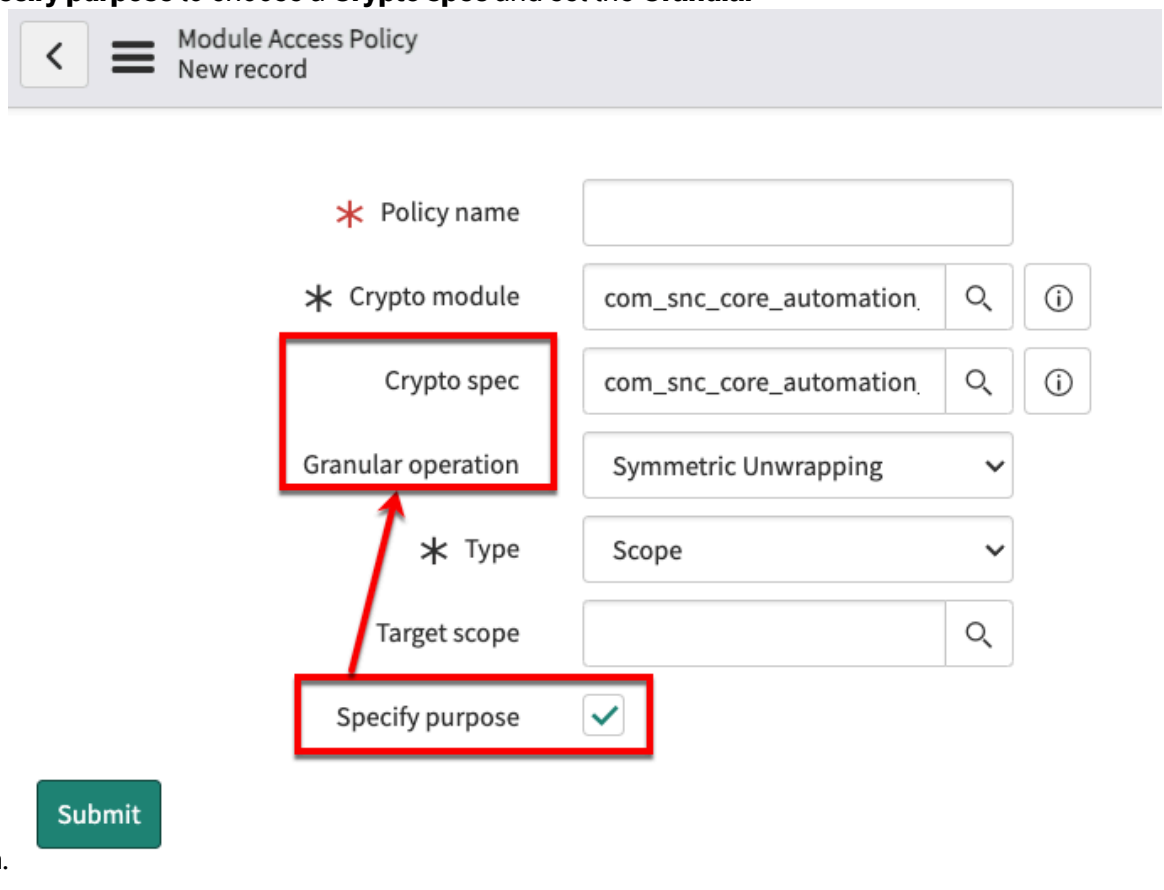
CLE_Ent functionality is available with a paid subscription. Refer to for supported features and options available with each offering. For more information, see Field Encryption Enterprise.

Note:
The default behavior of the module access policies (MAPs) is Reject to help prevent any unauthorized access, unless explicitly declared in MAP records.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Key Management** > **Module Access Policies** > **All**.
   If you don't create a cryptographic module configured for Symmetric Data Encryption/ Decryption, an auto-generated module access policy is created and listed in the table.
2. Select **New**.
   - Select **Specify purpose** to choose a **Crypto spec** and set the **Granular operation**.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- With cryptographic specifications for symmetric data encryption/decryption and symmetric wrapping/unwrapping, the **Granular operation** field is available if you select the **Specify purpose** check box.

3. Complete the form.

   Module Access Policies fields

Field	Description
Policy name	Enter a name for the policy.
Crypto module	Select the search icon ( ) to select a module.
Crypto spec	Select or create cryptographic specification while generating the module access policy. This field becomes available when the **Specify purpose** check box is selected.
Granular operation	Select the cryptographic purpose for the cryptographic specification. The values available depend upon the type of cryptographic specification that is selected. See for details on crypto purposes.
Type	○ **Scope**: Controls access by the application scope. ○ **System user**: Allows access for system users to crypto modules. ○ **Script**: Control access by script. See for more information

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	○ **Role**: Controls access by user role. ○ **Resource Exchange**: Control access using the Resource Exchange. See for more information. **Note:** Only Role type is supported with Field Encryption. All other types are available with Field Encryption Enterprise.
Target Scope	Field is visible as an identifier for the **Scope** type. Refers to the functionality for the policy. Select the applications from the search menu. **Note:** Target scope isn't supported and can only be set with Field Encryption Enterprise
Target Role	Field is visible as an identifier for the **Role** type. Role to which this policy applies.
Script Table Target Script	These fields appear when you select **Script** as the type. Field is visible as an identifier for the **Script** Type. Select a table to which this policy applies. Document to which this policy applies. Select the **Table name** and then the related document for the policy. The first time a script calls a cryptographic module, access to the module is denied, and the developer receives an error. This error gives the module owner the ability to grant or refuse access to the module.
Resource Exchange: ○ Crypto spec ○ Approval type ○ Target instance host	These options appear when you select as the type. Resource Exchange is supported by both KMF and by when the parent module is **column_level_encryption**. Select the crypto specification, One-time or Recurring, and the URL of the target instance. See for more information.
Impersonation	In role-based module access policies, users can access encrypted data using an impersonation session. When users, such as admins, impersonate other users, such impersonation-enabled module access policies are applied.
Specify purpose	Select to toggle the Cryptographic specification field as an available field for the policy.
Active	Select to activate the policy.
Result	Select one of the following:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	○ **StrictReject** rejects access under all circumstances. ○ **Reject** rejects users with the **Target Role** or **Target Scope** from accessing this cryptographic module unless another policy grants them access. ○ **Track** to permit access and monitor use of the module.

4. Select **Submit**.

Warning:

For legacy encryption support users:

If you're using the non-enterprise version of Field Encryption, you're limited to five modules. If you have exceeded this limit, you receive the following warning:

This insertion exceeds the number of published modules allowed for Field Encryption entitled with the subscription product. The Enterprise subscription for Field Encryption is required for additional modules. Please reach out to your Account team.

5. Select the policy name associated with the cryptographic module that you want to examine. Using Script type module access policy:

   A module access policy is auto-generated based on the default access setting when the script is run. The module name is preceded with `AutoGen-`. For example, the `Module-TestPolicy` module is listed as `AutoGen-Module-TestPolicy` in the Policy name column.

   The Cryptographic Caller Policy form lists the caller policy that you selected. The Target Scope field specifies the scope of the script attempting to use the module. See for additional information.

   Note:
   A maximum of five module access policies are permitted with Field Encryption. See for configuration options.

Create a granular role module access policy for symmetric encryption

Create a granular role module access policy (MAP) to secure data while permitting users not assigned to a specific MAP to submit forms on a public record.

Before you begin

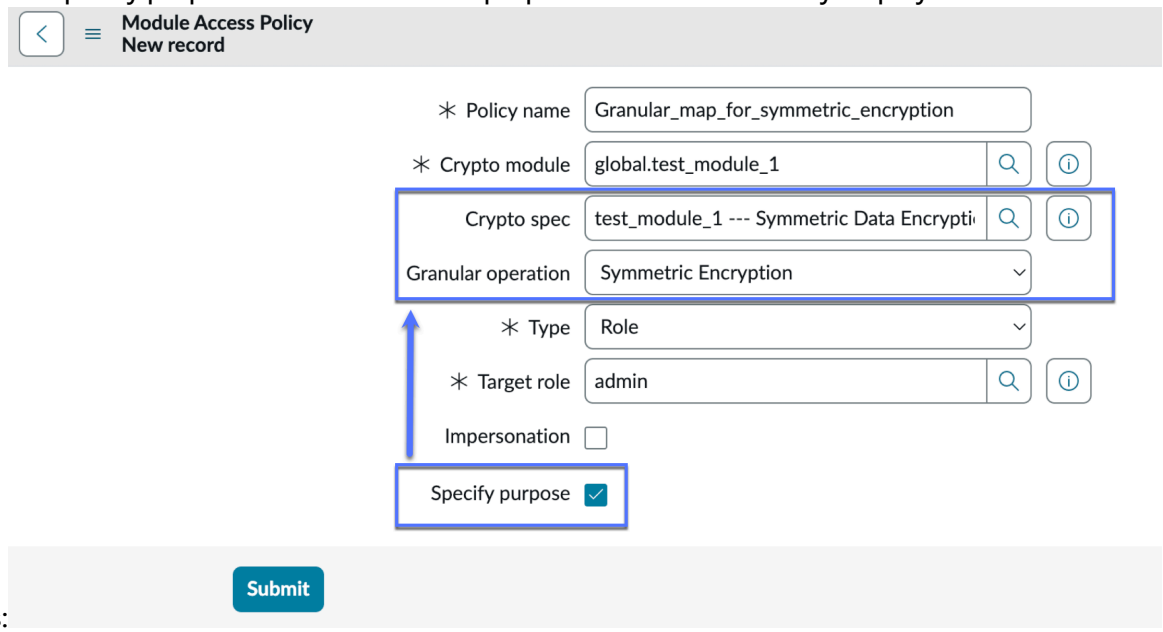
Role required: security_admin

Procedure

1. Navigate to **All** > **Key Management** > **Module Access Policies** > **All**.
2. Select **New**.
3. Enter a name for the policy.
4. Select the **Crypto module** that you'll be granting access to.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

5. Select the appropriate **Target role**.
6. Select the Specify purpose box and enter the purpose details in the newly displayed fields as follows:



- **Crypto spec**: Select the crypto spec to be used.
- **Granular operation**: Select Symmetric Encryption from the drop-down list.

7. Select the **Active** box.
8. For **Result** select **Track**.

Result

The granular role MAP enables a user that is not assigned to a MAP to submit public record forms while securing data.

Create a cryptographic module life-cycle policy

Create a cryptographic module life-cycle policy to place limits on cryptographic modules, such as how long the key is good for. Create policies to safeguard cryptographic modules by limiting their exposure.

Before you begin

Role required: sn_kmf.cryptographic_manager

About this task

A cryptographic module life-cycle policy is an instance-level policy. The more exposure that a cryptographic key has, the more likely it can be compromised. Safeguard keys by limiting how long the keys can be used and who can use them.

The following features govern cryptographic modules:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Instance policies set boundaries for the instance. For example, if you specify in an instance policy that the expiration date should never be more than two years after the activation date, you can't use the life-cycle rules to set an expiration date five years after the activation date.

- Instance life-cycle templates enable you to set different policies for different keys. Templates offer default life-cycle rules for cryptographic modules so that they don't have to be re-created for every module. For example, you can set different expiration dates for symmetric data encryption keys than for public key wrapping keys.

- Life-cycle rules affect the keys directly. For example, if you specify in the life-cycle rules that the expiration date should be two years after the activation date, keys will expire two years after the activation date.

Procedure

1. Navigate to **All** > **Key Management** > **Lifecycle Policies** > **Instance Policies**.
2. Select **New**.
3. Complete the form.

   Cryptographic Life-cycle Policies fields

Field	Description
Applies to	Read only. The key that the life cycle applies to.
Active	Select to activate the policy.
Policy condition	Conditional statements that specify when to activate, renew, deactivate, and destroy the cryptographic module.
Result	**Reject** to revoke access to the cryptographic module, or **Track** to permit access and monitor use of the cryptographic module.

What to do next

If you want to add exceptions to this life-cycle policy at the module level, see Create module life-cycle policy exceptions.

Create module life-cycle policy exceptions

Create a module policy exception to change the life-cycle policy of a key only for a specific on one instance.

Before you begin

Role required: sn_kmf.cryptographic_manager and sn_kmf.admin

Exceptions apply only to that module and not to the entire instance. For example, an administrator configured symmetric keys to be limited to one year at the instance level. An exception can be made at the module level to be two years.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Key Management** > **Cryptographic Modules All**.
2. Select the cryptographic module that will use the policy exceptions.
3. In the Cryptographic Module table, select the **Module Policy Exceptions** tab.
4. Select **New**.
5. Complete the form.

Module Policy Exceptions fields

Field	Description
Crypto Module	Name of the module selected. This field is read only.
Applies to	Specified key is auto-populated.
Key Type	Key type that the exception policies are related to. **Note:** You may only select a single key type, but multiple exception policies can be created per cryptographic module.
Policy condition	Customizable condition which determines when the policy exception applies.
Result	The result that occurs when the condition in the **Policy Condition** field is met. ○ **Reject** rejects usage of the key. ○ **Track** allows the key to be used.

6. Select **Submit** to be returned to the Cryptographic Module table.

Key Management Framework Reference

The Key Management Framework (KMF) API/UX lets you fully customize and manage how cryptographic operations are performed on your ServiceNow instance. The ServiceNow Key Management Framework provides a secure and comprehensive interface for instance-side cryptographic key management services.

Key Management Framework key life-cycle states

KMF supports several cryptographic key life-cycle states through the enforcement of specific allowable actions. For example, only keys that are in the active state can be used fully for their intended cryptographic purpose. The following table provides further detail on the varying key life-cycle states.

Roles installed with Key Management Framework

The Key Management Framework (KMF) introduces specific roles for cryptographic module and key management-related configurations.

Module access policy visualization

Use module access policy visualization to view all relevant cryptographic module information on a single UI page.

Module access policy debugger

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Use the module access policy debugger to review logging information and understand why your users are or aren't granted access to an encryption context.

Encryption and Key Management subscription bundle

With key management, Field Encryption is upgraded at no additional charge to the highly configurable encryption modules. You also have the option to upgrade to the unlimited-use license. Subscribe to the new encryption entitlement bundle, Platform Encryption, which includes Field Encryption Enterprise and Cloud Encryption.

Key Management Framework key life-cycle states

KMF supports several cryptographic key life-cycle states through the enforcement of specific allowable actions. For example, only keys that are in the active state can be used fully for their intended cryptographic purpose. The following table provides further detail on the varying key life-cycle states.

Key life-cycle state or action	Description
Active	The active key is used to generate new content, such as encrypting or signing. There can be only one active key for a given cryptographic specification in a cryptographic module.
Compromised	Compromised keys can't be used to generate new content, such as encrypting or signing, but may still be used to identify the purpose of existing content, such as decryption or verification. Several keys can exist in the compromised state for revocation in a given cryptographic specification in a cryptographic module. Any active or suspended key can be moved to a compromised state.
Deactivated	Any active key can be deactivated. There could be several keys in a deactivated state for a given cryptographic specification in a cryptographic module. For example, when the key is rotated, the current active key is deactivated. Deactivated keys cannot be used to generate new content, such as encrypting and signing, but may still be used to identify purposes of existing content, such as decryption or verification. **Note:** Compromised and revoked keys are treated as deactivated keys.
Destroyed	When a key is destroyed key material is permanently removed and can no longer be used for any cryptographic purpose. Any deactivated key can be destroyed using lifecycle automation when it hasn't been used in the configured designated time frame. There could be several keys in a destroyed state for a given cryptographic specification in a cryptographic module. **Warning:** Data associated with a destroyed key can no longer be accessed, therefore extreme caution should be exercised when performing a destroy key action.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Key life-cycle state or action	Description
Generated	Multiple keys can exist in the generated state for a given cryptographic specification in a cryptographic module. A generated key can be moved to an active state when no active key exists for the given cryptographic specification. The first key generated is automatically set to active. **Note:** If the choice is to generate a new key, then a new key is generated and made active even though there are keys in a generated state for the given cryptographic specification.
Renewed	An active key that has an expiration date can be renewed any number of times to extend the life-cycle period of the key. **Note:** The difference between the activation date and expiration date is calculated and the expiration date is postponed by that duration from the current day.
Resume	The UI action is available on suspended keys to move them back to an active state when no other active key exists for the given cryptographic specification.
Revoked	Any active or suspended key can be moved to the revoked state. Revoked keys can't be used to generate new content, such as encrypting or signing, but may still be used to identify the purpose of existing content, such as for decryption or verification. Several keys in a revoked state may exist for a given cryptographic specification in a cryptographic module.
Rotated	Key rotation results in deactivating the current active key and making another key active. Select the new active key from the following: • Generation of a new key. • Point to an existing imported key. Any active key can be rotated.
Suspended	There could be several keys in the suspended state for a given cryptographic specification in a cryptographic module. When the key is suspended, the key can be resumed and reassigned to an active state when no other active key exists for that cryptographic specification.

Roles installed with Key Management Framework

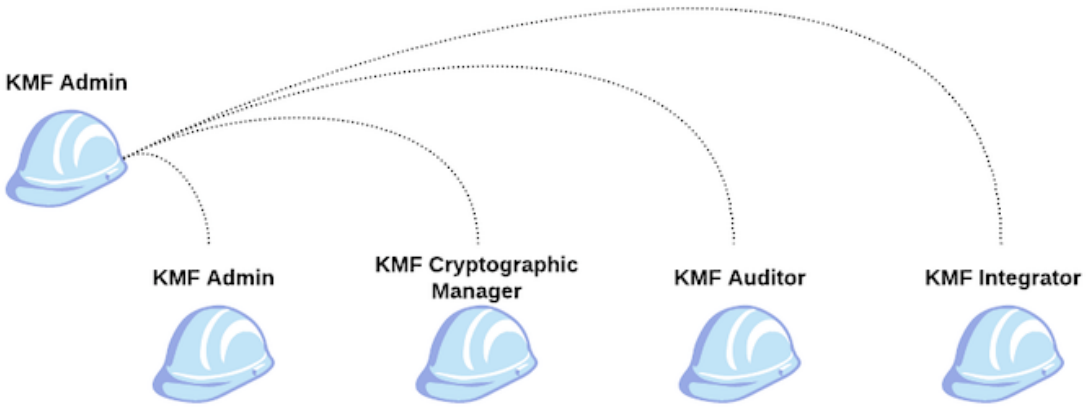
The Key Management Framework (KMF) introduces specific roles for cryptographic module and key management-related configurations.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Important:

KMF roles are required to use the Key Management Framework. Users without KMF roles are not be able to access lists, tables and modules used to configure key management.

To assign the KMF admin role, you must have the admin, security_admin, and sn_kmf_admin roles. Use the KMF admin role to assign other KMF roles. For details on assigning KMF roles, see Assign Key Management Framework roles.



KMF admin [sn_kmf.admin]

Assigns roles to other users to perform operations around the ServiceNow Key Management Framework.

Contains Roles

List of roles contained within the role.

None.

Groups

List of groups this role is assigned to by default.

None.

Special considerations

Important:
Avoid granting an admin role when more specialized roles are available.

- This role is assigned via the process shown in Assign Key Management Framework roles.
- Users with this role must also have the admin and security_admin
- You must have this role to assign#KMF roles, and in addition can perform all the capabilities of the KMF cryptographic manager.

KMF cryptographic manager [sn_kmf.cryptographic_manager]

Create, read, and update operations on cryptographic modules (association of keys to cryptographic usage and algorithm configurations) and module access policies. Also, KMF cryptographic managers can perform key management (generate, rotate, revoke) and life cycle operations.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Contains Roles

List of roles contained within the role.

None.

Groups

List of groups this role is assigned to by default.

None.

Special considerations

This role can only be assigned to a user by a KMF admin.

KMF cryptographic auditor [sn_kmf.cryptographic_auditor]

View cryptographic module information, key metadata, and life cycle-related details, as well as module access policy (MAP) information.

Contains Roles

List of roles contained within the role.

None.

Groups

List of groups this role is assigned to by default.

None.

Special considerations

This role can only be assigned to a user by a KMF admin.

KMF cryptographic integrator [sn_kmf.cryptographic_integrator]

Integrate Key Management Framework with external keystores or systems.

Contains Roles

List of roles contained within the role.

None.

Groups

List of groups this role is assigned to by default.

None.

Special considerations

This role can only be assigned to a user by a KMF admin.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

KMF cryptographic operator [sn_kmf.cryptographic_operator]

Access part of the ServiceNow Key Management Framework key lifecycle: renewal, rotation, revocation.

Contains Roles

List of roles contained within the role.

None.

Groups

List of groups this role is assigned to by default.

None.

Special considerations

None.

Assign KMF roles

Assign KMF roles to admins, who in turn can assign other KMF roles.

Before you begin

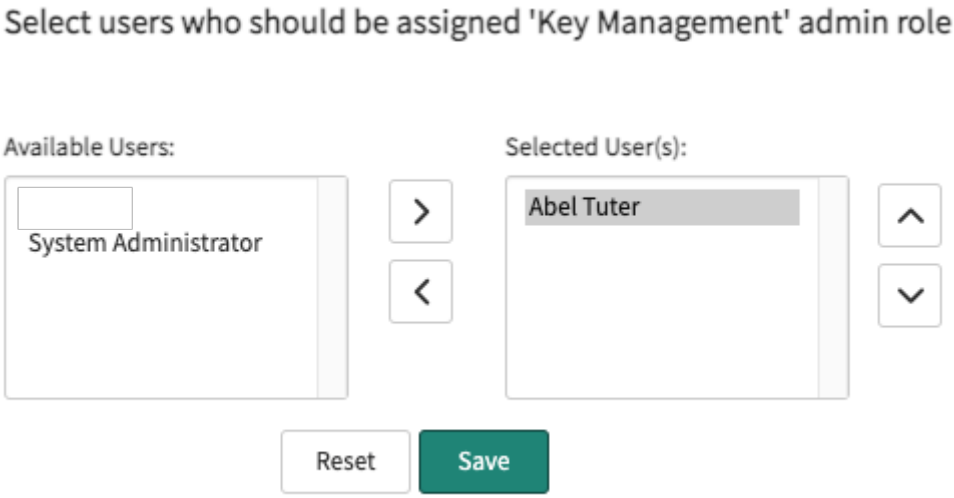
Role required: admin and security_admin

You must elevate to the security_admin role before assigning the KMF admin role. For instructions, see Elevate to a privileged role

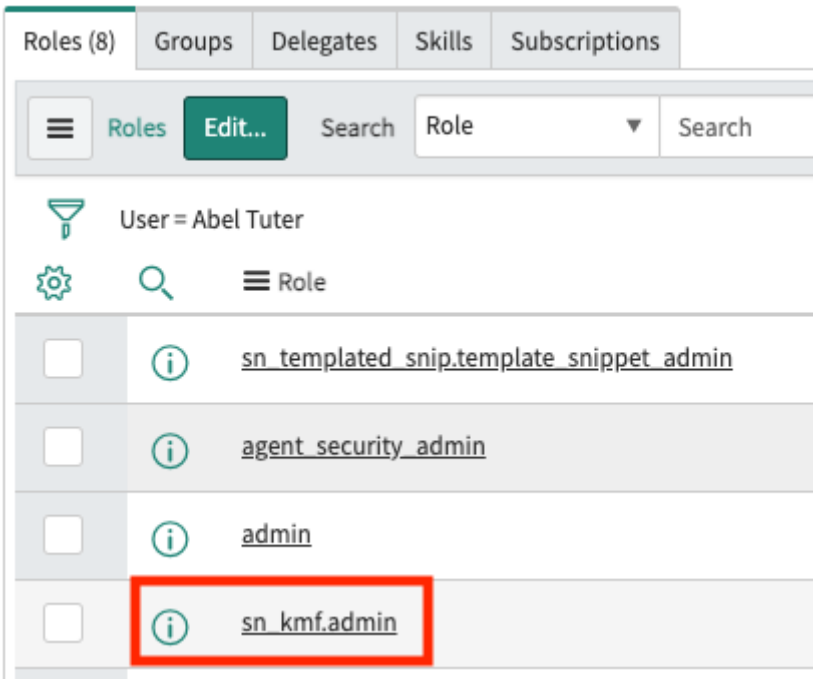
Procedure

1. Elevate to the security admin role.
2. Navigate to **User Administration** > **Users** and select the user you want to be the KMF admin.
3. Verify that the user already has the admin and security_admin roles.
   If not, select **Edit** under the Roles related list and add **admin** and **security _admin**.
4. Navigate to **System Security** > **Key Management Administration**.
5. Select the user that you want to be KMF admin in the **Available Users** column and move them to the **Selected User(s)** column.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



6. Select **Save**.
7. Navigate to **User Administration** > **Users** and select the user you just gave the sn_kmf.admin role to.
   The user has the sn_kmf.admin role in the **Roles** related list, and can assign other KMF roles.

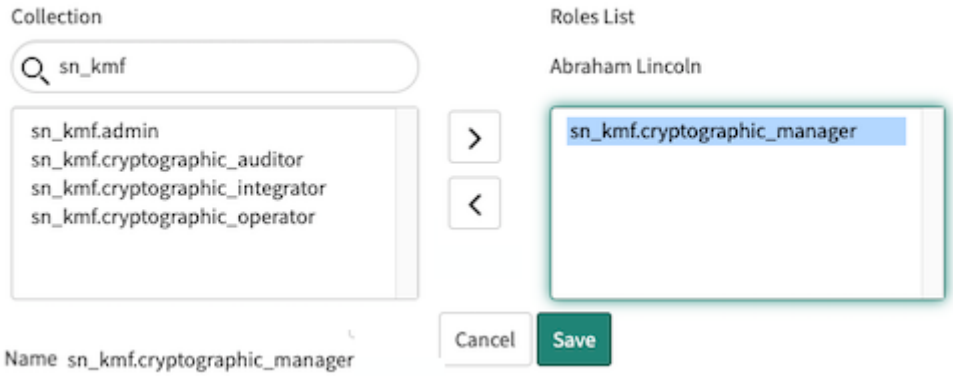


What to do next

If you have the KMF admin role, follow these steps for assigning other KMF roles:

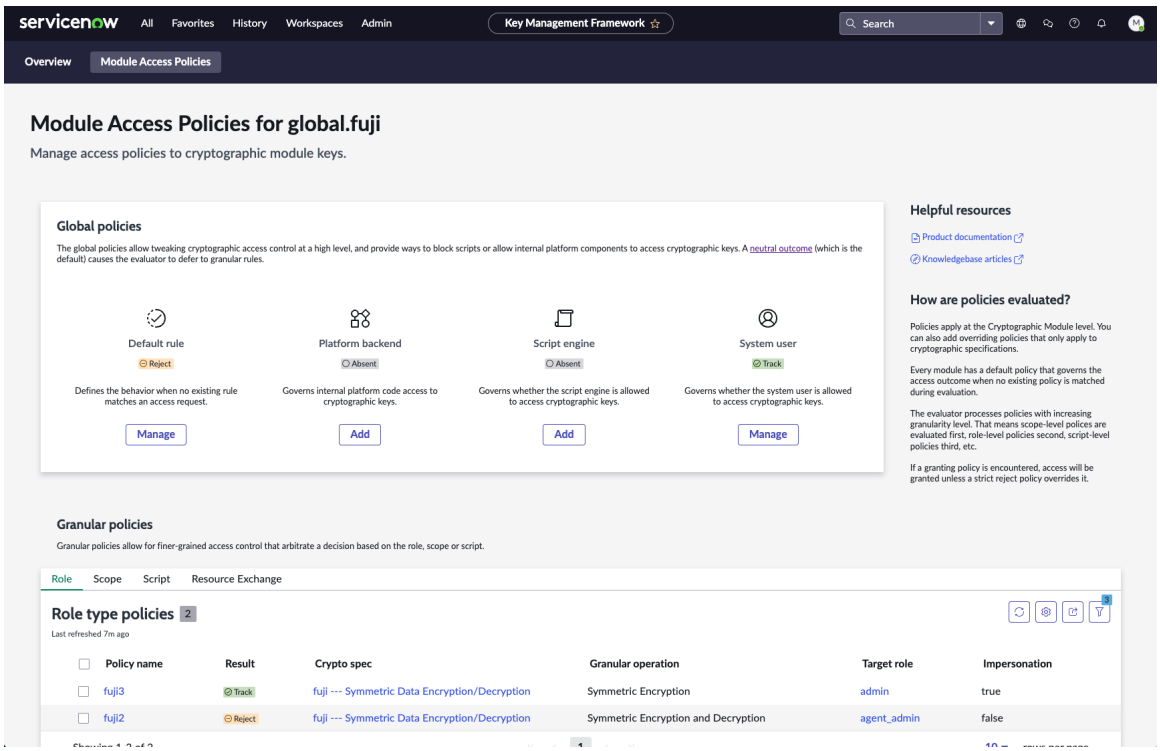
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

1. Navigate to **User Administration** > **Users** and select the user you want to have another KMF role, such as KMF Cryptographic Manager.
2. In the Roles related list, select **Edit** and select the KMF roles you want to assign the users. All KMF roles start with `sn_kmf`.



Module access policy visualization

Use module access policy visualization to view all relevant cryptographic module information on a single UI page.



Key Management Framework admins and cryptographic managers can use the module access policy UI page to view all access control mechanisms related to a single cryptographic module. Use the information collected on this UI page to determine who has access to encrypted information on your instance.

Users with the *`sn_kmf.admin`* or *`sn_kmf.cryptographic_manager`* roles can access the module access policy visualization UI page by navigating to **All** > **Key Management** > **Cryptographic Modules** > **All**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Results Labels

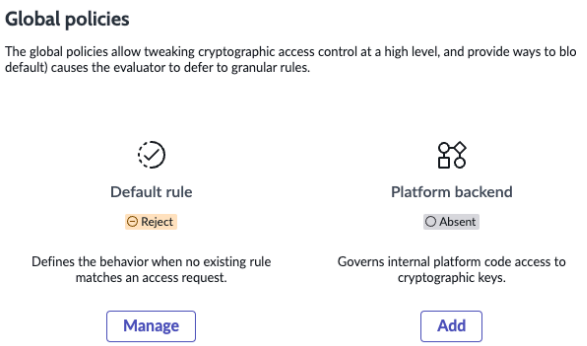
Module access policies contain a **Result** field, which determines whether to grant access to the selected cryptographic module. The UI page displays a label on elements on the UI page based on the value of that field.

UI label	Result field value	Definition
	Track or *Allow*	Access is granted to all users, including scripts.
	Reject	Access is denied unless a track module access policy is found.
	StrictReject	Access is denied.
	*N/A*	The module access policy doesn't exist on the instance. Access is denied to all.

Global policies

Use the **Global policies** section to review the module access policies that control platform-level access.

Select the **Manage** button below any of the policies to navigate to that policy record. If the policy doesn't exist, an **Add** button appears below that entry. Select the **Add** button to navigate to a new policy record where you can define the policy.



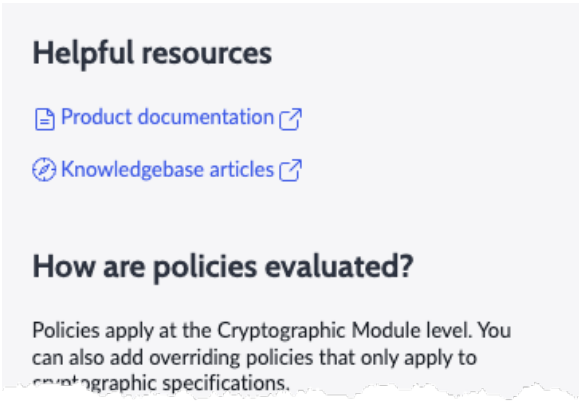
Policy	Definition
Default rule	The default rule policy defines the behavior when no existing rule matches an access request.
Platform backend	The platform backend policy governs internal platform code access to cryptographic keys.
Script engine	The script engine policy governs whether the script engine is permitted to access cryptographic keys.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Policy	Definition
System user	The system user policy governs whether the system user is permitted to access cryptographic keys.

Helpful resources

Use the **Helpful resources** section to find links to product documentation, relevant knowledge articles, and a brief description on how module access policies are evaluated on the platform. For a deeper look into how module access policies are evaluated, see Module access policy debugger.

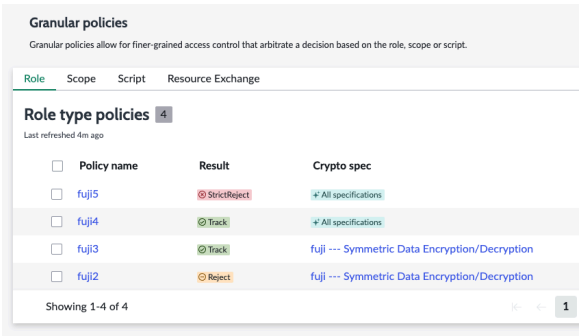


Granular policies

Use the **Granular policies** section to view lists of module access policies, separated by policy type. Use the tabs above the list to select a policy category to display.

- Role
- Scope
- Scope and Domain (if Domain Separation is active)
- Script
- Resource exchange (if the cryptographic module is a Password2 or Field Encryption submodule)
- Identity (if Secrets Management Enterprise is active)

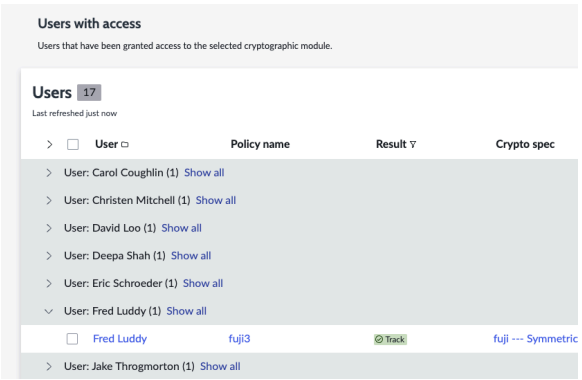
By default, the each list displays only active policies. Use the filter icon to change the default filter for the list.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Users with access

Use the **Users with access** section to see a list of all users that have access to the selected cryptographic module. The list is grouped by user, as single users can posses multiple roles that grant access to a cryptographic module.

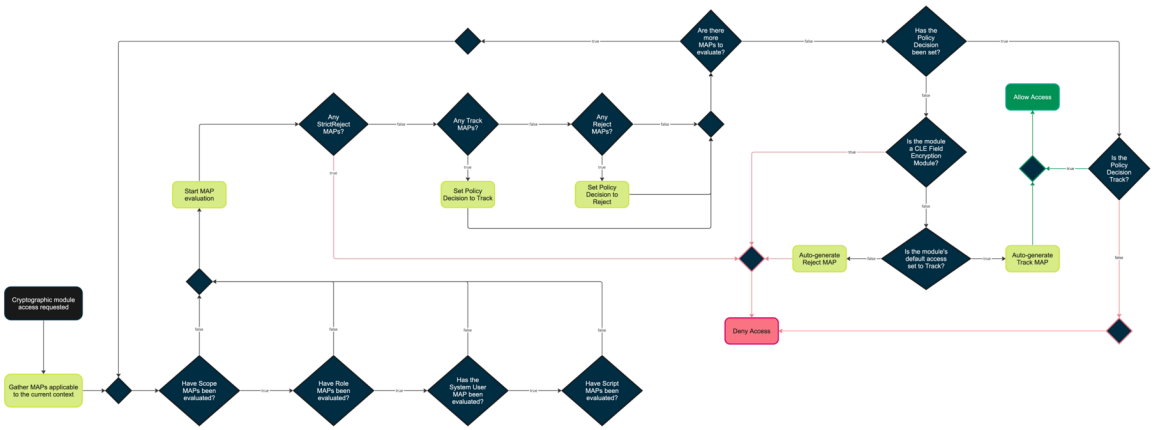


Module access policy debugger

Use the module access policy debugger to review logging information and understand why your users are or aren't granted access to an encryption context.

Module access policies (MAPs) define instance-level controls for access to cryptographic modules. Callers (for example, a user or script) require explicit access to use a cryptographic module for encryption and decryption. Use the debugger to see which policies are evaluated when a caller attempts to access a cryptographic module. You can also use the debugger and learn why access is or isn't being granted.

This flowchart shows how your instance evaluates requests for access to a cryptographic module.



Control access to the debug logs

Access to the module access debug logs is determined by role. Users with the *sn_kmf.admin* and *sn_kmf.cryptographic_manager* roles have access to the debugger. Grant access to other roles using the *glide.kmf.module_access_policies.debugger.authorized.roles* system property. The value of this property is a comma-separated list of roles that access the debug logs.

Enable or disable the debugger

To enable debug logging messages for module access policies, navigate to **All** > **Diagnostics** > **Session Debug** > **Debug Module Access Policies** > **.**

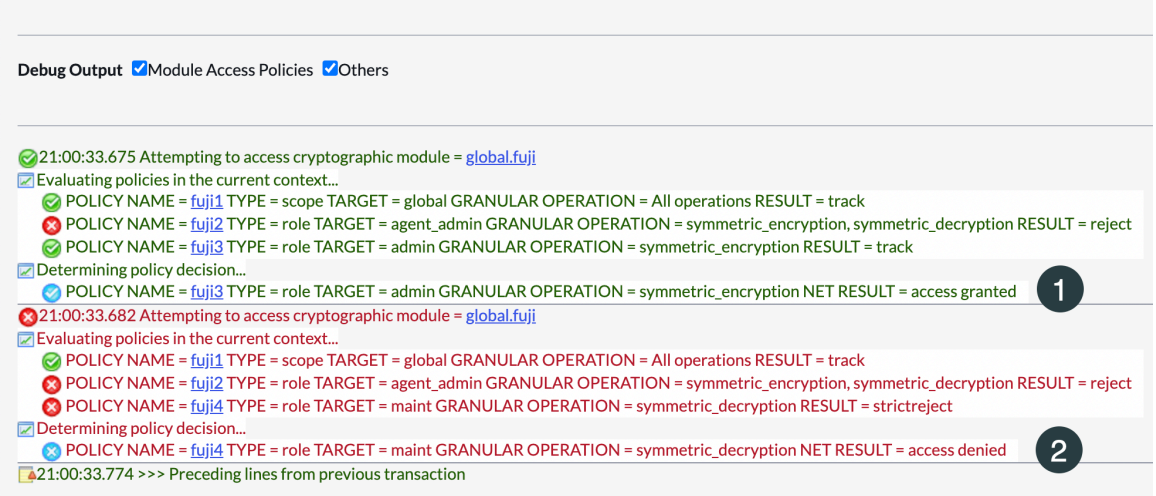
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

When you're finished debugging, you can disable the logging messages by navigating to **All** > **Diagnostics** > **Session Debug** > **Disable All** > **.**

Access the logs

After enabling debugging, navigate to a page that triggers a MAP evaluation to view the MAP debug logs. Debug messages appear at the bottom of the page.

Tip:
You can use impersonation to troubleshoot access for other users. For details on impersonation, see Impersonating users. To view the debug logs from the perspective of another user, make sure that your module access policies with the *role* type have the **Impersonation** field set as **true**.



In this example, a caller invokes two access requests to the `global.fuji` cryptographic module. A symmetric encryption, which is granted, and a symmetric decryption, which was denied.

Understanding log entries

Debugging information is structured using this format.

1. This first line displays the cryptographic module receiving the access request.
2. The lines between the first and last line displays the evaluated MAPs in the order that they were evaluated, and includes their name, type, target, granular operation, and result.
3. The last line displays the Policy Decision (if applicable) and the net access result for the caller (whether the caller is granted access).

Each line starts with an icon that indicates its message type.

Message icons

Icon	Message type
	Informational message
	Module access policy grants access
	Module access policy denies access

Additional information

To learn more about key management, see Exploring the Key Management FrameworkExploring the Key Management Framework.

Key management actions

One of the core features of KMF is to provide the capability to manage keys, such as revoking or rotating keys. KMF properly secures sensitive data with the most up-to-date encryption materials and life cycle operations.

The following table provides a summary of the key life cycle operations and management actions. The cryptographic module purpose is applied to the data with the cryptographic module configuration and has no impact on data.

Key management action	Description
Generate key	Generates a new key for the given cryptographic module. A first generated key is set to *active*.
Rotate key	Deactivates the current key and generates a new one. The new module key is set to current (active).
Revoke key	Marks the current key and life cycle state as revoked. The cryptographic module auto-generates a new key on new data and sets the key status to active. Revoked means that the key is no longer used for encryption. However, it can still be used for decryption. You can't destroy a key.
Suspend key	Marks the current key as suspended. Manually resume the suspended key or revoke the suspended key to generate a new module key before using the cryptographic module again.
Resume key	Marks a suspended key as the active key.
Renew key	Extends the life of the current key. The **Renew** button becomes available under the following circumstances: • You're assigned the cryptographic manager role. • The life-cycle state is marked to either **Active** or **Renewed**. • An expiration date is set in the module life cycle definition.

View and manage keys

Review the status of any key to determine further key action, such as when to renew, rotate, suspend, deactivate, or destroy a current key.

Before you begin

Role required: sn_kmf.cryptographic_manager

Procedure

1. Navigate to **All** > **Key Management** > **Cryptographic Modules** > **All**.
2. Select a cryptographic module.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The Cryptographic Module <module-name> form appears.

3. On the Module Keys tab, select the key alias to review the key status on the life cycle <key name> form.
4. Review the form, as all fields are read-only.

Cryptographic life cycle Key fields

Field	Description
Generation date	Displays the date when the key was generated.
Activation date	Displays the date when the key was activated.
Last renewal date	Displays the date when the key was last renewed.
Last rotated date	Displays the date when the key was last rotated.
Deactivation date	Displays the date when the key was deactivated.
Destruction date	Displays the date when the key was destroyed.
Key life-cycle state	Displays the key life-cycle state.
Future activation date	Displays the future key activation date.
Future renewal date	Displays the future key renewal date.
Future rotation date	Displays the future date for key rotation.
Future destruction date	Displays the future date when the key is destroyed.
Expiration date	Displays the date when the key expires.

5. To perform an action on the key, select one of the following to take effect immediately:

Note:
These actions can only be performed for custom Cryptographic Modules, not for base system Cryptographic Modules.

- **Revoke Key**: Select to deactivate the key and generate a new key. Enter the reason why you're revoking the key.
- **Rotate Key**: Select to deactivate the current key and to generate a new key in its place. The new key is listed in the Module Key table and the Key Version number increments by 1. See for details.
- **Suspend Key**: Select to deactivate the current key.
- **Resume Key**: Select to mark a suspended key as the active key. This option is only available after the active key has been suspended.

Rotate keys

For increased security, you can rotate your cryptographic keys on a pre-determined schedule. Key rotation is when you retire an encryption key and replace that old key by generating a new cryptographic key.

Before you begin

Role required: sn_kmf.cryptographic_manager

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

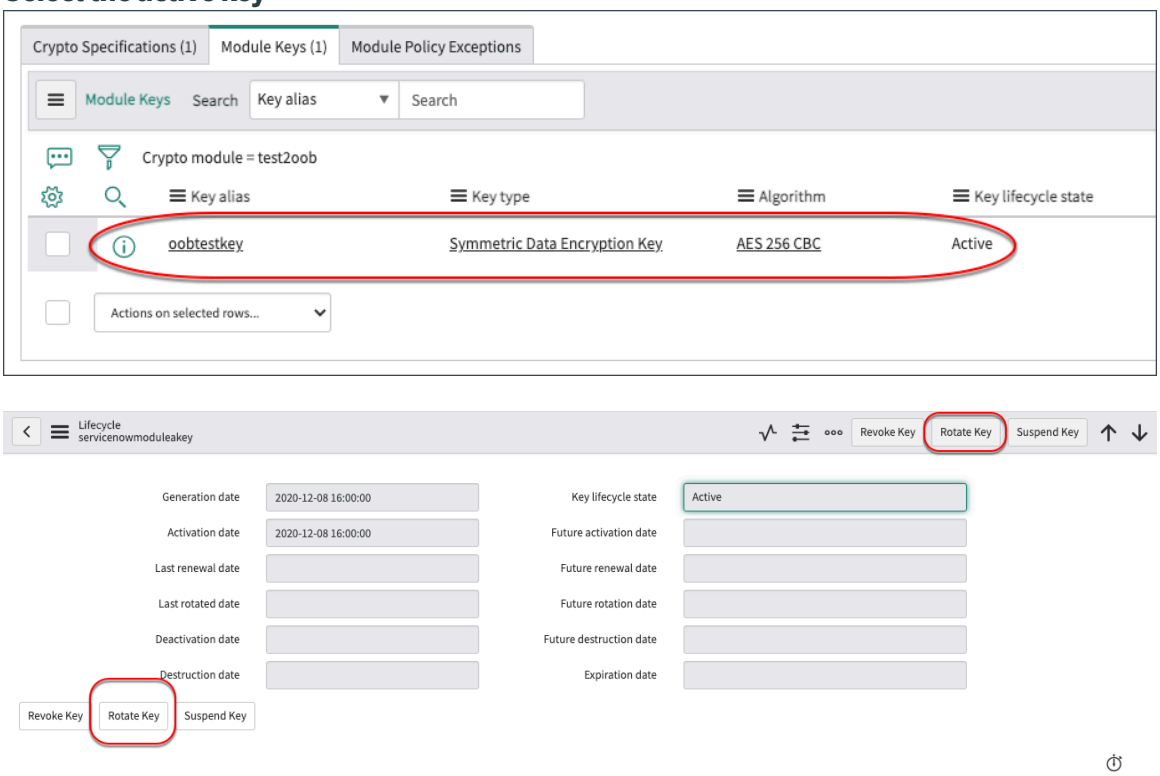
About this task

Encryption modules, unlike encryption contexts, support a rekey of records for re-encryption with a new key. The following demonstrates how to perform a key rotation operation manually on a cryptographic module.

Procedure

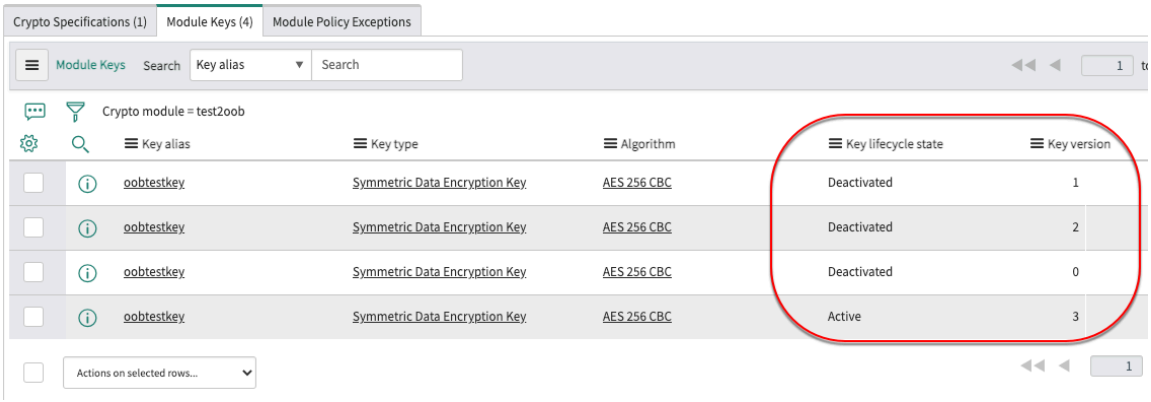
1. Navigate to **Key Management** > **Cryptographic Modules** > **All**.
2. Select the cryptographic module for key rotation.
3. On the **Module Keys** tab, select the Active key.

Select the active key



4. Select **Rotate Key**.
   The key life-cycle state changes to "Deactivated." The **Last rotated date**, **Deactivation date**, and **Key version** fields update.
5. Return to **Cryptographic Module** > **Module Keys**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



There's an extra module key listed in the table. The newly rotated key becomes "Active" and the last key is "Deactivated."

Import a key from a web service

Securely upload an external customer key onto your instance using import a key from a web service (for example the key REST API). Both symmetric and asymmetric public keys can be imported into a targeted KMF cryptographic module.

The key to be imported (the target key) must be encrypted with a wrapping key before it's uploaded into the instance's target cryptographic module. This wrapping key is the public component of a public/private key pair, which must be present on the instance. The key is a pre-requisite before the wrapped target key can be uploaded via Import From Web Services.

These two separate procedures (importing the wrapping key pair and importing the wrapped target key from a web service) are detailed in the following documentation. This key pair must be generated and uploaded to be available in the instance's internal Key Import cryptographic module.

Note:
This example uses OpenSSL for key and certificate generation and the Postman API test tool to show REST API use. Substitute other comparable tools based on your company requirements.

Import the wrapping / unwrapping key pair

Configure Key Management Framework import settings before importing a key.

Before you begin
Role required: sn_kmf.cryptographic_manager

About this task
This example uses OpenSSL for key and certificate generation. Substitute other comparable tools based on your company requirements.

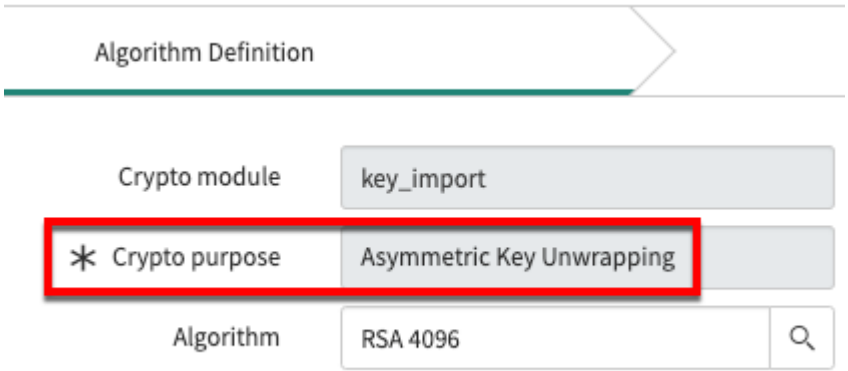
Procedure

1. In your local environment, use the terminal to create a certificate.
   For example: `openssl req -x509 -sha256 -nodes -days 365 -newkey rsa:4096 -keyout wrapping_private.key -out wrapping_public.crt`

   This certificate is a public component that contains a key. The certificate is used to wrap an AES symmetric key.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

2. In your local environment, use the terminal to create a keystore containing public cert (with the wrapping key), and private unwrapping key.
   For example:`openssl pkcs12 -export -in wrapping_public.crt -inkey wrapping_private.key -name "wrapping_key_alias" -out wrapping_keystore.p12`
3. On your instance, navigate to **All** > **Key Management** > **Import Settings** > **Key Import Settings**.
4. In the Algorithm Definition section, verify the **Crypto Purpose** is set to *`Asymmetric Key Unwrapping`*.



5. Select an appropriate algorithm that aligns with asymmetric key material for the imported keystore.
   See Cryptographic specification overview for additional information.
6. Select **Next**.
7. In the **Lifecycle Definition** section, select **Next** to continue.
8. In the **Key Origin** section, select either **Import from PKCS12** or **Import from BCFKS** in the **Origin** field.

   Note:
   If using the example keystore from step 1, select **Import from PKCS12**.

9. Enter a **Key Alias** to identify the key.
   This alias should match the key alias (or "friendly name") that was specified when generating the certificate or keystore to be uploaded. Continuing the example above, this would be `wrapping_key_alias`.
10. Select **Next**.
    The **Key Creation** section includes an **Import Key** link, which displays a dialog to upload the keystore. Continuing the example, this would be `wrapping_keystore.p12`.

Import a wrapped key from a web service

Upload your wrapped key into a cryptographic module using the import key from web service functionality. The example uses a symmetric key. Similar steps can be used to import an asymmetric key.

Before you begin

Role required: sn_kmf.cryptographic_manager (module configuration), sn_kmf.cryptographic_operator (REST operation basic authentication)

About this task

KMF Import key endpoint access is required to complete the key import process.

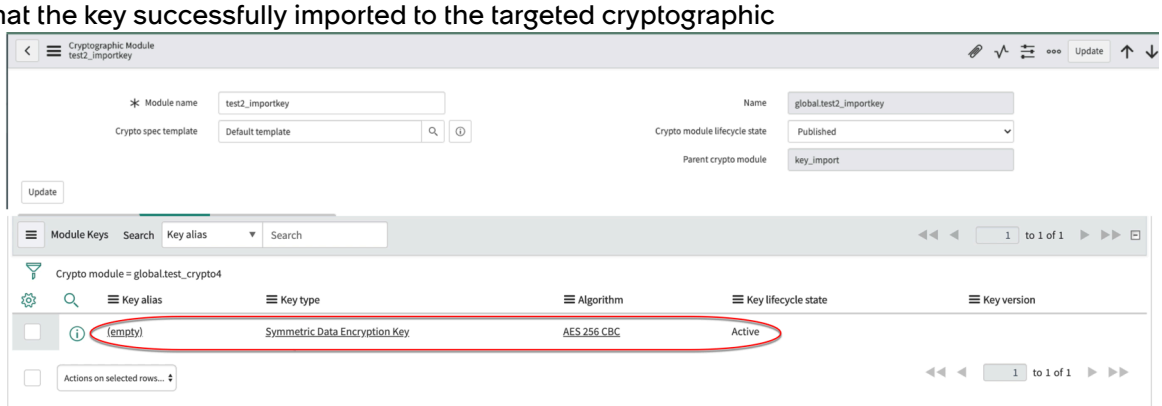
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

This example uses OpenSSL to generate keys and certificates. You may substitute other comparable tools based on your requirements.

Procedure

1. Using the terminal on your local device, wrap your symmetric key using the Key Import module public key wrapping key.
   For example: `openssl pkeyutl -encrypt -pubin -inkey public_wrapping_key.pem -in symmetric_key.bin -pkeyopt rsa_padding_mode:oaep -pkeyopt rsa_oaep_md:sha256 -out wrapped_symmetric_key.txt`
   This example creates a wrapped key file named `wrapped_symmetric_key.txt`.
2. Create a cryptographic module to be tied to the API.
   See or for additional information.
3. Add a cryptographic specification with the following selections.
   - **Crypto Purpose**: *Symmetric Data Encryption/Decryption*.
   - **Key Origin**: *Import from web service*

   
   See or for more information.
4. Execute an *HTTP POST request* to the import from a web service REST endpoint.
   Successful import of the public key results in an HTTP response message with *Status 200*.
5. Verify that the key successfully imported to the targeted cryptographic module.

Key Management Framework Health

Access on-demand health status information for the Key Management Framework. Warning and malfunction errors contain a detailed message.

Before you begin

Role required: sn_kmf_admin and either sn_kmf.cryptographic_auditor or sn_kmf.cryptographic_manager

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

About this task

Each component of the Key Management Framework is outlined and reports the following statuses and colors:

- Green/Operational: The component is operational, no errors to report.
- Gray/Disabled: The component is inactive, therefore no health check is performed.
- Yellow/Degraded: Warning, the component is working, but delays/transient issues are susceptible to occur.
- Red/Malfunction: A fatal error is preventing the component from operating, which is likely to cause partial outages.

Components can include subcomponents with individual reports and their own health status impacts the parent as follows:

- If all subcomponents are inactive, the parent shows as inactive. Inactive subcomponents don't impact the health of their parents.
- If one or more subcomponents is degraded or malfunctioned, the parent health shows as degraded.
- If all subcomponents report as malfunctioned, then the parent also reports as malfunctioned.

For additional information on subcomponents, see Instance level keys in the Key Management Framework.

Note:
Health checks run every 15 seconds. Refresh the health page to rerun the report.

Procedure

1. Navigate to **All** > **Key Management** > > **Diagnostics**.
2. Review the following health status information:

Diagnostic Information

Category	Details
Key Secure	Checks if encryption is being attempted.
File Key Store	Checks if an Instance Root Key (IRK) fetch attempt is occurring. **Note:** The File Key Store is an offline alternative to Key Secure used for on-premise instances and developer instances.
GlideEncrypter	Checks if a GlideEncrypter instance-level cryptographic module, specification, and key are present. **Note:** GlideEncrypter is a scriptable component that enables transparent encryption of Password2 fields and other legacy encryption usages through the Key Management Framework.
Instance Key Encryption Key (IKEK)	Checks if the key can be fetched from the File Key Store or KeySecure.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Category	Details
Instance HMAC Key	Checks if the key can be fetched from the File Key Store or KeySecure.
Vault PKI	Checks Vault connectivity to verify if the Instance Asymmetric Encryption Key (IAEK) and Instance Signature Key (ISK) are usable and can be fetched from Vault.
EJBCA PKI	Checks LDAP connectivity to verify if IAEK and ISK are usable and can be fetched from cache and LDAP.
Instance PKI	Checks the File Key Store and KeySecure for a key and whether the certificate is present and matches the symmetric key. **Note:** Instance PKI is only available on instances within a ServiceNow datacenter.

For assistance in troubleshooting, contact Customer Service and Support.

Prepare your instance for GlideEncrypter deprecation

Use an instance scan script to find and remove GlideEncrypter API calls on your instance. Removing these calls is a necessary step in deprecating 3DES encryption on your instance.

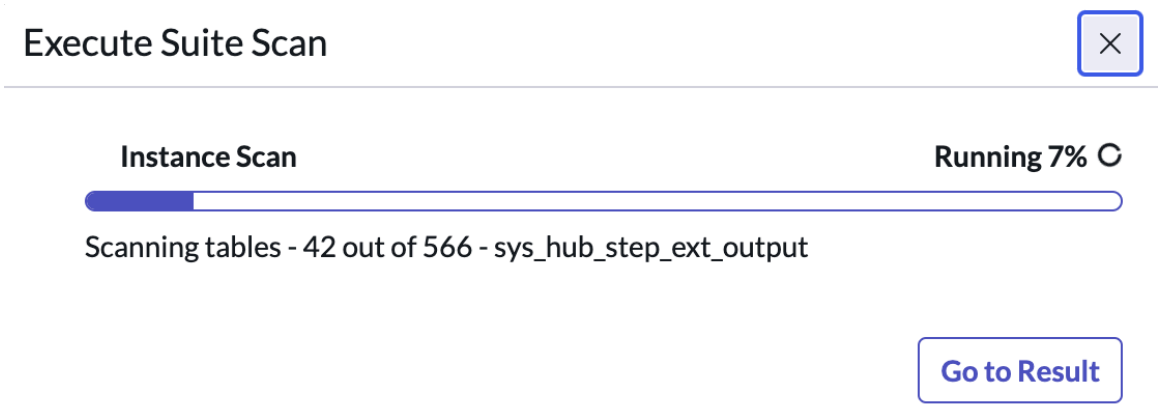
Before you begin

Role required: admin

The GlideEncrypter API is planned for deprecation as of the Zurich release of ServiceNow. Removing GlideEncrypter calls from your script is also a necessary step before deprecating 3DES encryption on your instance.

Procedure

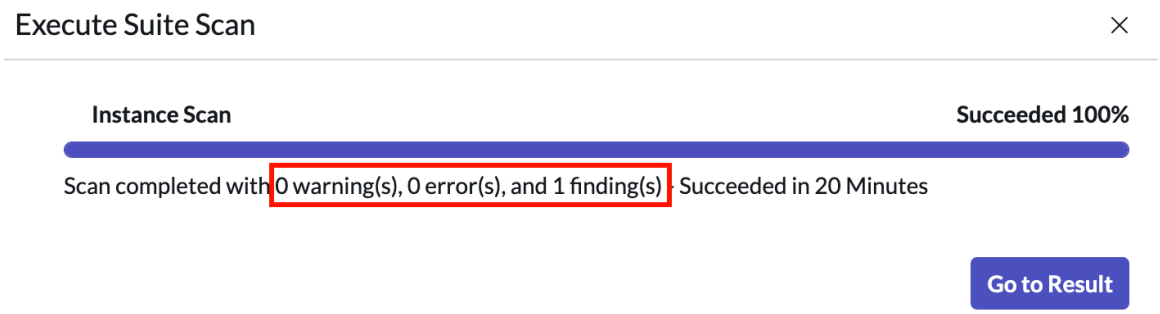
1. Navigate to **All** > **Instance Scan** > **Suites**.
2. In the **Suites** list, select **GlideEncrypter** to identify the records with GlideEncrypter usages.
3. In the **Suites** record, select **Execute Suite Scan**.
4. In the **Scan Suites Now** window, select **Full Instance**, then select **Execute Scan**.
   The suite scan executes. During the scan execution a **Execute Test Scan**, a window displays the progress of the scan.



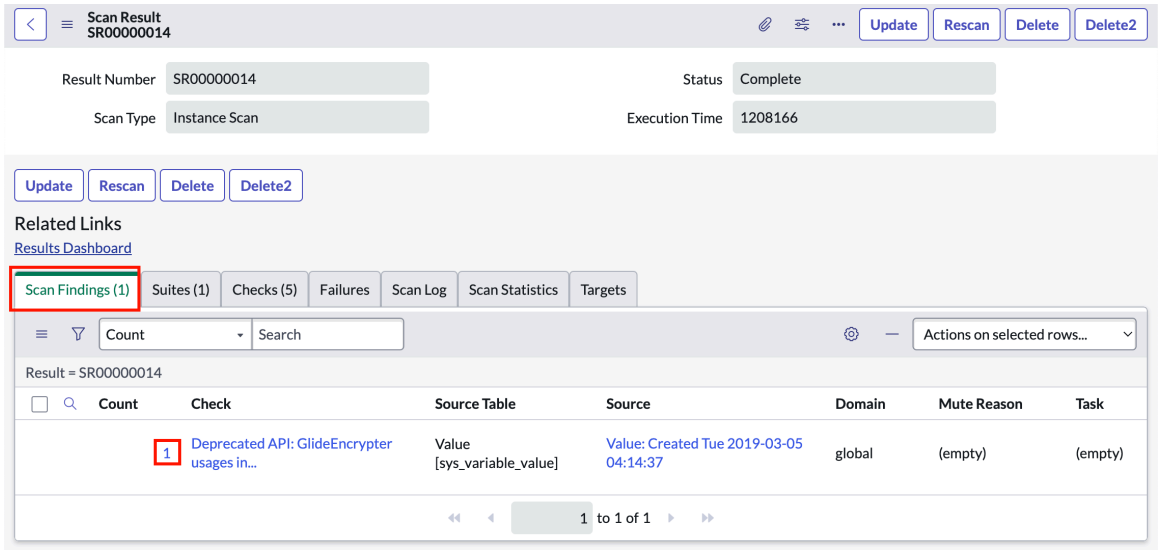
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
This scan checks only records that have been created or modified by the customer.

5. When the scan is complete, select **Go to Result** to view the **Scan Result** record.



6. In the **Scan Result** record, select the **Count** field on the **Scan Findings** list to navigate to a record.



7. Modify any scripts in the record that uses the **GlideEncrypter** API.
For details on alternatives to **GlideEncrypter**, see Alternatives to deprecated GlideEncrypter APIs.

Note:
You do not need to modify base system (out-of-box) records if you have not made any changes to them. These records are handled by ServiceNow.

8. After removing **GlideEncrypter** calls from your scripts, run the scan again to ensure that there are no remaining calls to the API.

What to do next

Deprecate GlideEncrypter usage of 3DES for password2 fields

GlideEncrypter deprecation

Learn how to remove the use legacy GlideEncrypter calls from the scripts on your instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

GlideEncrypter availability in the Zurich release

The availability of GlideEncrypter in the Zurich release depends on whether your instance was created in or upgraded from a previous release.

New instances

In new instances created in Zurich or later, this API turned off by default. All base system scripts have been updated and no longer use calls to this API.

Upgraded instances

Zurich instances that have been upgraded from a previous release are still able to use the legacy GlideEncypter API, but the API has been updated to use AES256-GCM encryption via the Key Management Framework. This change replaces the use of the legacy 3DES encryption standard to comply with NIST guidelines, while allowing any scripts still using GlideEncrypter to operate.

Enable or disable GlideEncrypter

The availability of GlideEncrypter is controlled by the *glide.security.glideencrypter.allow* system property. This system property is set to **false** by default in new Zurich instances and can't be updated. In instances upgraded to Zurich, this property can be changed by administrators with the security_admin role.

The glide.security.glideencrypter.allow system property

Value	Behavior
true	When true, GlideEncypter can still be called in scripts, but uses the AES256-GCM encryption via the Key Management Framework.
false	When false, GlideEncrypter calls return `null`, and administrators see this error: `Unsupported call to GlideEncrypter. Details: GlideEncrypter is deprecated and now returns null, please refer`

Deprecate GlideEncrypter usage of 3DES for password2 fields

Deprecate GlideEncrypter usage of 3DES encryption standard on your instance ensure that your instance uses the more secure Advanced Encryption Standard (AES) exclusively for the encryption and decryption of your Password2 data.

Beginning in Rome, password2 data is protected using the Key Management Framework, which uses the more modern Advanced Encryption Standard (AES) algorithm. However, some configurations and fallbacks in password2 logic can still use the 3DES algorithm for encryption and decryption.

In the Vancouver release, administrators can choose to deprecate the 3DES algorithm entirely. After completing this change, your instance uses AES encryption exclusively for all encryption and decryption tasks relating to password2 data. This change provides better instance security than compared with 3DES encryption, and is necessary to remain NIST compliant.

Considerations before deprecation

Transferring password2 data between instances

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

When transferring password2 encrypted texts to other instances, you must ensure that KMF Key Exchange is enabled between source and target instances. This configuration ensures that the keys used to encrypt password2 texts are available on both instances to decrypt the password2 encrypted texts. Before deprecating 3DES, Consider the following use cases that can impact password2 data between instances.

- If you have applications on your instance that use password2 data, ensure that KMF Resource Exchange is installed on that instance. KMF Resource Exchange ensures that instance level keys used to encrypt the password2 data on the source instance are available on the target instances for decryption. For more information, see Key Management Framework Resource Exchange.
- If you plan on exporting password2 data through XML or Data Sources, ensure that the target instance has KMF Key Exchange enabled. This configuration ensures that the instance level keys used to encrypt the password2 data on the source instance are available on the target instances for decryption. For details on this configuration, see Key Management Framework Key Exchange.

> **Important:**
> The examples above are more common scenarios, but if you're using any other means of transferring password2 encrypted text between instances, you must configure KMF Resource Exchange to ensure the target instance can decrypt password2 data.

Downgrading an instance after the 3DES deprecation

The following only applies for instances that have password2 fields have input lengths greater than 125 characters and you have already deprecated 3DES encryption.

To downgrade an instance to release earlier than Vancouver via Instance Cloning, take the following steps before initiating the clone.

1. Check if data preservation is configured to preserve password2 field data.
2. If yes, then before requesting a clone, contact ServiceNow support to disable 3DES deprecation. In the **Reason** field, use "Clone downgrade pre-requisite for password2 support."

Legacy password2 fields

Your instance uses 3DES encryption to convert password2 data to legacy (pre-Rome) password2 data. After deprecating 3DES encryption, this option is no longer available. If you still need this feature, request partial deprecation (see details in the next section).

How to deprecate 3DES

After you've reviewed the preceding use cases, use knowledge base article KB1704481, for a step by step process to safely deprecate the usage of DES or Triple DES algorithm in instance. For details see KB1704481.

> **Important:**
> You must elevate to security admin to see the **Security Compliance** module and perform these steps. For details on that process, see Elevate to a privileged role.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

After GlideEncrypter deprecation

After the deprecation process is complete, the following information applies to your instance.

- password2 fields still support decryption (but not encryption) of 3DES encrypted data.
- Existing 3DES encrypted data in password2 fields remain as is until the field value is updated by a user or workflow.
- Any update to the value of a password2 field removes 3DES encrypted text and replaces it with the text encrypted by KMF using AES.
- In some situations, your instance may display an error when saving password data:

  ```
  Action Aborted: Password value cannot be saved due to technical issue. Please see KB1296997 for help.
  ```

  If you see this error refer to support information in knowledge base article KB1296997.

Key Management Framework Resource Exchange

ServiceNow® Resource Exchange is a KMF feature that gives you the capability to exchange resources between instances in a secure manner.

Terminology

When using the Resource Exchange, reference the following terminology:

Resource Exchange Terminology

Name	Description
Resource Exchange	The process to exchange resources across instances.
Key Exchange (KE)	The process to exchange keys over instances.
Key Source instance (Key Source)	The instance that owns the keys.
Key Target instance (Key Target)	The instance that requests the keys.

Overview

Resource Exchange utilizes the KMF cryptographic APIs to provide confidentiality, integrity, authentication, and non-repudiation. Currently, Resource Exchange supports the Key Exchange functionality. See Key Management Framework Key Exchange for additional information.

Key Management Framework Key Exchange

KMF Key Exchange is a subset function of KMF Resource Exchange. Key Exchange securely transfers encrypted data across multiple instances.

Overview of Key Exchange

Key Exchange securely transfers keys across instances.

KMF Key Exchange provides a secure way for customers to exchange KMF keys between instances. One application use case is the data cloning process. With Key Exchange, crypto module keys are copied over during the data cloning of KMF components. Cryptographic modules, module key specifications, and module access policies are included in the cloning process. Transfer of keys isn't included.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

This functionality is included with the Key Management Framework, which is included in the ServiceNow AI Platform Encryption subscription bundle. For details on this product, see Key Management Framework.

Using Key Exchange

Administrators who use KMF for Field Encryption can use Key Exchange to clone the keys between production instances when performing data cloning. In data cloning, the administrator/ KMF cryptographic manager can perform the following:

- Exchange all keys to the other instances.
- Exchange particular keys one time or periodically to the other instance.
- Send on-demand requests from the target instance to the key source instance.
- Exchange keys from source to target for rekeying ciphertext.
  - Manage the expiration time of the request with the ability to delete keys or reject the key exchange request if the request has expired.
  - After the request is completed and the key is imported, the used key will be set as expired and timestamped.
  - Rekey ciphertext on the target instance that was encrypted with keys from the source.

Supported modes

Key Exchange supports several modes on the encryption module crypto specification level:

Mode	Description
Automatic (no configuration, default behavior)	All keys are sent over automatically during the data cloning process without additional configuration.
Configurable (one-time configuration setup)	The administrator configures the keys to be sent over during the data cloning process.
Manual (person in the loop)	The administrator sends an on-demand request on the target instance to the source. The request must be approved by an administrator on the key source instance.
Rekey (automated request)	The administrator selects the option of rekey during the cloning setup process.

Configure Key Exchange

Key Management Framework (KMF) generates automatic key exchange requests for supported cryptographic modules during the fresh installation or upgrade of the instance. manages the data encryption key locally for the instance.

Before you begin

A cryptographic module with a key must be created in both the target and source instances before using Key Exchange.

Role required: sn_kmf.cryptographic_manager

About this task

Key Exchange requests are initiated from the target instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Automatic Key Exchange is active by default when cloning an instance, where the property is cloned to the target instance. Along with KMF, configure system properties to manage how keys are handled during an instance clone:

- **Turn off automatic key exchange:** Set the *glide_encryption.auto_key_exchange.enabled* property to **false** for recurring clone requests.
- **Send auto key exchange requests**: Set this property to **true**.

Important:
The base system property is set to **true** by default, meaning that automatic key exchange is activated when cloning an instance. This value must be set to **false** if you're using the Rekey ciphertext with Key Exchange or the recurring Key Exchange functionality. See Recurring Key Exchange walkthrough for additional details.

Procedure

1. Navigate to **All** > **Key Management** > **Resource Exchange Requests** > **New**.
2. On the form, fill in the fields.

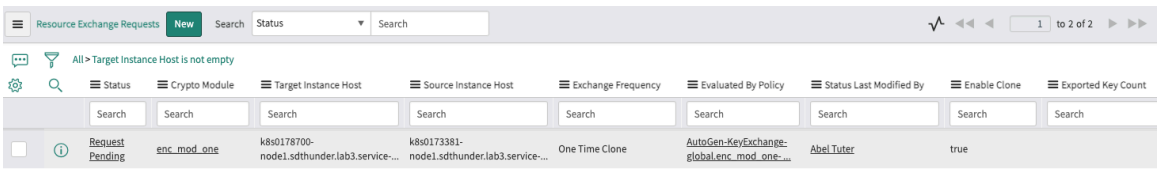
Resource Exchange Request form fields

Name	Description
Exchange Frequency	○ **Adhoc**: Sends requests from the key target instance to the source instance. Enter the instance sys_id and the Host information for the Source. Not supported with Rekey of Key Exchange. ○ **One Time Clone**: One-time exchange of the keys from the source crypto specifications to the target instance. ○ **Recurring Clone**: Exchange keys from the selected source crypto specifications to the target instance on a defined recurring clone.
<Source or Target> Instance sys_id	○ **Adhoc**: Enter the sys_id for the source instance to request the keys from. ○ **One Time Clone**, **Recurring Clone**: Enter the sys_id for the target instance that sends the requests. **Tip:** Enter `stats.do` in the application navigator to locate the instance ID.
<Source or Target> Instance Host	Enter the host location or name of the source or target instance. **Tip:** For example `instanceA.service-now.com`
Crypto Specifications	The keys from the crypto specification in a crypto module define the keys to clone. For both one-time and recurring clone requests, your instance automatically creates a **Resource Exchange** module access policy. You don't need to configure a policy manually. **Note:** Select the lookup using list icon (🔍) to browse the available cryptographic specifications.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

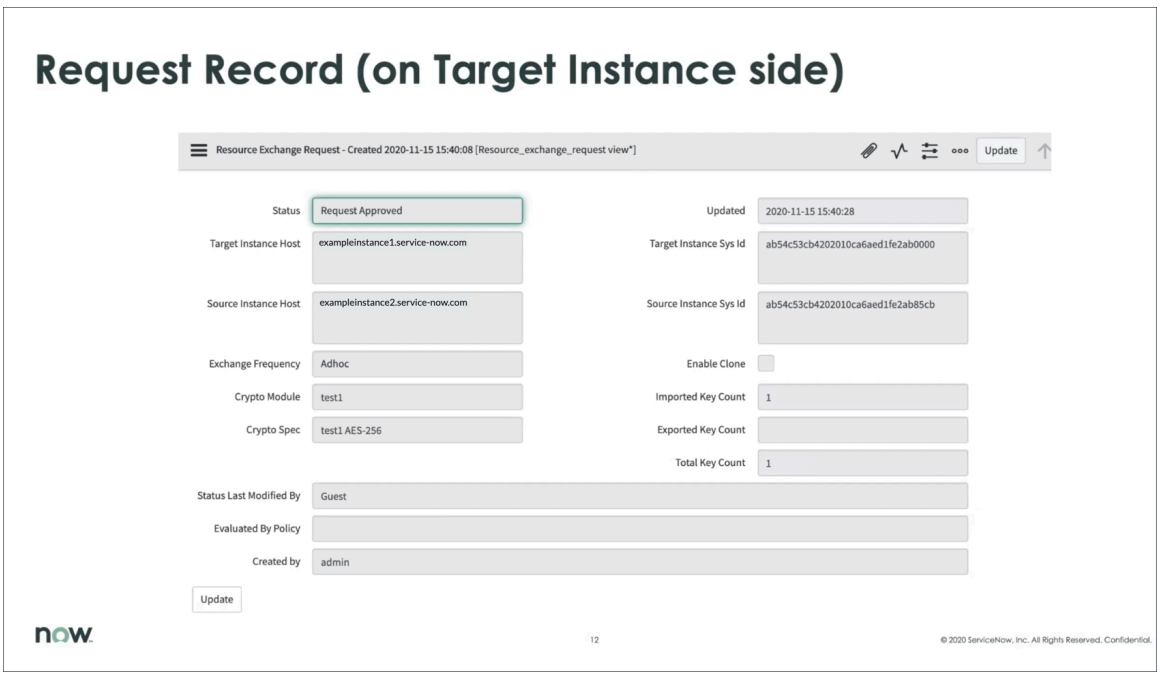
Name	Description
Enable Rekeying after Key Imported	Option to enable auto rekeying.

3. Select **Submit**.
   If successful, a confirmation displays at the top of the form. The Requests table is updated with an entry of **Request Pending** in both the source instance and in the target instance. Open the Request Record to view the status of the request, the Imported Key Count, and the Total Key Count on the target or source host.



4. The pending request is accepted in the source instance to complete the exchange.

   At clone time, the module access policy on the source instance is invoked to auto-approve the request and send keys to the newly cloned target.



Result

After a key exchange is attempted, your non-production instance updates the *`protected.script.values.kmf.rekeyed`* system property. This property is visible in the System Properties [sys_properties] table after a key exchange is attempted. If the encryption using the exchanged key is successful, this property has a value of **true**. Otherwise, the property has a value of **false**. If the value is false, the instance will attempt to encrypt again the next day.

Rekey ciphertext with Key Exchange

Resource Exchange supports rekeying of ciphertext on the target instance that was encrypted with keys from the source. Rekey activity is tracked in the key life-cycle.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Overview

Administrators who use KMF for Field Encryption can use Key Exchange to rekey cryptographic keys between production instances when performing data cloning. An active key must first be available on the target instance for rekey, as rekey requires an active key. An encryption job is automatically created and run by the system to rotate and rekey the source key and re-encrypt the ciphertext.

Use Key Exchange to do the following:

- Set an expiration time frame for rekey.

  If the request has expired, then the request is rejected and the key is deleted.

- Automate rekeying ciphertext that was encrypted with keys from source instances.

  A new cloned crypto key is used to re-encrypt ciphertext on the target instance.

- The Rekey purpose is set up during the cloning process and is automated as part of the clone.
- Rekey activity is tracked on the **Modules Key** tab of the cryptographic module. Access the Key life cycle state and Key version for key activity. See Rotate keys for additional information.

Configure a Key Exchange and select the **Enable Rekeying After Key Imported** check box for activation. See Configure Key Exchange for details.

Recurring Key Exchange walkthrough

Use this walkthrough to set up a recurring key exchange in your instance using and Resource Exchange.

Before you begin

Roles required: sn_kmf.cryptographic_manager

About this task

This example shows you how a target instance requests keys from a host instance.

- Before you can perform this procedure, you must clone an instance. See System clone for more information.
- **Automatic Key Exchange**: The base system property *glide_encryption.auto_key_exchange.enabled* is **true** by default, meaning that automatic is activated when cloning an instance. The property is cloned over to the target instance.
- Turn off automatic by setting the property to **false**.

Procedure

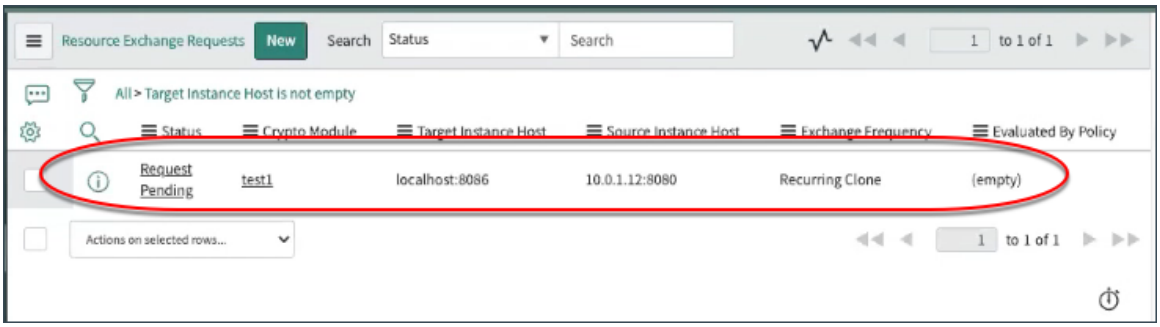
1. On the source instance, create a crypto module or access an existing crypto module using column_level_encryption and set up the encrypted field configurations for the ciphertext encryption for Key Exchange.
   See and for details.

   a. Ensure that keys have been generated in the crypto module.

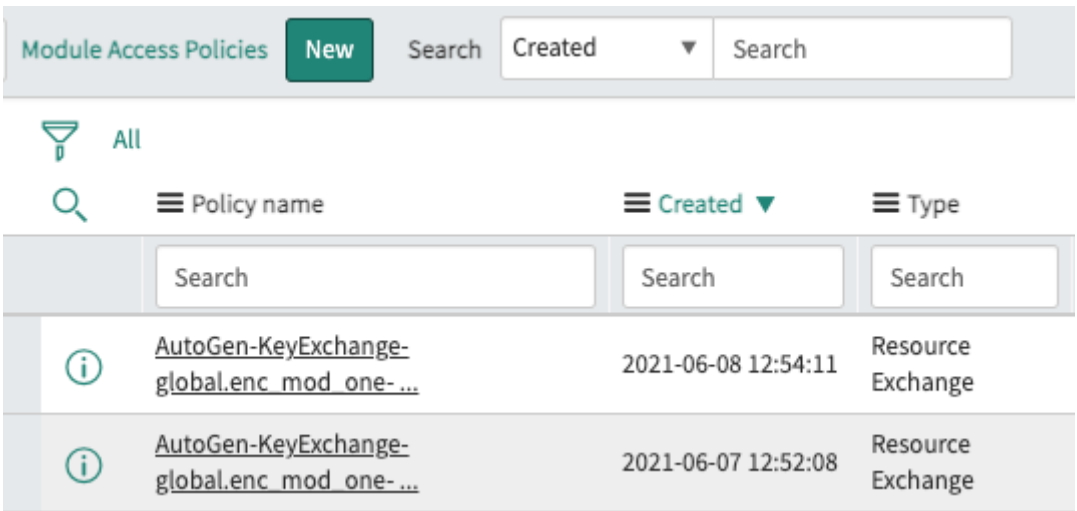
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
Your instance automatically creates a module access policy on the execution of the clone request.

2. From the cloned instance, navigate to **Key Management** > **Resource Exchange Requests** > **New**.
3. Complete the form and select **Recurring Clone** as the Exchange Frequency.
4. From the target instance of the clone, navigate to **Key Management** > **Resource Exchange Requests**.
   The request from the host instance is displayed in the table.

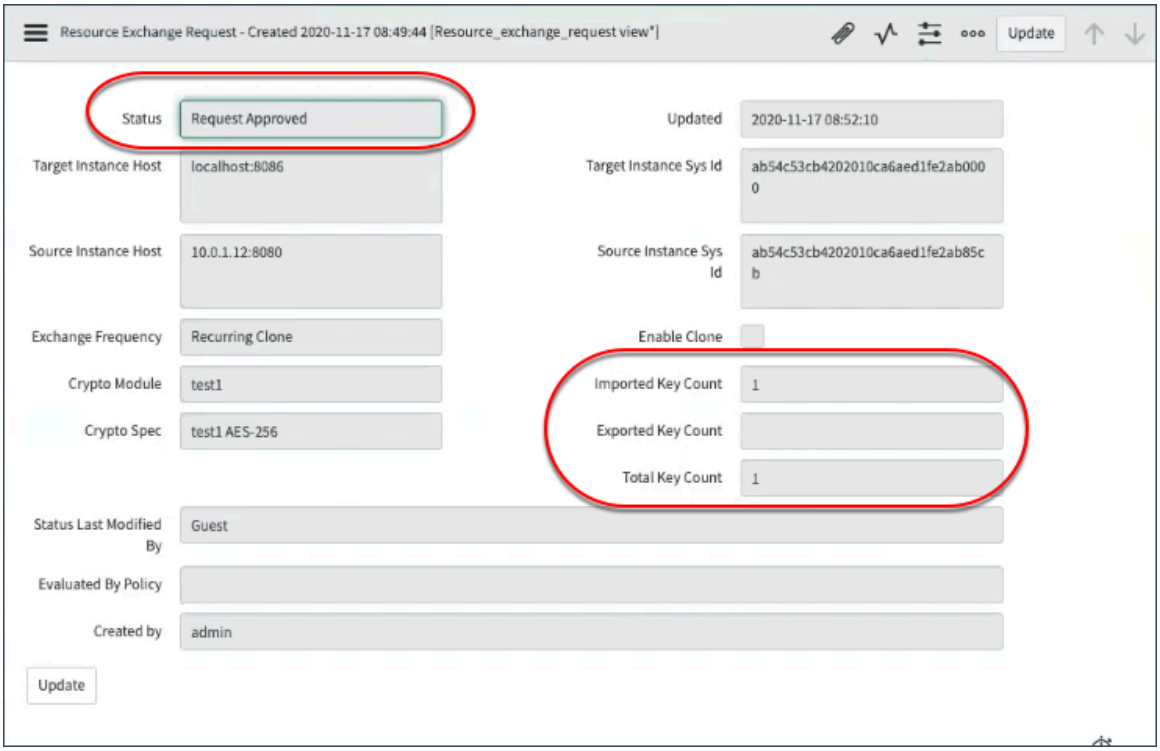


Important:
For both one-time and recurring clone requests, your instance creates a module access policy automatically. You don't need to configure a policy manually. At clone time, this policy on the source instance is invoked to auto-approve the request and send keys to the newly cloned target.

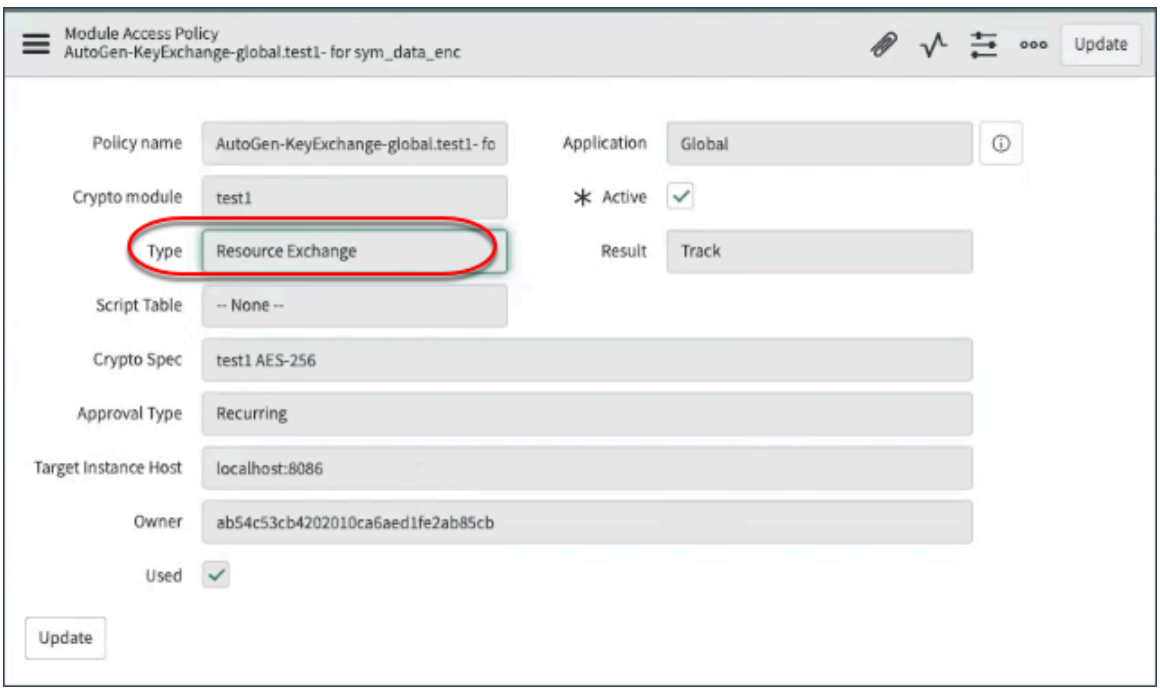


In the Requests form, the status updates to **Request Approved** and the **Imported Key Count** field appears on the record.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



5. Return to the host instance.
6. View the Request record to see the number of exported keys.
7. View the Module Access Policy record to see that the **Type** is Resource Exchange.



Note:
Resource Exchange also supports rekeying of ciphertext on the target instance. See for details.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Result
After a key exchange is attempted, your non-production instance updates the *protected.script.values.kmf.rekeyed* system property. This property is visible in the System Properties [sys_properties] table. If the encryption using the exchanged key is successful, this property has a value of **true**. Otherwise, the property has a value of **false**. If the value is false, your instance will attempt to encrypt again the next day.

Infrastructure Security

Use Infrastructure security tools to create, upload, and manage certificates your instance uses to encrypt traffic from client to server.

The Infrastructure Security plugin provides the tools that you can use to manage the Transport Layer Security (TLS) ciphers and certificates. Your instance uses TLS to encrypt traffic from the client to your server.

Select the Ciphers used on your instance

Using the **TLS page**, admins can configure which datacenter ciphers to use on their instance, as well as select the order in which ciphers are tried.

Generate and upload your own certificates

Use the infrastructure security tools to generate your own certificate signing requests, which can be signed by the certificate authority of your choice. Then, you can use the tools to upload the signed certificate to your instance's load balancer.

Monitor the status of your ciphers and certificates

Use the **TLS Settings** and **SYOC Settings** pages to view the status of changes you have made to your ciphers and certificates.

Install the Infrastructure Security plugin

Install the ServiceNow Infrastructure Security Settings (com.glide.infrastructure_security) plugin to get started using these features. For details on plugin activation, see Activate a plugin.

After installing the plugin, enable Sign Your Own Security (SYOC) functionality by setting the *sn_infra_sec.syoc.enabled* system property to `true`.

Note:
If the *sn_infra_sec.syoc.enabled* property isn't available on your instance, you must create it. For details on this process see Add a system property.

Generate a Certificate Signing Request

Use the Generate Certificate Signing (CSR) page to create a certificate signing request to support customer-signed certificates for your instance load balancer.

Before you begin
Role required: admin

The Infrastructure Security (com.glide.infrastructure_security) plugin must be installed to perform these steps. SeeInfrastructure Security for details on this plugin.

For information on using custom URLs with ServiceNow, see Set a custom URL as the instance URL.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Infrastructure Security Settings** > **Generate CSR**.
2. Add one or more domains to your request.

   a. Select the **Add** button under the **Domains** heading.

   b. In the pop-up window, enter the domain and select **OK**.

   c. Repeat these steps as needed to add more domains.

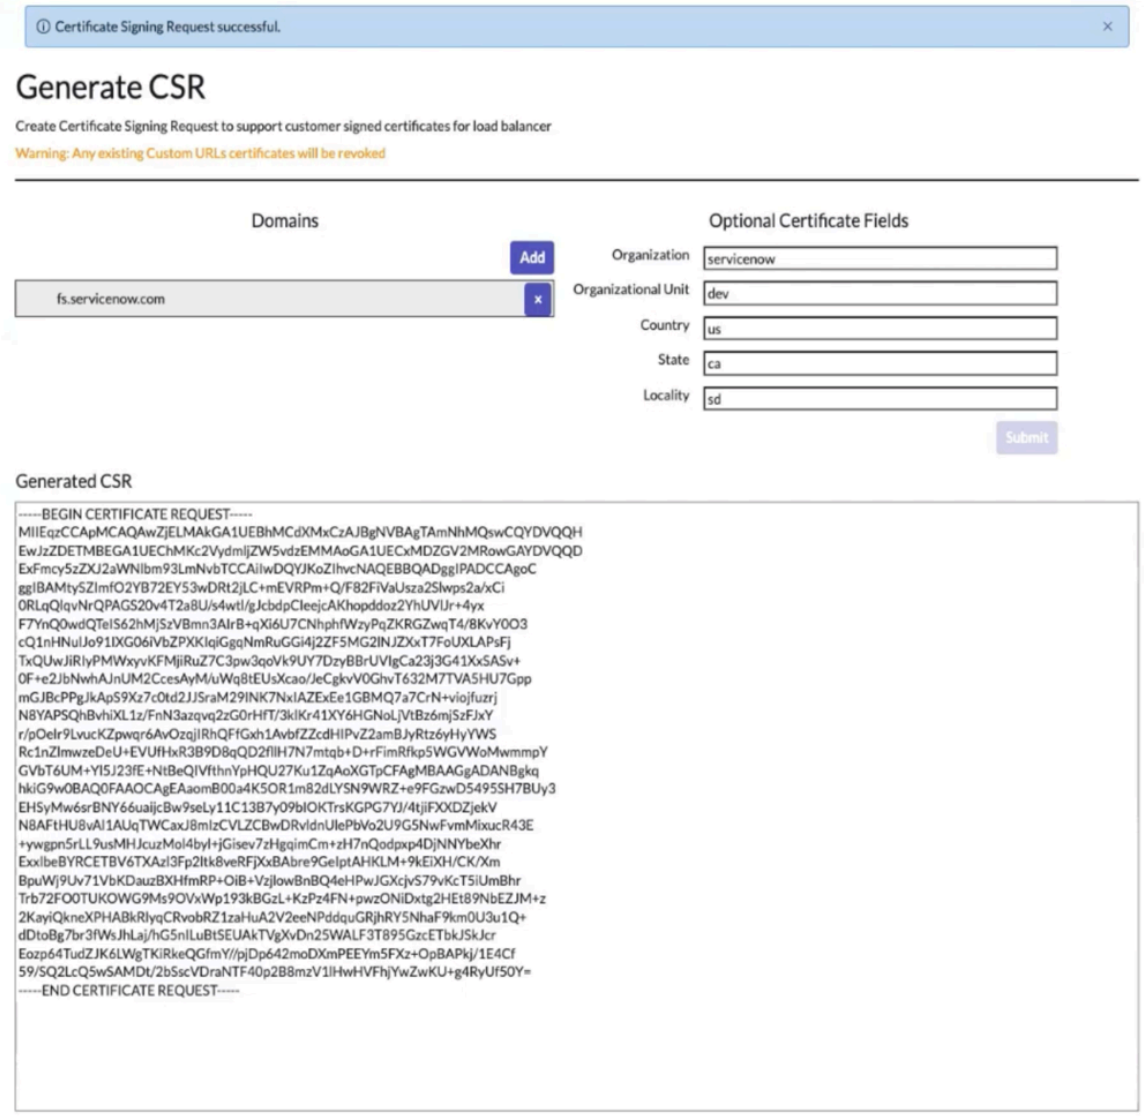
   Note:
   Domains can be removed by selecting the X button to the left of each domain entry.

3. Enter any information that you want included in your request in the **Optional Certificate Fields**.
4. Select **Submit**.

Warning:
You can't submit a request while another request is being generated. If this issue occurs, you see a "Resource in Conflict" error. To process, cancel the current request or wait for the current request to process before submitting another.

After selecting **Submit**, your instance will generate the certificate signing request. The request appears in the **Generated CSR** field.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



5. Copy the contents of the **Generated CSR** field.

Password2 encryption with the Key Management Framework (KMF)

Supported by the Key Management Framework, use the Password2 (2-way encrypted) field type to encrypt and decrypt custom fields with segregation of duties, key protection, and life-cycle management. It works in accordance with NIST 800-57 guidelines and provides FIPS 140-2-L3 protection.

Password2 is a text field that stores passwords with two-way encryption. The two-way encryption stores passwords as a secure encrypted value that can be decrypted within the instance.

Tip:
Beginning in the Vancouver release, administrators can deprecate 3DES encryption on password2 fields in favor of the newer Advanced Encryption Standard (AES). For details, see Deprecate GlideEncrypter usage of 3DES for password2 fields.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

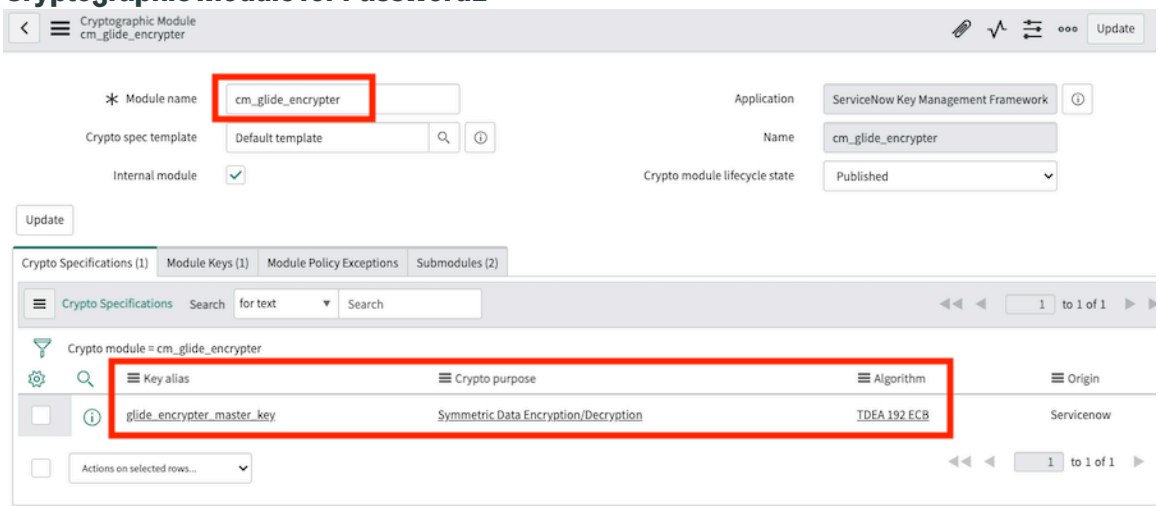
Activation

Password2 functionality is active by default. It's controlled by the *glide.kmf.encrypter.enabled* property, which is set to **true** for all new instances and upgrades. You don't need to enable Field Encryption Enterprise to use Password2.

How Password2 works

The Key Management Framework provides a base system parent cryptographic module **cm_glide_encrypter**. This module provides a cryptographic specification and a key that can decrypt legacy Password2 fields.

Cryptographic Module for Password2



This cm_glide_encrypter module can have submodules, each with their own module key and specification. If a submodule is present with the same application scope as the application where the Password2 field is, the system uses the submodule. For example, if a table in the ServiceNow® Customer Service application has a submodule, and you write information to a Password2 field on a table in the Customer Service application scope, the cryptographic process calls the Customer Service submodule. The process also uses that submodule's key for encryption and decryption with a unique AES 256 GCM encryption key. One submodule per application scope is allowed. Parent module isn't always used for global scope. Generally, new fields use instance_level_glide_encrypter.

Note:
You can't create your own submodules in Zurich. Submodules are provided in various application plugins on the ServiceNow AI Platform. You can rotate keys on submodules, but not the parent cm_glide_encrypter module.

Domain separation and on-premise customers

KMF Password2 doesn't support domain separation. You can use Password2 with on-premise instances.

Legacy Password2 and the current Password2

In Zurich, the existing Password2 field has been upgraded.

The current implementation of Password2:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Uses the Key Management Framework in accordance with NIST 800-57 key wrapping guidelines and provides FIPS 140-2-L3 protection for the entire key hierarchy.
- Includes capabilities to create dedicated and unique KMF Password2 submodules for specific applications, providing control through application scope. Each submodule has its own unique AES 256 GCM encryption key.

Password2 fields in scripts

When accessing Password2 fields with a script, run the script under the same scope as the table scope. Use `setDisplayValue()` to encrypt Password2 values and `getDecryptedValue()` to decrypt and read the value.

Note:
Don't use the `GlideEncrypter()` API on Password2 fields.

This example script shows you how to encrypt `my@Password` in the password2 column of table 'table_xyz'.

```
var  gr =  new GlideRecord('table_xyz');
gr.pwd2column_name.setDisplayValue('my@Password');

gr.insert();
```

Important:
You can't use the `setValue()` API for the Password2 field.

This example script shows you how to decrypt the same field to retrieve the value:

```
var  gr =  new GlideRecord('table_xyz');
gr.query();
gr.next();
var ge=gr.getElement('pwd2column_name');
var ged1 = ge.getDecryptedValue();
```

Important:
The `getDecryptedValue()` API isn't scoped. It's available globally.

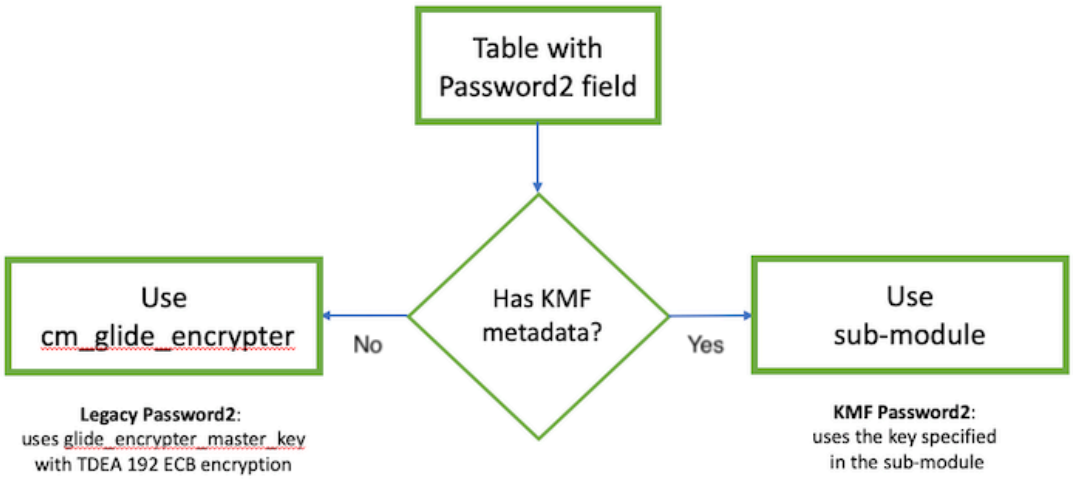
1. When you encrypt data in a Password2 field, the system determines the scope of the application where the Password2 field resides.
2. The system then looks for a submodule of the **cm_glide_encrypter** parent module with the same scope as the application if the property is set to *true*.

   Note:
   If a submodule with the same scope is present, it uses the submodule specification and key to perform the encryption.

This illustration explains how your instance decrypts data in Password2 fields:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Password2 decryption flow



KMF Password2 migration job

A migration job is provided for customers upgrading from previous releases. It takes data encrypted with a legacy Password2 encryption and re-encrypts it with the key in a KMF Password2 submodule key. The re-encryption only applies to tables with Password2 fields in application scopes that also have submodules created for that scope. For example, a legacy Password2 field in **XYZ_example** application (with **XYZ_example** application scope) is re-encrypted only if a submodule for the **XYZ_example** application scope exists under the cm_glide_encrypter parent module.

The KMF Password2 encryption keys in the submodule are protected (envelope encrypted) in the KMF key hierarchy.

Certificates

Your instance requires certificates to establish secure connections and validate signatures.

Explore	Configure
Learn the key features and business value of Certificates.	Plan your core configurations.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Upload

Plan and set-up the application.

Exploring Certificates

Your instance requires certificates to establish secure connections and validate signatures.

Certificates are used for features such as:

- LDAPS
- Outbound web service mutual authentication
- Web service security
- MID Server

In order to use a certificate, you must generate or purchase a certificate for the secured server, or client and upload it to an instance.

LDAP certificates

An SSL certificate is required for the instance to establish an LDAP over SSL (LDAPS protocol) connection with an LDAP server.

The instance accepts two types of LDAP certificates:

Certificate	Type	Required for
LDAP server certificate	Any supported type	All LDAP configurations
LDAP client certificate	Java keystore type	Mutual authentication

If there are multiple server certificates, the instance tries each server certificate in turn until the LDAP server allows the connection. If you use multiple LDAP servers, be sure to include the SSL certificate for each LDAP server.

Mutual authentication requires the client to present a certificate in addition to the server. If your LDAP server requires mutual authentication, you must also provide your LDAP server's client certificate in a Java keystore type certificate.

Certificate criteria

A valid certificate must meet these criteria:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- The certificate can have a key size up to 2048 bits.
- The certificate must have one of these file extensions:

Extension	Description
DER	The Distinguished Encoding Rules format is a binary message transfer syntax. This format also supports the .CER and .CRT file extensions.
CER	Certificate file extensions for certificates using the Distinguished Encoding Rules format.
CRT	Certificate file extensions for certificates using the Distinguished Encoding Rules format.
PEM	The Privacy Enhanced Mail format is a base-64 encoded DER certificate enclosed between "-----BEGIN CERTIFICATE-----" and "-----END CERTIFICATE-----" text strings.

Certificate trust

By default, your instance trusts only certificates from a Certificate Authority (CA) recognized in the Java Virtual Machine (JVM). Self-signed and enterprise-signed certificates aren't trusted.

Note:
To learn more about the properties that affect the use of certificates, see in Instance Security Hardening Settings.

Generating an LDAP client certificate

Generate an LDAP client certificate for mutual authentication using OpenSSL. The final output is a PKCS#12 certificate stored within a Java keystore.

Before you begin
Role required: admin

About this task
See the OpenSSL documentation for more information about generating certificates. These steps assume you have access to OpenSSL.

Enter these commands in a command line interface.

Procedure

1. Generate a self-signed client certificate.

   Example
   For example, this command creates a client certificate test1-cert.crt based on the test1-key.key private key.

   ```
   openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout
    test1-key.key -out test1-cert.crt
   ```

2. Convert both the certificate file and private key to PKCS#12 (a file with a .pfx or .p12 extension).

   Example
   For example, this command converts the client certificate and private key to a PKCS#12 certificate called test1-certificate.pfx.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
openssl pkcs12 -export -out test1-certificate.pfx -inkey
 test1-key.key -in test1-cert.crt
```

3. Generate the Java Key Store and import the pkcs12 file into it.

   Example
   For example, this command imports the certificate to the test1.jks Java keystore.

```
keytool -importkeystore -srckeystore test1-certificate.pfx
 -srcstoretype PKCS12 -destkeystore test1.jks
```

4. Upload the certificate in the keystore file (`test1.jks`) to the instance.

   Note:

   If you are uploading to an on-premise instance using a certificate with the .jks extension and you receive an error saying "No valid certificate found to process the application upload", use a certificate with the .pfx extension instead.

What to do next
Uploading a certificate to an instance

Generating a server certificate

You can use keytool to generate a new Java keystore file, create a certificate signing request (CSR), and import the private key, public certificate pair, and signed certificates into the keystore.

Before you begin
Role required: admin

About this task
See the Java keytool documentation for more information on generating keys and CSRs.

Enter these commands in a command line interface:

Procedure

1. Generate a Java keystore and key pair.

   Example
   For example, this command creates a keystore called my.keystore and generates a private key called mydomain within the keystore.

```
keytool -genkey -alias mydomain -keyalg RSA -keystore
 my.keystore
```

2. Generate a CSR for an existing Java keystore.

   Example
   For example, this command generates a CSR called mydomain.csr or the mydomain key.

```
keytool -certreq -alias mydomain -keystore my.keystore -file
 mydomain.csr
```

3. Import a root or intermediate certificate authority, or CA, certificate to the Java keystore.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Example
For example, this command imports the CA certificate for Thawte. This command assumes that Thwate was the CA that signed the CSR.

```
keytool -import -trustcacerts -alias root -file Thawte.crt
 -keystore my.keystore
```

4. Import a signed primary certificate to the Java keystore.

   Example
   For example, this command imports the signed certificate mydomain.crt into the keystore.

   ```
   keytool -import -trustcacerts -alias mydomain -file
    mydomain.crt -keystore my.keystore
   ```

5. Upload the certificate in the keystore file (my.keystore) to the instance.

What to do next
Uploading a certificate to an instance

Uploading a certificate to an instance

Add a certificate to the instance from the Certificates module.

Upload a certificate to an instance

Upload a certificate to an instance.

Before you begin
Role required: admin

About this task
When a certificate is updated on the ADFS server, you must also upload an updated certificate to the instance.

Procedure

1. Navigate to **All** > **System Definition** > **Certificates**.
2. Select **New**.
3. On the form, fill in the fields.

4. Select **Submit**.

   During the upload, the module extracts and displays the certificate's read-only properties in these fields:

   - Valid from date
   - Expiration date
   - Issuer
   - Subject of the certificate

5. Select **Validate Stores/Certificates** to check if the certificate is correct.
   If the instance encounters any errors with the certificate or keystore, it displays an error message.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Uploading a trusted server certificate

By uploading the service provider's trusted server certificate, the instance ensures it is connecting to a valid and secure service.

Before you begin

Role required: admin

About this task

The instance validates outbound Web Service calls by using the certificate provided by the service provider.

Procedure

1. Create a new Certificate record with the type **Trust Store Cert**.
2. Do one of the following actions:
   - Attach the service provider's DER formatted certificate.
   - Copy and paste the service provider's PEM format certificate into the **PEM Certificate** field.

Field Encryption

Protect encrypted data on your instance from unauthorized users, scripts, or system processes using Field Encryption.

Field Encryption is an encryption product based on the ServiceNow Key Management Framework. Field Encryption allows for the encryption of specific fields or attachments within an instance. Use Field Encryption in combination with Cloud Encryption and Access Control Lists (ACLs) to help protect sensitive information from logged in user who are not authorized to view it.

Field Encryption has two available versions.

Field Encryption Starter

Field Encryption Starter is included on the ServiceNow platform at no cost and supports encryption for a limited number of fields.

Field Encryption Enterprise

Field Encryption Enterprise is a premium, subscription version of the product available for customers subscribing to ServiceNow Vault, Platform Encryption, or Field Encryption Enterprise.

For more information on the difference between these versions, see Exploring Field Encryption.

Field Encryption replaces the Column Level Encryption product available in Xanadu and earlier releases.

Exploring Field Encryption

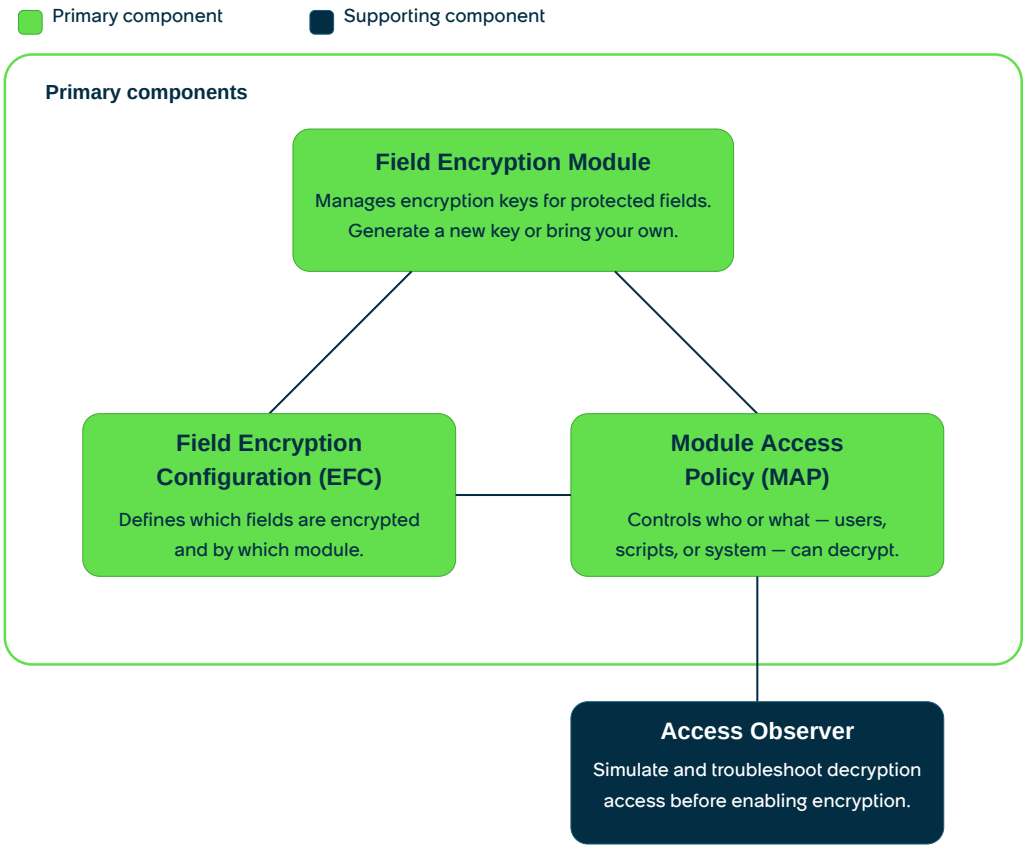
Learn the details of Field Encryption Starter and Field Encryption Enterprise

Encryption-backed access control

By default, Field Encryption blocks all users, scripts, and system processes from accessing encrypted data. However, Field Encryption has an access control feature that is used in combination with, but also separate from, Access Control Lists (ACLs) to ensure only the correct users, scripts, or system processes can access encrypted data.

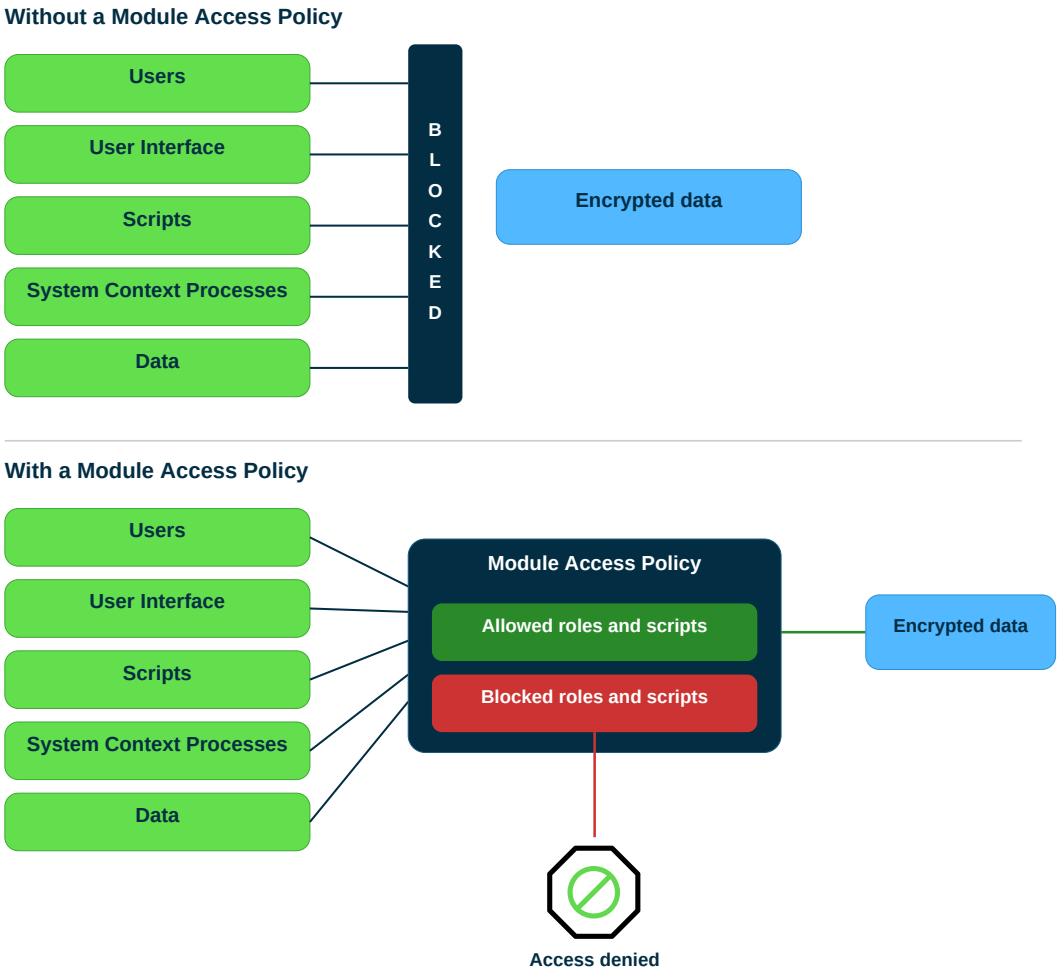
You can configure the access control feature of Field Encryption through a combination of Field Encryption Modules, Encrypted Field Configurations, and Module Access Policies. The next image shows how these three components work together.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



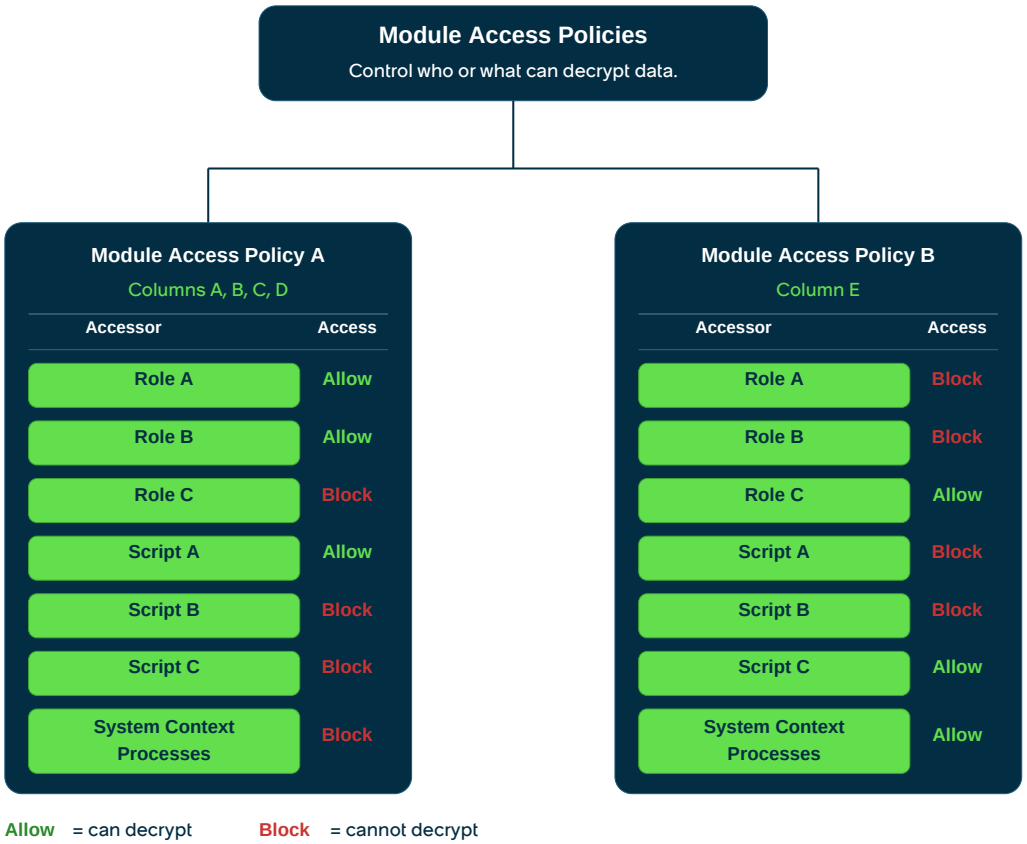
By default, encrypted data is locked down from all access. A MAP defines which accessor (users, scripts, and system processes) can be authorized to access the data.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



You can configure multiple MAPs to apply different access rules to different encrypted fields. In this diagram, Module Access Policy A covers columns A, B, C, and D, and Module Access Policy B covers column E — each with its own rules per accessor.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Access rules can differ between two policies for each accessor type. The following table reflects the access rules defined for Module Access Policy A, applied to columns A, B, C, and D, and Module Access Policy B, applied to column E.

Accessor	MAP A Columns A, B, C, D	MAP B Column E
Role A	Allow	Block
Role B	Allow	Block
Role C	Block	Allow
Script A	Allow	Block
Script B	Block	Block
Script C	Block	Allow
System Context Processes	Block	Allow

Differences between Field Encryption Starter and Field Encryption Enterprise

The feature-set is different between Field Encryption Starter and Field Encryption Enterprise.

Feature	Field Encryption Starter	Field Encryption Enterprise
Number of encrypted fields	Up to 5 encrypted fields	No restriction on number of encrypted fields

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Feature	Field Encryption Starter	Field Encryption Enterprise
	Note: Field Encryption Starter limits the number of encrypted fields, not encryption modules or contexts. Field Encryption replaces the deprecated Column Level Encryption product, which used a module and context-based limit.	
Attachment encryption	No	Yes
Key management	None (Contact ServiceNow Support for key rotation)	Manage keys from your instance with no involvement from ServiceNow Support
Supported data types	All supported data types	All supported data types
Number of Field Encryption Modules	No restriction	No restriction
Number of Module Access Policies	No restriction	No restriction

Field Encryption users

Users

User	Description
Key Management Framework (KMF)Admin or KMF Cryptographic Manager	These roles are used to configure elements of Field Encryption. • Field Encryption modules and module keys • Cryptographic Specifications • Module life-cycle policies • Encrypted field configurations for fields and attachments • Module Access Policies (MAPs) • Configures, wraps, and uploads customer supplied keys (for Field Encryption Enterprise) • Configures Access Observer and review Access Observer logs. • Schedule mass encryption, decryption, or re-keying
KMF Cryptographic Operator	Configures properties for customer supplied keys

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field Encryption and record history

Changes to fields encrypted with Field Encryption are not tracked in the activity stream for the record or in the record history [sys_history_set] table.

Encryption on system tables

Field Encryption currently doesn't support the encryption of fields and attachments of system tables (tables that begin with sys_).

What to explore next

To learn more about configuring and using Field Encryption, see:

- Configuring Field Encryption
- Using Field Encryption

Configuring Field Encryption

Learn how to activate and configure Field Encryption and manage migration from Encryption Support.

Activate Field Encryption

Learn how to active either Field Encryption or Field Encryption Enterprise.

Roles Required for Configuring Field Encryption

Learn about the roles required to configure Field Encryption.

Migration from encryption support

Use Scheduled jobs to migrate your keys and encrypted data from legacy Encryption Support to Field Encryption Enterprise. See details for this process at Migrating to Field Encryption

Change attachment encryption settings

Improve security by preventing users from attaching unencrypted files. For details, see Prevent users from attaching unencrypted files.

Activate Field Encryption

Activate either Field Encryption Starter or Field Encryption Enterprise.

Before you begin
Role required: admin

ServiceNow has replaced Column Level Encryption with Field Encryption beginning in the Yokohama release.

In the Yokohama release, customers that have not previously used Column Level Encryption may start using either Field Encryption Starter or Field Encryption Enterprise under the new entitlement structure.

Customers that were using Column Level Encryption in previous releases, and who want to begin using Field Encryption, have the following options:

Field Encryption Starter

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Column Level Encryption Starter customers can install Field Encryption Starter with no need for re-implementation. Field Encryption Starter takes over the existing configuration and adds new features seamlessly.

> **Warning:**
> There are differences in entitlement between Column Level Encryption Starter and Field Encryption Starter. Before installing Field Encryption Starter, ensure that your configuration complies with the entitlements. For information on entitlements for Field Encryption Starter, see Exploring Field Encryption.

Field Encryption Enterprise

Column Level Encryption Enterprise customers should work with their account teams to ensure they have the correct entitlement for Field Encryption Enterprise. Once that happens, the Field Encryption Enterprise plugin will be available to install in their instances.

> **Important:**
> Column Level Encryption Enterprise does not automatically grant an entitlement to Field Encryption Enterprise, as it is a different, but replacement, product.

Procedure

1. Navigate to **All** > **System Definition** > **Plugins**
2. Under **Search your licensed applications and plugins**, search for `Field Encryption`. The search should reveal the plugin. If you purchase a subscription for Field Encryption Enterprise, you can also see this plugin available.

> **Important:**
> To activate Field Encryption Enterprise, you must first purchase a subscription. Your account manager can arrange to have the plugin activated on your organization's production and non-production instances, generally within a few days.

3. Select or Field Encryption Enterprise, then select **Install**.

> **Note:**
> When domain separation and delegated admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

Role requirements for Field Encryption

Learn about the roles required to configure Field Encryption.

Managing requires the following roles. Since is based on the Key Management Framework, there are roles common to both.

- Admin
- Security Admin
- KMF Admin
- KMF Cryptographic Manager

For complete details on details on roles, see Roles installed with Key Management Framework.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Admin and Security Admin

Users must have the admin role to elevate to the Security Admin role. You need the Security Admin role to perform high Security Tasks, such as configuring encrypted field configurations and configuring Access Observer.

Admins can elevate to Security admin using this procedure.

1. Select on your profile picture at the top right of the screen.
2. In the drop-down menu, select **Elevate Role**.
3. Select **Security Admin**.
4. Select **Save**.

KMF Admin

Users with the Admin role can assign users to the KMF admin role using this process:

1. Navigate to **All** > **System Security** > **Key Management Administration**.
2. From the **Available Users** list, move a user who needs the KMF Admin role over to the **Selected User(s)** list.
3. Select **Save**.

> **Important:**
> For help prevent security issues, avoid granting the KMF Admin role to more than one users. Avoid assigning this role to users when more specialized roles are available.

KMF Cryptographic Manager

Users with the KMF Cryptographic Manager role can create and update operations on cryptographic modules and module access policies. KMF cryptographic managers can also perform key management and life cycle operations.

Use the following process to assign this role to a user.

1. Navigate to **All** > **System Security** > **Users**.
2. Select a user that needs to configure Field Encryption.
3. In the **Roles** related list, select **Edit**.
4. Search for `sn_kmf.cryptographic manager` and add the role the selected user.
5. Select **Save**.

Configure Field Encryption modules

Learn how to configure Field Encryption modules.

Before you begin

Role required: KMF Admin or KMF Cryptographic Manager

Procedure

1. Navigate to **All** > **System Security** > **Field Encryption** > **Field Encryption Modules**.
2. Select **New**
3. In the Module form fill out the fields as shown here.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Value
Module name	Choose a name for the module. This name is referenced when running scripts.
Crypto Spec Template	Automatically populated with **Default template**. This template is used to create the cryptographic module that contains mappings of many cryptographic purposes to cryptographic specifications and recommended algorithms.
Application	The application scope for this module. This field is automatically populated with the current application.
Name	This name automatically generated. It is the module name prepended with the application scope name to avoid conflict with other scoped applications. For example, if you create a module with the name `my_crypto_module` in the global application scope, the name is saved as `global.my_crypto_module`.
Crypto Module Lifecycle State	The term "lifecycle" refers to the creation, use, and deactivation of a cryptographic module. Set this value to **Draft** initially during configuration. Set it to **Published** for active use. **Note:** The Default template is automatically set to **Published**.
Parent Crypto Module	For Field Encryption, ensure this value is set to **column_level_encryption**.

4. Select **Submit**.

What to do next
Configure the purpose, algorithm, key length, mode, and origin of your encryption key in Cryptographic specifications for Field Encryption.

Cryptographic specifications for Field Encryption

Use cryptographic specifications to define the purpose, algorithm, key length, mode, and origin of your encryption key.

Before you begin
Role required: KMF Admin or KMF Cryptographic Manager

About this task
This procedure shows how to configure generated keys. A data encryption key (known as a Module Key) is automatically populated once you have configured the Crypto Specifications.

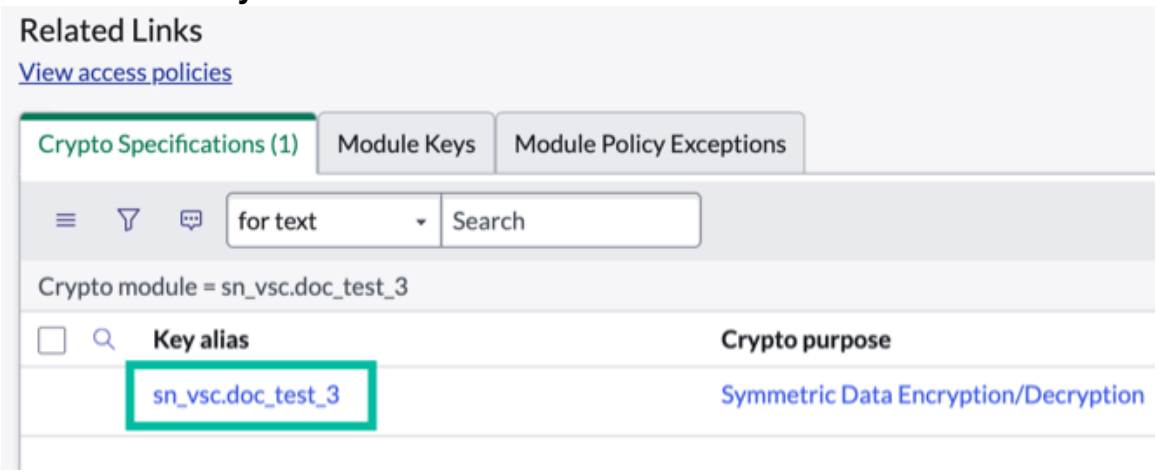
For customer-supplied key configuration, see Configure Customer-supplied keys for Field Encryption Enterprise.

Procedure
1. Navigate to **All** > **System Security** > **Field Encryption** > **Field Encryption Modules**.
2. In the **Cryptographic Modules** list, open the module record you want to configure.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
The names displayed in the list are appended with the scope, for example, `global.[your Field Encryption Module name]`.

3. In the **Crypto Specifications** related list, open the cryptographic specific record by selecting the name under **Key alias**.



4. In the Cryptographic Specifications form, fill out the fields as needed.

Note:
The fields are divided into sections. Select the **Next** or **Back** buttons to navigate between sections.

Section	Field	Description
Algorithm Definition	Crypto module	Displays the name of the selected cryptographic module.
	Crypto purpose	The purpose of the selected algorithm, key, length, and mode. For Field Encryption, this field is read only and has a value of **Symmetric Data Encryption/Decryption**.
	Algorithm	Select a type of algorithm used to accomplish the cryptographic purpose. The options available are filtered to align to the selected cryptographic purpose.
Lifecycle Definition	Applies to	Displays the selected key that the lifecycle applies to.
	For field	Select the type of control for the key that you want to apply for the lifecycle. ○ Expiration date ○ Future activation date ○ Future destruction date ○ Future renewal date ○ Future rotation date
	Key type	
	Lifecycle default	

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Section	Field	Description
	Order	Order in which to process the key lifecycle state for the crypto specification. Lower values execute before higher values.
	Relative duration	Number of years, months, or days the key is valid.
	Relative duration type	Duration type of the lifecycle. Select from **Years**, **Months**, or **Days**.
	Relative operation	Choose **Before** or **After**.
	Relative to	Select a field that the duration is relative to. ○ Activation date ○ Compromise date ○ Deactivation date ○ Destruction date ○ Expiration date ○ Generation date ○ Last renewal date ○ Last rotated date ○ Revocation date **Note:** This field works together with the value selected in the **Relative operation** field.
	Type	Select if the value for the key lifecycle is relative or absolute. **Relative** Enter a value that depends on other data entries in the system, such as key generation, activation, and deactivation. **Absolute** Enter an exact value, such as a date.
Key Origin	Crypto module	Displays the Name of the selected cryptographic module.
	Origin	Whether the key originated from or is supplied by the customer. ○ For starter, select **Servicenow** ○ For Enterprise, select **Servicenow** or **Customer Supplied**
	Key alias	Name of the cryptographic module with the scope appended to the front of the name.
	Crypto purpose	Displays the purpose of the selected algorithm, key, length, and mode. For Field Encryption, this field is read only and has a value of **Symmetric Data Encryption/Decryption**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Section	Field	Description
	Algorithm	Displays the algorithm used to accomplish the crypto purpose.
Key Creation	Crypto module	Displays the name of the selected cryptographic module.
	Key alias	Displays the name of the cryptographic module with the scope appended to the front of the name.
	Generate Key	Select this link to generate your data encryption key if you're using a generated key, and not a customer supplied key.
	Auto generate key	If you don't select the **Generate key** link, a data encryption key is automatically generated during the first time data must be encrypted using the cryptographic module.
	Crypto purpose	Displays the purpose of the selected algorithm, key, length, and mode. For Field Encryption, this field is read only and has a value of **Symmetric Data Encryption/Decryption**.
	Origin	Displays the value that was selected during the **Key Origin** section.
	Algorithm	Displays the algorithm used to accomplish the crypto purpose.

5. Select **Go To Crypto Module** to return to your Module record.
   In the Module record, there's now an entry in the **Module Keys** related list. The **Key alias** field in the **Crypto Specifications** related list is now empty, since the key alias has moved to the new module key.

What to do next

For information on using a customer supplied key, see Configure Customer-supplied keys for Field Encryption Enterprise.

Module keys for Field Encryption

The Module Keys tab shows you summary level information about your Field Encryption Data Encryption Key(s). You can view the Key alias, Key type, Algorithm, Key lifecycle state, and Key version.

Accessing module key information

Access your module keys by from records in the Cryptographic Module [sys_kmf_crypto_module] table. From a Cryptographic Module record, you can select the **Key alias** field in records in the **Module Keys** related list.

The information available depends on which version of Field Encryption you have active on your instance.

Field Encryption Starter

Using Field Encryption Starter, you can view key usage audit data.

Field Encryption Enterprise

You to perform manual key operations such as Renew, Revoke, Rotate, or Suspend, in addition to viewing key usage audit data.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Module key information

Information on your module keys is displayed on the module key record in the fields listed here. These fields are read-only and used for information purposes only.

Field	Description
Generation date	When the Module key was generated
Activation date	When the Module key was activated.
Last renewal date	When the Module key was last renewed.
Last rotated date	When the Module Key was last rotated.
Deactivation date	When the Module Key was deactivated.
Destruction date	When the Module Key was destroyed.
Future activation date	When the Module Key will be activated.
Future renewal date	When the Module Key will be renewed.
Future rotation date	When the Module Key will be rotated.
Future destruction date	When the Module Key will be destroyed.
Key lifecycle state	Current the state of the Module Key.

Module lifecycle policy exceptions for Field Encryption

Use module lifecycle policy exceptions to customize the lifecycle of your module keys.

Before you begin

Role required: KMF Admin or KMF Cryptographic Manager

About this task

Module lifecycle policy exceptions change the lifecycle policy of Field Encryption modules from the standard Instance-level lifecycle policy. For example, if you've configured symmetric keys to be limited to one year at the instance level, you can create a module lifecycle policy exception for a specific Field Encryption module to allow its key to remain active for two years.

Procedure

1. Navigate to **All** > **System Security** > **Field Encryption** > **Field Encryption Modules**.
2. Select the field encryption module record that requires a module lifecycle policy exception.
3. In the field encryption module record, select **New** in the **Module Policy Exceptions** related list.
4. In the key lifecycle policy form, fill in the fields as needed.

Field	Description
Crypto Module	Displays the name of the field encryption module that will use this policy exception.
Applies To	The specified key is auto populated.
Key Type	Select the key type. Exception policies are related to a specific key. Multiple exception policies can be created per Field Encryption Module.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Policy Condition	Create qualifying conditions from the drop-down menu and complete the additional constraint criteria.
Result	Select **Reject** to reject use of the key or **Track** to allow use of it when the criteria are met.

5. Select **Submit**.

Configure Customer-supplied keys for Field Encryption Enterprise

Bring your own data encryption key to the platform instead of using the one that ServiceNow generates.

Before you begin

Role required: KMF Admin or KMF Cryptographic Manager

About this task

If you're using Field Encryption Enterprise, you can use your own data encryption key to the platform rather than one generated by ServiceNow.

You must have a symmetric key that has been generated outside of ServiceNow. The examples in this document rely on OpenSSL. For more information on OpenSSL, see details at https://www.openssl.org. If you are using other cryptographic tools, such as LibreSSL or GnuTLS, refer to the documentation for those products for similar steps.

Procedure

1. In a command line on your machine (example: Terminal), run the following command: `openssl rand -out mykey.bin -hex 32`.
   Save the `mykey.bin` file, which will be used in following steps.
2. On your instance, navigate to **All** > **System Security** > **Field Encryption** > **Field Encryption Settings**.
3. Change the **Key Source** field from **ServiceNow Generated Keys** to **Customer Supplied Keys**.
4. Select **Submit**.

What to do next

Use the symmetric key you've created on your instance by following these steps:

1. Configure properties for customer-supplied key
2. Wrap your customer-supplied key
3. Upload your customer-supplied key

Configure properties for customer-supplied key

Review the system properties for the ephemeral public wrapping key that your instance uses to unwrap customer-supplied keys.

Before you begin

Role required: KMF Admin or KMF Cryptographic Operator

About this task

You must wrap your symmetric data encryption key with a ServiceNow ephemeral public wrapping key before you can upload it to your instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

When your key is uploaded to your instance, the instance unwraps it using the private side of the public key.

You can use system properties on your instance to define key padding, ephemeral key pair size, and a key validity period for this ephemeral public key.

System Property	Description	Default value
glide.kmf.ephemeral.key_padding	Key padding scheme for the ephemeral key.	`OAEPWithSHA256AndMGF1Padding` OAEP SHA256, but SHA1 is supported.
glide.kmf.ephemeral.key_size	Key size of the ephemeral key pair.	`4096` 4096 bits, but 2048 bits are also supported.
Glide.kmf.ephemeral.key_validity_period	Period for which ephemeral key pair is valid.	`02 : 00 : 00` 2 Hours

Procedure

Contact ServiceNow Support if you need to change any of these properties.

Note:
These system properties are not visible to admins, and do not appear in the System properties [sys_properties] list. Use the table above to see their default values.

What to do next
Once your properties are configured to your needs, proceed to Wrap your customer-supplied key.

Wrap your customer-supplied key

Wrap your symmetric data encryption key with an ephemeral public wrapping key before you can upload it to your instance.

Before you begin
Role required: KMF Admin or KMF Cryptographic Operator

You must have a symmetric data encryption key in a `.bin` to use these steps. For instructions on this process, see Configure Customer-supplied keys for Field Encryption Enterprise.

Important:
Your symmetric data encryption key must be in a binary format (.BIN). If another format is used, the following error message:

```
Token failed validation. Please reattach the unmodified token.
```

About this task
To modify optional properties that control the size, padding algorithm, and validity period of the key, see Configure properties for customer-supplied key.

You must have a cryptographic tool to wrap your key. The example in this document uses OpenSSL 1.1. For more information on OpenSSL, see details at https://www.openssl.org. If

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

you're using other cryptographic tools, such as LibreSSL or GnuTLS, refer to the documentation for those products for similar steps.

Procedure

1. Navigate to **All** > **System Security** > **Field Encryption** > **Field Encryption Modules**.
2. Open a field encryption module that you've previously created.

   Note:
   If you haven't created a field encryption module yet, you can create one using the steps in Configure Field Encryption modules.

3. In the **Module** related list, open the cryptographic specific record by selecting the name under **Key alias**.
4. Select the **Next** button until you reach the **Key Origin** section.
5. Verify that the **Origin** field has a value of **Upload customer supplied key**.
   If that value can't be selected, refer to steps 3–5 in Configure Customer-supplied keys for Field Encryption Enterprise.
6. In the **Key Alias** field, create an alias.
   Your key uses this alias once it's uploaded.
7. Select **Next**.
8. Select the link in the **Download wrapping key** field.

   A `token_publickey` file downloads to your computer. Don't rename this file.

9. On your local machine, unzip and open the `token_publickey` folder.
   You should see an import token file (.txt) and a public key file (.PEM) in this folder.
10. Move your symmetric data encryption key that you generated into this folder.
11. Copy the name of the `token_publickey` file to your clipboard.
12. Open a terminal session and navigate to the `token_publickey` folder.
13. Enter the following command:

Important:
Replace any bracketed text (<>) with your specific file names and information. Use the following key wrapping command examples table as a guide.

```
openssl pkeyutl -encrypt -pubin -inkey publickey_<keyname>.
PEM -in <keyname.bin> -out wrapped_key_material -pkeyopt
rsa_padding_mode:oaep -pkeyopt rsa_oaep_md:sha256
```

Key wrapping command examples

Directions	Command	Example
Input the publickey_<keyname>.PEM	`openssl pkeyutl -encrypt -pubin -inkey publickey_<keyname>.PE`	`openssl pkeyutl -encrypt -pubin -inkey publickey_567898643ffff.PEM`
Input the name of your symmetric data encryption key	`-in <keyname.bin>`	`-in mykey.bin`

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Directions	Command	Example
Enter the <-out> command and specify whether the wrapped key material should use 256-bit encryption	`-out wrapped_key_material -pkeyopt rsa_padding_mode:oaep -pkeyopt rsa_oaep_md:sha256`	NA

What to do next

Now that your key is wrapped, you can upload it to your instance using the procedure in Upload your customer-supplied key.

Upload your customer-supplied key

Upload your wrapped symmetric data encryption key to your instance to begin using it work encryption.

Before you begin

Role required: KMF Admin or KMF Cryptographic Manager

About this task

Note:
If you don't want to supply your own key, you can use the steps in Configure Field Encryption modules to use a ServiceNow. You cannot revoke a customer supplied key.

Procedure

1. Navigate to **All** > **System Security** > **Field Encryption** > **Field Encryption Modules**.
2. Open a field encryption module where you want to use your key.
3. In the **Module** related list, open the cryptographic specific record by selecting the name under **Key alias**.
4. Select the **Next** button until you reach the **Key Origin** section.
5. Verify that the **Origin** field has a value of **Upload customer supplied key**.
   If it doesn’t, and you don’t can choose that value, please refer to steps 3–5 in Configure Customer-supplied keys for Field Encryption Enterprise.
6. Confirm that you have a value in the **Key Alias** field.
7. Select **Next**.
8. Select the **Upload customer supplied key** link.
   This link should appear underneath the **Download wrapping key** link that you selected as part of wrapping your key.
9. Select **Browse**, and select two files:
   a. The wrapped_key_material file
   b. The “import token” file
10. Select **OK**.

Result

A confirmation message displays a successful upload of the customer-supplied key. The key is also listed in the **Module Keys** related list with an **Origin** of `customer-supplied key`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Now that your encryption key is configured, you can begin to specify which fields and attachments are encrypted. For details, see Configure encrypted field configurations for fields or attachments.

Configure encrypted field configurations for fields or attachments

Create an encrypted field configuration to specify which fields are encrypted on a table, and whether that tables attachments are encrypted.

Before you begin

Role required: KMF Admin or KMF Cryptographic Manager, Security Admin

You must have a configured field encryption module with a ServiceNow or customer-supplied key. If you have not yet configured a module, see Configure Field Encryption modules.

Procedure

1. Ensure that you are in the same application scope as the table you want to encrypt.
2. Navigate to **All** > **System Security** > **Field Encryption** > **Encrypted Field Configurations**.
3. Select **New**.
4. In the **Encrypted Field Configuration** form, fields in the fields as needed.

Field	Value
Type	Select either **Column** or **Attachment** **Note:** Attachment encryption is only available with Field Encryption Enterprise.
Table	Select the table which will have it's fields or attachments encrypted.
Column	If you have chosen **Column** in the **Type** field, select the fields to be encrypted. **Note:** If the field you want to encrypt is not available, it may not be a supported type. The supported field types are: ○ String (including Full UTF-8) ○ Date ○ Date/Time ○ URL ○ HTML ○ Journal ○ Translated ○ Email ○ Phone
Active	Whether the configuration is active.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Value
	Important: When active, your instance is actively encrypting new data in the selected fields or attachments. Users will not have access to this data unless they have permission via an associated Module Access Policy. Do not check if the field is not yet ready to begin encrypting and enforcing Module Access Policies. To ensure historical data is encrypted after an Encrypted Field Configuration is active, you'll need to run a Mass Encryption Job on the column. For details, see "Schedule Mass Encryption, Decryption, or Rekeying" .
Crypto Module	The field encryption module use by this encrypted field configuration.
Method	Select **Single Module** to ensure all fields or attachments are encrypted by a single field encryption module. Select **Multi Module** to allow for different field encryption modules to be used for different rows within a column or different attachments. For details on multi-module configuration, see .
Algorithm Equality Preserving	Displays whether **Equality Preserving** is enabled in the field encryption module selected in the **Crypto Module** field.

5. Select **Submit**.

Configure multi-module encrypted field configurations

Create an encrypted field configuration that uses more than one encryption module.

Before you begin

Role required: KMF Admin or KMF Cryptographic Manager, Security Admin

You must have a configured field encryption module with a ServiceNow or customer-supplied key. If you have not yet configured a module, see Configure Field Encryption modules.

About this task

Use multiple encryption modules for a single encrypted field configuration to encrypt different rows within a column (or different attachments on the same table) using different module keys. For example, users with different roles can encrypt data on the same table, but still be prevented from decrypting each others encrypted data.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

⚠ Warning:

Note these limitations on multi-module encrypted field configuration before proceeding:

- Mass encryption isn't supported for multi-module encrypted field configurations.
- You can't change a field configuration from a multi-module to a single module. Instead, you must deactivate the multi-module field configuration and create a new single module one.
- Which module key a multi-module field configuration uses is determined by the first user to enter data into a field. Because the field encryption module is set on a per-record basis, fields in a list can be encrypted by different field encryption modules. However, within a single record, the field can be encrypted by only one field encryption module.

Procedure

1. Verify that you are in the same application scope as the table you want to encrypt.
2. Confirm that you have the field encryption modules you want to use created.
   If you have not done so, see Configure Field Encryption modules.
3. Confirm that each of your modules has a module access policy.
   If you have not done so, see Configure module access policies for field encryption.
4. Navigate to **All** > **System Security** > **Field Encryption** > **Encrypted Field Configurations**.
5. Open of create an encrypted field configuration record.
6. In the **Method** field, select **Multiple Modules**.
7. Select **Column** or **Attachment** in the **Type** field, depending on your need.
8. Select a table in the **Table** field, and column in the **Column** field, if applicable.
9. Select **Submit**.

Result

After the record is saved, and the **Active** field is enabled, new data created for the specified field is encrypted with the module key of the relevant field encryption module. When a user with the role in module access policy "A" writes to the specified table, the data is encrypted with field encryption modules "A"'s module key. In this case, only users with the same role are able to decrypt that data.

Example: Encrypting the Short Description column on the Incident table using a multi-module encrypted field configuration

1. Create two field encryption modules, referred to A and B in this example.
2. For each field encryption module, create a module access policy (MAPs A and B).
   a. For field encryption module A, give users with an HR role access to Module Access Policy A.
   b. For field encryption module B, give users with a Sales role access to Module Access Policy B.
3. Create an encrypted field configuration record specifying the Short Description column on the Incident table, and make sure that you select **Multiple Modules** in the **Method** field.
4. Have two users:
   - One with the HR Role related to MAP A and field encryption module A (User A)
   - One with the Sales role related to MAP B and field encryption module B (User B)

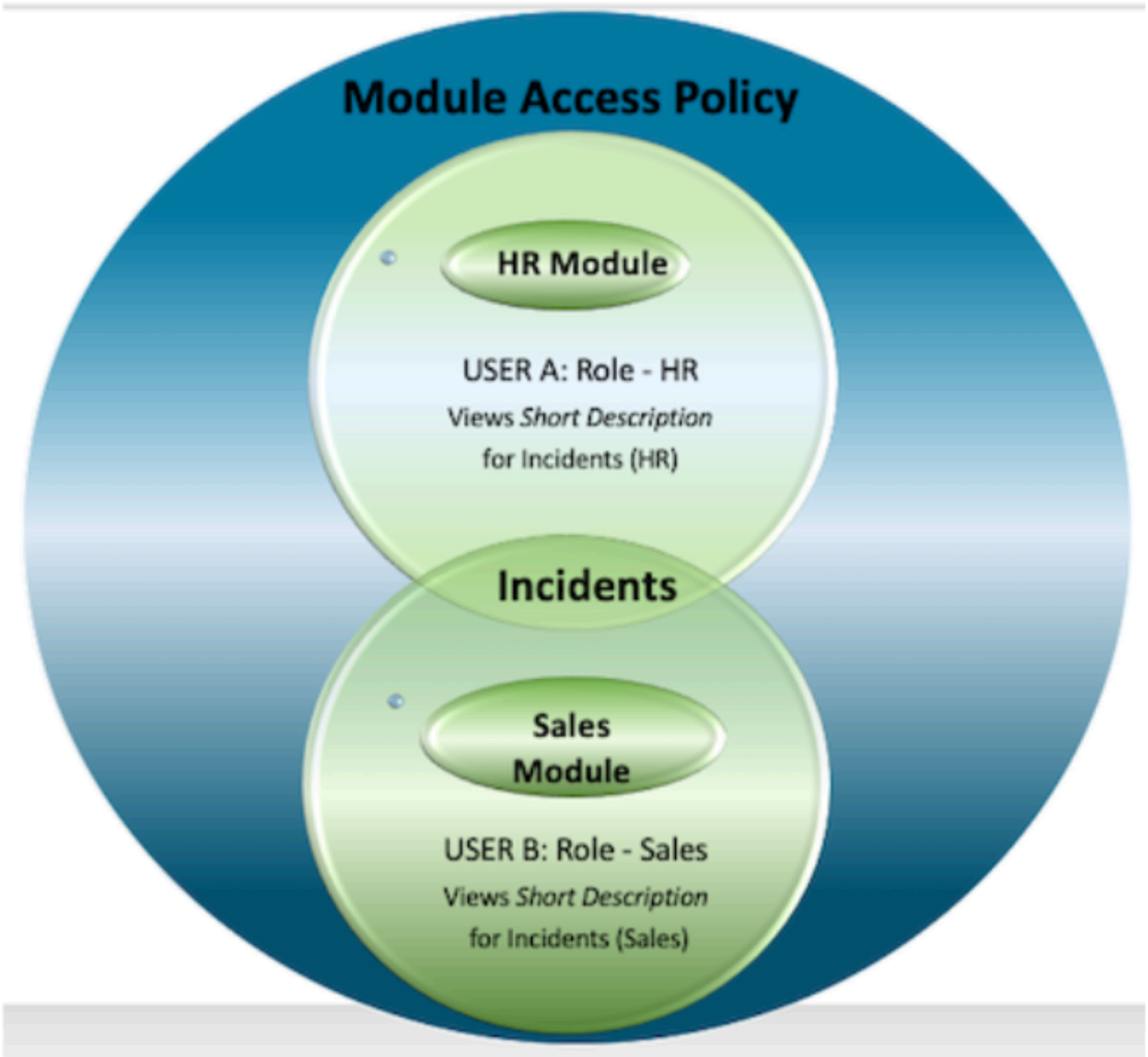
   create an incident record with a short description value. Have both users look at the list of incidents.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

a. The short description for the incident record created by User A is encrypted with the key for field encryption module A.

b. The short description for the incident record created by User B is encrypted with the key for field encryption module B.

5. Users with the HR and Sales roles have access to incidents. Only a user with the HR role can decrypt and view the short description for those incidents created by User A (who had the HR Role). Only users with the Sales role can decrypt and view the short descriptions for those incidents created by User B (who has the Sales role).



Configure module access policies for field encryption

Create a module access policy to control which users, scripts, or system processes can encrypt or decrypt data encrypted by a field encryption module.

Before you begin

Role required: KMF Admin or KMF Cryptographic Manager, Security Admin

You must have a published field encryption module to use this process. If you have not done so, see Configure Field Encryption modules.

About this task

Module access policies (MAPs) are the access controls you apply to your field encryption modules to define which users, scripts, or system processes can encrypt or decrypt data.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Configure MAPs for users (via roles), scripts, or processes running in the “system” context. Without a MAP, users, scripts, or system processes aren’t able to encrypt or decrypt data, which can result in end-to-end workflow processes not working correctly.

MAPs are separate from access control lists (ACL), but can be used in combination with them. See Exploring Field Encryption for more information about the purpose behind MAPs.

For Field Encryption Enterprise, review to plan for which users, scripts, or system processes need a MAP.

Procedure

1. Navigate to **All** > **Key Management** > **Module Access Policies** > **All**.
2. Select **New**.
3. In the Module Access Policy form, fill in the fields as needed.

Field	Description
Policy Name	Name of your MAP
Crypto Module	Select the field encryption module to be governed by this MAP.
Crypto Spec	Optional. Select or create a new Cryptographic Specification for this MAP. This field appears only when the **Specify Purpose** field is enabled.
Type	Decide who or what should have access to this MAP to encrypt or decrypt data. **Scope** Anything within the specified Application Scope has access to this MAP. **Role** Only users with the specific role can access this MAP. **Script** Ensure a specified script can access this MAP. **System Access** Allows processes running in “System Context” access to this MAP. **Resource Exchange** Allows for the Resource Exchange feature access to this MAP. For more information on how these different types of MAP work, see Exploring Field Encryption.
Target Scope	Select a scope to that this MAP applies to. This field appears only if the **Type** field is set to **Scope**.
Specify Purpose	Optional. Enable to display the **Crypto Spec** field on the form. Enable this option to configure granular operations, such as some users being able to encrypt, but not decrypt.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Granular Operation	Optional. Select the cryptographic purpose for the Crypto Spec. The values available depend upon the type of Crypto Spec that is selected. For example, you can specify that this MAP only allows users to encrypt, but not decrypt, or the opposite, or both. This field appears only if there's a value in the **Crypto Spec** field. ○ If a user has encrypt access, but not decrypt access, the field displays in edit mode and the data entered displays as asterisks. ○ If a user has decrypt access, but not encrypt access, the field displays the decrypted data in read-only mode. ○ If a user has encrypt and decrypt access, both read and write functionality are available for the encrypted field.
Target Role	Select which role should have access to this MAP. This field appears only when the **Type** field is set to **Role**
Script Table	Select which type of script applies to this MAP: ○ Access Control ○ Activity Designer ○ Business Rule ○ Inbound Email Action ○ Record Producer ○ Scheduled Script Execution ○ Script Include ○ UI Action ○ Widget ○ Workflow Activity This field appears only if the **Type** field is set to **Script**.
Target Script	Choose the specific script of the type table selected in the **Script Table** field that should have access to this MAP. This field appears only if the **Type** field is set to **Script**.
Check Script Version	When selected, the system checks the version of the script that is run with the version specified in the **Target Script** field. If the versions are different, the admin is notified. This field appears only if the **Type** field is set to **Script**.
Approval Type	Select either **One Time** or **Recurring**: **One Time** Allows for the symmetric data encryption key in the associated field encryption module to be securely shared to the target instance one time.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Recurring Allows for the symmetric data encryption key in the associated field encryption module to be securely shared to the target instance on a recurring basis. This field appears only if the **Type** field is set to **Resource Exchange**.
Target Instance Host	Enter the URL for the target instance that the symmetric data encryption key in the associated field encryption module is being sent to. This field appears only if the **Type** field is set to **Resource Exchange**.
Impersonation	When enabled, a user impersonating another user gains any MAP permissions from both users. If disabled, a user impersonating another user only has any MAP permissions that were granted to them from before the impersonation.
Active	Enable to activate this MAP.
Result	Select one of the following: **Track** Permits access and monitors use of the MAP. **Reject** Rejects access unless a different MAP grants access. **StrictReject** Rejects access under all circumstances, even if a different MAP grants access.

4. Select **Submit**.

Migrating to Field Encryption

Scheduled jobs migrate your keys and encrypted data from Encryption Support to Field Encryption.

When you install Field Encryption, the migration process triggers automatically. Once the key migration job completes, encryption context keys are restricted to decryption only. Use cryptographic module keys for all new encryption operations going forward.

You can review the scheduled jobs by navigating to **System Security** > **High Security Settings** > **Security Jobs**:

- **autoKeyMigration**: Migrates encryption context keys to Key Management Framework (KMF) cryptographic module keys.
- **autoDataMigration**: Migrates data that you already encrypted to use the KMF cryptographic module key.

You can modify when these scheduled jobs run, and can pause or restart them at any time.

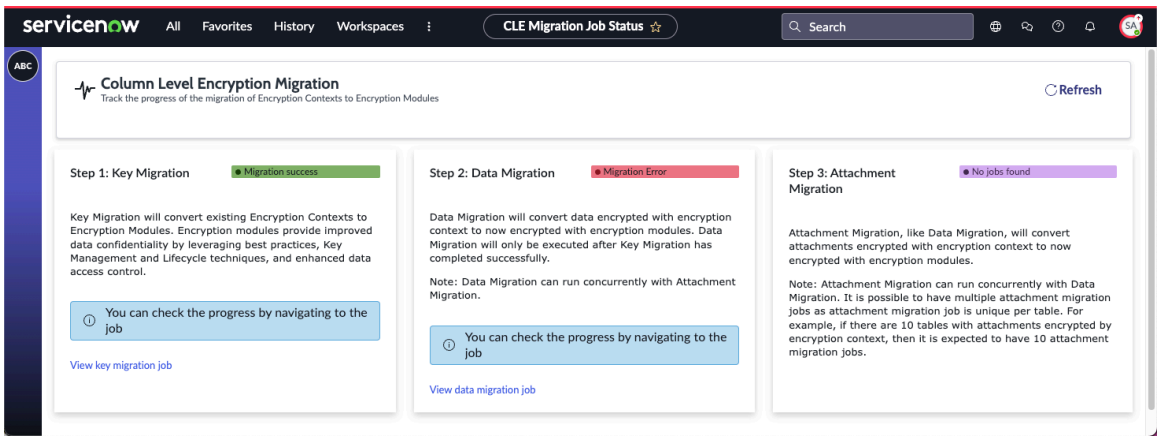
Verify that the encrypted field configurations are using your newly migrated module keys by navigating to **System Security** > **Field Encryption** > **Encrypted Field Configurations**. Look for the following items:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- The **Method** field is **Single Module**.
- The **Crypto module** field is populated with the name of the cryptographic module that the system automatically creates. You can review that module and the module access policy, both of which are active and published.

Field Encryption migration status page

Use the migration status page to track the migration of encryption contexts to encryption modules.

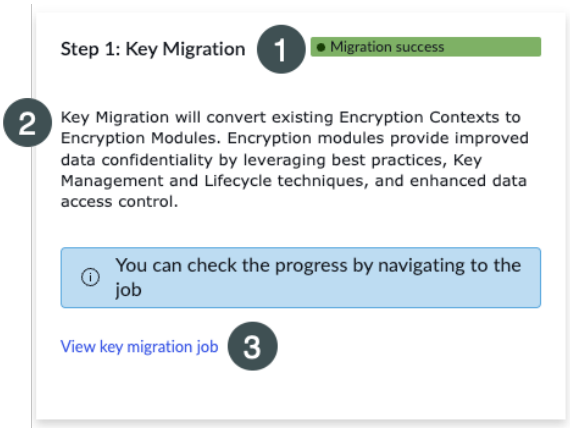


The Field Encryption Migration page displays the status of the steps involved in migrating encryption contexts to encryption modules. Each of the three sections displays the status of a specific step in the process.

Page section cards

The page contains three cards representing the steps in the migration progress. These cards display:

- (1) The status of the current step. This status will display whether the step has completed successfully, or if there are no jobs to process.
- (2) A description of the listed step.
- (3) A link to the relevant encryption job [sys_mass_encryption_job] record.



Migrate from Edge Encryption to Field Encryption

Migrate from Edge Encryption to Field Encryption to take advantage of the latest security features.

Migration process

This topic covers, which comprise the following steps:

1. Migrate columns and attachment from Edge Encryption to Field Encryption.
2. Stop and disabling Edge Encryption proxy servers.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. De-tokenize your data
4. Decrypt Service Catalog item variables.

Limitations

- Field Encryption doesn't currently support tokenizing data in the same way that Edge Encryption does. Data that is tokenized through Edge Encryption must be included in an encrypted field configuration for Field Encryption.
- Field Encryption doesn't currently support encrypting Service Catalog item variables.

Configure Field Encryption for your Edge Encrypted fields

Before migrating your existing edge encrypted fields to Field Encryption, you must configure field encryption for these fields.

Before you begin

Role required: admin

This process assumes you have existing edge encrypted fields that you want to migrate to Field Encryption.

Procedure

1. Navigate to **All** > **Key Management** > **Cryptographic Modules** > **All** > **.**
2. In the Cryptographic Modules list, select **New**.
3. In the form, fill in these fields.

Field	Value
Name	Select descriptive name
Crypto spec template	Default template
Crypto module lifecycle state	Published
Parent crypto module	column_level_encryption

4. Right-click the form header and select **Save**.
5. In the **Crypto Specifications** related list, open the record on the list.
6. In the **Crypto Specification** record, select **Next** three times to complete the algorithm definition, lifecycle definition, and key origin sections.
   You don't need to modify any fields in these sections.
7. In the **Generate Key** field, select the **Generate Key** link to generate a key.
8. Navigate to **All** > **System Security** > **Field Encryption** > **Encrypted Field Configuration**.
9. In the encrypted field configuration list, select **New**.
10. In the form, fill in these fields.

Field	Value
Type	Select Column or Attachment, depending on what you want to encrypt.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Value
Crypto module	Select the cryptographic module that you created in earlier steps.
Table	Select the table containing the data that you want encrypted.
Method	Select `Single Module`
Column	Select the column (field) on the table that you want to be encrypted.

Note:
The data to encrypt is determined by the Table and Column fields. These fields should be the table and column (field) where you're currently using Edge Encryption.

11. Select **Submit**.
12. Navigate to **All** > **Key Management** > **Module Access Policies** > **All**.
13. Select **New**.
14. In the form, fill in these fields.

Field	Value
Policy name	Select descriptive name
Crypto module	Select the cryptographic module that you created in earlier steps.
Type	Select `Role`
Target role	Select a role to be used. This role must be able to encrypt and decrypt data in the column.
Result	Select the desired action.

15. Select **Submit**.
16. To verify your configuration, navigate to the table you want encrypted with Field Encryption, and open a record.

    For example, to access the User [sys_user] table, enter `sys_user.list` into the navigation filter.

    The field you have selected for encryption in the previous steps now has a lock icon next to the field label.

Result
You edge encrypted field is ready to be migrated to field encryption. To configure more fields, repeat the preceding steps for each of those fields.

Field Encryption and system clones

Cloning an instance with Field Encryption installed automatically generates new field encryption module encryption keys on the target clone instance.

If Field Encryption is installed on your instance, a new field encryption module encryption key is automatically generated on the target clone instance as a part of clone process. These keys are generated for all modules to which the user has access, and that does not have a key already.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Because of this, field encryption modules on the target clone instance may have two module encryption keys present:

- An active module encryption key. This is the new key generated after clone, as long as the module is accessible to the user and has no prior keys.
- A deactivated encryption module key (from the automated key exchange transfer

  The active module encryption key is used to encrypt inserted data as needed on the target clone instance. The deactivated module is used to decrypt existing data that was cloned over as part of the system clone.

  To use a single key to decrypt and encrypt all data, you can run a module rekeying job. For more information about module rekeying jobs, see Schedule mass encryption, decryption, and rekeying jobs.

Prevent users from attaching unencrypted files

Modify the com.glide.encryption.enable_attachment_key_ui property to prevent your users with access to an encryption module key from attaching unencrypted attachments.

Before you begin

Role required: security_admin

You must elevate to the security_admin role performing these steps. For instructions, see Elevate to a privileged role

By default, users who have access to an encryption module key are able to upload unencrypted attachments. Use the *com.glide.encryption.enable_attachment_key_ui* system property to change this behavior.

When attaching, your users see a UI picker on records that have a multi-module encrypted field configuration. When this property is set to false, users no longer see an option not to encrypt an attachment.

Procedure

1. Navigate to **All** > **System Properties** > **All Properties**.
2. In the system properties list, find and open the system property.
3. Set the **value** of the property to `false`.

Using Field Encryption

Use Field Encryption to manage access to encrypted data on your instances.

There are two methods of encrypting field data:

- Single module - Permits data encryption using a single encryption module in a deterministic method.
- Multi module - Permits data encryption using multiple encryption modules in a non-deterministic method. Row Conditions is the new and preferred method of applying multiple modules to a field. Row Conditions applies the multi module capability in a deterministic way.

Use the related links to find information on common Field Encryption tasks.

Create cryptographic module for Field Encryption

Create a Field Encryption cryptographic module to define the mechanisms used for cryptographic operations.

Before you begin

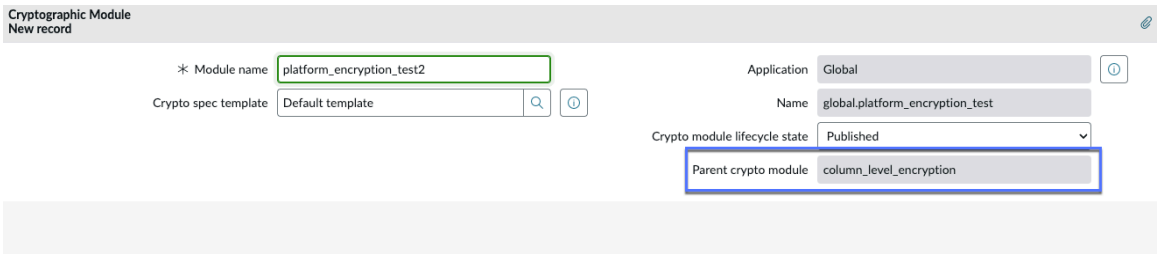
Role required: sn_kmf.cryptographic_manager or sn_kmf_admin, security_admin, admin

About this task

This procedure describes options that are available with Field Encryption with the base system and additional configuration options that become available with Field Encryption Enterprise functionality. Field Encryption Enterprise is available with a paid subscription. Refer to Encryption and Key Management subscription bundle for supported features and options available with each offering. See Activate Field Encryption for more information on obtaining Field Encryption Enterprise.

Procedure

1. Navigate to **All** > **System Security** > **Field Encryption Modules** > **New**.



2. On the form, fill in the fields.

Cryptographic Module form

Field	Description
Module name	Alphanumeric string to be referenced when running scripts.
Crypto spec template	Default template used to create the cryptographic module that contains mappings of many crypto purposes to crypto specifications and recommended algorithms.
Application	The selected application scope.
Name	Encryption module name is prepended with application scope name to avoid conflict with other scoped applications on module creation. For example, if you created a module with the name `my_crypto_module` in the global application scope, the name is saved as `global.my_crypto_module`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Crypto module lifecycle state	The term lifecycle refers to the creation, use, and deactivation of a cryptographic module. Set to **Draft** initially during configuration. When using the module, set to **Published**. The Default template is automatically set to **Published**.
Parent crypto module	The parent is populated automatically as **column_level_encryption**.

3. Click **Submit**.

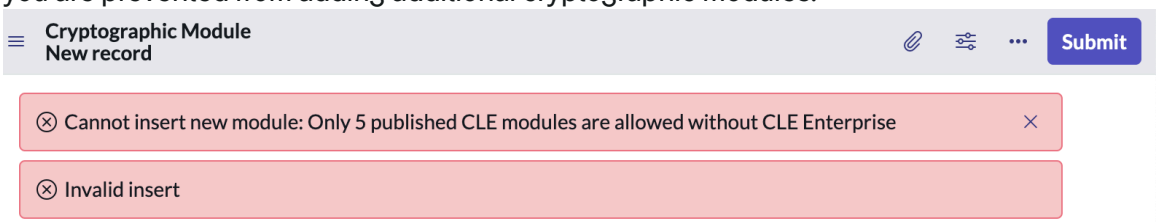
   After submitting successfully, your cryptographic module is listed in the Cryptographic Modules table.

> **Warning:**
>
> **For legacy encryption support users:**
>
> If you're using the non-enterprise version of Field Encryption, you're limited to five fields. If you've exceeded this limit, you receive the following warning:
>
> This insertion exceeds the number of published fields limit for Field Encryption #entitled with the Subscription Product. The Enterprise subscription for Field Encryption is required for additional fields. Please reach out to your Account team.

   A default cryptographic specification is created with the crypto purpose set to Symmetric Data Encryption/Decryption and the algorithm as AES 256 CBC. Select the algorithm for updates.

4. To open the configuration options, click the newly created cryptographic module.

> **Note:**
> A maximum of five Field Encryption fields are allowed before upgrading to Field Encryption Enterprise. An error message displays and you are prevented from adding additional cryptographic modules.



What to do next

Create a cryptographic specification for Field Encryption.

Using multiple encryption modules

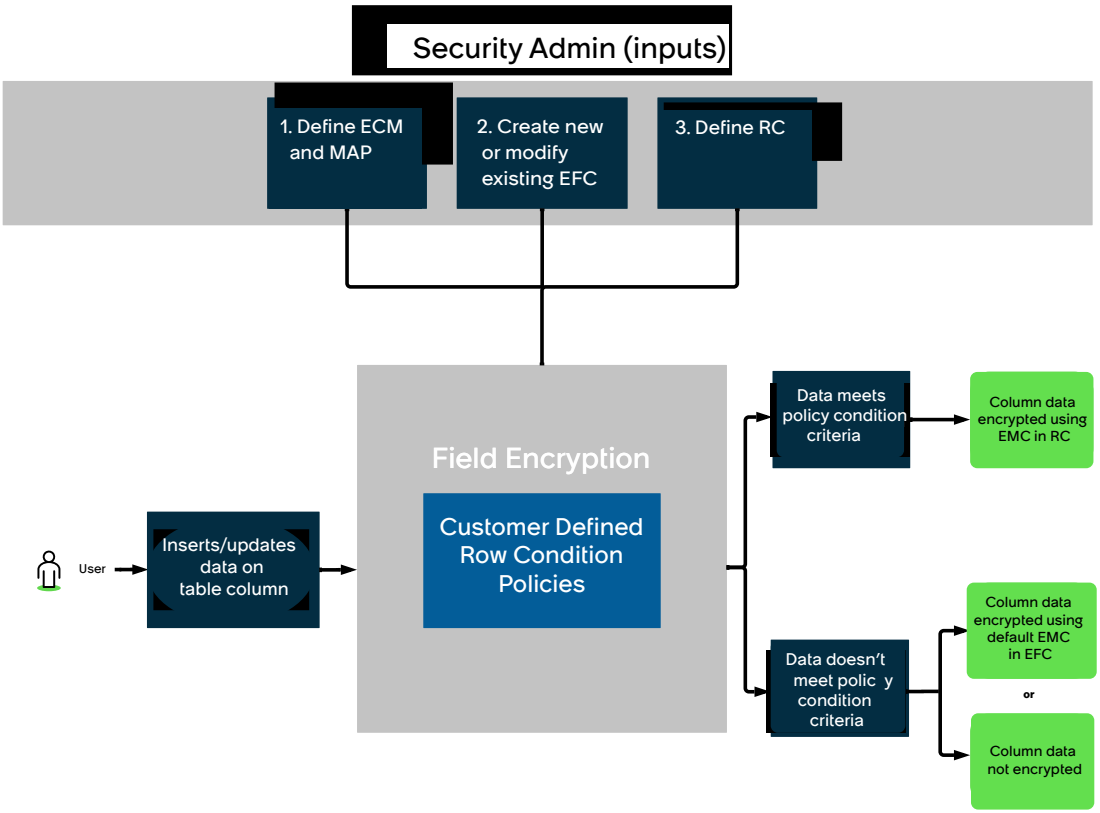
Multiple encryption modules enable data to be encrypted with more than one encryption module. If each module has its own access policy based on a role, for example, users with different roles can encrypt data on the same table but used to help prevent them from viewing each other's encrypted data.

There are two ways to encrypt data using multiple encryption modules in the platform: Row Conditions and multiple module.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Row Conditions

Enables admins to define the encryption crypto module to be used. This option provides a deterministic approach and permits multiple Encryption Field Configurations (EFCs) to a single column. You can encrypt different records for a field or attachment by configuring distinct encryption keys to specific fields. This is achieved by assigning multiple Encryption Field Configurations (EFCs). Row Conditions is the preferred method of encrypting data with multiple modules. See Encrypt data using Row



Conditions.

Multiple module

Enables users to the crypto module to use to encrypt data. Since multiple module depends on the user selecting the correct crypto module to encrypt the data, this configuration is nondeterministic and is considered legacy and not preferred, even though the feature is still currently available. See Encrypt data using the Multiple Modules feature.

Encrypt data using Row Conditions

Encrypt fields with multiple Field Encryption modules using Row Conditions to define the data being encrypted and the associated encryption keys. Row Conditions can also be used to define the users that have access using the condition builder.

Before you begin
Role required: sn_kmf.cryptographic_manager or sn_kmf.admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

About this task

Note:
The following guidelines apply when using Row Conditions:

- Row Conditions is only supported on encrypted columns and attachments.
- Mass encryption isn't available when using the multiple encryption modules method.
- You can't change a field using multiple encryption modules to use a single encryption module.
- Row Conditions enables data to be encrypted on the main record. Dot-walking isn't supported in the condition builder.
- Row Conditions isn't supported by the following service catalog tables:
  - Options [sc_item_option]
  - Question Answer [question_answer]
  - Multi Row Question Answer [sc_multi_row_question_answer]

The field is encrypted by the encryption module of the first user to enter data. Because the encryption module is set on a per record basis, fields in a list can have different encryption modules. Within a single record, the field can be encrypted by only one module.

Procedure

1. Create multiple cryptographic modules and an access policy for each one.

   Make sure that you grant different roles to the different cryptographic modules through the access policies.

2. Navigate to **System Security** > **Field Encryption** > **Encrypted Field Configurations** > **New**.

   If you need more information on Encrypted Field Configurations, see Set encrypted field configurations.

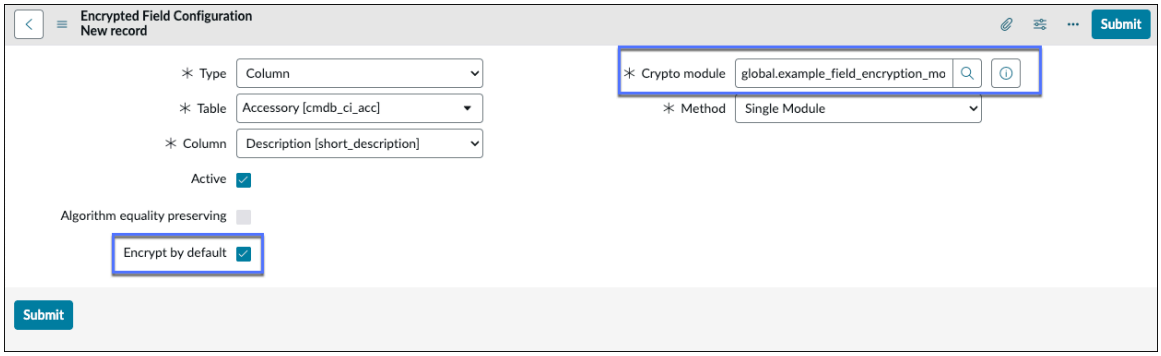
3. Select the **Table** and the **Column** in the table that you want to encrypt.
4. Select **Encrypt by default** to encrypt saved records that don't meet a defined row condition.

   If you select this option, make sure to select the **Crypto Module** to be used as a default encryption module.

   If this box isn't selected and records that are added don't meet a row condition, they aren't encrypted.

   For example, a Row Condition can be defined to encrypt records to declare that the "Department" field on the record equals "IT." Then, the records in which the "Department" field doesn't equal "IT" wouldn't be encrypted unless **Encrypt by default** is selected. This example utilizes a custom created "Department" Choice field on the sn_customerservice_case table, but other custom or default fields, if they are a supported data type of Row Conditions.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



5. Select **Submit**.
6. Navigate to the condition builder **All** > **System Security** > **Field Encryption** > **Encrypted Field Configurations** and select the newly created Encrypted Field Configuration (EFC).
7. Select **New** under the **Encrypted Row Configurations** related list.
8. Define Row Conditions by filling out the required fields.
9. Select **Submit**.

Result

Note:
Repeat this process as needed to ensure that the number of Row Conditions meet your required Encryption Crypto Modules (ECMs). When selecting Encrypt by default in the ECM setup, a Row Condition must also be established to define the default ECM selected.

Newly created data for the specified field is encrypted with the key for the relevant module. When a user with the role specified in module A's access policy writes to the specified table, the data is encrypted with module A's key. Only users with the same role can read the data.

Example:
This example explains how to encrypt the Short Description field on the Incident table. This example works similarly if you want to encrypt a different field in a table.
For encrypting the Short Description, you would do the following:

1. Create two Field Encryption modules A and B.
2. For each module, create a Module Access Policy (MAP) and define access as follows:
   a. Module A – to users with an HR role.
   b. Module B – to users with a Sales role.
3. Create an Encrypted Field Configuration (EFC) record.
   a. Navigate to **System Security** > **Field Encryption** > **Encrypted Field Configurations** > **New**.
   b. Select **Incident** in the Table field.
   c. Select **Short Description** in the Column field.
   d. Select the **Encrypt by default** box if you must verify any records that fall outside of the condition builder criteria are still encrypted by the default field encryption module. Not selecting this option would mean that any records that fall outside of the condition builder criteria won't be encrypted.

      Enter the default crypto module in the related **Crypto module** field.

   e. Select **Submit**.
4. Create the Row Conditions.
5. Run the appropriate encryption job:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

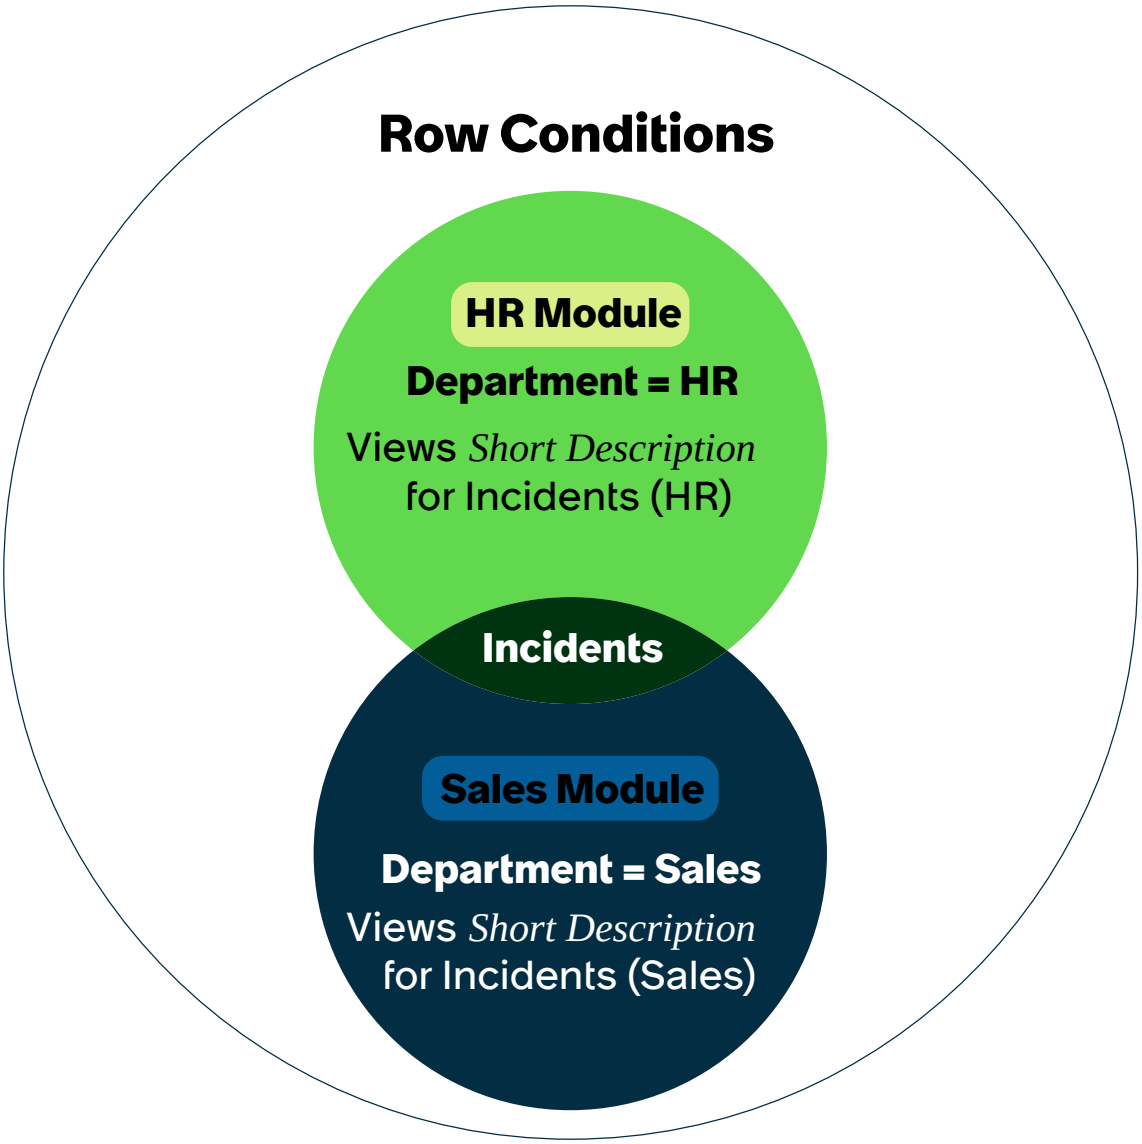
- Mass Encryption - Run this job when a new Row Condition is created.
- Mass Rekeying - Run this job when an existing Row Condition is modified.

See Schedule mass encryption, decryption, and rekeying jobs.

6. Have a user from Module A and a user from Module B create an incident with a short description. Have both users view the list of incidents.

The short description for the incident created by the user with the HR role is encrypted by the key for module A. The short description for the incident created by the user with the Sales role is encrypted by the key for module B.

All users with the HR and Sales roles have access to incidents. However, only a user with the HR role can decrypt and view the short description for those incidents created by another user with the HR role. Likewise, only users with the Sales role can decrypt and view the short descriptions for those incidents created by the user B, who had the Sales role.



What to do next
Perform one of the following operations:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Schedule a **Mass Encryption** job to update the encryption of the condition field.
- If modifying an existing Row Condition run a **Mass Rekeying** job to encrypt necessary data with the updated encryption module.

See Schedule mass encryption, decryption, and rekeying jobs

Encrypt data using the Multiple Modules feature

Encrypt data with more than one encryption module permitting the user to determine which keys are used for specific rows within the encrypted data.

Before you begin

Role required: sn_kmf.cryptographic_manager or sn_kmf.admin

About this task

The Multiple Modules option is considered non-deterministic and isn't the preferred method because the user determines which key to use for a given record. The ability to use multiple modules for a column is being replaced by Row Conditions. See Using multiple encryption modules. This non-deterministic implementation is still supported because it was created first and is still in use, but it's preferred to use Row Conditions for any new multiple modules use cases.

Note:
Only encryption on columns supports multiple modules. Attachment encryption doesn't. Mass encryption isn't available when using the multiple encryption modules method.

You can't change a field using multiple encryption modules to use a single encryption module.

The field is encrypted by the encryption module of the first user to enter data. Because the encryption module is set on a per record basis, fields in a list can have different encryption modules. Within a single record, the field can be encrypted by only one module.

Procedure

1. Create multiple Field Encryption modules and a Module Access Policy (MAP) for each one.

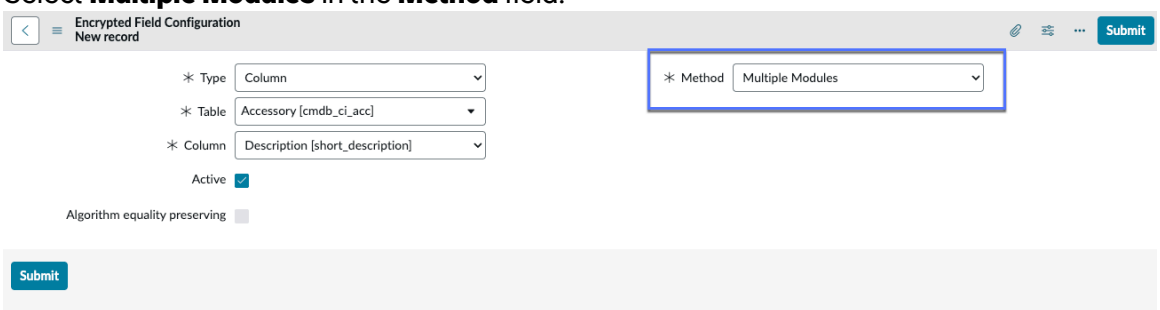
   Make sure that you grant different roles to the different cryptographic modules through the access policies.

2. Navigate to **System Security** > **Field Encryption** > **Encrypted Field Configurations** > **New**.

   If you need more information on Encrypted Field Configurations, see Set encrypted field configurations.

3. In the **Type** field, you must select **Column**.
   Attachment encryption doesn't support multiple modules.

4. Select **Multiple Modules** in the **Method** field.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

5. Select the **Table** and the **Column** in the table that you want to encrypt.
6. Select **Submit**.

Result

Newly created data for the specified field is encrypted with the key of the relevant module. When a user with the role specified in module A's access policy writes to the specified table, the data is encrypted with module A's key. Only users with the same role can read the data.

Example:

To encrypt the Short Description column on the Incident table. You would do the following:

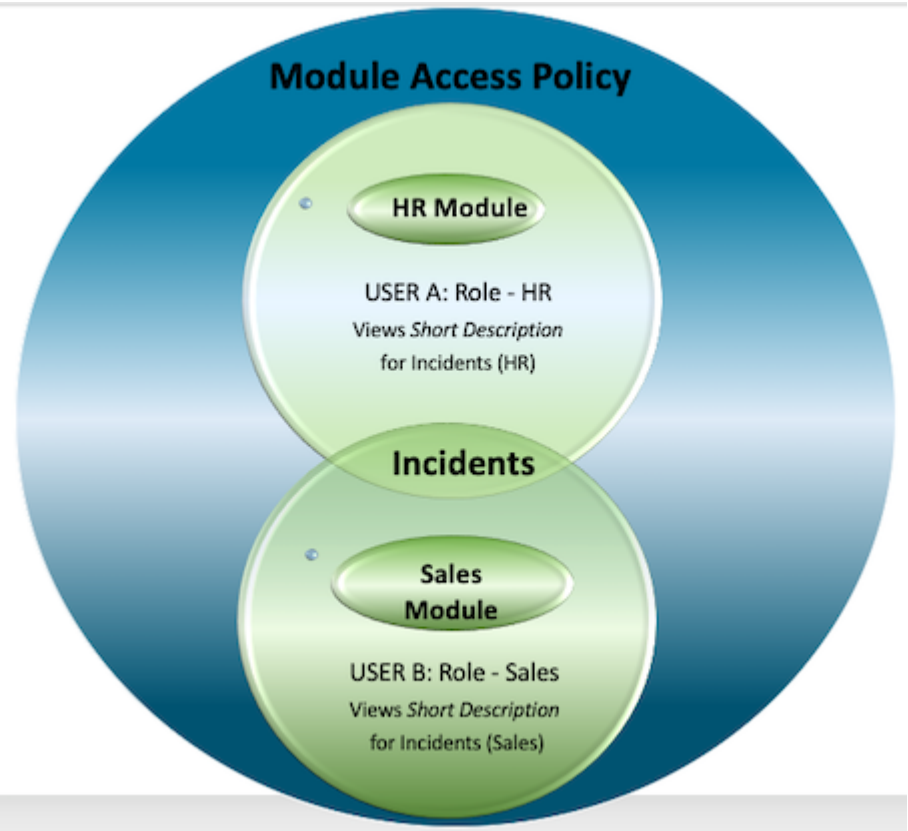
1. Create two cryptographic modules A and B.
2. For each module, create a module access policy.

   For module A, give users with an HR role access. For module B, give users with a Sales role access.

3. Create an Encrypted Field Configuration record specifying the Short Description column on the Incident table, and make sure that you select **Multiple Modules** in the **Method** field.
4. Have two users, one with the HR role (user A) and one with the Sales role (user B), create an incident with a short description, and then have both users look at the list of incidents.

   The short description for the incident created by the user with the HR role is encrypted by the key for module A. Likewise, the short description for the incident created by the user with the Sales role is encrypted by the key for module B.

   Although all users with the HR and Sales roles have access to incidents, only a user with the HR role can decrypt and view the short description for those incidents created by user A, who had the HR role. Likewise, only users with the Sales role can decrypt and view the short descriptions for those incidents created by the user B, who had the Sales role.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Create a cryptographic specification for Field Encryption

After you create a cryptographic module, access the corresponding cryptographic specification to define the algorithm.

Before you begin

Role required: sn_kmf.cryptographic_manager or sn_kmf_admin and security_admin or admin

About this task

This procedure describes options that are available with Field Encryption with the base system and additional configuration options that become available with Field Encryption Enterprise functionality. Field Encryption Enterprise functionality is available with a paid subscription. Refer to Encryption and Key Management subscription bundle for supported features and options available with each offering. See Activate Field Encryption for more information on obtaining Field Encryption Enterprise.

A cryptographic specification will be created by the system when you create a cryptographic module for Field Encryption Enterprise.

Procedure

1. Navigate to **System Security** > **Field Encryption Modules** > **All**.
2. Select the cryptographic module to open the configuration options.
   Cryptographic module information is displayed at the top of the screen. A Symmetric Data Encryption/Decryption crypto specification is auto-created with an AES 256 CBC algorithm.
3. Select the crypto specification from the table to open the Algorithm Definition.
   For Field Encryption Enterprise see Configure advanced algorithms for Field Encryption Enterprise.
4. Click **Next** to access the Key Lifecycle.

What to do next

Perform one of the following operations:

- Select an entry in the Key Lifecycle table to define key lifecycle behavior. See Configure key lifecycle states for details to complete the lifecycle definition for the key.
- Click **Next** to create a cryptographic key. For details on this process, see Generate a ServiceNow cryptographic key.

Configure advanced algorithms for Field Encryption Enterprise

Create a cryptographic specification to define the algorithm for a cryptographic module. Customize the encryption specifications with advanced options that are available for Field Encryption Enterprise.

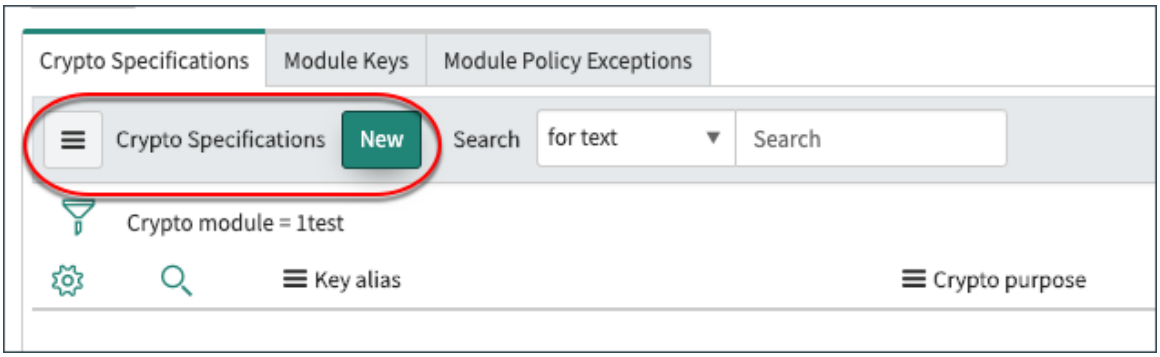
Before you begin

Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. On the **Crypto Specifications (#)** tab, click **New**.



2. On the form, fill in the fields.

Algorithm Definition form

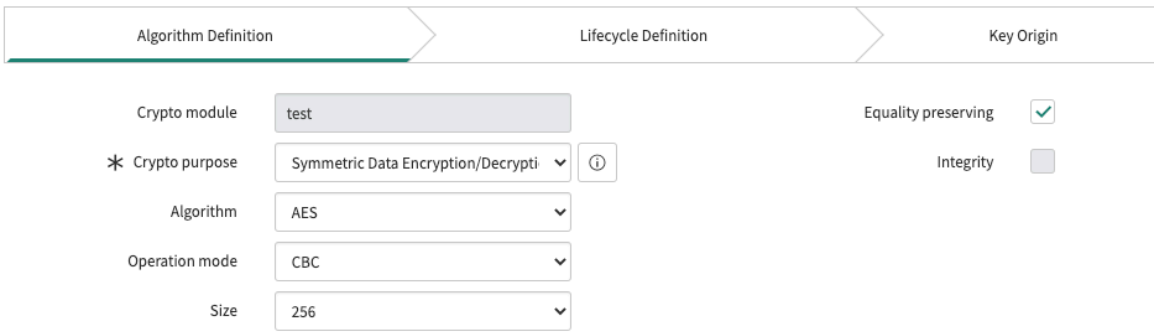
Field	Description
Crypto module	Name of the selected cryptographic module populates.
Crypto purpose	The value is **Symmetric Data Encryption/ Decryption** for Field Encryption Enterprise.
Algorithm	The value is **AES** for Field Encryption Enterprise.
Operation mode	The value is **CBC** for Field Encryption Enterprise.
Size	Possible values are **256** and **128**. **Note:** 256-bit size is most secure for encryption and is used for Symmetric Data Encryption/Decryption for Field Encryption Enterprise.
Equality preserving	Option to enable deterministic encryption. **Note:** Selecting this option means that the encrypted value of a field should be the same when the field value remains the same. Option to enable **Symmetric Data Encryption/Decryption** with **AES** in **Cipher Block Chaining (CBC)** mode.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Integrity	Option to provide Integrity in GCM operation and does not apply for Field Encryption Enterprise functionality.

3. Click **Submit**.

   The following example shows AES CBC-256 encryption. When Field Encryption Enterprise is active and the parent module is column_level_encryption, only Symmetric Data Encryption/Decryption AES CBC-256 applies as the crypto purpose. See Cryptographic specification overview for details.



What to do next

Perform one of the following operations:

- Select an entry in the Key Lifecycle table to define key lifecycle behavior. See Configure key lifecycle states for details to complete the lifecycle definition for the key.
- Select **Next** to create a cryptographic key. See one of the following tasks for key generation:
  - Generate a ServiceNow cryptographic key.
  - Configure properties for customer-supplied keys.
  - Import the wrapping / unwrapping key pair.

Using customer supplied keys with Field Encryption Enterprise

You can use your own customer-supplied key instead of using the ServiceNow® system-generated keys.

Important:
These topics only apply instances using Field Encryption Enterprise, which is only available with the *com.glide.now.platform.encryption* plugin. See Activate Field Encryption for more information on obtaining this plugin.

With Field Encryption Enterprise you can use your own keys for encryption. Administrators have the choice to use ServiceNow® supplied keys or your own customer-supplied keys (CSK) for encryption on the ServiceNow AI Platform.

Important:
To make use of the customer supplied key option, you must have your own cryptographic key.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Once you have your key, you can being using it on your instances by following these steps.

1. **Configure properties for customer-supplied keys**

   There are three system properties which define the size, padding algorithm, and validity period of the wrapping RSA key pair. Review these properties and adjust their values if the defaults to not fit your needs.

2. **Wrap your customer-supplied key**

   Use a cryptographic tool to wrap your key like OpenSSL to wrap the symmetric key to use for encryption with the downloaded public key.

Configure and upload your customer supplied key

Upload your wrapped your customer supplied key and configure cryptographic module to begin using your key for encryption on your instance.

Configure properties for customer-supplied keys

If the Field Encryption Enterprise plugin is enabled, you can use system properties to define key padding, ephemeral key pair size, and a key validity period of your customer-supplied keys.

Field Encryption Enterprise with Key Management lets you manage the full key lifecycle of your data encryption keys. Optionally, you can securely exchange data encryption keys generated within your environment.

Platform Encryption with Key Management lets you manage the full key life cycle of your data encryption keys. Optionally, you can securely exchange data encryption keys generated within your environment.

System properties for defining key-pair attributes

When you provide your own key, you must wrap it with the RSA public key. Three properties define the size, padding algorithm, and validity period of the wrapping RSA key pair:

- *glide.kmf.ephemeral_key.key_padding* controls the key padding scheme for the ephemeral key. The default scheme is OAEP SHA256, but SHA1 is also supported.
- *glide.kmf.ephemeral_key.key_size* controls the key size of the ephemeral key pair. The default is 4096 bits, but 2048 bits are also supported.
- *glide.kmf.ephemeral_key.key_validity_period* defines the period for which the ephemeral key pair is valid. The default value is two hours.

After the data encryption key is imported to the instance, a secure wrapping key protects new module keys on the instance. The wrapping key is an instance key encryption key (IKEK) generated by a hardware security module (HSM) on SafeNet KeySecure. See Instance level keys in the Key Management Framework for details in key types.

Continue to Wrap your customer-supplied key.

Wrap your customer-supplied key

Wrap the symmetric key to use for encryption with the downloaded public key.

Before you begin

Note:
This procedure describes options that are available with KMF base system and options to be used with Field Encryption Enterprise functionality. Field Encryption Enterprise functionality is available only when the *com.glide.now.platform.encryption* plugin is active. See Activate Field Encryption for more information on obtaining Field Encryption Enterprise.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Some of the steps in this document require the use of a cryptographic tool installed on your local device. The examples in this task use the OpenSSL tool. For more information on this tool see https://www.openssl.org. If you are using other cryptographic tools, such as LibreSSL or GnuTLS, refer to the documentation for those products for similar steps.

- Modify optional properties that control the size, padding algorithm, and validity period of the key. See Configure properties for customer-supplied keys.
- You must have your symmetric key (.BIN) for encryption.

> **Important:**
> Your key must be in binary format. If another format is used, a `Token failed validation. Please reattach the unmodified token.` error message displays.

- You must have a cryptographic tool to wrap your key. This example uses OpenSSL 1.1.

Role required: sn_kmf.cryptographic_manager or sn_kmf.admin

Procedure

1. Navigate to **All** > **Key Management Framework** > **Cryptographic Modules** > **All**.
2. Select the cryptographic module that you created for the customer supplied key from the Crypto Specifications related list.
3. You will be directed to the **Key Creation** step.
4. If you have not previously downloaded the wrapping key, click the link to download the *token_publickey<id>.zip* file and save it to the same location as your key.

   > **Note:**
   > Do not rename the downloaded *token_publickey<id>* file.

5. Unzip the file to your local network.
   The zip file contains two files, an import token and a public key `.PEM` certificate. Wrap your symmetric key with the public key to encrypt it.
6. Copy the name of the *token_publickey* file to your clipboard.
7. From a command line, use the copied *token_publickey* file name to open the folder of the unzipped files as a placeholder for the wrapped key.
8. Edit this script by replacing the examples with the names of your crypto files.

```
"downloads user.name$ cd token_publickey_<token>
openssl pkeyutl -encrypt -pubin -inkey publickey_<keyname>.PEM
-in <keyname.bin>
-out wrapped_key_material -pkeyopt rsa_padding_mode:oaep
 -pkeyopt rsa_oaep_md:sha<128 or 256> "
```

Review the key wrapping commands in the following table for more information.

Key wrapping commands

Directions	Command	Example
Open the file directory where	`cd`	`cd token_publickey123456789`

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Directions	Command	Example
you downloaded the wrapping token.		
Paste the name of the `publickey.PEM` certificate.	`openssl pkeyutl -encrypt -pubin -inkey`	`publickey_586798643ffff.PEM`
Paste the name of your key here.	`-in`	`mykey.bin`
Enter the <-out> command and specify if the key is 128 bit or 256 bit.	`-out wrapped_key_material -pkeyopt rsa_padding_mode:oaep -pkeyopt rsa_oaep_md:sha256`	N/A

9. Run the command.
   A system message displays `token_publickey_<keynumber>`. The key will be generated and a *`wrapped_key_material`* file added to the directory.
10. Upload the wrapped key.

What to do next
Return to Configure and upload your customer supplied key to upload your wrapped key.

Configure and upload your customer supplied key

You can use your own customer-supplied key instead of using the ServiceNow® system-generated keys.

Before you begin
Roles required: security_admin, sn_kmf.cryptographic_manager

If you're NOT supplying your own keys, you don't need to perform this procedure. To create a cryptographic module with ServiceNow® keys, go to Create a cryptographic module or Create cryptographic module for Field Encryption.

Note:
This procedure only applies to Field Encryption Enterprise functionality. See Activate Field Encryption for more information.

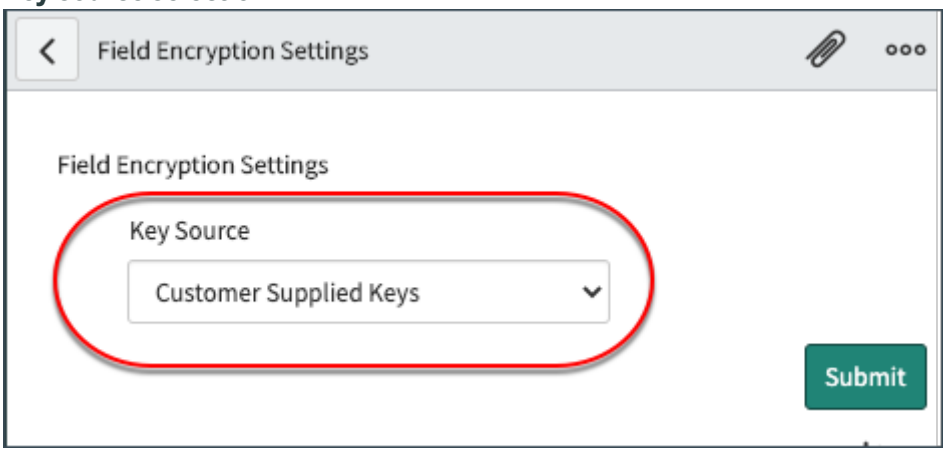
Important:
You can't revoke a customer supplied key.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

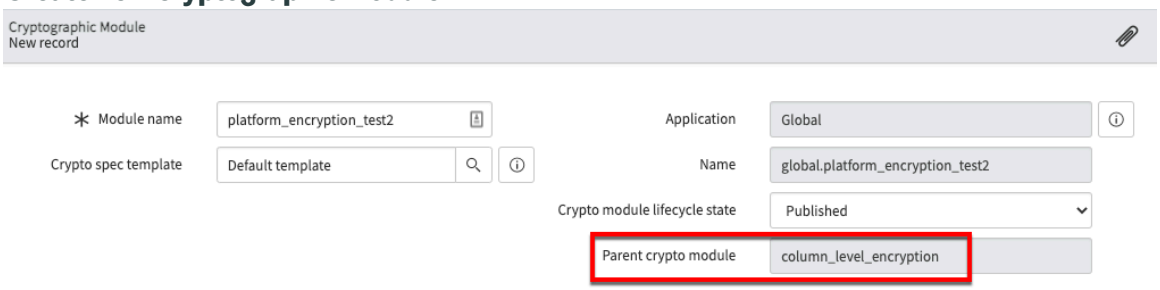
1. Navigate to **All** > **System Security** > **Field Encryption Settings** and verify that **Customer Supplied Keys** is selected.

Key source selection



2. Select **Submit**.
3. Return to **System Security** > **Field Encryption Modules** > > **Create New**.

Create new cryptographic module



4. Complete the Cryptographic Module form as follows:

Cryptographic Module fields

Field	Description
Module Name	Enter a name for the module.
Crypto spec template	The default cryptographic template is selected.
Name	Auto-populates based on the module name and prepends the name with the scope to ensure which application is being applied. In this case, the global scope is applied.
Crypto module lifecycle state	Select **Published** to activate the crypto module.

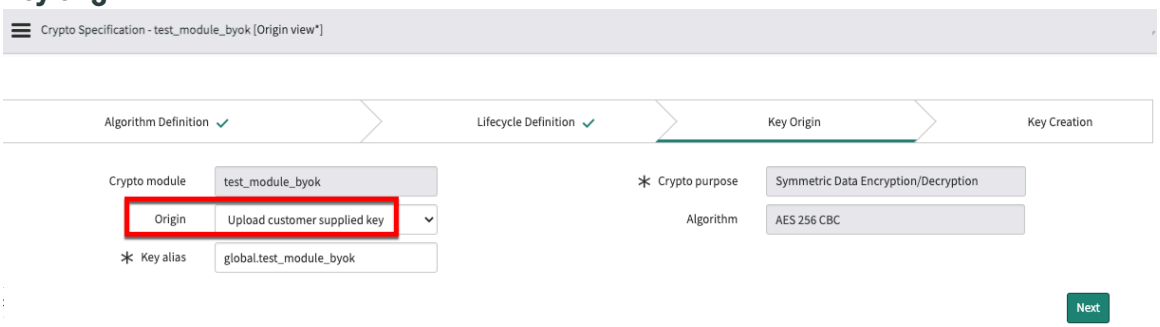
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Parent crypto module	The parent module **column_level_encryption** is selected automatically when using customer-supplied keys and encryption modules.

5. Select **Submit**.
6. Select the newly created cryptographic module from the table.
   In the **Crypto Specifications** related list, select the auto-generated key alias with the AES 256 CFB algorithm.

   The system populates the Crypto purpose and the Algorithm for Field Encryption automatically and jumps to the **Key Origin** stage.
7. Notice that **Upload customer supplied key** is the **Origin** and the **Key alias** is already populated.

Key origin

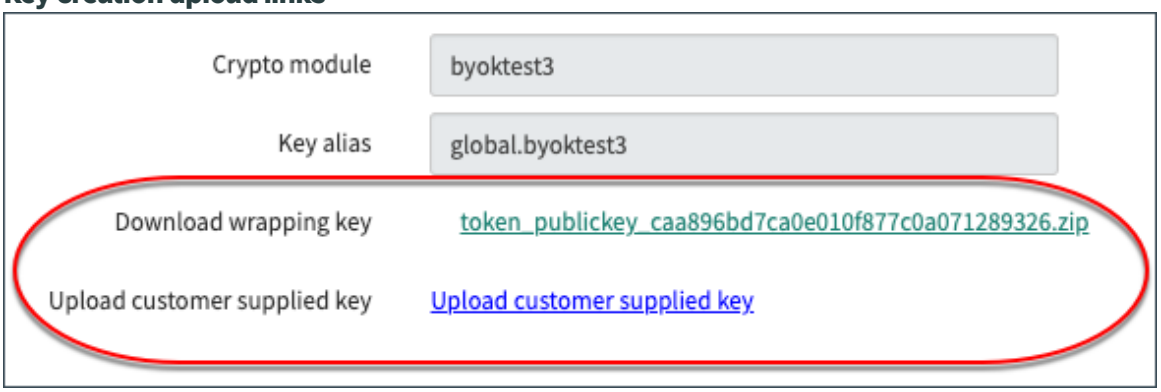


8. Select **Next** to move to the **Key Creation** stage.

   There are two links:

   - **Download wrapping key** downloads the key in a zip file containing an import token and a public key certificate, `.PEM` file. Use the import token to verify successful key wrapping according to security specification for the instance. Use the public key certificate `.PEM` file to wrap your customer supplied key securely before uploading it along with the token.
   - **Upload customer supplied key** opens the file browser to select the token and the encrypted key that you wrapped.

Key creation upload links



9. Select **Download wrapping key** to save the token.
   Save the token to the same destination location as the key is saved on your system. Don't rename the downloaded token.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

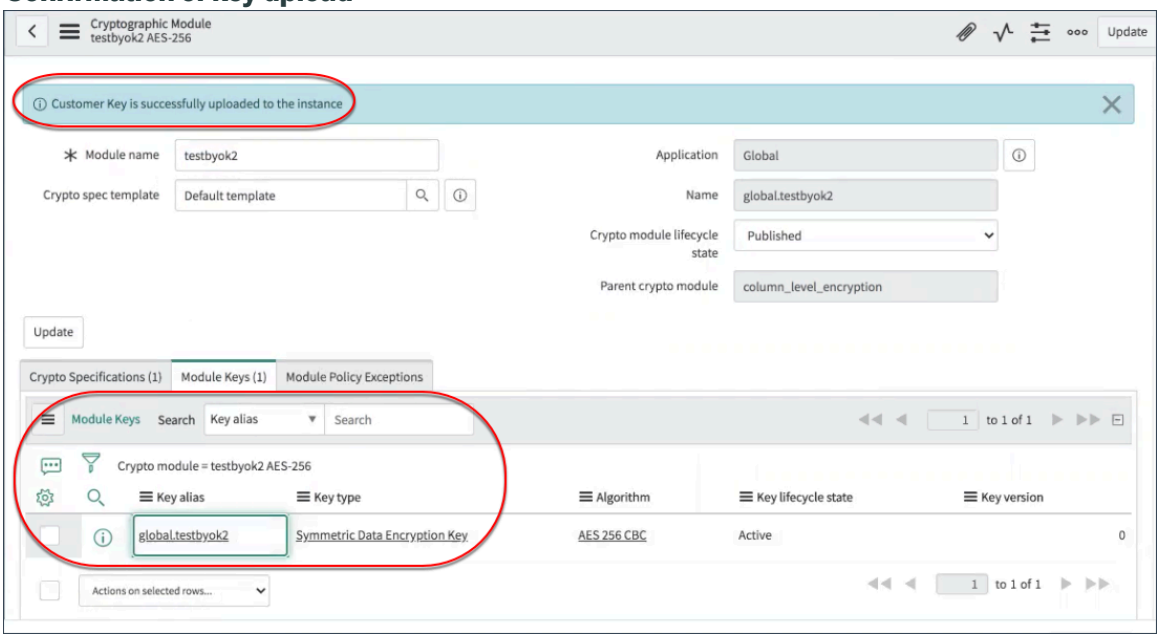
10. Run the BYOK command on a terminal to wrap the key.
    For more information, refer to Wrap your customer-supplied key.
11. Select **Upload customer supplied key**.
12. Select **Browse** to select the two files, the wrapped key and the token file.
    The Attachments window displays the two files.

Wrapped key attachments upload

Select a file to remove and reupload, if necessary.

13. Select **OK**.
    You're returned to the Cryptographic Module screen. A confirmation message displays for a successful upload of the customer key. The key is also listed in the Module Keys related list.

Confirmation of key upload



What to do next

Now that you have finished configuring your cryptographic module with your customer-supplied key, move on to Create a module access policy

Encrypting fields and attachments

Once cryptographic modules are created, a security admin can define the encrypted fields configuration (EFC) and opt to encrypt a field or attachment on a table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

How to encrypt fields

Note:
Encrypted fields aren't audited by design. This behavior isn't configurable.

1. Specify the key source: ServiceNow generated keys or your customer-supplied keys (bring your own key) in **System Security** > **Field Encryption Settings**.
2. After specifying the key source, create a cryptographic module or use an existing cryptographic module. Start with Create a cryptographic module for instructions.

   Note:
   If you use customer-supplied keys, follow the directions in Create cryptographic module for Field Encryption and Configure properties for customer-supplied keys.

3. Create an encrypted field configuration to define where the encryption is applied. Here, you specify the target table and choose whether to encrypt a column or attachments within the table. See Set encrypted field configurations to get started.

Note:
See Field Encryption Enterprise examples that illustrates how to encrypt fields and attachments using customer-supplied keys.

Set encrypted field configurations

Configure which table columns or attachments that the system encrypts using a preconfigured cryptographic module.

Before you begin
Role required: sn_kmf.cryptographic_manager and security_admin or elevate role to security admin.

About this task
Make sure you are in the correct application scope so you can see the tables in that scope.

Only users with access to the cryptographic module used in this configuration can read the data in the encrypted table column or access the attachment.

- If a user has write access but not read access, the field displays in edit mode and the data entered displays as asterisks.
- If a user has read access but not write access, the field displays the decrypted data in read-only mode.
- If a user has all access, both read/write functionality is available on the encrypted field.

See Create a cryptographic module or Create cryptographic module for Field Encryption to begin.

Important:

After encrypting a column, any new data inserted into the column is encrypted automatically. However, data that existed in the column before the encryption was active is not automatically encrypted.

In order to encrypt data that existed before the column was encrypted, you must run a separate mass encryption job. Learn more about mass encryption in Run mass encryption or decryption.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **System Security** > **Field Encryption** > **Encrypted Field Configurations** > **New**.
2. Select **New**.
3. Complete the form.

Field	Description
Type	**Column** to encrypt a table column or **Attachment** to encrypt all of a table's attachments. Types of data encrypted are: ○ String text (Full UTF-8) ○ Attachments ○ Date, Date/Time: **Note:** You can create encrypted field configurations to encrypt existing Date and Date/Time fields. You can add a new encryption configuration to a parent table only. You can't add a new encryption configuration to a child table. ○ URL ○ HTML ○ Journal ○ Translated
Table	Table whose fields or attachments are to be encrypted.
Column	Column (field) to be encrypted if you selected **column** as the type.
Active	Select to mark the configuration active. Deselect if the configuration isn't yet in use.
Crypto module	The cryptographic module that the encrypted field configuration applies to.
Method	Select **Single Module** to set the field configuration across one module. Select **Multiple Modules** for role-based access that spans across more than one cryptographic module. **Single Module** Use this option to encrypt all attachments using a single module. Your users need access to this module, otherwise they aren't able to upload attachments. **Multiple Modules** Use this option to allow users to choose a module when uploading attachments. Users with access to at least one module can select a module to use for encryption. Users with no module access can upload unencrypted attachments.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Algorithm Encrypted Preserving [read-only]	Indicates if the crypto module that you selected is already configured to support non-deterministic encryption. This means that if the same data is encrypted more than once, the encryption is different each time.

4. Select **Submit**.

Script access for cryptographic modules

Scripts can be run to access a cryptographic module policy for a cryptographic purpose.

For Key Management Framework, policies can be based scripts. When an access policy is triggered for script access, the backend script can execute the module policy actions from the script.

Cryptographic modules can support one or more encryption purposes, such as Asymmetric Data Decryption and Symmetric Data Decryption. Each cryptographic purpose requires the generation of an encryption key and defined cryptographic purpose.

Consider the following when executing an encryption script request:

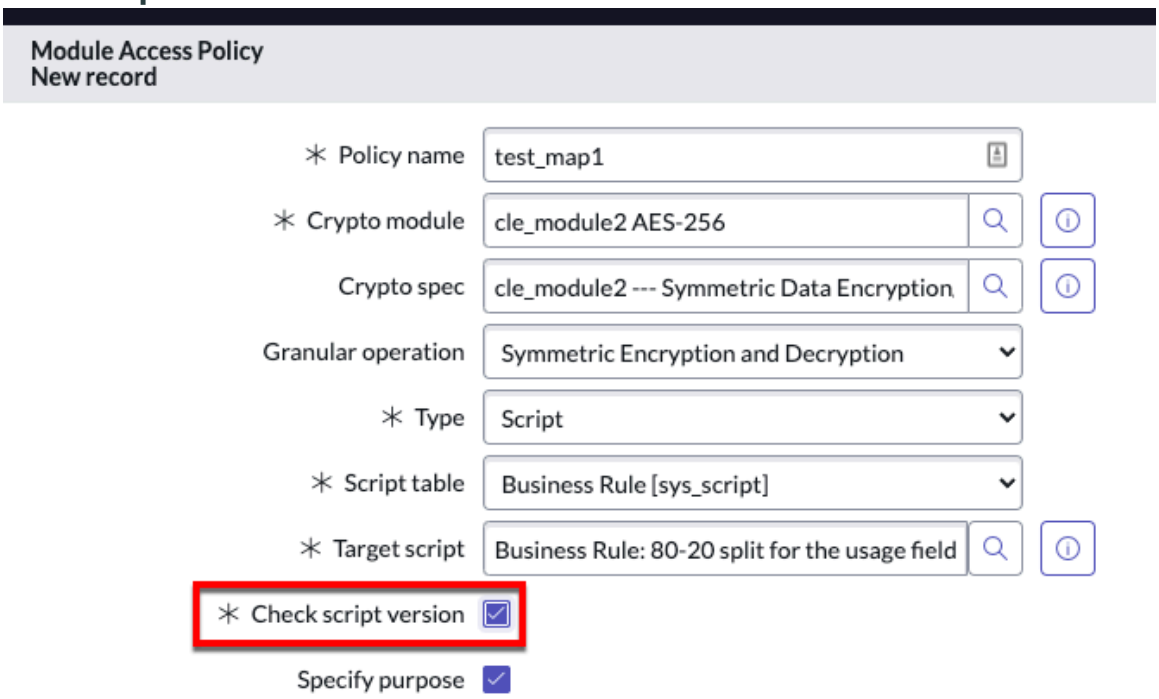
- The referenced cryptographic purpose must be defined in the cryptographic module.
- An active generated key must exist for the cryptographic module.
- The Module Access Policy type must be set to **script**.

Check script version

When creating a module access policy that is set to the script type, there is an option available to validate the integrity of the script version being accessed. Only the assigned version of the script is allowed access to the encryption modules. When the **Check script version** check box is selected in the module access policy, anytime the script is run, the system performs a version comparison. If the script has been changed, the user is notified.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Check script version check box



Configure script access to encrypted data

Execute a script to run the cryptographic module policy for a cryptographic purpose. Specific read (decrypt/unwrap) or write (encrypt, wrap) access can be defined based on the module access policy operation granularity.

Before you begin

Role required: sn_kmf.cryptographic_manager

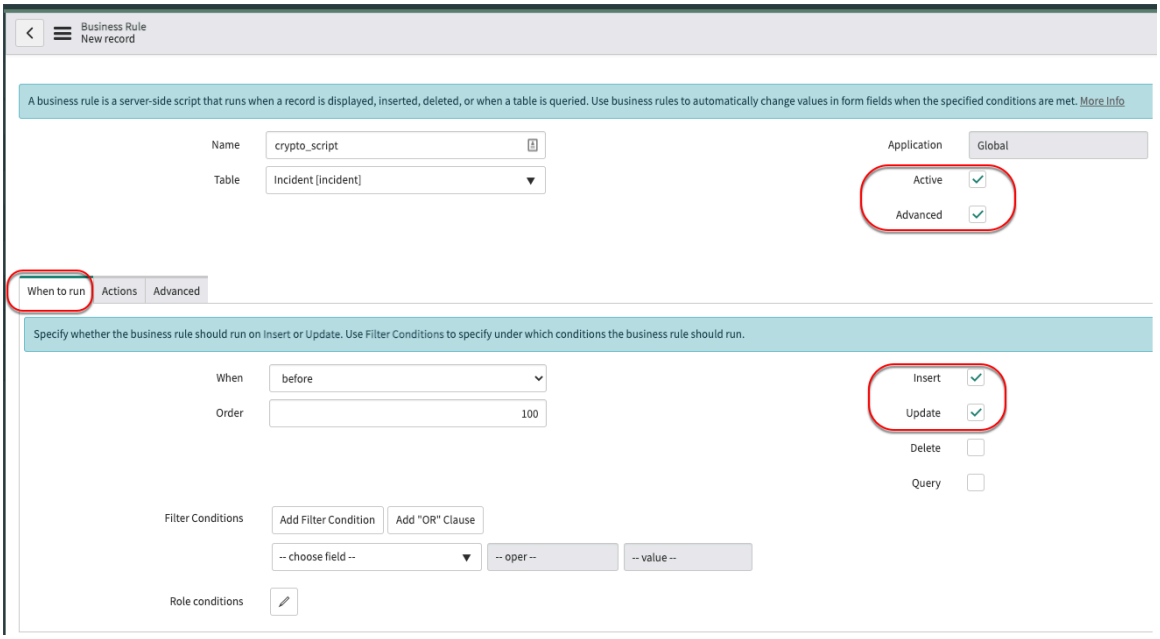
About this task

Examples of uses are for Business Rules and Script Includes. This procedure uses a script for Business Rules.

Procedure

1. Create a cryptographic module with the symmetric data encryption/decryption algorithm. Refer to Create a cryptographic module for details. Specific access to the data or attachment is controlled with a module access policy with the following characteristics:
   - Symmetric encryption: The script is able to encrypt data but unable to decrypt the data.
   - Symmetric decryption: The script is able to decrypt uploaded encrypted data or attachment but unable to encrypt data or attachments.
   - Symmetric encryption and decryption: The script is able to both encrypt and decrypt data or attachments.
2. Navigate to **System Definition** > **Business Rules**.
3. Click **New**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



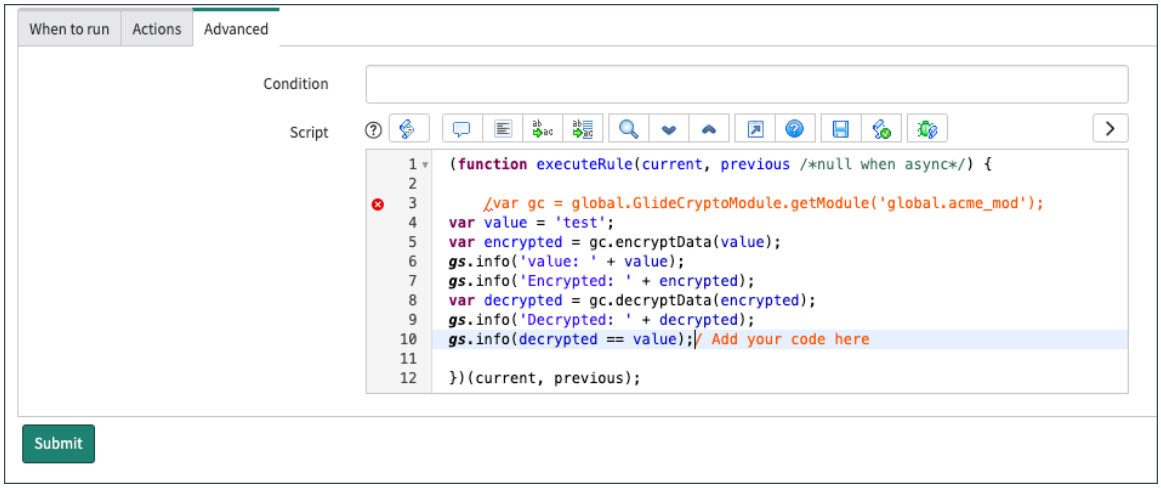
4. Complete the form on the **When to run** tab and enter the script on the **Advanced** tab:

Business Rule fields

Field	Description
Name	Enter a name for the business rule.
Table	Select **Incident [incident]**from the drop-down list.
Application	**Global** is selected by default.
Active	Mark the rule as **Active**.
Advanced	Select the check box to display advanced options.
When to run tab	On the **When to run** tab, enable **Insert** and **Update** fields.

Advanced tab	On the **Advanced** tab, paste the following script text at line 3:
	`var gc = global.GlideCryptoModule.getModule('global.acme_mod');`
	`var value = 'test';`
	`var encrypted = gc.encryptData(value);`
	`gs.info('value: ' + value);`
	`gs.info('Encrypted: ' + encrypted);`
	`var decrypted = gc.decryptData(encrypted);`
	`gs.info('Decrypted: ' + decrypted);`
	`gs.info(decrypted == value);`
	Note: Refer to the "Business Rules Advanced Tab" image for details.

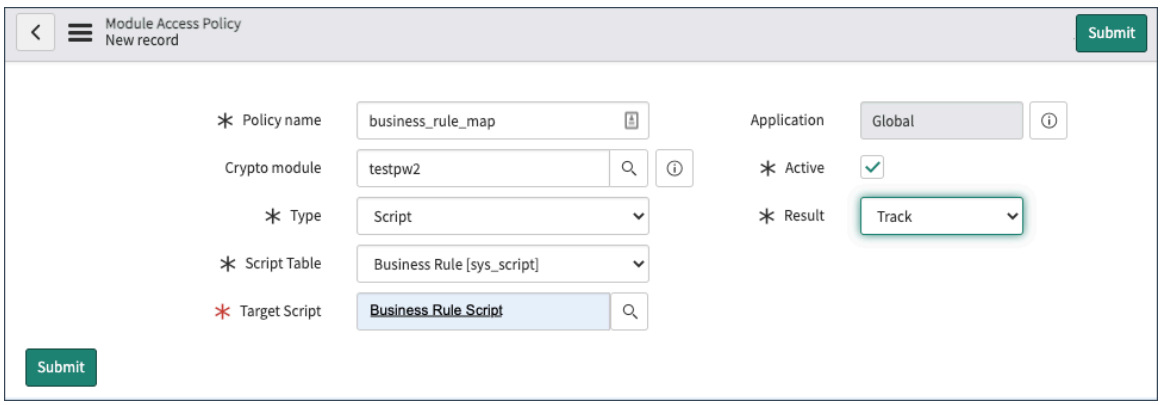
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



5. Click **Submit**.
6. Navigate to **Key Management** > **Module Access Policies** > **All**.

> **Note:**
> For additional information, refer to Create a module access policy.

7. Click **New**.
8. Complete the form.



Module Access Policies fields

Field	Description
Policy name	Enter a name for the policy.
Crypto module	Click the search icon to select a module with the symmetric data encryption/decryption algorithm.
Type	Select **Script** to control access by script.
Script Table	Select a value from the script table drop-down list. For this example, select **Business Rule [sys_script]**.
Target Script	Select the script document for the policy. Select the **Table name** and then the related document for the policy. For this example,

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	select the Business Rule that you created in previous steps.
Active	Select to activate the policy.
Result	To give the script access to the module, select **Track** in the **Result** field.

9. Click **Submit**.
   The Module Access Policy for the script is now available in the system.

View declined cryptographic module usage requests

View cryptographic modules that rejected encryption requests made by scripts because of unsupported encryption mechanisms.

Before you begin
Role required: sn_kmf.cryptographic_manager

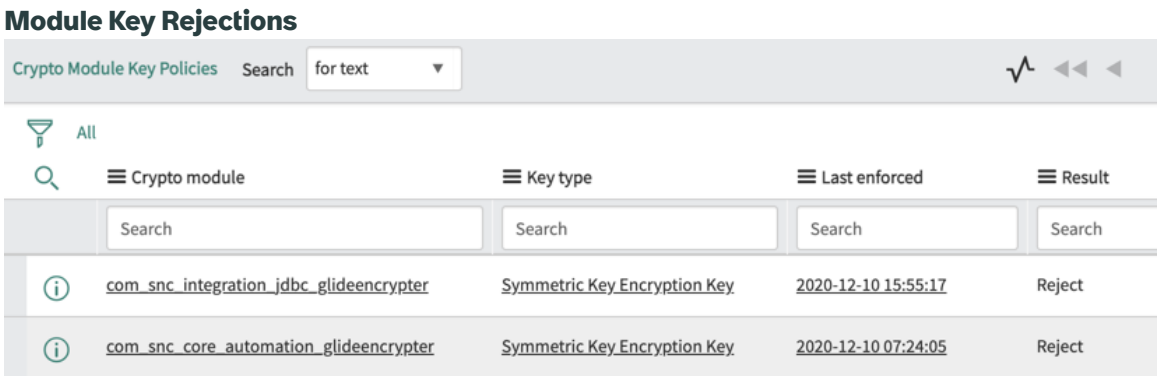
About this task
Cryptographic modules can support one or more encryption purposes, such as Asymmetric Data Decryption and Symmetric Data Decryption. Encrypted data can only be accessed based on the module access policy. If a script tries to use a cryptographic module for a purpose not defined in the module, the script cannot access to the encrypted data.

In the following example, a cryptographic purpose was assigned to a cryptographic module, but a key was never generated for it.

Procedure

Navigate to **All** > **Key Management** > **Module Key Policies** > **Module Key Rejections**.

A list of cryptographic modules that rejected requests displays along with the encryption key used in the corresponding script.



Note:
If a different script attempts to use the same cryptographic module using the same key type, the value for **Last enforced** updates. Another row does not generate.

In this example, at 2020-02-10_15:55:17, the first module rejected a request because module1's key is compromised. At 2020-02-10_07:24:05, the second module rejected a request because the second module's key is suspended.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

To grant scripts permission to use the encryption module the next time they run, create a module access policy for script encryption. For more information, refer to Configure script access to encrypted data.

Schedule mass encryption, decryption, and rekeying jobs

Schedule encryption, decryption, and rekeying jobs to run at a time that is best for your instance.

Before you begin

Encryption, decryption, and rekeying jobs can be time and resource intensive, so consider scheduling at non-peak hours. Also ensure that the user scheduling the job has the appropriate access for each job.

Role required: sn_kmf.cryptographic_manager

About this task

Mass encryption and decryption is also available from the Encrypted Field Configurations form. See Run mass encryption or decryption for instructions.

Procedure

1. Navigate to **All** > **System Security** > **Security Jobs**.
2. Click **New**.
3. Complete the scheduling form.

Field	Description
Name	Name of the encryption, decryption, or re-keying job.
Type	Job type: ○ **Key Migration Context to Module:** Mass migration of Encryption Context keys to Encryption Modules, including creation of Module Access Policies records for access controls on the Encryption Modules ○ **Data Migration Context to Module**: Migrates data encrypted by Encryption Contexts to Encryption Modules ○ **Mass Decryption Attachment**:Decrypts all encrypted attachments in records for a single table you define in the **Table** field. ○ **Mass Encryption Attachment**: Encrypts all attachments in records for a single table you define in the **Table** field. ○ **Mass Encryption**: Encrypts any pre-existing value in the defined column/field used in the Field Encryption Configuration ○ **Mass Decryption Module**: Decrypts any pre-existing value in the defined column/field used in the Field Encryption Configuration with Single Module. ○ **Mass Decryption Multi Module**: Decrypts any pre-existing value in the defined column/field used in the Field Encryption Configuration with Multiple Module. ○ **Mass Rekeying**: Re-encrypts any pre-existing value in the defined column/field used in the Field Encryption Configuration using the current active key for the module. ○ **Migrate Attachment Context to Module**: Encrypts any pre-existing attachment on the table defined in the Field Encryption Configuration. Any attachment previously encrypted with a context is re-encrypted with the module.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
State	The initial job state is New. After the job has been executed as scheduled, the state will update accordingly.
Time window start	Start time for the job in 24-hour format.
Time window end	End time for the job in 24-hour format.
Table	Table to be encrypted or decrypted.
Field	Field to be encrypted or decrypted.
Summary	Job status information when the job is running, has completed, or has errors.

Note:
Because of system overhead, you should schedule mass encryption, decryption, and rekeying jobs to run at non-peak hours. The ServiceNow AI Platform runs the job between the **Time window start** and **Time window end**. If the job is not complete in one processing window, it continues during the next specified processing window until all processing is complete.

4. Click **Submit**.
5. After you schedule a job, you can do the following.
   - Click **Cancel Job** to cancel a running job.
   - Click **Start** to start a job immediately.
   - Click **Update** to save any changes you make to the job schedule.
   - Click **Delete** to delete the scheduled job.

Run mass encryption or decryption

You can run mass encryption on encryption configurations, as well as a mass decryption to decrypt previously encrypted values.

Before you begin
Role required: security_admin

About this task
You can also create scheduled jobs for mass encryption and decryption. See Schedule mass encryption, decryption, and rekeying jobs for instructions.

Mass encryption and decryption are available only when an encrypted field configuration uses the single cryptographic module. Mass decryption is available for both the single and multiple encryption method.

Note:
You should run mass encryption and decryption only during non-peak hours because the operations are resource and time intensive.

Procedure

1. Navigate to **All** > **System Security** > **Field Encryption** > **Encrypted Field Configurations**.
2. Open the encrypted field configuration for the field you would like to mass encrypt or decrypt.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. Under Related Links, select an available option.
   - **Schedule Mass Decryption job**
   - **Schedule Mass Encryption job**
4. Confirm your selection in the dialog.

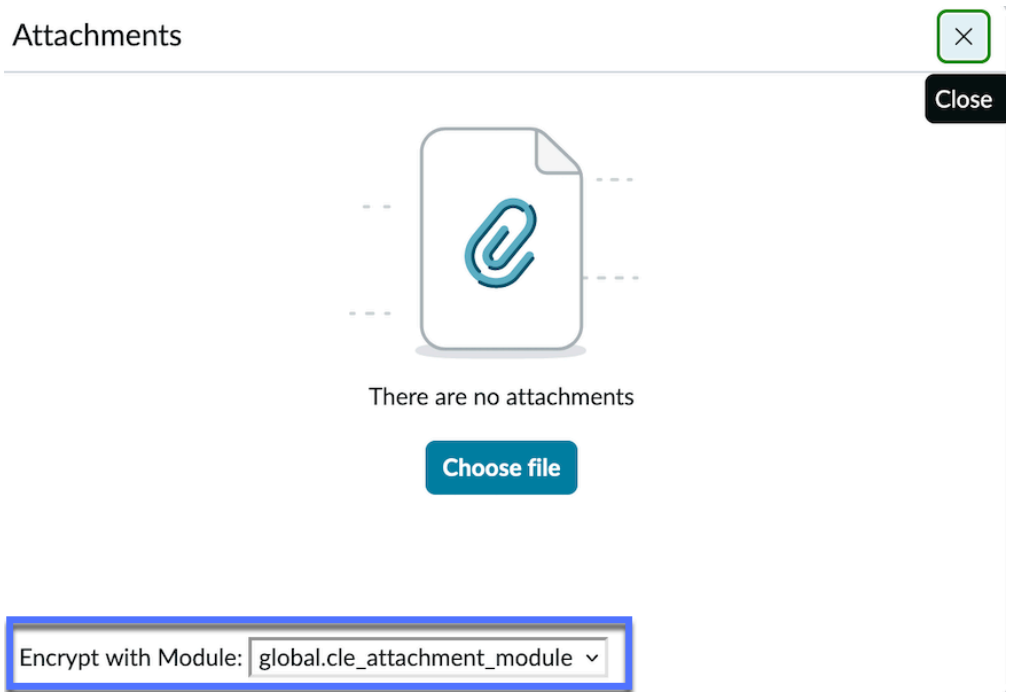
Result
If running a mass encryption, all values are encrypted with the encryption module defined in the encrypted field configuration record. If running a mass decryption, only fields encrypted with an encryption module you have access to are decrypted.

Upload attachments for encryption

Protect sensitive files by encrypting record attachments using Field Encryption and Row Conditions.

Before you begin
Role required: Any role that aligns with the module access policy (MAP) created by the admin.

Procedure
1. Navigate to a record.
2. Select the **Manage Attachments** paperclip icon.
3. In the **Attachments** window, select the module to encrypt with from the **Encrypt with Module** drop-down options.



Note:
If Row Conditions have been added to the Encryption Field Configuration, this option isn't displayed. The attachment would then be automatically encrypted with the module defined in the Row Condition. Similarly, this drop-down option only displays when using the Manage Attachments icon and not if the attachment is added by dragging and dropping.

4. Select **Choose file** to locate the attachment and select **Open** to attach it.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Result
Attached files display at the top of the form. Encrypted attachments are denoted by a lock icon. Only users with the encryption module to view encrypted files will see them listed.

Field Encryption Enterprise examples

These examples walk you through the encryption of fields and attachments using customer-supplied keys.

Field Encryption Enterprise walkthrough

This walkthrough shows you how to encrypt a field in your instance using Field Encryption Enterprise with the Key Management Framework (KMF). It also shows you how to use your own key.

Before you begin

Note:
This procedure only applies to Field Encryption Enterprise functionality. See Activate Field Encryption for more information on obtaining Field Encryption Enterprise.

Role required: admin or security_admin

Note:
security_admin is a privileged role, for details on using privileged roles, see Elevate to a privileged role

About this task
This walkthrough starts with an instance where you have already created and uploaded your personal cryptographic key. You could use the ServiceNow key, but this example uses a customer-supplied key.

After the key has been stored in a cryptographic module, you can start configuring fields in your instance, such as salary or social security numbers that have limited access from certain users. In the Encrypted Field Configuration, specify which authorized personnel can access sensitive data.

This task demonstrates two scenarios. One example encrypts the **Short Description** field in an Incident for users who are not authorized to view the sensitive data.

Attachments can also be encrypted and only visible to users who are granted access, or is visible to all users that are not restricted from viewing the data. See Attachment encryption walkthrough to encrypt an attachment.

Procedure

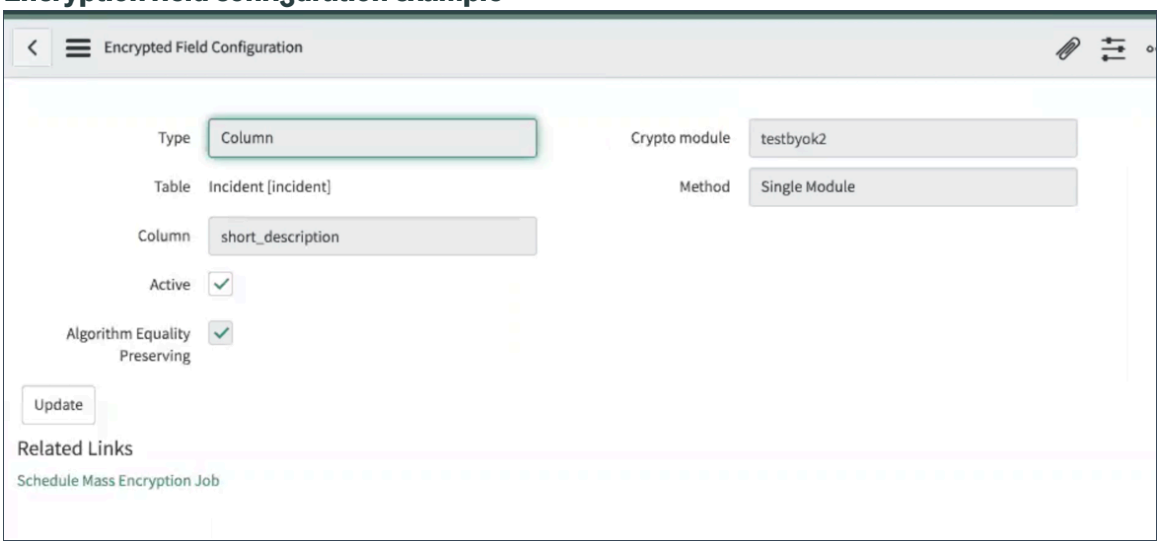
1. Make sure that Field Encryption Enterprise is enabled.
2. Create a cryptographic module for column_level_encryption.
   See Create cryptographic module for Field Encryption Create a cryptographic module for more information.
3. Navigate to **System Security** > **Encrypted Field Configurations**.
4. Click **New**.
5. On the form, fill in the fields.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Encrypted field configuration form

Field	Description
Type	**Column** is required to use your personal key.
Table	Table that stores the sensitive information. For this example, select **Incident [incident]**.
Column	Column, or specific information, that represents the sensitive date to be encrypted. For this example, select **short_description**.
Active	Option to mark **Active** to use the field configuration.
Algorithm Equality Preserving	The option is automatically selected.
Crypto module	Module that you created to use with the personal key.
Method	The **Single Module** option is used to apply the policies for one module. **Multiple Modules** is used to apply the policies across multiple modules.

Encryption field configuration example



6. Click **Submit**.

   Establish a Module Access Policy to assign access to the cryptographic module. See Create a module access policy for additional information.

7. Navigate to **Key Management** > **Module Access Policies** > > **Create New** > **.**
8. On the form, fill in the fields.

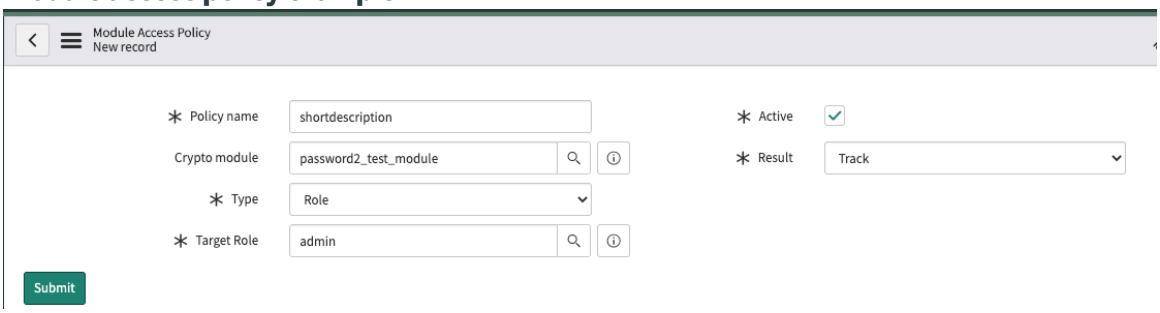
Module access policy form

Field	Description
Policy name	Name for the policy, such, as `short description`.
Crypto module	Crypto module that you created to encrypt your key.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

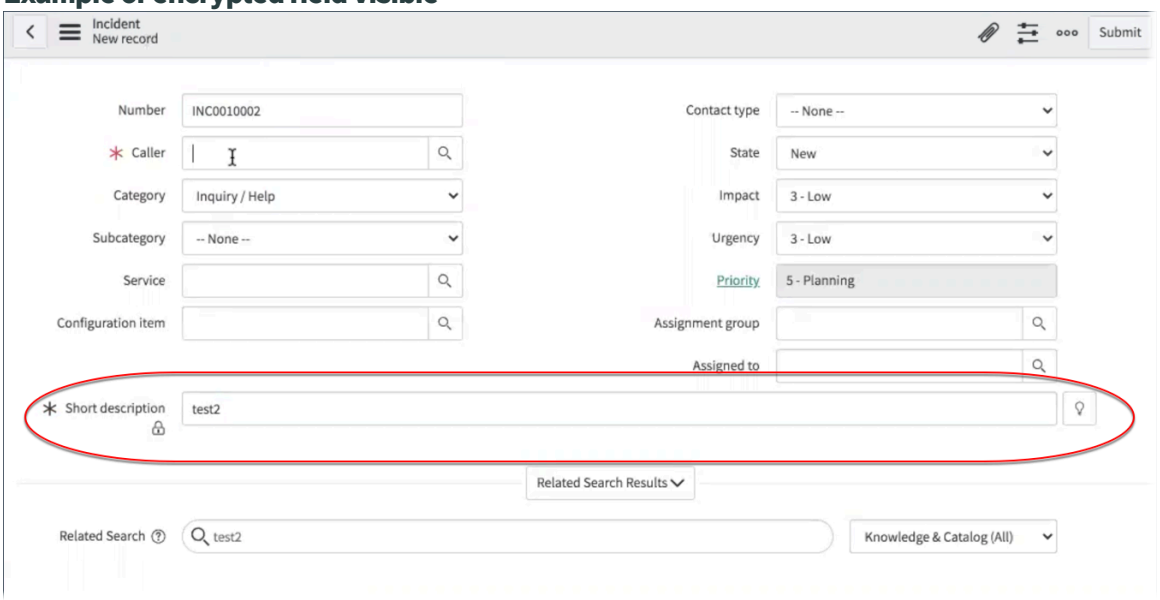
Field	Description
Type	Type of access designation for the crypto policy. Use **Role** to grant access to the encrypted field to only those users that have the assigned role.
Target Role	The role that has access to the encrypted field. For this example, select **Admin**.
Active	Option to activate the Module Access Policy.
Result	The **Track**option enables the access to the field for the selected role. (To restrict access to that field for the selected role, select **Reject** or**Strict Reject**.)

Module access policy example



9. Click **Submit**.
10. As a user with the sn_kmf.admin role, navigate to **Incident** > **New**.

Example of encrypted field visible



You can now view the Short description field based on the module access policy configuration.

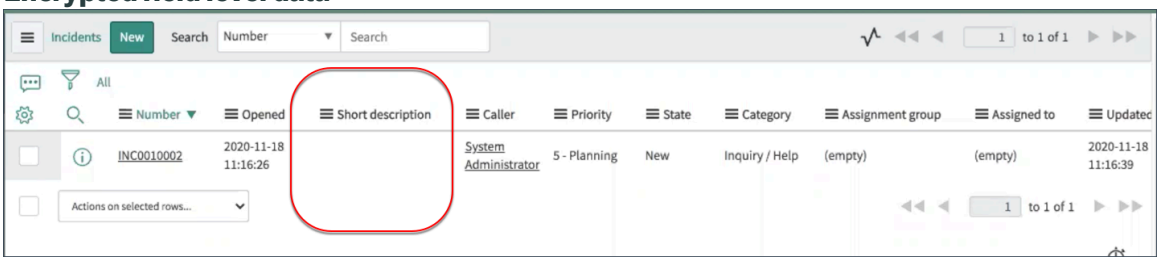
Note:
The sn_kmf.admin role was granted user access to the encrypted field, Short description, by setting the module access policy to **Track**. Notice the lock icon ( ) under the field name indicating that the field is an encrypted field.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

You can now access the **Incidents** module as an end user to test the encrypted field configuration.

11. Log in as a user to be restricted from viewing the encrypted data in the configured field.

Encrypted field level data



When you access the incident number, the data in the Short description will not be visible.

Result

You have successfully used your symmetric key to control access to a specific field using Field Encryption Enterprise.

Attachment encryption walkthrough

This walkthrough shows you how to encrypt an attachment in your instance using Field Encryption Enterprise with the Key Management Framework (KMF). It also shows you how to use your own key.

Before you begin

Note:
This procedure only applies to Field Encryption Enterprise functionality. See Activate Field Encryption for more information on obtaining Field Encryption Enterprise.

Role required: kmf cryptographic manager

About this task

This walkthrough starts with an instance where you have already created and uploaded your customer-supplied cryptographic key. You could use the key, but this example uses a customer-supplied key.

Upload confidential attachments in your instance and limit access from certain users. Use Encrypted Field Configuration to specify which authorized personnel can access sensitive data.

We show you how to encrypt attachments to only be visible to users who are granted access, or be visible to all users that are not restricted from viewing the data. In this example, we restrict a certain role from being able to access an attachment in the **Incidents** module.

Note:
Although you can use multiple modules with Field Encryption Enterprise, attachment encryption must use single modules.

Procedure

1. Make sure that Field Encryption Enterprise is enabled.
2. Create a cryptographic module.
   See Create cryptographic module for Field Encryption for more information.
3. Navigate to **System Security** > **Encrypted Field Configurations**.

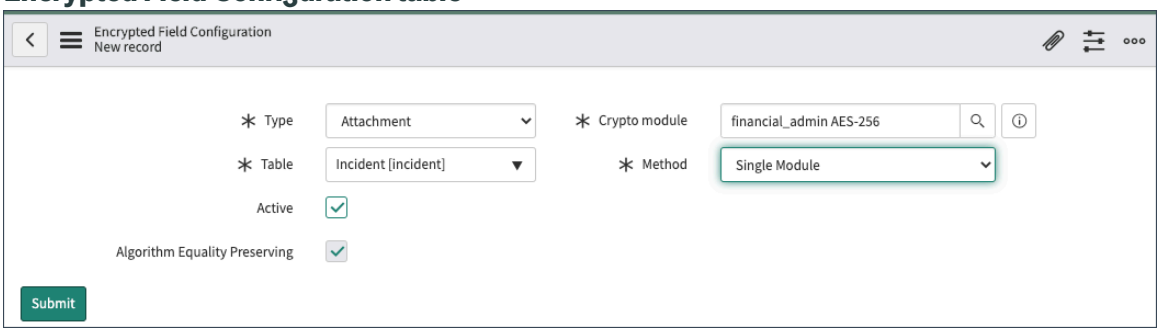
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Click **New**.
5. Complete the form:

Encrypted field configuration fields

Field	Description
Type	Select **Attachment** to use your personal key for encrypting an attachment from the selected **Table** For this example, select **Incident**.
Table	Select the table to access the sensitive information. For this example, select **Incident [incident]**.
Active	Mark **Active** to be able to use the field configuration.
Algorithm Equality Preserving	When selecting Field Encryption Enterprise, this field is visible based on the table selected.
Crypto module	Select the module that you created to use with the personal key.
Method	The **Single Module** option is used to apply the policies for one module. **Multiple Modules** is used to apply the policies across multiple modules.

Encrypted Field Configuration table



6. Click **Submit**.

Establish a Module Access Policy to assign access to the cryptographic module. Refer to Create a module access policy for additional information.

7. Navigate to **Key Management** > **Module Access Policies** > **All**.
8. Click **New**.
9. Complete the form:

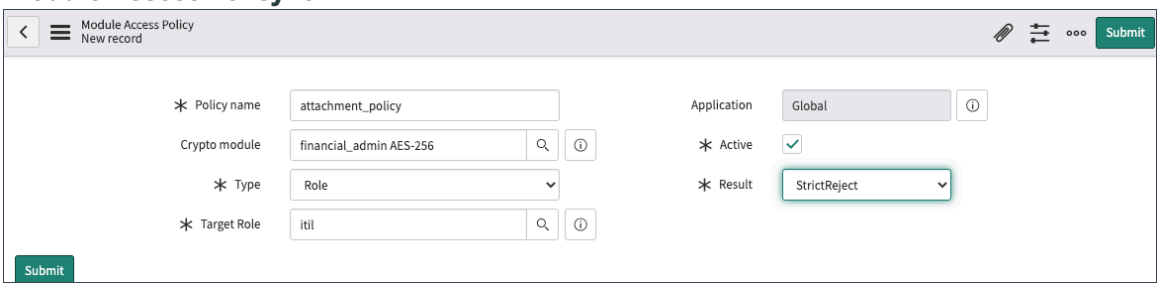
Module access policy fields

Field	Description
Policy name	Enter a name for the policy, such, as "Attachment policy."
Crypto module	Select the crypto module that you created to encrypt your key.
Type	Select **Role** to restrict access to the encrypted field from users with the assigned role.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

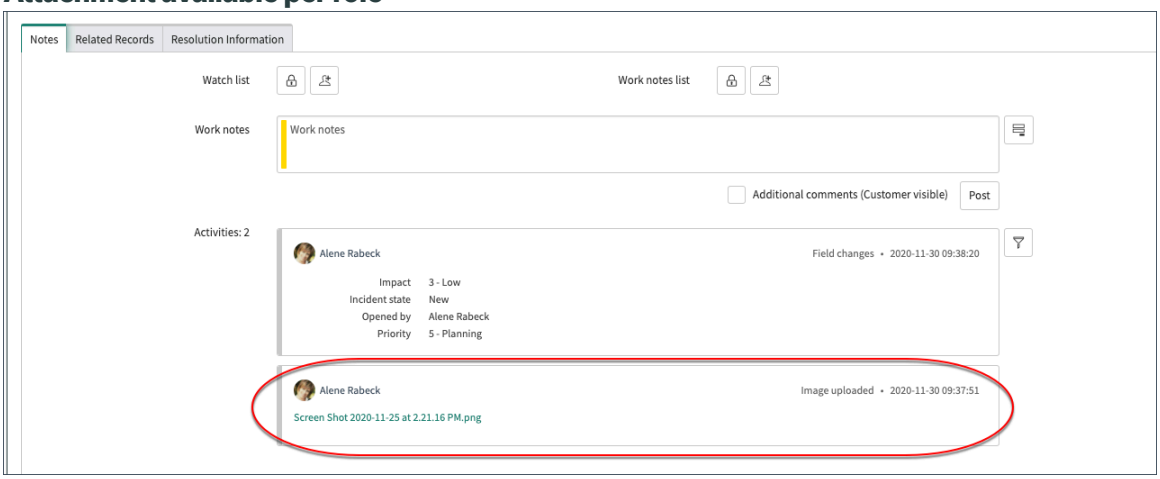
Field	Description
Target Role	Select the role that will not have access to the encrypted field. For this example, select **itil**.
Active	Select this check box to be able to use the Module Access Policy.
Result	Select **Strict Reject** to control the access to the attachment from the selected role. (To grant access for the selected role, select **Track**.)

Module Access Policy form



10. Click **Submit**.
11. As admin or as a person that created the incident, navigate to **Incidents** and add an attachment to **Activities** on the **Notes** related list.

Attachment available per role



12. Log in as a user that restricted from accessing the encrypted attachment.
13. Open the incident and scroll to the **Activities:** section.
    The link to open the attachment is not accessible for users with the restricted role.
14. You have now successfully used your customer-supplied key to control access to a specific attachment using Field Encryption Enterprise.

Field Encryption Enterprise

Field Encryption Enterprise uses the Key Management Framework (KMF) to enable you to customize and manage how fields and attachments are encrypted and decrypted on your instance. A subscription is required to use Field Encryption Enterprise.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Important:
This topic covers the enterprise version of Field Encryption. For information on the standard version of Field Encryption, or to learn the differences between the two versions, see Exploring Field Encryption.

Field Encryption Enterprise is premised with Field Encryption and uses the Key Management Framework and its full support of key management functions. Field Encryption Enterprise provides key-protection and key life-cycle management for application-level field encryption. All keys are protected with a key-wrapping hierarchy ultimately rooted in FIPS (Federal Information Processing Standards) 140-2-L3 Hardware Security Modules (HSM).

Field Encryption Enterprise gives you the ability to manage how supported fields are encrypted and decrypted in accordance with NIST 800-57 practices. It also uses the most updated version of field-level encryption, including integration for proper key protection and management.

Specifically, Field Encryption Enterprise uses the KMF encryption modules, granting you more control of server-side encryption. KMF verifies proper data encryption key protection using key hierarchy and envelope encryption. Your instance encrypts data through cryptographic modules that you configure. You can create an access policy for each module then configure cryptographic specifications and access policies and control key life-cycle management control.

Field Encryption Enterprise supports module access policies based on:

- Scope
- Role
- Script
- Resource Exchange
- System User

See Create a module access policy for additional information.

Note:
For details on the supported features of Field Encryption and how to upgrade and subscribe to the Field Encryption Enterprise entitlement refer to Encryption and Key Management subscription bundle.

© 2026 ServiceNow, Inc. All rights reserved.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Encryption terms

Term	Description
Key management	Support for key management Fundamental to Field Encryption Enterprise is the Key Management Framework (KMF). Gain the following capabilities: • Key life-cycle management. • Key rotation. See Rotate keys for details. • Key protection and key generation with FIPS 140-2-L3 Hardware Security Modules (HSMs). • Segregation of roles and duties. • The secure transfer of data encryption keys between instances, such as production and non-production instances. • Customer Supplied Keys (CSK) with key-wrapping. • Non-deterministic encryption. • Mass encryption/decryption. • Auditing of key access/use. See Key Management Framework Reference for details.
Customer-supplied key 	Support for customer supplied keys One of the biggest benefits of Field Encryption Enterprise is that you can use your own keys for encryption. Administrators have the choice to use ServiceNow supplied keys or your own customer-supplied keys (CSK) for encryption on the ServiceNow AI Platform®. You can also manage the key life cycle and decide when to revoke, rotate, and inactivate the keys. After you enable customer-supplied keys and create a cryptographic module, you download a token and public ephemeral key. You use the token and public key to wrap your key and then upload to the instance. To use customer-supplied keys, see Configure field encryption settings to select key type and Using customer supplied keys with Field Encryption Enterprise.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Term	Description
Field Encryption 	Support for both field encryption and attachment encryption Both field encryption and attachment encryption use cryptographic modules and access policies through Encrypted Field Configurations. The Encrypted Field Configuration form is used to choose an encryption type of column or attachment encryption. See Set encrypted field configurations for more information and supported field types.
Non-deterministic encryption 	Support for non-deterministic encryption Field Encryption Enterprise supports non-deterministic encryption for enhanced security. If the system encrypts the same data more than once, the ciphertexts are different each time. Non-deterministic encryption is available with Advanced Encryption Standard (AES) encryption with Cipher Block Chaining (CBC). You can enable this feature through the Equality Preserving option on the Algorithm Definition stage of the cryptographic specification. Create a cryptographic specification for a crypto module and define an algorithm for encryption and generate the key. See Create a cryptographic module to define the mechanisms used for cryptographic operations and for more information on enabling non-deterministic encryption.
Resource Exchange 	Resource Exchange Field Encryption Enterprise keys instance to instance in a secure manner using the KMF cryptographic APIs to provide confidentiality, integrity, authentication, and non-repudiation. Resource Exchange is a KMF feature that gives you the capability to exchange resources between instances in a secure manner. See Key Management Framework Resource Exchange for details.

Note:
If you choose not to activate Field Encryption Enterprise, you can still use Field Encryption. See Exploring Field Encryption for information.

Field Encryption Enterprise supports on-premise customers. It doesn't support Domain Separation.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Support for additional encrypted fields

The standard version of Field Encryption is limited to five encrypted columns. Field Encryption Enterprise supports an unlimited number of encrypted columns.

Supported field information

The following field types can be encrypted:

- Attachments
- Date
- Date/Time
- Email
- HTML
- Journal
- Journal Input
- Journal List
- Phone
- String text
- Translated Field
- Translated HTML
- Translated Text
- URL

Attachment Encryption

Attachment encryption by default

Customers using Field Encryption have attachments encrypted by default in tables that have an active Encrypted Field Configuration (EFC) type of *Attachment*.

This default encryption defined by the EFC configuration means that admins don't need to manually declare that an attachment should be encrypted on upload for these tables.

Administrators can disallow users from attaching unencrypted files

For details, see Prevent users from attaching unencrypted files.

Opt out of default encryption

If you don't want attachments encrypted by default based on EFC configuration, you can opt out of this option by contacting ServiceNow support.

To opt out of this feature, create a support case with ServiceNow support, and include this statement in a comment on the case record:

```
"I [customer name], understand that I am asking ServiceNow to turn off a recommended security best practice for attachments, and that [customer company] assumes any additional risk related to their configuration and use of unencrypted attachments in the ServiceNow application."
```

API support

Field Encryption Enterprise enables the following APIs.

Note:
The API behavior described in the following table represents the default configuration for the latest base system package. If you are working with older package versions, you may experience different functionality.

Field Encryption APIs

API	Description	Parameters	Return type
`changeEncryptionContext()`	Updates an active Encryption Context (EC) used to encrypt an attachment. When CLE is enabled with the CLE Starter plugin using KMF Crypto Module (CM), the API locates the CM for the EC and uses it to encrypt the attachment. **Note:** This API is only available in the Global scope.	• sourceTable – Name of table that has the attachment. • sourceID – Table record system id. • attachmentID – The sys_attachment record system id. • newEncryptionContextID - System ID of the new context.	Boolean
`changeCryptoModule()`	Updates an active encryption module used to encrypt an attachment. **Note:** This API is only available in the Global scope.	• sourceTable – Name of table that has the attachment. • sourceID – Table record system id. • attachmentID – The sys_attachment record system id. • newCryptoModuleId - System ID of the new encryption module to encrypt the attachment.	Boolean
`disableEncryption()`	Disable active encryption on an attachment.	• sourceTable – Name of table that contains the attachment.	Boolean

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field Encryption APIs (continued)

API	Description	Parameters	Return type
		• sourceID – Table record system id. • attachmentID – The sys_attachment record system id.	
`getDisplayValue()`	Returns the cleartext display value of an encrypted field.		String
`getValue()`	Returns the cleartext value of an ecrypted field when glide_encryption.set_value_support_cle.disabled is false (requires Module Access Policy (MAP)). Returns the encrypted value of an encrypted field when glide_encryption.set_value_support_cle.disabled is true.		String
`setDisplayValue()`	Inserts encrypted data into an encrypted field for display purposes.	• name – Field name. • value – Field value.	Boolean
`setValue()`	Inserts encrypted data into an encrypted field, controlled by a system property. Encrypts data when glide_encryption.set_value_support_cle.disabled is false (requires MAP); writes unencrypted data when set to true (no MAP required), when glide_encryption.set_value_support_cle.disabled is true.	• name – Field name. • value – Field value.	Boolean

The following script illustrates API changes when the Incident short description is encrypted:

```
var gr = new GlideRecord('incident'); //creates a new incident
gr.setValue('short_description','test123'); //sets the value
 to test123
var sys_ID = gr.insert(); //inserts the record in the Incident
 table.
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
gs.info(gr.getValue('short_description')); //displays the
 unencrypted value
```

When the Field Encryption plugin is installed, `glide_encryption.set_value_support_cle.disabled` is set to false by default.

Column Level Encryption

Column Level Encryption permits and denies access to encrypted data based on user role. Column Level Encryption includes basic key management using encryption modules.

Important:

Starting with the Zurich release, Column Level Encryption (CLE) and Column Level Encryption Enterprise (CLEE) are being prepared for future deprecation. They will be hidden and no longer activated on new instances but will continue to be supported. Field Encryption and Field Encryption Enterprise provide the latest experience for this functionality.

For details, see the Deprecation Process [KB0867184] article in the Now Support knowledge base.

With Column Level Encryption, you can encrypt specific fields within your tables, as opposed to encrypting the entire table or database. Use this method to help ensure that your sensitive data remains protected without the need to encrypt and entire table. The ability to encrypt only the portions of your tables that require it helps to reduce the time spent encrypting and decrypting data.

Column Level Encryption grants access to encrypted data based on a user's role. Because of this approach, users must be associated with a role to view data encrypted by Column Level Encryption. Users can be associated with a role directly, or they can be assigned to a group that is associated with a role. This role-based approach simplifies the process of making sure that your data is visible only to users who need it.

Role-based encryption example

In this example, you can see four users attempting to access data stored in two fields on a form. These fields are encrypted by an encryption context, which is only accessible to users who are associated with a specific role (Role 1).

- User 1 is a member of Role 1, which provides access to encryption module 1. User 1 can see the contents of Field A and Field B.
- User 2 and User 3 are members of Group 1. Group 1 is a member of Role 1, which enables everyone in Group 1 access to encryption module 1 and enables User 2 and User 3 to see the contents of Field A and Field B.
- User 4 isn't a member of any group or role and has no access to encryption module 1. User 4 does note access to Field A or Field B. User 4 also doesn’t see these fields on a form. In a list view, these fields are visible, but the values are be empty.

Exploring Column Level Encryption

Learn more about Column Level Encryption.

Column Level Encryption overview

Column Level Encryption is a base system feature that permits encryption of data stored within an instance using AES128, or AES256.

Column Level Encryption enables you to encrypt selected database fields and stored files through the use of encryption contexts. In these contexts you define what is encrypted, choose which algorithm to use, and supply the encryption key, which is stored within your instance.

After the context is created, you can associate it to a user role. Users assigned to this role, either directly of through a group, are able to access the encrypted data.

Because Column Level Encryption bases access to data on role assignment, it's important to be familiar with administering roles on your instance. For more information, see Managing roles.

Field Encryption benefits

Benefit	Feature	Required Roles
Configure access to your encrypted data based on assigned user roles.	Role-based access to encrypted data	security admin
Protect your data using the Advanced Encryption Standard (AES). You can choose to use either the AES-128 or AES-256 encryption algorithms.	AES Encryption	security admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Benefit	Feature	Required Roles
Create up to 5 modules and module access policies (MAP)s using the standard version of Column Level Encryption. MAPs expand on role-based access to allow considerations for: • System users • Scripts • KMF Resource Exchange Column Level Encryption Enterprise supports additional MAPs.	Support for up to 5 modules and module access policies (MAP)s	security admin
Encrypt common field types using the standard version of Column Level Encryption. Column Level Encryption Enterprise supports additional field types.	Encryption for String text, Date and Date/Time fields, attachments, and URLs	security admin
Choose between standard and equality preserving encryption. When enabled, equality preserving encryption ensures that the encrypted value of a field is the same when the field value remains the same. This type of encryption enables equality comparisons and group by operations on a field. **Note:** Non-deterministic encryption isn't supported.	Equality preserving encryption support	security admin
Use `getDisplayValue()` and `setDisplayValue()` APIs to return cleartext values and insert encrypted data for encrypted fields.	`getDisplayValue()` and `setDisplayValue()` APIs	security admin, developer

Column Level Encryption Enterprise benefits

Column Level Encryption Enterprise builds on the existing Column Level Encryption framework and provides these additional features after you purchase a subscription.

Benefit	Feature	Required Roles
Encrypt additional field types.	Support for additional field types: • HTML • Journal • Translated	security admin
Column Level Encryption Enterprise supports more than 5 modules and module access	Support for additional modules and MAPs	security admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Benefit	Feature	Required Roles
policies to provide more options for access to secured data.		
Keys from a key vault can be rotated on an automated schedule you configure. Using automatic key rotation can improve security while reducing administrative overhead.	Configurable automatic key rotation	security admin
Manage the full life cycle of your data encryption keys. Optionally, you can securely exchange data encryption keys generated within your environment.	Customer supplied keys	security admin
Ephemeral keys are cryptographic keys that are generated for each execution of a cryptographic process. These keys more secure because they're generated for use in a single session.	Ephemeral cryptographic keys	security admin
Updated `setDisplayValue()` and `setDisplayValue()` APIs can insert encrypted data for encrypted fields.	Updated `getDisplayValue()` and `setDisplayValue()` APIs	security admin, developer

Column Level Encryption Guided Tour

The tour gives a brief overview of the Column Level Encryption setup needed to encrypt table fields or attachments. Steps for the creation of Field Encryption Modules, Module Access Policies, and Encrypted Field Configurations are also covered. The tour includes links to detailed documentation and the ServiceNow University Column Level Encryption Overview course.

Before you begin

Role required: sn_kmf.crypto_manager or security_admin

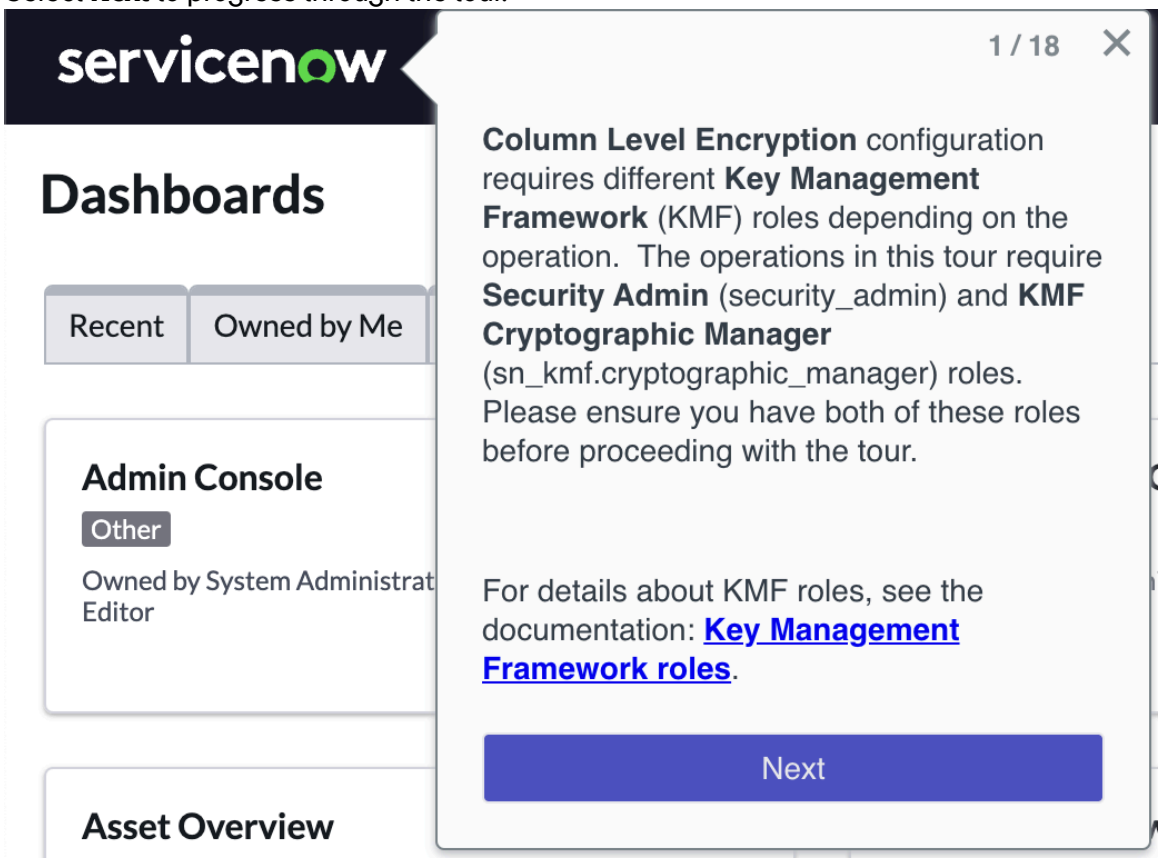
Note:
The guided tour is not yet available when Next Experience is enabled.

Procedure

1. Navigate to the **$pa_dashboards_overview.do** UI page on your instance.
   For example: `http://yourcompany.servicenow.com/nav_to.do?uri=%2F$pa_dashboards_overview.do` Replace `yourcompany` with the name of your instance.
2. Open the **Show Help** icon (in the upper left corner.
3. Select **Take a Tour** at the bottom of the sidebar.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Select **Next** to progress through the tour.



Configuring Column Level Encryption

Learn how to activate and configure Column Level Encryption and manage migration from Encryption Support.

Activate Column Level Encryption Enterprise

Learn how to active either Column Level Encryption or Column Level Encryption Enterprise.

Roles Required for Configuring Field Encryption

Learn about the roles required to configure Column Level Encryption.

Migration from encryption support

Use Scheduled jobs to migrate your keys and encrypted data from legacy Encryption Support to Column Level Encryption Enterprise. See details for this process at Migrating to Field Encryption

Change attachment encryption settings

Improve security by preventing users from attaching unencrypted files. For details, see Prevent users from attaching unencrypted files.

Activate Column Level Encryption Enterprise

With subscription to Column Level Encryption Enterprise, an admin can activate the com.glide.now.platform.encryption plugin.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin

Role required: admin

To purchase a subscription, contact your ServiceNow account manager. The account manager can arrange to have the plugin activated on your organization's production and non-production instances, generally within a few days.

About this task

Activating the Column Level Encryption Enterprise plugin (`com.glide.now.platform.encryption`) makes the following changes to your instance:

- The Encryption Support (com.glide.encryption) plugin is also activated.

  Note:
  The Key Management Framework (com.glide.kmf.global) plugin is already active by default.

- The `glide_encryption.set_value_support_cle.disabled` property is set to **false**, which turns on the SetValue feature. The SetValue support enables both `setDisplayValue()` and `setValue()` APIs to support encrypted data. It also enables both `getDisplayValue()` and `getValue()` to return clear text values.
- Two scheduled jobs are enabled:

  - **autoKeyMigration**: Migrates encryption context keys to Key Management Framework (KMF) cryptographic module keys.
  - **autoDataMigration**: Migrates data that you already encrypted to use the KMF cryptographic module key.

  Administrators can modify when these scheduled jobs run, and can pause or restart them at any time.

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the plugin, *`Platform Encryption - com.glide.now.platform.encryption`* using the filter criteria and search bar.
   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install**, and then in the Activate Plugin dialog box, select **Activate**.

   Note:
   When domain separation and delegated admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

Migrating to Column Level Encryption Enterprise

Scheduled jobs migrate your keys and encrypted data from Encryption Support to Field Encryption Enterprise.

You can review the scheduled jobs by navigating to **System Security** > **High Security Settings** > **Security Jobs**:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **autoKeyMigration**: Migrates encryption context keys to Key Management Framework (KMF) cryptographic module keys.
- **autoDataMigration**: Migrates data that you already encrypted to use the KMF cryptographic module key.

You can modify when these scheduled jobs run, and can pause or restart them at any time.

Verify that the encrypted field configurations are using your newly migrated module keys by navigating to **System Security** > **Field Encryption** > **Encrypted Field Configurations**. Look for the following items:

- The **Method** field is **Single Module**.
- The **Crypto module** field is populated with the name of the cryptographic module that the system automatically creates. You can review that module and the module access policy, both of which are active and published.

Column Level Encryption Enterprise and system clones

If Column Level Encryption Enterprise is installed on your instance, a new field encryption module encryption key is automatically generated on the target clone instance as a part of clone process. These keys are generated for all modules to which the user has access, and that does not have a key already.

Because of this, field encryption modules on the target clone instance may have two module encryption keys present:

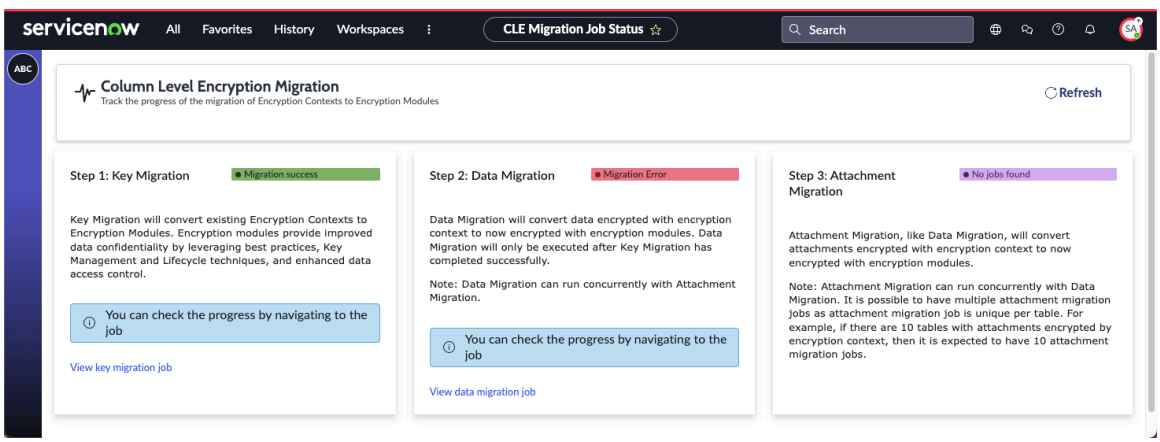
- An active module encryption key. This is the new key generated after clone, as long as the module is accessible to the user and has no prior keys.
- A deactivated encryption module key (from the automated key exchange transfer

  The active module encryption key is used to encrypt inserted data as needed on the target clone instance. The deactivated module is used to decrypt existing data that was cloned over as part of the system clone.

  To use a single key to decrypt and encrypt all data, you can run a module rekeying job. For more information about module rekeying jobs, see Schedule mass encryption, decryption, and rekeying jobs.

Column Level Encryption migration status page

Use the migration status page to track the migration of encryption contexts to encryption modules.



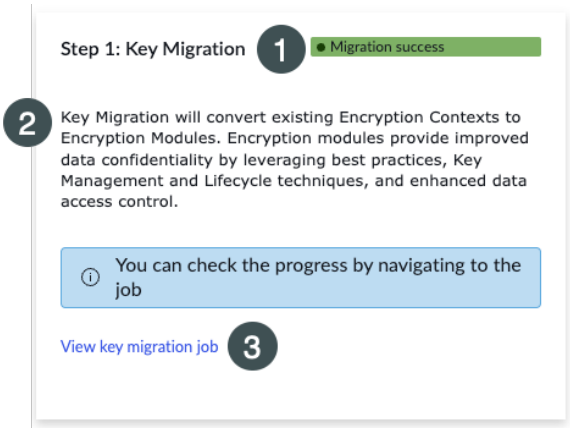
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The Column Level Encryption Migration page displays the status of the steps involved in migrating encryption contexts to encryption modules. Each of the three sections displays the status of a specific step in the process.

Page section cards

The page contains three cards representing the steps in the migration progress. These cards display:

- (1) The status of the current step. This status will display whether the step has completed successfully, or if there are no jobs to process.
- (2) A description of the listed step.
- (3) A link to the relevant encryption job [sys_mass_encryption_job] record.



Prevent users from attaching unencrypted files

Modify the com.glide.encryption.enable_attachment_key_ui property to prevent your users with access to an encryption module key from attaching unencrypted attachments.

Before you begin

Role required: security_admin

You must elevate to the security_admin role performing these steps. For instructions, see Elevate to a privileged role

By default, users who have access to an encryption module key are able to upload unencrypted attachments. Use the *com.glide.encryption.enable_attachment_key_ui* system property to change this behavior.

When attaching, your users see a UI picker on records that have a multi-module encrypted field configuration. When this property is set to false, users no longer see an option not to encrypt an attachment.

Procedure

1. Navigate to **All** > **System Properties** > **All Properties**.
2. In the system properties list, find and open the system property.
3. Set the **value** of the property to `false`.

Using Column Level Encryption

Use Column Level Encryption to manage access to encrypted data on your instances.

Use the related links to find information on common Field Encryption tasks.

Configure properties for customer-supplied keys

Encrypting fields and attachments

Column Level Encryption Enterprise

Create cryptographic module for Column Level Encryption

Create a Column Level Encryption cryptographic module to define the mechanisms used for cryptographic operations.

Before you begin

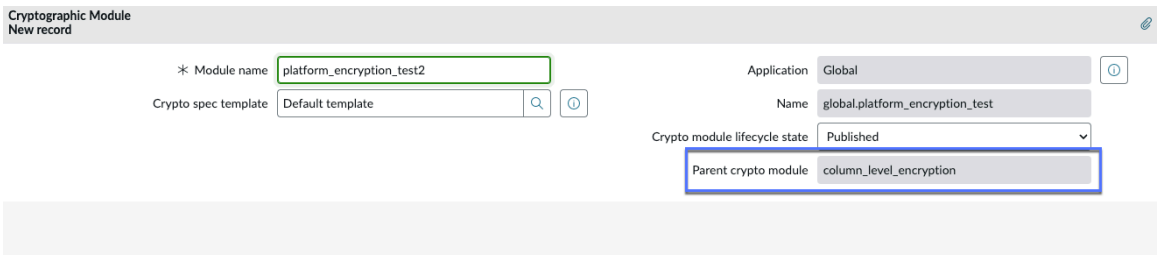
Role required: sn_kmf.cryptographic_manager or sn_kmf_admin, security_admin, admin

About this task

This procedure describes options that are available with Column Level Encryption with the base system and additional configuration options that become available with Column Level Encryption Enterprise functionality. Column Level Encryption Enterprise is available with a paid subscription. Refer to Encryption and Key Management subscription bundle for supported features and options available with each offering. See Activate Column Level Encryption Enterprise for more information on obtaining Column Level Encryption Enterprise.

Procedure

1. Navigate to **All** > **System Security** > **Field Encryption Modules** > **New**.



2. On the form, fill in the fields.

Cryptographic Module form

Field	Description
Module name	Alphanumeric string to be referenced when running scripts.
Crypto spec template	Default template used to create the cryptographic module that contains mappings of many crypto purposes to crypto specifications and recommended algorithms.
Application	The selected application scope.
Name	Encryption module name is prepended with application scope name to avoid conflict with other scoped applications on module creation. For example, if you created a module with the name `my_crypto_module` in the global application scope, the name is saved as `global.my_crypto_module`.
Crypto module lifecycle state	The term lifecycle refers to the creation, use, and deactivation of a cryptographic module. Set to **Draft** initially during configuration. When using the module, set to **Published**. The Default template is automatically set to **Published**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Parent crypto module	The parent is populated automatically as **column_level_encryption**.

3. Click **Submit**.

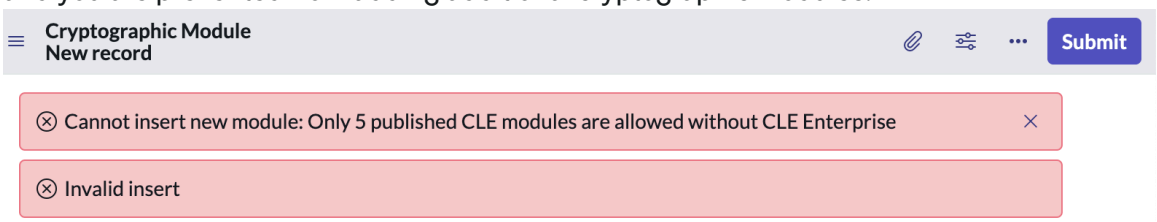
   After submitting successfully, your cryptographic module is listed in the Cryptographic Modules table.

> **Warning:**
>
> **For legacy encryption support users:**
>
> If you're using the non-enterprise version of Column Level Encryption, you're limited to five fields. If you've exceeded this limit, you receive the following warning:
>
> This insertion exceeds the number of published fields limit for Column Level Encryption #entitled with the Subscription Product. The Enterprise subscription for Column Level Encryption is required for additional ields. Please reach out to your Account team.

   A default cryptographic specification is created with the crypto purpose set to Symmetric Data Encryption/Decryption and the algorithm as AES 256 CBC. Select the algorithm for updates.

4. To open the configuration options, click the newly created cryptographic module.

> **Note:**
> A maximum of five Column Level Encryption fields are allowed before upgrading to Column Level Encryption Enterprise. An error message displays and you are prevented from adding additional cryptographic modules.



What to do next

Create a cryptographic specification for Column Level Encryption.

Encrypt data using the Multiple Modules feature

Encrypt data with more than one encryption module permitting the user to determine which keys are used for specific rows within the encrypted data.

Before you begin

Role required: sn_kmf.cryptographic_manager or sn_kmf.admin

About this task

The Multiple Modules option is considered non-deterministic and isn't the preferred method because the user determines which key to use for a given record. The ability to use multiple modules for a column is being replaced by Row Conditions. See Using multiple encryption modules. This non-deterministic implementation is still supported because it was created first and is still in use, but it's preferred to use Row Conditions for any new multiple modules use cases.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
Only encryption on columns supports multiple modules. Attachment encryption doesn't. Mass encryption isn't available when using the multiple encryption modules method.

You can't change a field using multiple encryption modules to use a single encryption module.

The field is encrypted by the encryption module of the first user to enter data. Because the encryption module is set on a per record basis, fields in a list can have different encryption modules. Within a single record, the field can be encrypted by only one module.

Procedure

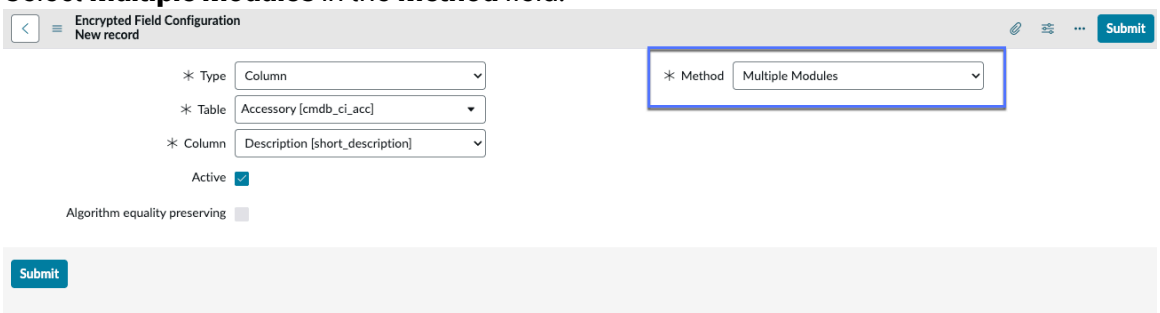
1. Create multiple Field Encryption modules and a Module Access Policy (MAP) for each one.

   Make sure that you grant different roles to the different cryptographic modules through the access policies.

2. Navigate to **System Security** > **Field Encryption** > **Encrypted Field Configurations** > **New**.

   If you need more information on Encrypted Field Configurations, see Set encrypted field configurations.

3. In the **Type** field, you must select **Column**.
   Attachment encryption doesn't support multiple modules.
4. Select **Multiple Modules** in the **Method** field.



5. Select the **Table** and the **Column** in the table that you want to encrypt.
6. Select **Submit**.

Result

Newly created data for the specified field is encrypted with the key of the relevant module. When a user with the role specified in module A's access policy writes to the specified table, the data is encrypted with module A's key. Only users with the same role can read the data.

Example:

To encrypt the Short Description column on the Incident table. You would do the following:

1. Create two cryptographic modules A and B.
2. For each module, create a module access policy.

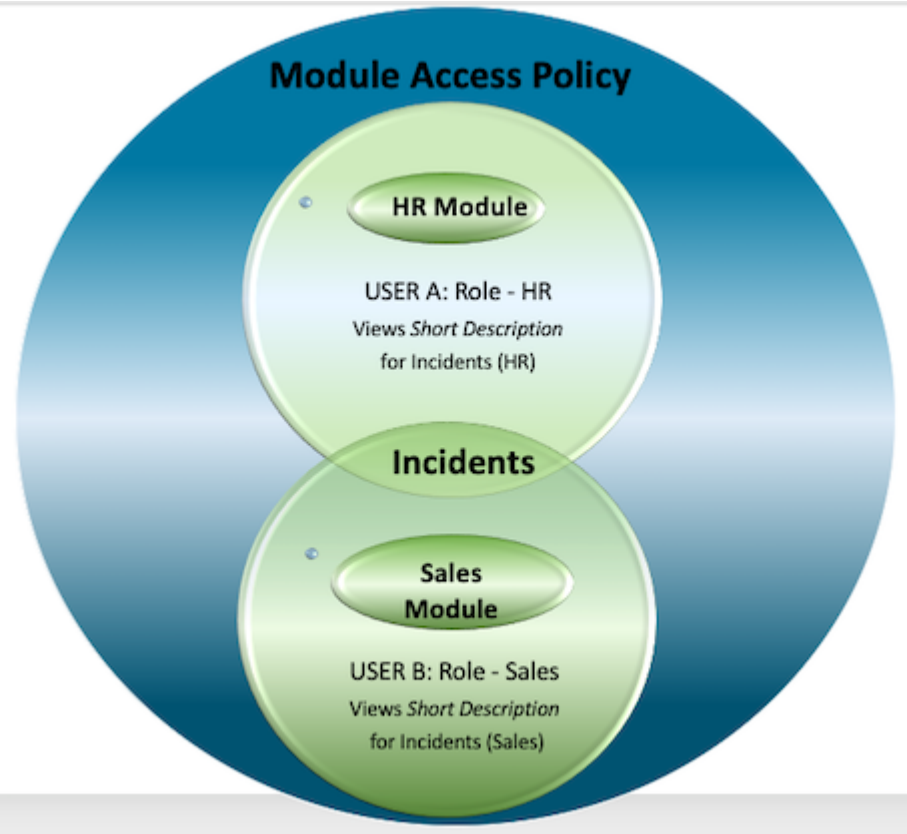
   For module A, give users with an HR role access. For module B, give users with a Sales role access.

3. Create an Encrypted Field Configuration record specifying the Short Description column on the Incident table, and make sure that you select **Multiple Modules** in the **Method** field.
4. Have two users, one with the HR role (user A) and one with the Sales role (user B), create an incident with a short description, and then have both users look at the list of incidents.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The short description for the incident created by the user with the HR role is encrypted by the key for module A. Likewise, the short description for the incident created by the user with the Sales role is encrypted by the key for module B.

Although all users with the HR and Sales roles have access to incidents, only a user with the HR role can decrypt and view the short description for those incidents created by user A, who had the HR role. Likewise, only users with the Sales role can decrypt and view the short descriptions for those incidents created by the user B, who had the Sales role.



Create a cryptographic specification for Column Level Encryption

After you create a cryptographic module, access the corresponding cryptographic specification to define the algorithm.

Before you begin

Role required: sn_kmf.cryptographic_manager or sn_kmf_admin and security_admin or admin

About this task

This procedure describes options that are available with Column Level Encryption with the base system and additional configuration options that become available with Column Level Encryption Enterprise functionality. Column Level Encryption Enterprise functionality is available with a paid subscription. Refer to Encryption and Key Management subscription bundle for supported features and options available with each offering. See Activate Column Level Encryption Enterprise for more information on obtaining Column Level Encryption Enterprise.

A cryptographic specification will be created by the system when you create a cryptographic module for Column Level Encryption Enterprise.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **System Security** > **Field Encryption Modules** > **All**.
2. Select the cryptographic module to open the configuration options.
   Cryptographic module information is displayed at the top of the screen. A Symmetric Data Encryption/Decryption crypto specification is auto-created with an AES 256 CBC algorithm.
3. Select the crypto specification from the table to open the Algorithm Definition.
   For Column Level Encryption Enterprise see Configure advanced algorithms for Column Level Encryption Enterprise.
4. Click **Next** to access the Key Lifecycle.

What to do next

Perform one of the following operations:

- Select an entry in the Key Lifecycle table to define key lifecycle behavior. See Configure key lifecycle states for details to complete the lifecycle definition for the key.
- Click **Next** to create a cryptographic key. For details on this process, see Generate a ServiceNow cryptographic key.

Configure advanced algorithms for Column Level Encryption Enterprise

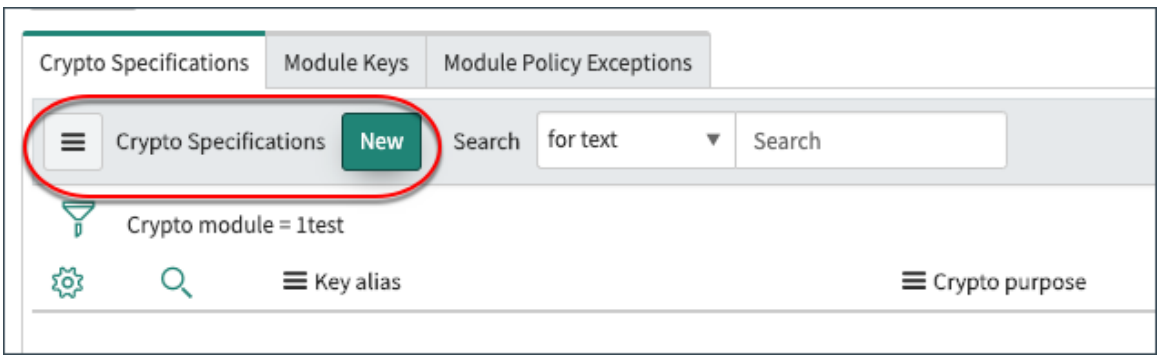
Create a cryptographic specification to define the algorithm for a cryptographic module. Customize the encryption specifications with advanced options that are available for Column Level Encryption Enterprise.

Before you begin

Role required: admin

Procedure

1. On the **Crypto Specifications (#)** tab, click **New**.



2. On the form, fill in the fields.

Algorithm Definition form

Field	Description
Crypto module	Name of the selected cryptographic module populates.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

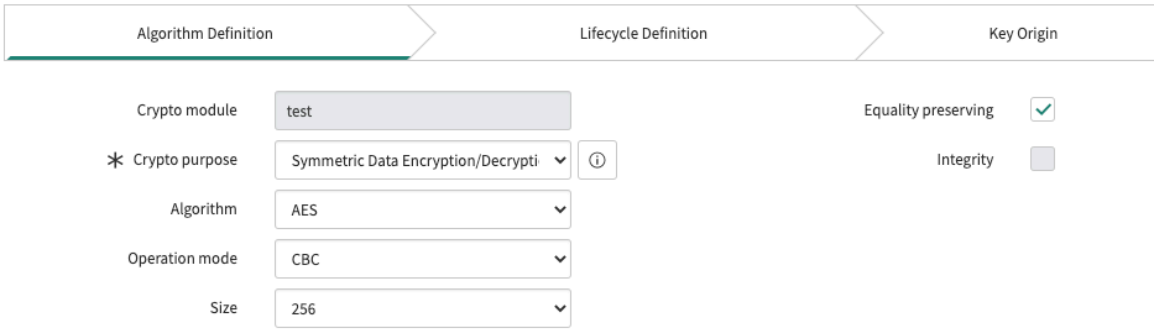
Field	Description
Crypto purpose	The value is **Symmetric Data Encryption/ Decryption** for Column Level Encryption Enterprise.
Algorithm	The value is **AES** for Column Level Encryption Enterprise.
Operation mode	The value is **CBC** for Column Level Encryption Enterprise.
Size	Possible values are **256** and **128**. **Note:** 256-bit size is most secure for encryption and is used for Symmetric Data Encryption/Decryption for Column Level Encryption Enterprise.
Equality preserving	Option to enable deterministic encryption. **Note:** Selecting this option means that the encrypted value of a field should be the same when the field value remains the same. Option to enable **Symmetric Data Encryption/Decryption** with **AES** in **Cipher Block Chaining (CBC)** mode.
Integrity	Option to provide Integrity in GCM operation and does not apply for Column Level Encryption Enterprise functionality.

3. Click **Submit**.

   The following example shows AES CBC-256 encryption. When Column Level Encryption Enterprise is active and the parent module is column_level_encryption, only Symmetric Data

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Encryption/Decryption AES CBC-256 applies as the crypto purpose. See Cryptographic specification overview for details.



What to do next

Perform one of the following operations:

- Select an entry in the Key Lifecycle table to define key lifecycle behavior. See Configure key lifecycle states for details to complete the lifecycle definition for the key.
- Select **Next** to create a cryptographic key. See one of the following tasks for key generation:
  - Generate a ServiceNow cryptographic key.
  - Configure properties for customer-supplied keys.
  - Import the wrapping / unwrapping key pair.

Using customer supplied keys with Column Level Encryption Enterprise

You can use your own customer-supplied key instead of using the ServiceNow® system-generated keys.

Important:
These topics only apply instances using Column Level Encryption Enterprise, which is only available with the `com.glide.now.platform.encryption` plugin. See Activate Column Level Encryption Enterprise for more information on obtaining this plugin.

With Column Level Encryption Enterprise you can use your own keys for encryption. Administrators have the choice to use ServiceNow® supplied keys or your own customer-supplied keys (CSK) for encryption on the ServiceNow AI Platform.

Important:
To make use of the customer supplied key option, you must have your own cryptographic key.

Once you have your key, you can being using it on your instances by following these steps.

1. **Configure properties for customer-supplied keys**

   There are three system properties which define the size, padding algorithm, and validity period of the wrapping RSA key pair. Review these properties and adjust their values if the defaults to not fit your needs.

2. **Wrap your customer-supplied key**

   Use a cryptographic tool to wrap your key like OpenSSL to wrap the symmetric key to use for encryption with the downloaded public key.

Configure and upload your customer supplied key

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Upload your wrapped your customer supplied key and configure cryptographic module to begin using your key for encryption on your instance.

Configure properties for customer-supplied keys

If the Field Encryption Enterprise plugin is enabled, you can use system properties to define key padding, ephemeral key pair size, and a key validity period of your customer-supplied keys.

Field Encryption Enterprise with Key Management lets you manage the full key lifecycle of your data encryption keys. Optionally, you can securely exchange data encryption keys generated within your environment.

Platform Encryption with Key Management lets you manage the full key life cycle of your data encryption keys. Optionally, you can securely exchange data encryption keys generated within your environment.

System properties for defining key-pair attributes

When you provide your own key, you must wrap it with the RSA public key. Three properties define the size, padding algorithm, and validity period of the wrapping RSA key pair:

- *glide.kmf.ephemeral_key.key_padding* controls the key padding scheme for the ephemeral key. The default scheme is OAEP SHA256, but SHA1 is also supported.
- *glide.kmf.ephemeral_key.key_size* controls the key size of the ephemeral key pair. The default is 4096 bits, but 2048 bits are also supported.
- *glide.kmf.ephemeral_key.key_validity_period* defines the period for which the ephemeral key pair is valid. The default value is two hours.

After the data encryption key is imported to the instance, a secure wrapping key protects new module keys on the instance. The wrapping key is an instance key encryption key (IKEK) generated by a hardware security module (HSM) on SafeNet KeySecure. See Instance level keys in the Key Management Framework for details in key types.

Continue to Wrap your customer-supplied key.

Wrap your customer-supplied key

Wrap the symmetric key to use for encryption with the downloaded public key.

Before you begin

Note:
This procedure describes options that are available with KMF base system and options to be used with Field Encryption Enterprise functionality. Field Encryption Enterprise functionality is available only when the *com.glide.now.platform.encryption* plugin is active. See Activate Field Encryption for more information on obtaining Field Encryption Enterprise.

Some of the steps in this document require the use of a cryptographic tool installed on your local device. The examples in this task use the OpenSSL tool. For more information on this tool see https://www.openssl.org. If you are using other cryptographic tools, such as LibreSSL or GnuTLS, refer to the documentation for those products for similar steps.

- Modify optional properties that control the size, padding algorithm, and validity period of the key. See Configure properties for customer-supplied keys.

- You must have your symmetric key (.BIN) for encryption.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Important:
Your key must be in binary format. If another format is used, a `Token failed validation. Please reattach the unmodified token.` error message displays.

- You must have a cryptographic tool to wrap your key. This example uses OpenSSL 1.1.

Role required: sn_kmf.cryptographic_manager or sn_kmf.admin

Procedure

1. Navigate to **All** > **Key Management Framework** > **Cryptographic Modules** > **All**.
2. Select the cryptographic module that you created for the customer supplied key from the Crypto Specifications related list.
3. You will be directed to the **Key Creation** step.
4. If you have not previously downloaded the wrapping key, click the link to download the *token_publickey<id>.zip* file and save it to the same location as your key.

   Note:
   Do not rename the downloaded *token_publickey<id>* file.

5. Unzip the file to your local network.
   The zip file contains two files, an import token and a public key `.PEM` certificate. Wrap your symmetric key with the public key to encrypt it.
6. Copy the name of the *token_publickey* file to your clipboard.
7. From a command line, use the copied *token_publickey* file name to open the folder of the unzipped files as a placeholder for the wrapped key.
8. Edit this script by replacing the examples with the names of your crypto files.

```
"downloads user.name$ cd token_publickey_<token>
openssl pkeyutl -encrypt -pubin -inkey publickey_<keyname>.PEM
-in <keyname.bin>
-out wrapped_key_material -pkeyopt rsa_padding_mode:oaep
 -pkeyopt rsa_oaep_md:sha<128 or 256> "
```

Review the key wrapping commands in the following table for more information.

Key wrapping commands

Directions	Command	Example
Open the file directory where you downloaded the wrapping token.	`cd`	`cd token_publickey123456789`
Paste the name of the `publickey.PEM` certificate.	`openssl pkeyutl -encrypt -pubin -inkey`	`publickey_586798643ffff.PEM`

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Directions	Command	Example
Paste the name of your key here.	`-in`	`mykey.bin`
Enter the <-out> command and specify if the key is 128 bit or 256 bit.	`-out wrapped_key_material -pkeyopt rsa_padding_mode:oaep -pkeyopt rsa_oaep_md:sha256`	N/A

9. Run the command.
   A system message displays `token_publickey_<keynumber>`. The key will be generated and a *`wrapped_key_material`* file added to the directory.
10. Upload the wrapped key.

What to do next
Return to Configure and upload your customer supplied key to upload your wrapped key.

Configure and upload your customer supplied key

You can use your own customer-supplied key instead of using the ServiceNow® system-generated keys.

Before you begin
Roles required: security_admin, sn_kmf.cryptographic_manager

If you're NOT supplying your own keys, you don't need to perform this procedure. To create a cryptographic module with ServiceNow® keys, go to Create a cryptographic module or Create cryptographic module for Field Encryption.

Note:
This procedure only applies to Field Encryption Enterprise functionality. See Activate Field Encryption for more information.

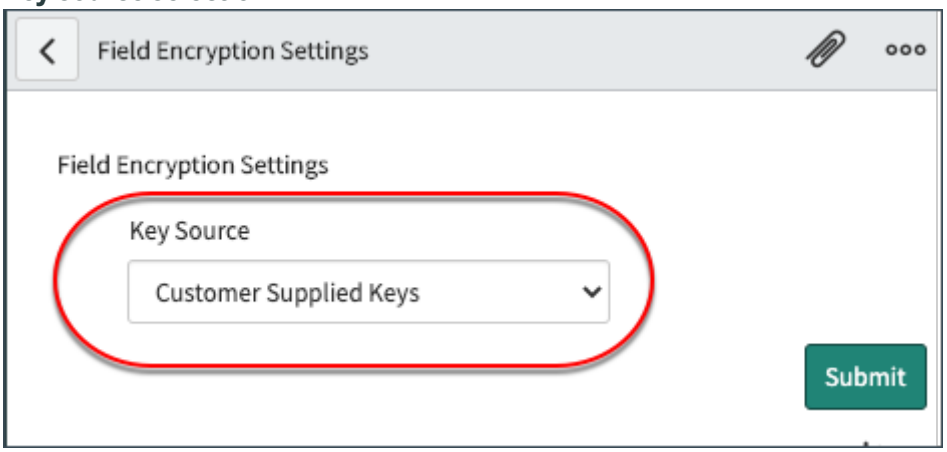
Important:
You can't revoke a customer supplied key.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

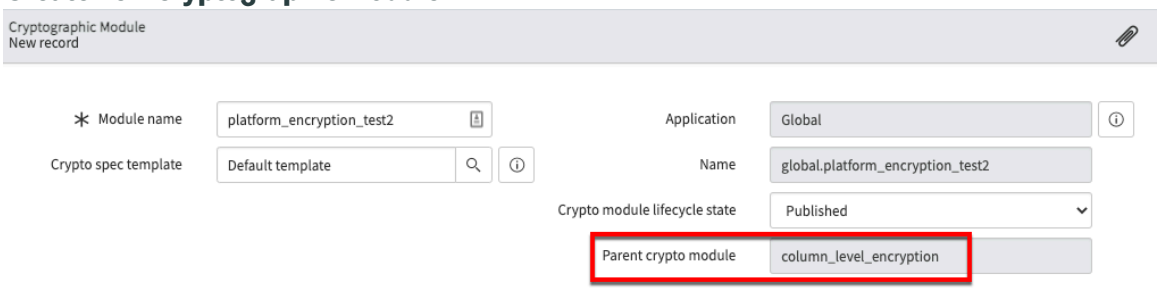
1. Navigate to **All** > **System Security** > **Field Encryption Settings** and verify that **Customer Supplied Keys** is selected.

Key source selection



2. Select **Submit**.
3. Return to **System Security** > **Field Encryption Modules** > > **Create New**.

Create new cryptographic module



4. Complete the Cryptographic Module form as follows:

Cryptographic Module fields

Field	Description
Module Name	Enter a name for the module.
Crypto spec template	The default cryptographic template is selected.
Name	Auto-populates based on the module name and prepends the name with the scope to ensure which application is being applied. In this case, the global scope is applied.
Crypto module lifecycle state	Select **Published** to activate the crypto module.

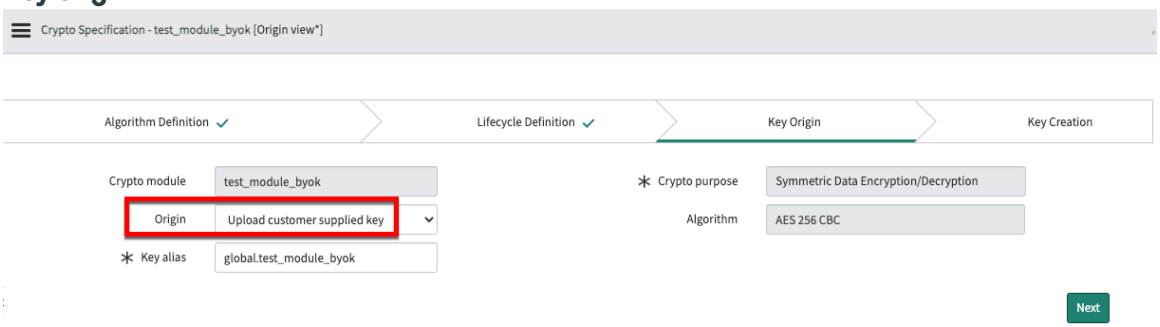
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Parent crypto module	The parent module **column_level_encryption** is selected automatically when using customer-supplied keys and encryption modules.

5. Select **Submit**.
6. Select the newly created cryptographic module from the table.
   In the **Crypto Specifications** related list, select the auto-generated key alias with the AES 256 CFB algorithm.

   The system populates the Crypto purpose and the Algorithm for Field Encryption automatically and jumps to the **Key Origin** stage.
7. Notice that **Upload customer supplied key** is the **Origin** and the **Key alias** is already populated.

Key origin

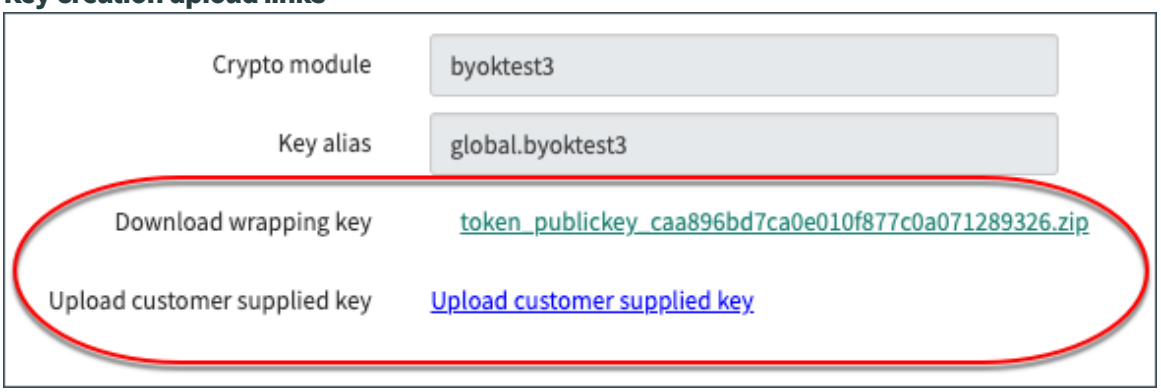


8. Select **Next** to move to the **Key Creation** stage.

   There are two links:

   - **Download wrapping key** downloads the key in a zip file containing an import token and a public key certificate, `.PEM` file. Use the import token to verify successful key wrapping according to security specification for the instance. Use the public key certificate `.PEM` file to wrap your customer supplied key securely before uploading it along with the token.
   - **Upload customer supplied key** opens the file browser to select the token and the encrypted key that you wrapped.

Key creation upload links



9. Select **Download wrapping key** to save the token.
   Save the token to the same destination location as the key is saved on your system. Don't rename the downloaded token.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

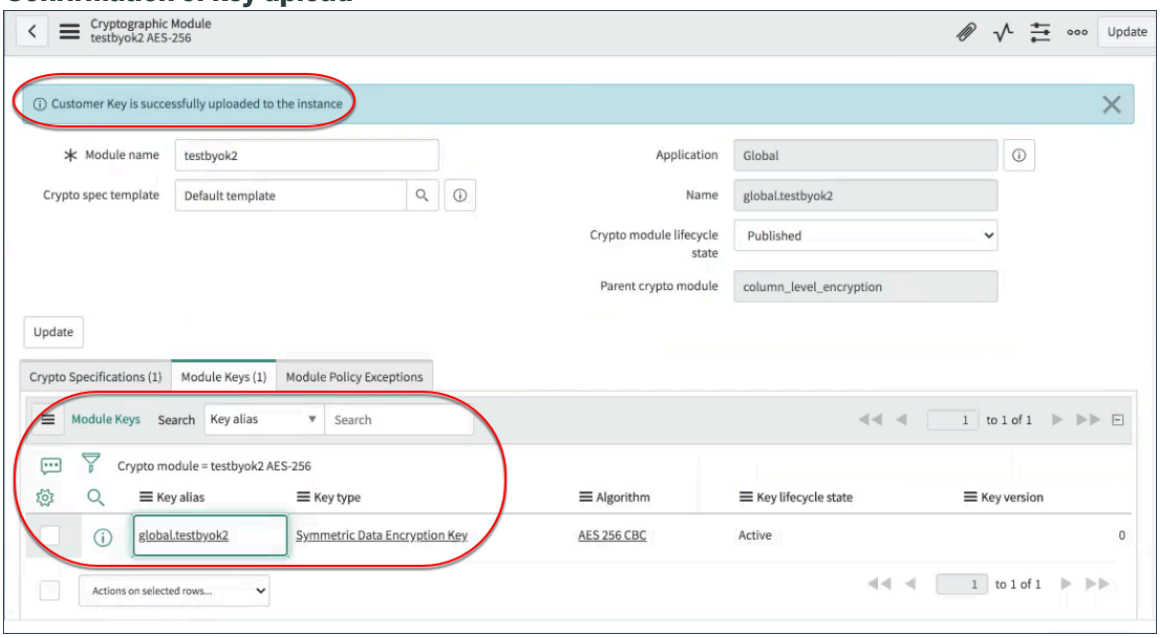
10. Run the BYOK command on a terminal to wrap the key.
    For more information, refer to Wrap your customer-supplied key.
11. Select **Upload customer supplied key**.
12. Select **Browse** to select the two files, the wrapped key and the token file.
    The Attachments window displays the two files.

Wrapped key attachments upload

Select a file to remove and reupload, if necessary.

13. Select **OK**.
    You're returned to the Cryptographic Module screen. A confirmation message displays for a successful upload of the customer key. The key is also listed in the Module Keys related list.

Confirmation of key upload



What to do next

Now that you have finished configuring your cryptographic module with your customer-supplied key, move on to Create a module access policy

Encrypting fields and attachments

Once cryptographic modules are created, a security admin can define the encrypted fields configuration (EFC) and opt to encrypt a field or attachment on a table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

How to encrypt fields

Note:
Encrypted fields aren't audited by design. This behavior isn't configurable.

1. Specify the key source: ServiceNow generated keys or your customer-supplied keys (bring your own key) in **System Security** > **Field Encryption Settings**.
2. After specifying the key source, create a cryptographic module or use an existing cryptographic module. Start with Create a cryptographic module for instructions.

   Note:
   If you use customer-supplied keys, follow the directions in Create cryptographic module for Field Encryption and Configure properties for customer-supplied keys.

3. Create an encrypted field configuration to define where the encryption is applied. Here, you specify the target table and choose whether to encrypt a column or attachments within the table. See Set encrypted field configurations to get started.

Note:
See Field Encryption Enterprise examples that illustrates how to encrypt fields and attachments using customer-supplied keys.

Set encrypted field configurations

Configure which table columns or attachments that the system encrypts using a preconfigured cryptographic module.

Before you begin
Role required: sn_kmf.cryptographic_manager and security_admin or elevate role to security admin.

About this task
Make sure you are in the correct application scope so you can see the tables in that scope.

Only users with access to the cryptographic module used in this configuration can read the data in the encrypted table column or access the attachment.

- If a user has write access but not read access, the field displays in edit mode and the data entered displays as asterisks.
- If a user has read access but not write access, the field displays the decrypted data in read-only mode.
- If a user has all access, both read/write functionality is available on the encrypted field.

See Create a cryptographic module or Create cryptographic module for Field Encryption to begin.

Important:

After encrypting a column, any new data inserted into the column is encrypted automatically. However, data that existed in the column before the encryption was active is not automatically encrypted.

In order to encrypt data that existed before the column was encrypted, you must run a separate mass encryption job. Learn more about mass encryption in Run mass encryption or decryption.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **System Security** > **Field Encryption** > **Encrypted Field Configurations** > **New**.
2. Select **New**.
3. Complete the form.

Field	Description
Type	**Column** to encrypt a table column or **Attachment** to encrypt all of a table's attachments. Types of data encrypted are: ○ String text (Full UTF-8) ○ Attachments ○ Date, Date/Time: **Note:** You can create encrypted field configurations to encrypt existing Date and Date/Time fields. You can add a new encryption configuration to a parent table only. You can't add a new encryption configuration to a child table. ○ URL ○ HTML ○ Journal ○ Translated
Table	Table whose fields or attachments are to be encrypted.
Column	Column (field) to be encrypted if you selected **column** as the type.
Active	Select to mark the configuration active. Deselect if the configuration isn't yet in use.
Crypto module	The cryptographic module that the encrypted field configuration applies to.
Method	Select **Single Module** to set the field configuration across one module. Select **Multiple Modules** for role-based access that spans across more than one cryptographic module. **Single Module** Use this option to encrypt all attachments using a single module. Your users need access to this module, otherwise they aren't able to upload attachments. **Multiple Modules** Use this option to allow users to choose a module when uploading attachments. Users with access to at least one module can select a module to use for encryption. Users with no module access can upload unencrypted attachments.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Algorithm Encrypted Preserving [read-only]	Indicates if the crypto module that you selected is already configured to support non-deterministic encryption. This means that if the same data is encrypted more than once, the encryption is different each time.

4. Select **Submit**.

Script access for cryptographic modules

Scripts can be run to access a cryptographic module policy for a cryptographic purpose.

For Key Management Framework, policies can be based scripts. When an access policy is triggered for script access, the backend script can execute the module policy actions from the script.

Cryptographic modules can support one or more encryption purposes, such as Asymmetric Data Decryption and Symmetric Data Decryption. Each cryptographic purpose requires the generation of an encryption key and defined cryptographic purpose.

Consider the following when executing an encryption script request:

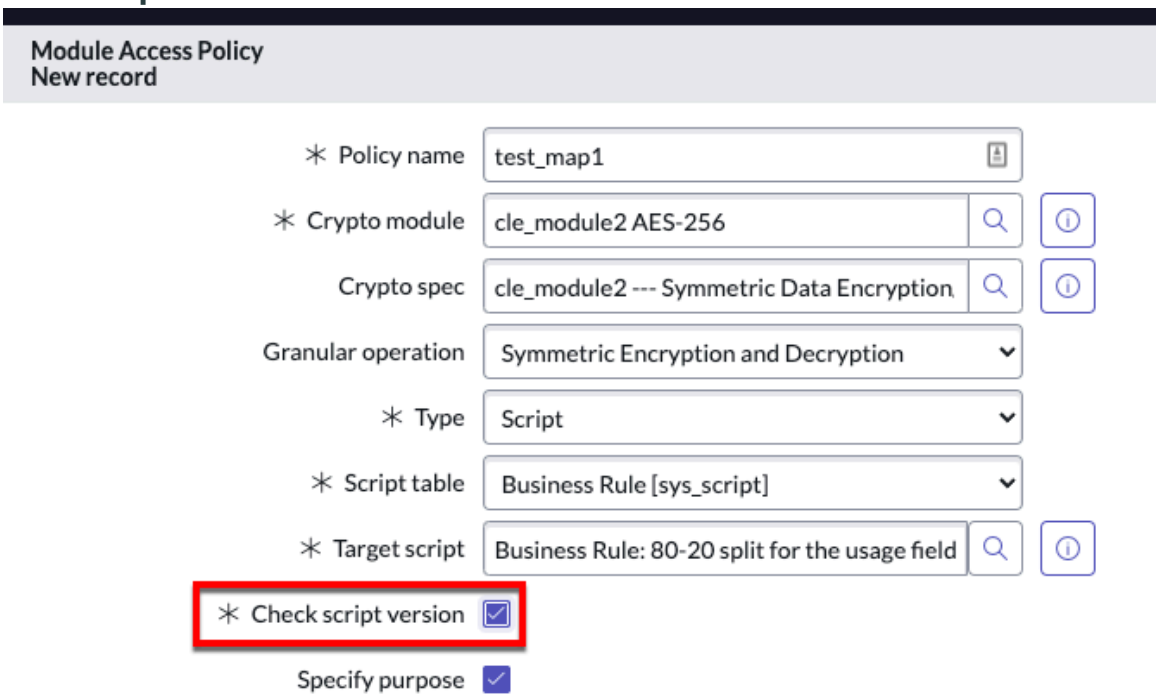
- The referenced cryptographic purpose must be defined in the cryptographic module.
- An active generated key must exist for the cryptographic module.
- The Module Access Policy type must be set to **script**.

Check script version

When creating a module access policy that is set to the script type, there is an option available to validate the integrity of the script version being accessed. Only the assigned version of the script is allowed access to the encryption modules. When the **Check script version** check box is selected in the module access policy, anytime the script is run, the system performs a version comparison. If the script has been changed, the user is notified.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Check script version check box



Configure script access to encrypted data

Execute a script to run the cryptographic module policy for a cryptographic purpose. Specific read (decrypt/unwrap) or write (encrypt, wrap) access can be defined based on the module access policy operation granularity.

Before you begin

Role required: sn_kmf.cryptographic_manager

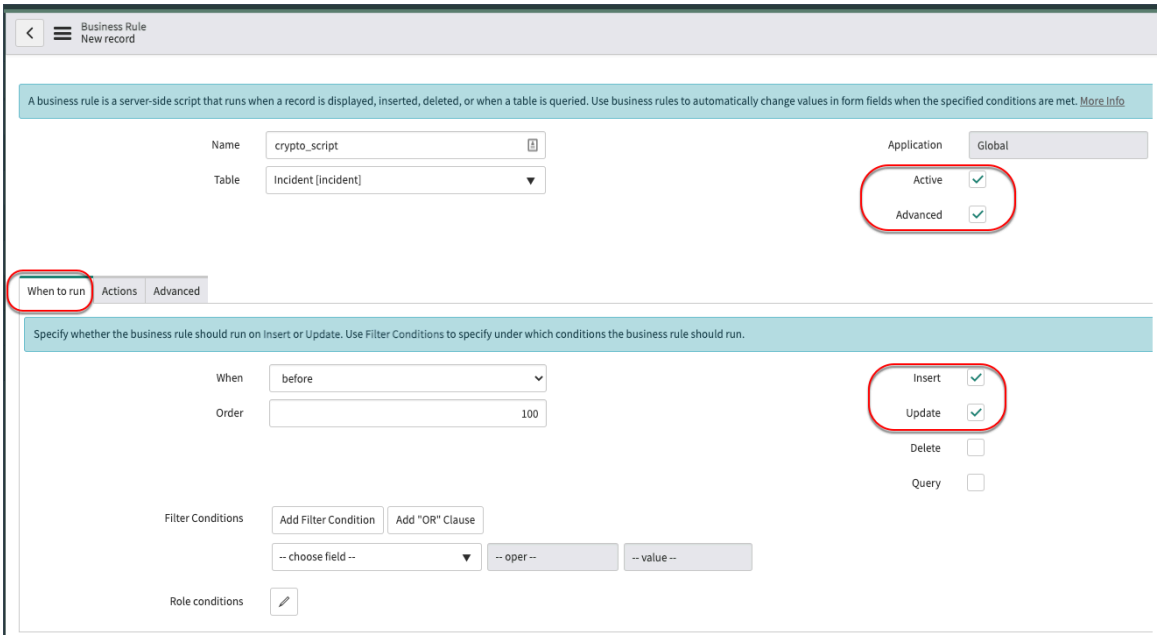
About this task

Examples of uses are for Business Rules and Script Includes. This procedure uses a script for Business Rules.

Procedure

1. Create a cryptographic module with the symmetric data encryption/decryption algorithm. Refer to Create a cryptographic module for details. Specific access to the data or attachment is controlled with a module access policy with the following characteristics:
   - Symmetric encryption: The script is able to encrypt data but unable to decrypt the data.
   - Symmetric decryption: The script is able to decrypt uploaded encrypted data or attachment but unable to encrypt data or attachments.
   - Symmetric encryption and decryption: The script is able to both encrypt and decrypt data or attachments.
2. Navigate to **System Definition** > **Business Rules**.
3. Click **New**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



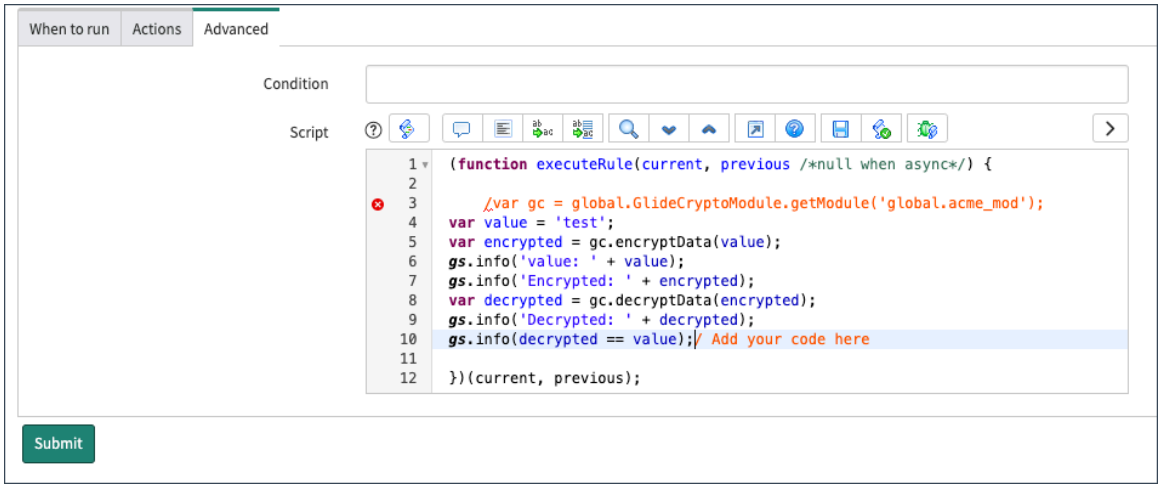
4. Complete the form on the **When to run** tab and enter the script on the **Advanced** tab:

Business Rule fields

Field	Description
Name	Enter a name for the business rule.
Table	Select **Incident [incident]**from the drop-down list.
Application	**Global** is selected by default.
Active	Mark the rule as **Active**.
Advanced	Select the check box to display advanced options.
When to run tab	On the **When to run** tab, enable **Insert** and **Update** fields.

Advanced tab	On the **Advanced** tab, paste the following script text at line 3:
	`var gc = global.GlideCryptoModule.getModule('global.acme_mod');`
	`var value = 'test';`
	`var encrypted = gc.encryptData(value);`
	`gs.info('value: ' + value);`
	`gs.info('Encrypted: ' + encrypted);`
	`var decrypted = gc.decryptData(encrypted);`
	`gs.info('Decrypted: ' + decrypted);`
	`gs.info(decrypted == value);`
	Note: Refer to the "Business Rules Advanced Tab" image for details.

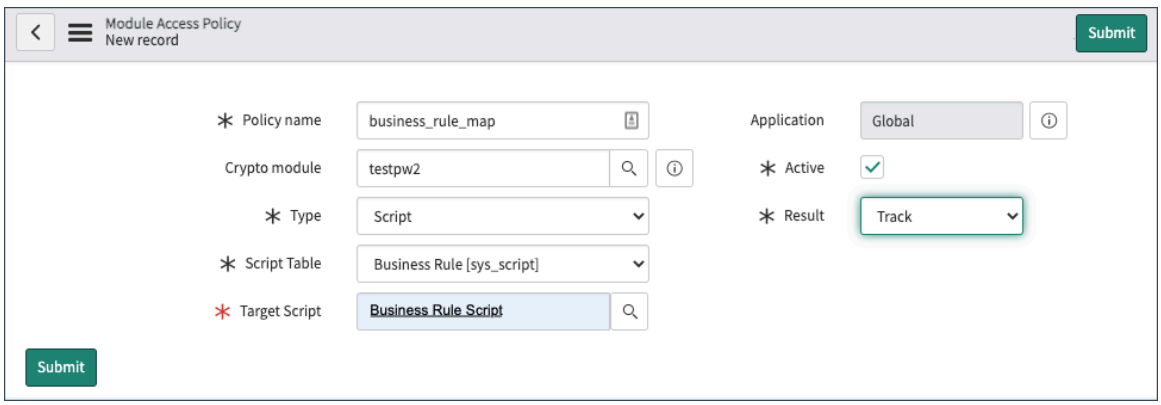
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



5. Click **Submit**.
6. Navigate to **Key Management** > **Module Access Policies** > **All**.

> **Note:**
> For additional information, refer to Create a module access policy.

7. Click **New**.
8. Complete the form.



Module Access Policies fields

Field	Description
Policy name	Enter a name for the policy.
Crypto module	Click the search icon to select a module with the symmetric data encryption/decryption algorithm.
Type	Select **Script** to control access by script.
Script Table	Select a value from the script table drop-down list. For this example, select **Business Rule [sys_script]**.
Target Script	Select the script document for the policy. Select the **Table name** and then the related document for the policy. For this example,

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	select the Business Rule that you created in previous steps.
Active	Select to activate the policy.
Result	To give the script access to the module, select **Track** in the **Result** field.

9. Click **Submit**.
   The Module Access Policy for the script is now available in the system.

View declined cryptographic module usage requests

View cryptographic modules that rejected encryption requests made by scripts because of unsupported encryption mechanisms.

Before you begin
Role required: sn_kmf.cryptographic_manager

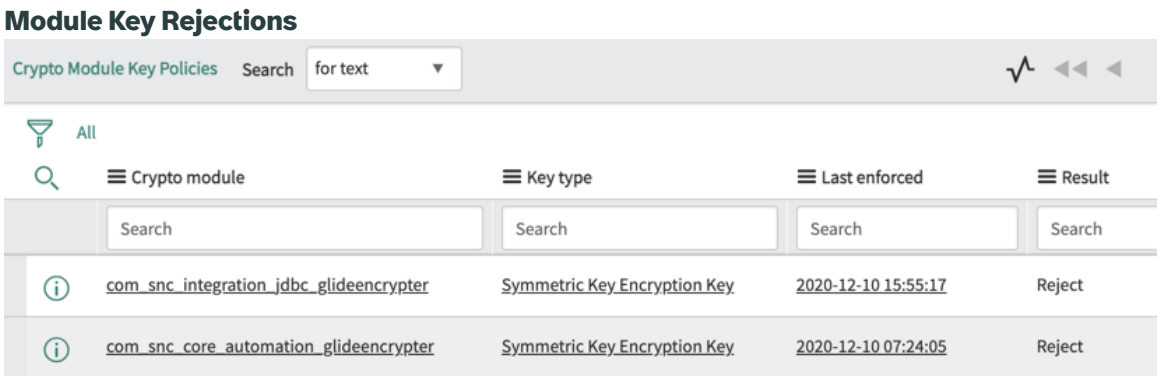
About this task
Cryptographic modules can support one or more encryption purposes, such as Asymmetric Data Decryption and Symmetric Data Decryption. Encrypted data can only be accessed based on the module access policy. If a script tries to use a cryptographic module for a purpose not defined in the module, the script cannot access to the encrypted data.

In the following example, a cryptographic purpose was assigned to a cryptographic module, but a key was never generated for it.

Procedure

Navigate to **All** > **Key Management** > **Module Key Policies** > **Module Key Rejections**.

A list of cryptographic modules that rejected requests displays along with the encryption key used in the corresponding script.



Note:
If a different script attempts to use the same cryptographic module using the same key type, the value for **Last enforced** updates. Another row does not generate.

In this example, at 2020-02-10_15:55:17, the first module rejected a request because module1's key is compromised. At 2020-02-10_07:24:05, the second module rejected a request because the second module's key is suspended.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

To grant scripts permission to use the encryption module the next time they run, create a module access policy for script encryption. For more information, refer to Configure script access to encrypted data.

Schedule mass encryption, decryption, and rekeying jobs

Schedule encryption, decryption, and rekeying jobs to run at a time that is best for your instance.

Before you begin

Encryption, decryption, and rekeying jobs can be time and resource intensive, so consider scheduling at non-peak hours. Also ensure that the user scheduling the job has the appropriate access for each job.

Role required: sn_kmf.cryptographic_manager

About this task

Mass encryption and decryption is also available from the Encrypted Field Configurations form. See Run mass encryption or decryption for instructions.

Procedure

1. Navigate to **All** > **System Security** > **Security Jobs**.
2. Click **New**.
3. Complete the scheduling form.

Field	Description
Name	Name of the encryption, decryption, or re-keying job.
Type	Job type: ○ **Key Migration Context to Module:** Mass migration of Encryption Context keys to Encryption Modules, including creation of Module Access Policies records for access controls on the Encryption Modules ○ **Data Migration Context to Module**: Migrates data encrypted by Encryption Contexts to Encryption Modules ○ **Mass Decryption Attachment**:Decrypts all encrypted attachments in records for a single table you define in the **Table** field. ○ **Mass Encryption Attachment**: Encrypts all attachments in records for a single table you define in the **Table** field. ○ **Mass Encryption**: Encrypts any pre-existing value in the defined column/field used in the Field Encryption Configuration ○ **Mass Decryption Module**: Decrypts any pre-existing value in the defined column/field used in the Field Encryption Configuration with Single Module. ○ **Mass Decryption Multi Module**: Decrypts any pre-existing value in the defined column/field used in the Field Encryption Configuration with Multiple Module. ○ **Mass Rekeying**: Re-encrypts any pre-existing value in the defined column/field used in the Field Encryption Configuration using the current active key for the module. ○ **Migrate Attachment Context to Module**: Encrypts any pre-existing attachment on the table defined in the Field Encryption Configuration. Any attachment previously encrypted with a context is re-encrypted with the module.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
State	The initial job state is New. After the job has been executed as scheduled, the state will update accordingly.
Time window start	Start time for the job in 24-hour format.
Time window end	End time for the job in 24-hour format.
Table	Table to be encrypted or decrypted.
Field	Field to be encrypted or decrypted.
Summary	Job status information when the job is running, has completed, or has errors.

Note:
Because of system overhead, you should schedule mass encryption, decryption, and rekeying jobs to run at non-peak hours. The ServiceNow AI Platform runs the job between the **Time window start** and **Time window end**. If the job is not complete in one processing window, it continues during the next specified processing window until all processing is complete.

4. Click **Submit**.
5. After you schedule a job, you can do the following.
   - Click **Cancel Job** to cancel a running job.
   - Click **Start** to start a job immediately.
   - Click **Update** to save any changes you make to the job schedule.
   - Click **Delete** to delete the scheduled job.

Run mass encryption or decryption

You can run mass encryption on encryption configurations, as well as a mass decryption to decrypt previously encrypted values.

Before you begin
Role required: security_admin

About this task
You can also create scheduled jobs for mass encryption and decryption. See Schedule mass encryption, decryption, and rekeying jobs for instructions.

Mass encryption and decryption are available only when an encrypted field configuration uses the single cryptographic module. Mass decryption is available for both the single and multiple encryption method.

Note:
You should run mass encryption and decryption only during non-peak hours because the operations are resource and time intensive.

Procedure

1. Navigate to **All** > **System Security** > **Field Encryption** > **Encrypted Field Configurations**.
2. Open the encrypted field configuration for the field you would like to mass encrypt or decrypt.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. Under Related Links, select an available option.
   - **Schedule Mass Decryption job**
   - **Schedule Mass Encryption job**
4. Confirm your selection in the dialog.

Result

If running a mass encryption, all values are encrypted with the encryption module defined in the encrypted field configuration record. If running a mass decryption, only fields encrypted with an encryption module you have access to are decrypted.

Column Level Encryption Enterprise

These examples walk you through the encryption of fields and attachments using customer-supplied keys.

Column Level Encryption Enterprise walkthrough

This walkthrough shows you how to encrypt a field in your instance using Column Level Encryption Enterprise with the Key Management Framework (KMF). It also shows you how to use your own key.

Before you begin

Note:
This procedure only applies to Column Level Encryption Enterprise functionality. See Activate Column Level Encryption Enterprise for more information on obtaining Column Level Encryption Enterprise.

Role required: admin or security_admin

Note:
security_admin is a privileged role, for details on using privileged roles, see Elevate to a privileged role

About this task

This walkthrough starts with an instance where you have already created and uploaded your personal cryptographic key. You could use the ServiceNow key, but this example uses a customer-supplied key.

After the key has been stored in a cryptographic module, you can start configuring fields in your instance, such as salary or social security numbers that have limited access from certain users. In the Encrypted Field Configuration, specify which authorized personnel can access sensitive data.

This task demonstrates two scenarios. One example encrypts the **Short Description** field in an Incident for users who are not authorized to view the sensitive data.

Attachments can also be encrypted and only visible to users who are granted access, or is visible to all users that are not restricted from viewing the data. See Attachment encryption walkthrough to encrypt an attachment.

Procedure

1. Make sure that Field Encryption Enterprise is enabled.
2. Create a cryptographic module for column_level_encryption.
   See Create cryptographic module for Column Level Encryption Create a cryptographic module for more information.

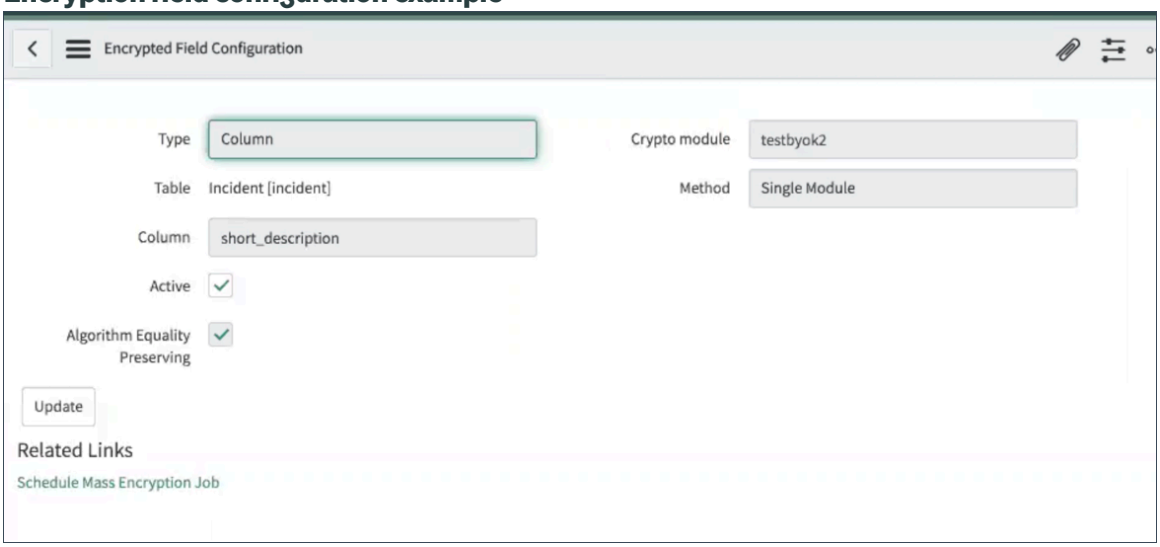
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. Navigate to **System Security** > **Encrypted Field Configurations**.
4. Click **New**.
5. On the form, fill in the fields.

Encrypted field configuration form

Field	Description
Type	**Column** is required to use your personal key.
Table	Table that stores the sensitive information. For this example, select **Incident [incident]**.
Column	Column, or specific information, that represents the sensitive date to be encrypted. For this example, select **short_description**.
Active	Option to mark **Active** to use the field configuration.
Algorithm Equality Preserving	The option is automatically selected.
Crypto module	Module that you created to use with the personal key.
Method	The **Single Module** option is used to apply the policies for one module. **Multiple Modules** is used to apply the policies across multiple modules.

Encryption field configuration example



6. Click **Submit**.

Establish a Module Access Policy to assign access to the cryptographic module. See Create a module access policy for additional information.

7. Navigate to **Key Management** > **Module Access Policies** > > **Create New** > **.**
8. On the form, fill in the fields.

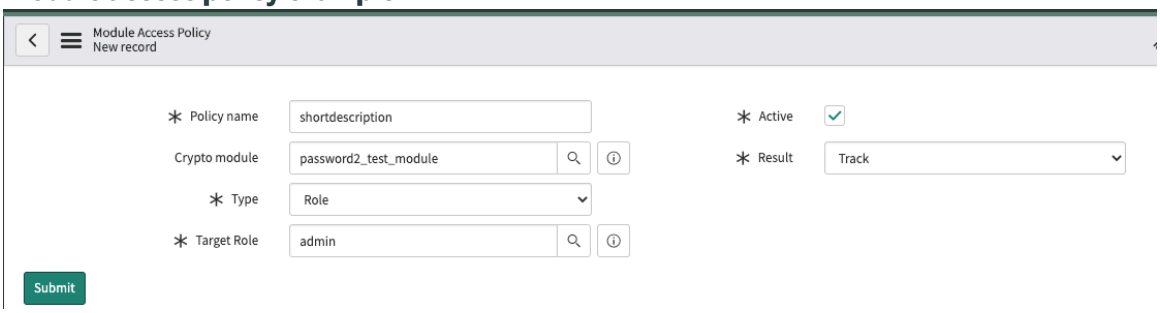
Module access policy form

Field	Description
Policy name	Name for the policy, such, as `short description`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

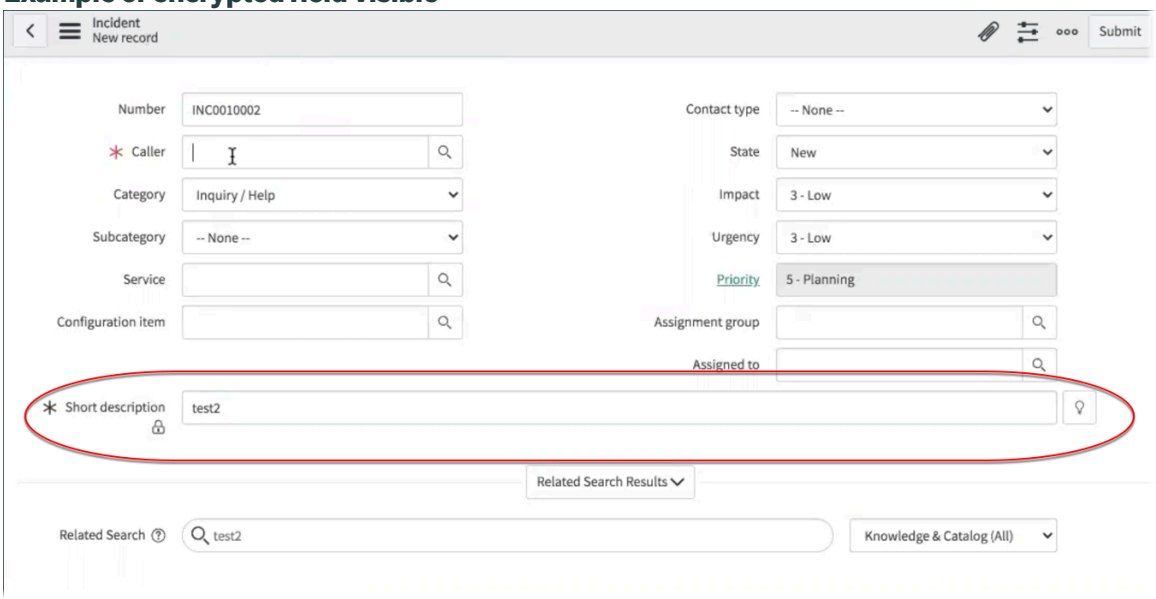
Field	Description
Crypto module	Crypto module that you created to encrypt your key.
Type	Type of access designation for the crypto policy. Use **Role** to grant access to the encrypted field to only those users that have the assigned role.
Target Role	The role that has access to the encrypted field. For this example, select **Admin**.
Active	Option to activate the Module Access Policy.
Result	The **Track**option enables the access to the field for the selected role. (To restrict access to that field for the selected role, select **Reject** or**Strict Reject**.)

Module access policy example



9. Click **Submit**.
10. As a user with the sn_kmf.admin role, navigate to **Incident** > **New**.

Example of encrypted field visible



You can now view the Short description field based on the module access policy configuration.

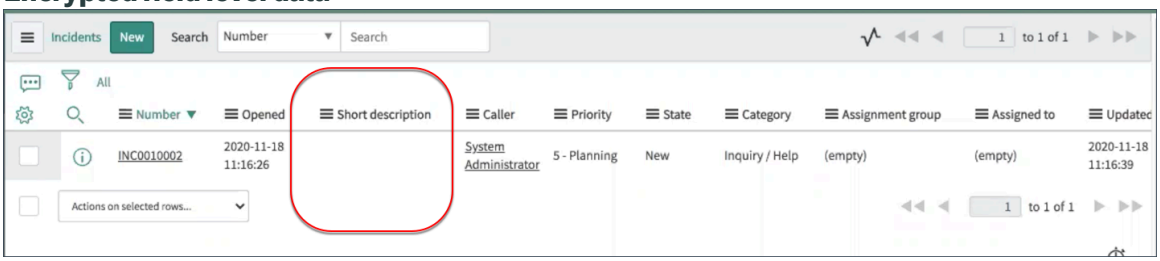
Note:
The sn_kmf.admin role was granted user access to the encrypted field, Short description, by setting the module access policy to **Track**. Notice the lock icon ( ) under the field name indicating that the field is an encrypted field.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

You can now access the **Incidents** module as an end user to test the encrypted field configuration.

11. Log in as a user to be restricted from viewing the encrypted data in the configured field.

Encrypted field level data



When you access the incident number, the data in the Short description will not be visible.

Result

You have successfully used your symmetric key to control access to a specific field using Column Level Encryption Enterprise.

Attachment encryption walkthrough

This walkthrough shows you how to encrypt an attachment in your instance using Field Encryption Enterprise with the Key Management Framework (KMF). It also shows you how to use your own key.

Before you begin

Note:
This procedure only applies to Field Encryption Enterprise functionality. See Activate Field Encryption for more information on obtaining Field Encryption Enterprise.

Role required: kmf cryptographic manager

About this task

This walkthrough starts with an instance where you have already created and uploaded your customer-supplied cryptographic key. You could use the key, but this example uses a customer-supplied key.

Upload confidential attachments in your instance and limit access from certain users. Use Encrypted Field Configuration to specify which authorized personnel can access sensitive data.

We show you how to encrypt attachments to only be visible to users who are granted access, or be visible to all users that are not restricted from viewing the data. In this example, we restrict a certain role from being able to access an attachment in the **Incidents** module.

Note:
Although you can use multiple modules with Field Encryption Enterprise, attachment encryption must use single modules.

Procedure

1. Make sure that Field Encryption Enterprise is enabled.
2. Create a cryptographic module.
   See Create cryptographic module for Field Encryption for more information.
3. Navigate to **System Security** > **Encrypted Field Configurations**.

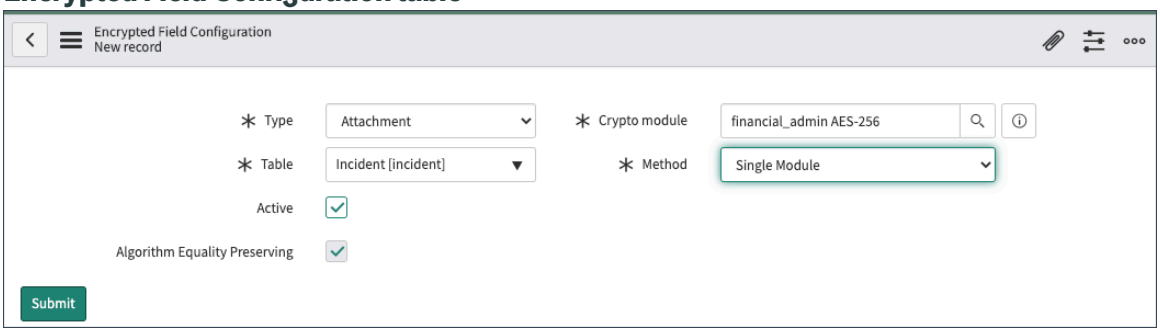
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Click **New**.
5. Complete the form:

Encrypted field configuration fields

Field	Description
Type	Select **Attachment** to use your personal key for encrypting an attachment from the selected **Table** For this example, select **Incident**.
Table	Select the table to access the sensitive information. For this example, select **Incident [incident]**.
Active	Mark **Active** to be able to use the field configuration.
Algorithm Equality Preserving	When selecting Field Encryption Enterprise, this field is visible based on the table selected.
Crypto module	Select the module that you created to use with the personal key.
Method	The **Single Module** option is used to apply the policies for one module. **Multiple Modules** is used to apply the policies across multiple modules.

Encrypted Field Configuration table



6. Click **Submit**.

Establish a Module Access Policy to assign access to the cryptographic module. Refer to Create a module access policy for additional information.

7. Navigate to **Key Management** > **Module Access Policies** > **All**.
8. Click **New**.
9. Complete the form:

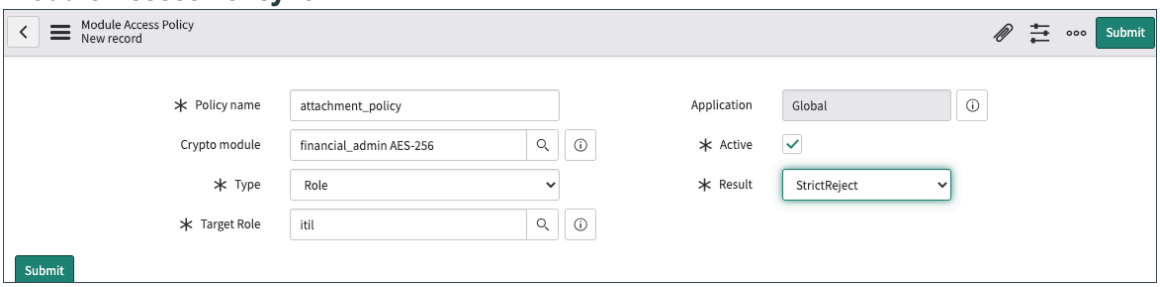
Module access policy fields

Field	Description
Policy name	Enter a name for the policy, such, as "Attachment policy."
Crypto module	Select the crypto module that you created to encrypt your key.
Type	Select **Role** to restrict access to the encrypted field from users with the assigned role.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

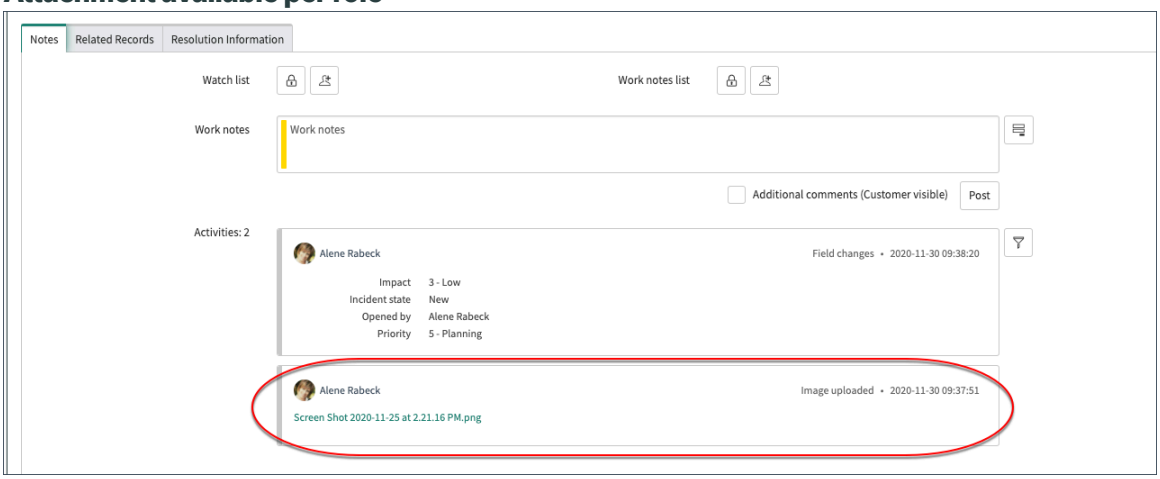
Field	Description
Target Role	Select the role that will not have access to the encrypted field. For this example, select **itil**.
Active	Select this check box to be able to use the Module Access Policy.
Result	Select **Strict Reject** to control the access to the attachment from the selected role. (To grant access for the selected role, select **Track**.)

Module Access Policy form



10. Click **Submit**.
11. As admin or as a person that created the incident, navigate to **Incidents** and add an attachment to **Activities** on the **Notes** related list.

Attachment available per role



12. Log in as a user that restricted from accessing the encrypted attachment.
13. Open the incident and scroll to the **Activities:** section.
    The link to open the attachment is not accessible for users with the restricted role.
14. You have now successfully used your customer-supplied key to control access to a specific attachment using Field Encryption Enterprise.

Column Level Encryption Enterprise

Column Level Encryption Enterprise uses the Key Management Framework (KMF) to enable you to customize and manage how fields and attachments are encrypted and decrypted on your instance. A subscription is required to use Column Level Encryption Enterprise.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Important:

Starting with the Zurich release, Column Level Encryption (CLE) and Column Level Encryption Enterprise (CLEE) are being prepared for future deprecation. They will be hidden and no longer activated on new instances but will continue to be supported. Field Encryption and Field Encryption Enterprise provide the latest experience for this functionality.

For details, see the Deprecation Process [KB0867184] article in the Now Support knowledge base.

Column Level Encryption Enterprise is premised with Column Level Encryption and uses the Key Management Framework and its full support of key management functions. Column Level Encryption Enterprise provides key-protection and key life-cycle management for application-level field encryption. All keys are protected with a key-wrapping hierarchy ultimately rooted in FIPS (Federal Information Processing Standards) 140-2-L3 Hardware Security Modules (HSM).

Important:
This topic covers the enterprise version of Column Level Encryption. For information on the standard version of Column Level Encryption, or to learn the differences between the two versions, see Exploring Column Level Encryption.

Column Level Encryption Enterprise gives you the ability to manage how supported fields are encrypted and decrypted in accordance with NIST 800-57 practices. It also uses the most updated version of field-level encryption, including integration for proper key protection and management.

Specifically, Column Level Encryption Enterprise uses the KMF encryption modules, granting you more control of server-side encryption. KMF verifies proper data encryption key protection using key hierarchy and envelope encryption. Your instance encrypts data through cryptographic modules that you configure. You can create an access policy for each module then configure cryptographic specifications and access policies and control key life-cycle management control.

Column Level Encryption Enterprise supports module access policies based on:

- Scope
- Role
- Script
- Resource Exchange
- System User

See Create a module access policy for additional information.

Note:
For details on the supported features of Column Level Encryption and how to upgrade and subscribe to the Column Level Encryption Enterprise entitlement refer to Encryption and Key Management subscription bundle.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Encryption terms

Term	Description
Key management	Support for key management Fundamental to Column Level Encryption Enterprise is the Key Management Framework (KMF). Gain the following capabilities: • Key life-cycle management. • Key rotation. See Rotate keys for details. • Key protection and key generation with FIPS 140-2-L3 Hardware Security Modules (HSMs). • Segregation of roles and duties. • The secure transfer of data encryption keys between instances, such as production and non-production instances. • Customer Supplied Keys (CSK) with key-wrapping. • Non-deterministic encryption. • Mass encryption/decryption. • Auditing of key access/use. See Key Management Framework Reference for details.
Customer-supplied key 	Support for customer supplied keys One of the biggest benefits of Column Level Encryption Enterprise is that you can use your own keys for encryption. Administrators have the choice to use ServiceNow supplied keys or your own customer-supplied keys (CSK) for encryption on the ServiceNow AI Platform®. You can also manage the key life cycle and decide when to revoke, rotate, and inactivate the keys. After you enable customer-supplied keys and create a cryptographic module, you download a token and public ephemeral key. You use the token and public key to wrap your key and then upload to the instance. To use customer-supplied keys, see Configure field encryption settings to select key type and Using customer supplied keys with Column Level Encryption Enterprise.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Term	Description
Column Level Encryption	Support for both field encryption and attachment encryption Both field encryption and attachment encryption use cryptographic modules and access policies through Encrypted Field Configurations. The Encrypted Field Configuration form is used to choose an encryption type of column or attachment encryption. See Set encrypted field configurations for more information and supported field types.
Non-deterministic encryption 	Support for non-deterministic encryption Column Level Encryption Enterprise supports non-deterministic encryption for enhanced security. If the system encrypts the same data more than once, the ciphertexts are different each time. Non-deterministic encryption is available with Advanced Encryption Standard (AES) encryption with Cipher Block Chaining (CBC). You can enable this feature through the Equality Preserving option on the Algorithm Definition stage of the cryptographic specification. Create a cryptographic specification for a crypto module and define an algorithm for encryption and generate the key. See Create a cryptographic module to define the mechanisms used for cryptographic operations and for more information on enabling non-deterministic encryption.
Resource Exchange 	Resource Exchange Column Level Encryption Enterprise keys instance to instance in a secure manner using the KMF cryptographic APIs to provide confidentiality, integrity, authentication, and non-repudiation. Resource Exchange is a KMF feature that gives you the capability to exchange resources between instances in a secure manner. See Key Management Framework Resource Exchange for details.

Note:
If you choose not to activate Column Level Encryption Enterprise, you can still use Column Level Encryption. See Exploring Column Level Encryption for information.

Column Level Encryption Enterprise supports on-premise customers. It doesn't support Domain Separation.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Support for additional encrypted fields

The standard version of Column Level Encryption is limited to five encrypted columns. Column Level Encryption Enterprise supports an unlimited number of encrypted columns.

Supported field information

The following field types can be encrypted:

- Attachments
- Date
- Date/Time
- Email
- HTML
- Journal
- Journal Input
- Journal List
- Phone
- String text
- Translated Field
- Translated HTML
- Translated Text
- URL

Attachment Encryption

Attachment encryption by default

Customers using Column Level Encryption have attachments encrypted by default in tables that have an active Encrypted Field Configuration (EFC) type of *`Attachment`*.

This default encryption defined by the EFC configuration means that admins don't need to manually declare that an attachment should be encrypted on upload for these tables.

Administrators can disallow users from attaching unencrypted files

For details, see Prevent users from attaching unencrypted files.

Opt out of default encryption

If you don't want attachments encrypted by default based on EFC configuration, you can opt out of this option by contacting ServiceNow support.

To opt out of this feature, create a support case with ServiceNow support, and include this statement in a comment on the case record:

```
"I [customer name], understand that I am asking ServiceNow to turn off a recommended security best practice for attachments, and that [customer company] assumes any additional risk related to their configuration and use of unencrypted attachments in the ServiceNow application."
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

API support

Column Level Encryption Enterprise enables the following APIs.

Note:
The API behavior described in the following table represents the default configuration for the latest base system package. If you are working with older package versions, you may experience different functionality.

Field Encryption APIs

API	Description	Parameters	Return type
`changeEncryptionContext()`	Updates an active Encryption Context (EC) used to encrypt an attachment. When CLE is enabled with the CLE Starter plugin using KMF Crypto Module (CM), the API locates the CM for the EC and uses it to encrypt the attachment. **Note:** This API is only available in the Global scope.	• sourceTable – Name of table that has the attachment. • sourceID – Table record system id. • attachmentID – The sys_attachment record system id. • newEncryptionContextID - System ID of the new context.	Boolean
`changeCryptoModule()`	Updates an active encryption module used to encrypt an attachment. **Note:** This API is only available in the Global scope.	• sourceTable – Name of table that has the attachment. • sourceID – Table record system id. • attachmentID – The sys_attachment record system id. • newCryptoModuleId - System ID of the new encryption module to encrypt the attachment.	Boolean
`disableEncryption()`	Disable active encryption on an attachment.	• sourceTable – Name of table that contains the attachment.	Boolean

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field Encryption APIs (continued)

API	Description	Parameters	Return type
		• sourceID – Table record system id. • attachmentID – The sys_attachment record system id.	
`getDisplayValue()`	Returns the cleartext display value of an encrypted field.		String
`getValue()`	Returns the cleartext value of an ecrypted field when glide_encryption.set_value_support_cle.disabled is false (requires Module Access Policy (MAP)). Returns the encrypted value of an encrypted field when glide_encryption.set_value_support_cle.disabled is true.		String
`setDisplayValue()`	Inserts encrypted data into an encrypted field for display purposes.	• name – Field name. • value – Field value.	Boolean
`setValue()`	Inserts encrypted data into an encrypted field, controlled by a system property. Encrypts data when glide_encryption.set_value_support_cle.disabled is false (requires MAP); writes unencrypted data when set to true (no MAP required), when glide_encryption.set_value_support_cle.disabled is true.	• name – Field name. • value – Field value.	Boolean

The following script illustrates API changes when the Incident short description is encrypted:

```
var gr = new GlideRecord('incident'); //creates a new incident
gr.setValue('short_description','test123'); //sets the value
 to test123
var sys_ID = gr.insert(); //inserts the record in the Incident
 table.
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
gs.info(gr.getValue('short_description')); //displays the
 unencrypted value
```

When the Column Level Encryption plugin is installed, `glide_encryption.set_value_support_cle.disabled` is set to false by default.

Cloud Encryption with Key Management

ServiceNow® Cloud Encryption offers encrypted storage for the database using block encryption, along with enhanced key management. Cloud Encryption is available with the ServiceNow® Platform Encryption subscription bundle.

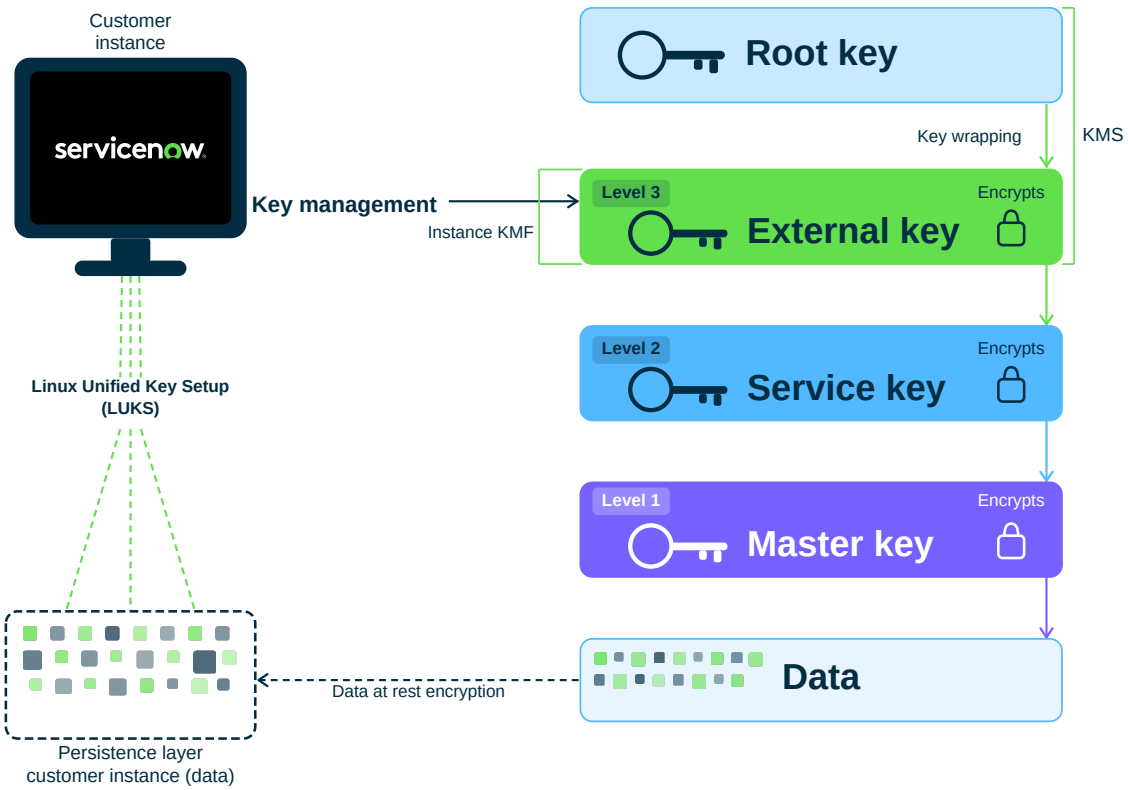
Cloud Encryption offers:

- Segregation of duties.
- Rotation of ServiceNow Managed keys.
- Customer-Managed keys option.

> **Note:**
> Consider this option if your organization requires you to use key material generated by your own cryptographic tools or libraries, an enterprise key management system, or a hardware security module (HSM). See Key management operations for details.

The following diagram shows how Cloud Encryption works.

Cloud Encryption Overview



The Cloud Encryption Key Management module consists of the following submodules:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Key management operations:
  - Access the list of keys.
  - Perform key rotation operations.
  - Withdraw customer-managed key.
- Key management transactions:

  Reference all transactions that have occurred for the keys that have been used.

  Use your own customer-managed key for encryption.

In certain circumstances, you may opt for a key withdrawal request when using a customer-managed key. To do so, you must license the Cloud Encryption Withdraw and Resupply optional add-on SKU and then request the key withdrawal functionality be activated by a Customer Service and Support team member.

The Quorum Control Policy Settings option becomes available when the withdrawal feature is activated, otherwise the module isn't visible on the menu. This feature can be activated only when using customer-managed keys. This policy enables settings to be configured regarding quorum when the withdrawal feature is activated. For more details on this feature, see Quorum Control Policy.

Cloud Encryption supports production and non-production instances for MariaDB and RaptorDB databases. Cloud Encryption is supported in the ServiceNow Commercial Cloud, Government Customer Cloud (GCC) pod 101, and ServiceNow Protected Platform – Australia (SPP-AU).

Licensing and enabling Cloud Encryption

For information about licensing Cloud Encryption, see Encryption and Key Management subscription bundle.

For licensed customers with new instances, the new instance provisioning will include Cloud Encryption.

For licensed customers with existing instances, to request an instance be moved to Cloud Encryption, follow the instructions in KB1117369. You must have the customer admin or partner admin role to request the Service Catalog item to Enable Cloud Encryption on your instance. Enabling this feature requires a one-hour maintenance window.

Cloud Encryption UI

When Cloud Encryption is enabled, the Cloud Encryption user interface (UI) is visible to the security_admin user when this user has the sn_kmf.admin role.

To access the Cloud Encryption UI by searching for **Cloud Encryption Key Management** in the navigation bar. Navigate to the **Key Management Operations** section to see information about encryption keys, such as details of the active key, and whether Cloud Encryption is enabled for the instance.

Key management operations

The Key Management Operations submodule provides access to view and manage all encryption keys used with ServiceNow Cloud Encryption.

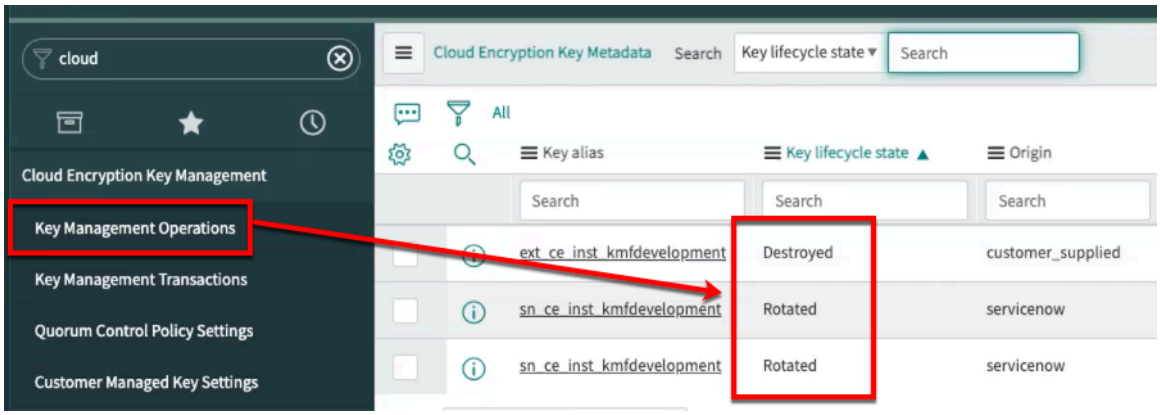
Getting started with Cloud Encryption

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Key life cycle states

There's only one active key in the system at any given time. When selecting a key, you access the activity for the selected key, such as which keys were rotated or withdrawn and the corresponding timestamp.

The key life-cycle state updates according to the key management operation performed.



See Rotate a ServiceNow managed key or Rotate a customer managed key for details.

Note:
The key rotation process may take up to 20 minutes to complete.

Rotate a ServiceNow managed key

Rotate the active Cloud Encryption ServiceNow managed key.

Before you begin

Roles required: sn_kmf.admin or sn_kmf.cryptographic_manager

Important:
If you're using customer-managed keys, see Rotate a customer managed key.

Procedure

1. Navigate to **All** > **Cloud Encryption Key Management** > **Key Management Operations**.
   The Cloud Encryption Key Metadata list loads. All keys used in your Instance are listed. Only one key can be active at a given time.

   If accessing the Cloud Encryption module for the first time, key entries will be available after an initial key rotation is performed. A ServiceNow managed key is the default in the system.
2. Select the active key from the table.
   The Key Definition table displays with general information about your ServiceNow generated key.
3. Select the **Rotate Key** button.
   A notification displays with the option to continue the key rotation or to cancel the operation.
4. Select **OK** to rotate the key.
   A confirmation message displays at the top of the Key Definition page.
5. Return to the Key Management Operations screen to refresh the Cloud Encryption Key Metadata table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Entries are listed for the current active key and the key that is being generated to rotate in place of the current active key. See Key Management Framework key life-cycle states for the different available states.

The active key is listed with a key version of `0` and the generated key has a version of `1`.

6. Open the entry for the original key to view the Key Management Transactions.
   For more information, see Key management transactions for more information.
   The previously active key, version `0`, updated to the key life cycle state of `Rotated` and the new key, version `1` is `Active`.

Prepare your customer managed key

Follow these steps to prepare your customer managed key for upload to your instance.

Before you begin

Roles required: sn_kmf.admin or sn_kmf.cryptographic_manager

About this task

For a customer managed key, you may use any cryptographic library or HSM to generate your key. This key must be an AES 256-bit key and be wrapped by a Cloud Encryption wrapping certificate with an RSAES_OAEP_SHA_256 encryption schema.

Note:

If you choose to use the OpenSSL cryptographic tool to generate your key, the OpenSSL version must be version 1.1.1x or later.

If you're creating and wrapping your customer-managed key using Windows, you must generate the wrapped key via Bash shell support applications such as Git Bash.

Procedure

1. Generate a random value to use as your AES-256 bit symmetric key using OpenSSL.

   For example, using openSSL you can generate this key with the `openssl rand 32` command.

   For compatibility, your symmetric key must have the following attributes:

Attribute	Value
Key type	Advanced Encryption Standard (AES) algorithm-based symmetric key.
Key size	256 bits (32 bytes)
Key wrapping requirement	○ RSA encryption algorithm ○ Optimal Asymmetric Encryption Padding (OAEP) ○ SHA-256 hash function (RSAES_OAEP_SHA_256) ○ Encoded using Base64 algorithm

2. Save the key to a file.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

For example, the openSSL command `openssl rand 32 > plaintext_key.bin` generates a 32-byte key and saves it to a file named `plaintext_key.bin`.

Important:
Save this file securely for future reference. This key is wrapped with the public key for upload.

3. Extract the public key from the downloaded wrapping certificate file from your instance:

```
openssl x509 -pubkey -noout -in wrapping_cert.pem >
 public_key.pem
```

Note:
Refer to for information to download the wrapping certificate.

4. Wrap the generated key with the public key downloaded with the wrapping certificate using the RSAES_OAEP_SHA_256 algorithm:

```
cat plaintext_key.bin | openssl pkeyutl -encrypt -inkey
 public_key.pem -pubin -pkeyopt rsa_padding_mode:oaep -pkeyopt
 rsa_oaep_md:sha256 | openssl base64 -A -out wrapped_key.txt
```

A file specified on this command contains a wrapped customer-managed key that can be provided to SN for the CMK process.

Switch between ServiceNow and customer-managed keys

Switch between customer-managed key or a ServiceNow managed keys for use in ServiceNow Cloud Encryption.

By default, your instance is configured to use ServiceNow managed keys, and ServiceNow encryption key generation is active. However, administrators can choose to use customer-managed keys. They may also choose to return to ServiceNow managed keys.

Rotate a customer managed key

Rotate your customer managed key to your instance after you've wrapped your customer managed key for Cloud Encryption.

Before you begin

Roles required: sn_kmf.admin or sn_kmf.cryptographic_manager

Procedure

1. Navigate to **All** > **Cloud Encryption Key Management** > **Key Management Operations**.
   The **Cloud Encryption Key Metadata** list loads. All keys that have been used in your instance are listed.
2. In the **Cloud Encryption Key Metadata** list, open the record for your active key.
   If you have multiple keys, select the key that has a **Key Lifecycle state** of `Active`. There's only one active key on your instance.
3. In the key definition record, select the **Rotate Key** button.
4. In the **Upload Customer Managed key** window perform the listed steps.

   a. Select **Download Wrapping Certificate**.
   The *`public_certificate....zip`* downloads to your local machine and is used to wrap your customer managed key.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

> **Warning:**
> Avoid potential certificate-related issues by downloading the wrapping certificate each time you rotate to or switch to a customer managed key.

b. Select **Browse** to upload your customer manged key, then locate and select your wrapped encryption key.
To choose a different file, select the file and select **Remove**.

c. Close the Attachments window.

d. Select **OK** to upload your key.
If the key is in the proper format, a confirmation message appears, otherwise an error message displays. The key file is attached to the Key Definition record.

In the Key Management Transactions table, the certificate download and key upload steps are listed. See Key management transactions for details on the request steps.

5. Navigate to **All** > **Cloud Encryption Key Management** > **Key Management Operations** to see the list of keys.
In the list of keys, you can see a new record for your customer managed key. This new key has a **Origin** value of **customer_supplied** and is in the **Active** state. Your previous key has be in the **Rotated** state.

Switch to a customer managed key

Use your customer managed key for ServiceNow Cloud Encryption.

Before you begin

Role required: sn_kmf.admin or sn_kmf.cryptographic_manager

To switch to a customer managed key, you must have a wrapped customer managed key ready to upload as part of these steps. For details on preparing this key for upload, see Prepare your customer managed key. After uploading your key, this process will initiate a key rotation to your new key.

Procedure

1. Navigate to **All** > **Cloud Encryption Key Management** > **Key Management Operations**.
2. In the **Cloud Encryption Key Metadata** list, open the record for your active key.
If you have multiple keys, select the key that has a **Key Lifecycle state** of `Active`. There's only one active key on your instance.
3. In the **Related Links** section of the form, select the **Switch To Customer Managed Key** link.
4. In the **Switch to Customer Managed Key** dialog box, select the **Upload Managed Key** button.
5. In the **Upload Customer Managed Key** dialog box, perform the listed steps.

a. Select **Download Wrapping Certificate**.

> **Warning:**
> Avoid potential certificate-related issues by downloading the wrapping certificate each time you rotate to or switch to a customer managed key.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

b. Select **Browse**, and follow the prompts to select and upload your key from your device.

c. Select **Switch to Customer Managed Key**.

A request is generated by the instance to switch to your customer managed key. In the current form, you can see that the **Key lifecycle state** of the originally active key has changed to **Rotated**.

6. Navigate to **All** > **Cloud Encryption Key Management** > **Key Management Operations** to see the list of keys.
In the list of keys, you can see a new record for your customer managed key. This new key has a **Origin** value of **customer_supplied** and is in the **Active** state.

Result
Your instance now uses your customer managed key for ServiceNow Cloud Encryption.

Important:
Ensure that a copy of your encryption key is always available in a secure location for key management operations. Without this key, your instance may be rendered inaccessible.

Switch to a ServiceNow managed key

Switch from a customer managed key back to a managed key for ServiceNow Cloud Encryption.

Before you begin
Role required: sn_kmf.admin or sn_kmf.cryptographic_manager

Procedure

1. Navigate to **All** > **Cloud Encryption Key Management** > **Key Management Operations**.
2. In the **Cloud Encryption Key Metadata** list, open the record for your active key.
If you have multiple keys, select the key that has a **Key Lifecycle state** of `Active`. There's only one active key on your instance.
3. In the **Related Links** section of the form, select the **Switch To ServiceNow Managed Key** link.
4. In the **Switch to ServiceNow Managed Key** dialog box, select the **Switch to ServiceNow Managed Key** button.
A request is generated by the instance to switch to a ServiceNow managed key. In the current form, you can see that the **Key lifecycle state** of the originally active key has changed to **Rotated**.
5. Navigate to **All** > **Cloud Encryption Key Management** > **Key Management Operations** to see the list of keys.
In the list of keys, you can see a new record for a ServiceNow managed key is. This new key has a **Origin** value of **ServiceNow** and is in the **Active** state.

Schedule key rotation

Set a schedule for automatic rotation of your ServiceNow managed keys. This process automatically retires an encryption key and replaces the old key with a newly generated cryptographic key. If you're using a customer managed key, this schedule can provide a reminder to rotate your custom keys manually.

Before you begin
Role required: sn_kmf.admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Cloud Encryption Key Management** > **Scheduled Key Rotation Settings**.
2. Select the **Enable scheduled key rotation** check box.
3. Fill in the remaining fields based on your business needs.

Scheduled key rotation settings

Field	Description
Number of months between key rotations (Maximum of 60 months)	Number of months between key rotations. This value is 12 by default and can have a maximum of 60 months.
Day of the week to perform key rotation	Day of the week the key rotation is performed.
Time of day to perform key rotation	Time of day the key rotation is performed.
Date and time of next key rotation	Date and time of the next scheduled key rotation. This value isn't editable directly, and is automatically calculated based on your choices.
Number of days before key rotation to send reminder (Maximum of 15 days)	Number of days before the date of your key rotation that your instance sends notifications.
Email notifications are sent to the following list of your approved security administrators	List of users who receive notifications for key rotation. The **System Administrator** is on this list by default.

4. Select **Submit**
   After selecting submit, you can see a notification at the top of the form. The notifications confirm your key rotation and notification schedule.

⚠ Warning:

Each scheduled key rotation has a unique signature, which ensures the integrity of a job and detect any unauthorized modification. The signature for a scheduled job is unique on each instance. Cloning a scheduled key rotation job from a source instance A to a target instance B, the scheduled job on the instance B will fail the signature validation. If this occurs, you can re-create the signature by de-selecting and then reselecting the **Enable scheduled key rotation** check box. For more details on this issue, see KB1247113.

Withdraw a customer managed key

After the customer managed key withdrawal functionality is activated, a withdrawal operation becomes available in the Key Management Operations page. Withdraw key and quorum approval operations can also be managed.

Before you begin

Roles required: sn_kmf.admin or sn_kmf.cryptographic_manager

This section applies only if you've licensed Cloud Encryption Withdraw and Resupply, an optional add-on to Cloud Encryption.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Cloud Encryption Key Management** > > **Key Management Operations**.
2. Select the active customer managed key from the table.
   The Key Definition table displays with general information about your customer key. A withdraw key function is now available.
3. Select the **Withdraw Key** to trigger the withdrawal process.

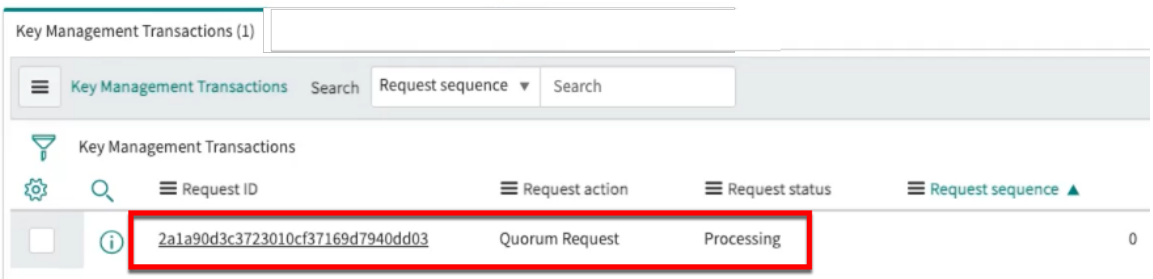
Warning:

A Withdraw Key warning message displays. The withdrawal of the key triggers a shutdown of your instance until a restore operation is performed with the withdrawn key.

Danger:
You can only perform a restore operation with the same key that was withdrawn. If you want to rotate to another key, you must do so after restoring the key that was withdrawn.

If the withdrawn customer managed key isn't restored within the time frame for which ServiceNow retains backups (see the Backup and Restoration SOP [Standard Operating Procedure] for details), your instance database backups will no longer be accessible. Backup data lost in this way isn't recoverable.

4. Select **OK** to withdraw the key.
   Select **Cancel** if there's any doubt about the key withdrawal function.
   You're returned to the Key Definition screen and a confirmation message displays.
5. Refresh the Key Definition page to view the pending withdrawal request.



If the Quorum Control Policy has been activated, the approval workflow must be completed successfully to complete the key withdrawal. See Manage Quorum Control for details.

Resupply a customer managed key

After a key withdrawal operation has completed, your customer managed key must be resupplied into your instance.

Before you begin

Role required: sn_kmf.admin or sn_kmf.cryptographic_manager

Note:
This section applies only if you've licensed Cloud Encryption Withdraw and Resupply.

Procedure

1. Go to Now Support and navigate to **Service Catalog** > **Catalog** > **Instance Management** > **Instance Restore - Resupply Managed Key**.
2. Click **Request**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. In the **Instance Restore - Resupply Managed Key** window, select your instance in the **Select Instance** drop-down.
4. Download the wrapping certificate by clicking on the **wrapping certificate** text.

> **Warning:**
> You must download a new wrapping certificate each time you rotate or upload a customer managed key.

5. Prepare your key for upload.
   For details on this process, see Prepare your customer managed key.
6. In the **Step 4** section, click **Browse and upload** to upload your wrapped key from your local device.
   After your key is uploaded, you can see the key under **Uploaded below file successfully**. If you need to re-upload the key, click **Remove file** and upload your key again as described in previous steps.
7. Click **Rotate key** to complete the re-supply.

Quorum Control Policy

The Quorum Control Policy specifies the minimum number of approvals required among the total number of selected approvers to reach quorum for customer managed key withdrawal.

> **Warning:**
> You must sign a legal addendum to activate the key withdrawal functionality. The Quorum Control Policy Settings option becomes available when the withdrawal feature is enabled, otherwise the module isn't visible on the app menu. After key withdrawal, your instance is no longer available until the encryption key is resupplied and is active again.

In certain circumstances, you may want to create a key withdrawal. You must first request the key withdrawal functionality from Customer Service and Support.

The Quorum Control Policy specifies the minimum number of approvals required among the total number of selected approvers to reach quorum for customer managed key withdrawal. For instance, there are a total of five approvers, but only four approvals are required to reach quorum. When four approvals are obtained, the withdrawal request is processed and the key withdrawn.

Whenever a withdrawal operation is performed in a group enabled for quorum approval, a workflow for quorum approval is triggered. An email notification is sent to all users who can grant approval. Tasks are also generated in the approvers' accounts, which they see on the dashboard when they log in to their ServiceNow account.

The users can grant approvals from the Instance, the email, or the Key Management Operations page. The key withdrawal operation is blocked until the quorum is met.

Once the minimum number of approvers is reached, quorum is reached and the key withdrawal will trigger. The withdrawal is performed and is logged, including the names of users who approved the request.

See Configure Quorum Control Policy Settings for setup details.

Configure Quorum Control Policy Settings

Follow these steps to configure Quorum Control Policy Settings.

Before you begin
Roles required: sn_kmf.admin

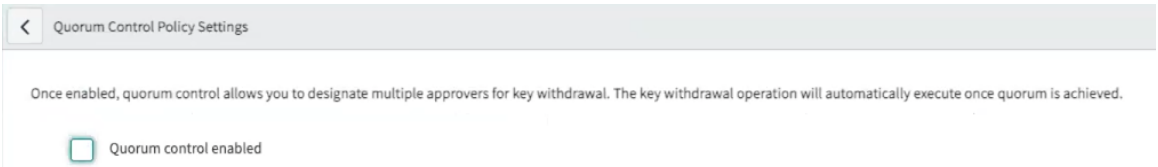
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

About this task

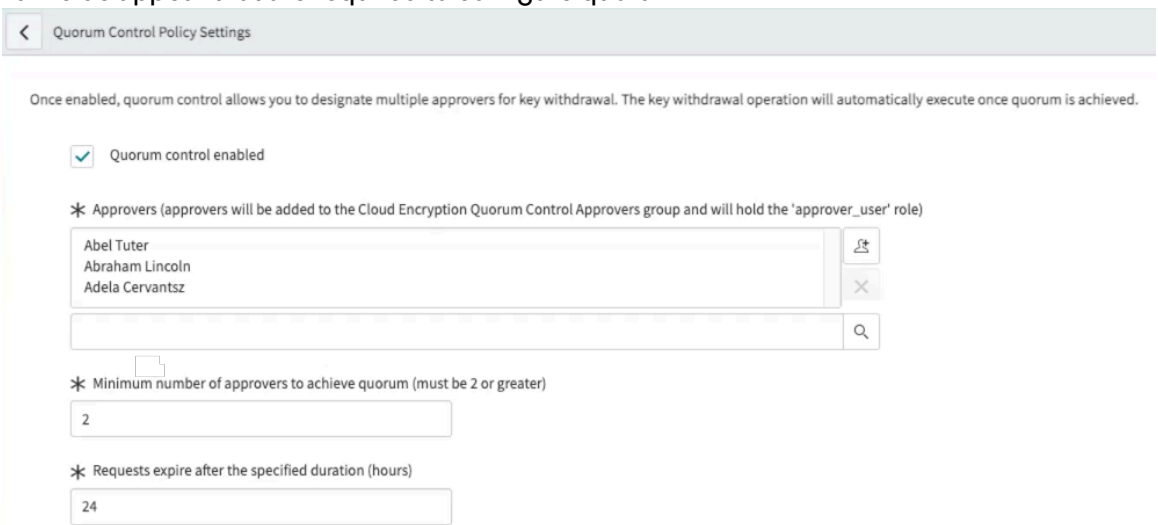
> **Warning:**
> You must sign a legal addendum to activate the key withdrawal functionality. The Quorum Control Policy Settings option becomes available when the withdrawal feature is enabled, otherwise the module is not visible on the app menu. After key withdrawal, your instance is no longer available until the encryption key is active again.

Procedure

1. Request the key withdrawal functionality from Customer Service and Support.
2. Navigate to **Cloud Encryption Key Management** > **Quorum Control Policy Settings**.
3. Select the **Quorum control enabled** check box.



Additional fields appear that are required to configure quorum control.



4. Fill in the fields to complete the form.
5. Click **Submit**.
   A confirmation message is displayed.

What to do next

The withdrawal actions are available in Key management operations.

Manage Quorum Control

After a withdrawal operation workflow is triggered, quorum actions can be managed from the Key Management Operations page. The key withdrawal operation is blocked until the quorum is met.

Before you begin

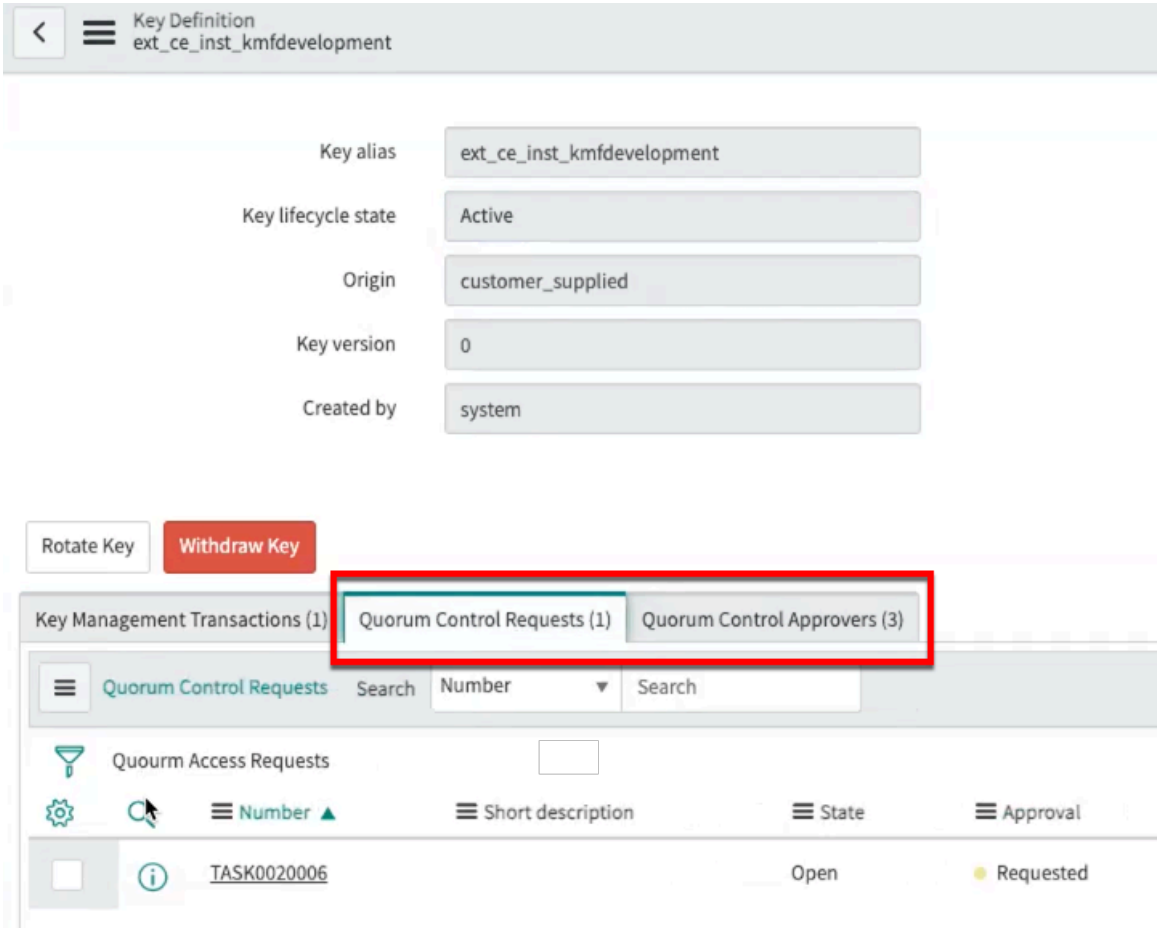
Role required: sn_kmf.admin or sn_kmf.cryptographic_manager

When the quorum has been either approved or rejected, the requestor of the key withdrawal will receive an email notating if quorum was achieved or denied.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Perform the steps to withdraw a customer managed key found in Key management operations.
2. View the *Quorum Control Requests* and *Quorum Control Approvers* tabs that activated.



3. Open the **Quorum Control Requests** tab to view the actual request that is created.
   - State:
     - Open: The key withdrawal action is pending the quorum being met.
     - Closed Complete: The quorum has been met and can be no further action on this particular quorum request.
   - Approval:
     - Requested: Approval emails have been sent and the workflow has been triggered to reach quorum.
     - Approved: The key will be withdrawn and the instance will be shut down.
     - Denied: The quorum request is canceled and no further action is taken with this request. A new withdrawal request will be required to withdraw the key.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Open the Quorum Control Approvers tab to view the list of approvers and the state of the approval request.

   State:

   - Requested: The approver has not yet taken action on the approval request.
   - Approved: The request has been approved either from the email or the approvals page.

5. Select the **Key Management Transactions** tab to view the progress of the request step for the key withdrawal.
   - Step 0 - Quorum Request: The actual quorum request. The quorum request must be completed in order to trigger the key withdrawal steps.
   - Step 1 - Key Withdrawal: The key withdrawal step. This is composed of steps two through seven.
   - Step 2 - Request_preparation: Creates a request to trigger and the wrapping and rotation.
   - Step 3 - request_integrity_check: Validates that the request is legitimate and secure.
   - Step 4 - request_validation: Validates that there is a request in progress, only one rotate request can process at a time.
   - Step 5 - hsm_key_delete: Makes the call to KeySecure to delete the active key.
   - Step 6 - key_metadata_withdraw: Converts the active key metadata lifecycle state to "destroyed."
   - Step 7 - post_withdraw: Makes a call to shut down the instance.

Approve or deny a quorum control request

Approve or deny a quorum control request from Key Management Transactions.

About this task

When a quorum request has been created, the minimum number of approvals is required by the members. After a withdrawal operation workflow is triggered, quorum actions can be managed using several methods. The users can grant approvals from the Key Management Operations page, My Approvals in the Instance, or directly from the request email. The key withdrawal operation is blocked until the quorum is met.

This procedure describes how to approve or deny a quorum request from the Key Management Operations page.

Before you begin

Roles required: sn_kmf.admin or sn_kmf.cryptographic_manager

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Cloud Encryption Key Management** > **Key Management Transactions** > **Quorum Control Approvers**.
2. Select your user name from the table.
3. Approve or deny the request.

Approve or deny a quorum request

When a quorum request has been created, the minimum number of approvals is required by the members. After a withdrawal operation workflow is triggered, quorum actions can be managed using several methods. The users can grant approvals from the Key Management Operations page, **My Approvals** in the Instance, or directly from the request email. The key withdrawal operation is blocked until the quorum is met.

Before you begin

Roles required: sn_kmf.admin or sn_kmf.cryptographic_manager

Key management transactions

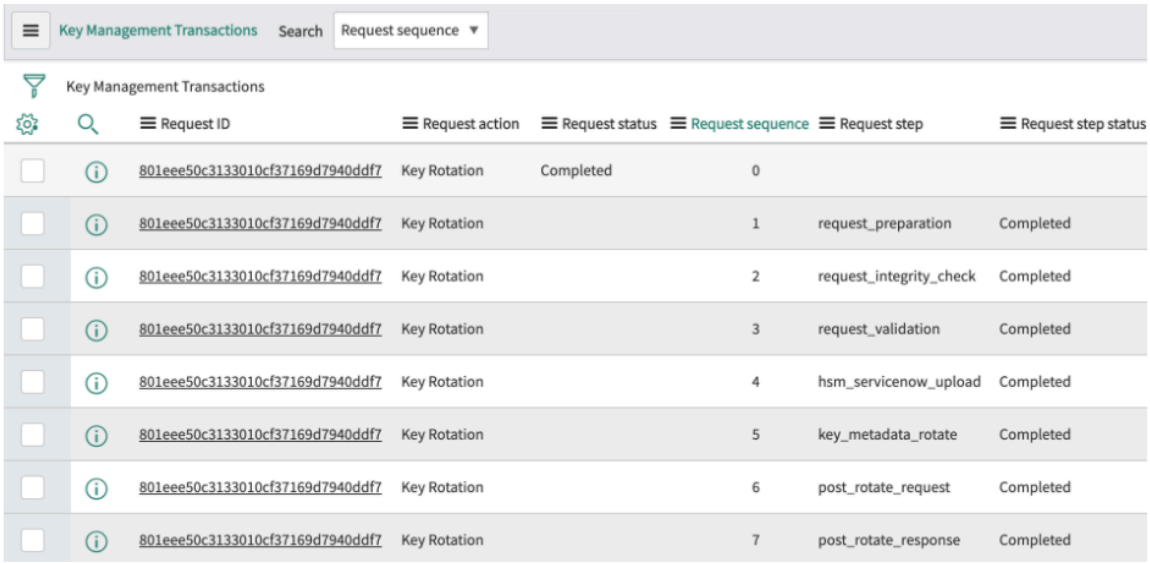
The Key Management Transactions submodule displays all transactions that have occurred for the keys in your ServiceNow instance.

- A key transaction is defined by the following:
  - composed of several request steps.
  - A single *Request ID* is shared across all request steps.
  - The initial step, request sequence 0, of a transaction provides the current state of the overall transaction.

    As seen in the image below, the initial step 0 has an overall *Request Status* of Completed.
- The following can be identified for the transaction by the individual request step:
  - The order of each step in a transaction can be identified by the sequence number for the step.
  - The status of each transaction is visible through the status of the request step.
  - If any steps beyond the initial step fail, the overall transaction has a status of Failed. If all steps are completed, the transaction status is also completed.

The following screen is a sample of the type of information that displays with a ServiceNow key rotation.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



The following table displays the field information available on the Key Managements Transactions page.

Key Management Transactions

Field	Description
Request ID	Unique system-generated Id for the action being performed One request ID is shared across all request steps.
Request action	Displays the action for the key operation being performed.
Request status	• Processing: A request has been entered but hasn't yet been completed. • Completed: The request has been completed successfully. • Failed: An issue occurred and the process hasn't been completed. **Note:** Contact Customer Service and Support and provide the request number where the failure occurred.
Key alias	Alphanumeric entry.
Key life-cycle state	See Key Management Framework key life-cycle states for definitions.
Origin	• ServiceNow key • Customer-managed key
Key version	When a key rotates, the version number increments.
Request sequence	Displays the order in which a request is being processed in the system.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Key Management Transactions (continued)

Field	Description
Request step	Displays whether a step is being processed in the system during key rotation. The quantity and content of the steps vary based on the type of key operation performed. **1.** request_preparation: Creates a request to trigger and the wrapping and rotation. **2.** request_integrity_check: Validates that the request is legitimate and secure. **3.** request_validation: Validates that there's a request in progress, only one rotate request can be processed at a time. **4.** attachment_process: Extracts the wrapped key material from the attachment. (Additional step when rotating a Customer Managed key.) **5.** hsm_<key type>_upload: Uploads the wrapped key material to the HSM, KeySecure. **6.** key_metadata_rotate: Generates the new key metadata. **7.** post_rotate_request: Sends a request to perform the key rotation. **8.** post_rotate_response: Response to perform the key rotation based on the request from the customer instance. **Note:** Provide the request step to Customer Service and Support to analyze the status progression in case a request step doesn't complete.
Request step status	• Completed: Rotation is successful. • Failed: Rotation isn't successful. **Note:** Provide the request step to Customer Service and Support to analyze the status progression in case a request step doesn't complete.

Cloud Encryption logging

Learn about logging options for Cloud Encryption.

Cloud Encryption logging tables

Use these tables to find logging information related to Cloud Encryption transactions on your instance.

Table	Description
Cloud Encryption Metadata [dare_key_metadata]	Cloud Encryption Metadata captures key life-cycle management metadata. On this table you can find key life-cycle, state, and version information. This table is updated after each key operation.
Key Management Transactions [dare_key_request]	Key Management Transactions captures key management transaction information.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Table	Description
	On this table you can find logging for each step of a transaction. The table records any error information for a transaction in the **error message** field.
Sys Audits[sys_audit]	The Sys Audits table captures inserts and updates to all audited records on your instance. On this table you can find changes to records on your instance, when the changes were made, and which user account initiated the change.

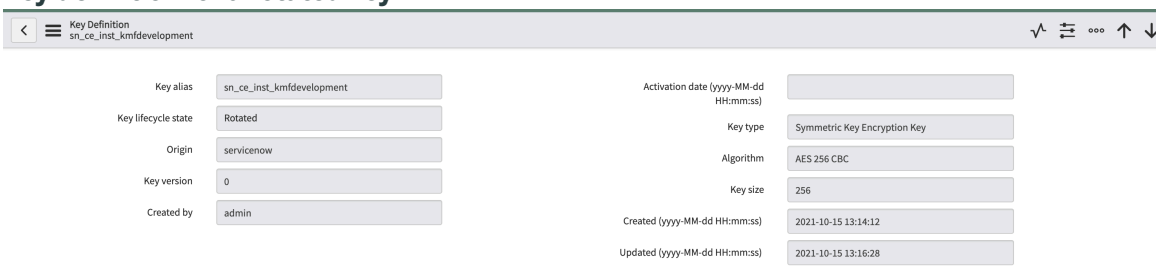
Monitor key rotation operations

Use the Cloud Encryption Key Metadata [dare_key_metadata] table to find information on the life-cycle of your key. In this table you can find information like the origin, activation date, state, and version of your keys.

Use the Key Management Transactions [dare_key_request] table to monitor transactions of key operations. In this table you can find all requests relating to your keys, including the state, status, and which step in the process the request is in. Completed requests are retained on this table with the **Completed** status.

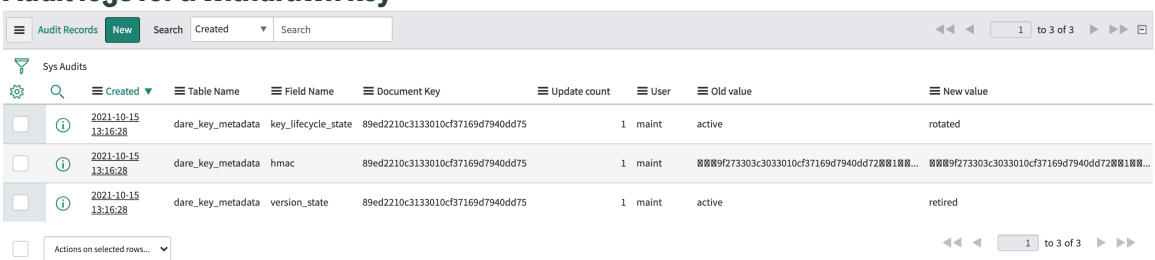
This example shows a key rotation operation. During this operation, the old key life- cycle state updates from active to rotated, and the version state updates from active to retired.

Key definition for a rotated key



Looking at the Sys Audits[sys_audit] table, admins can see changes made to records on the Cloud Encryption Key Metadata [dare_key_metadata] table. Admins can see which records were updated and when. The log entries also record the field that was changed, and the old and new values.

Audit logs for a withdrawn key



Admins can view the records on the Cloud Encryption Key Metadata [dare_key_metadata] table. In the audit records below, the request status was changed from processing to completed.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Logging for key withdrawal operations

Logging information on key withdrawal is stored in the Audits [sys_audit] table. This logging information contains information on who initiated the key withdrawal and when the withdrawal took place.

This example shows a key withdrawal operation. During this operation, the key lifecycle state updates from generated, to active, to destroyed. The key version updates from unknown, to active, to retired.

Key definition for a withdrawn key

Tamper Detection

Use tamper detection to improve security by detecting unauthorized changes to your quorum control settings.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Tamper detection process

When enabled, tamper detection validates your quorum control settings by checking for any unauthorized modifications (tampering). Tamper detection uses hash-based message authentication code (HMAC).

1. When a setting is changed or created, your instance creates an HMAC. The HMAC is based on the value of the setting (dare_property) record.
2. Whenever your instance uses these settings, tamper detection validates it using the HMAC.
3. If the setting validates successfully, it can be used by the platform, otherwise it cannot.

Tamper detection runs daily on your instance

Tamper detection checks your settings for tampering using a daily scheduled job, and reports validation failures in your node and security logs. Tamper detection send a notification to Security and KMF admins for validation failures.

Tamper detection runs before executing a key withdrawal

Tamper detection also validates your properties when you request a key withdrawal. If your settings do not pass validation, the key withdrawal does not execute. In this case, you must resolve any validation issues before key withdrawal can compete.

\

Identifying tampering

Tamper detection updates your logs when validation fails.

If tamper detection fails to validate any of your quorum control settings, these failures appear in your node and security logs. The log entry includes the sys_id of the settings (dare_property) record that failed validation.

```
2022-06-28 13:45:46 (582) Default-thread-5
 B6FAC1F6C3D01110CF37169D7940DD6E txid=231c4d72c310
 SEVERE HMAC_VALIDATION_FAILED:The dare_property record
 with sys_id: 776e3200c3210110900b169d7940dd76 failed
 HMAC validation

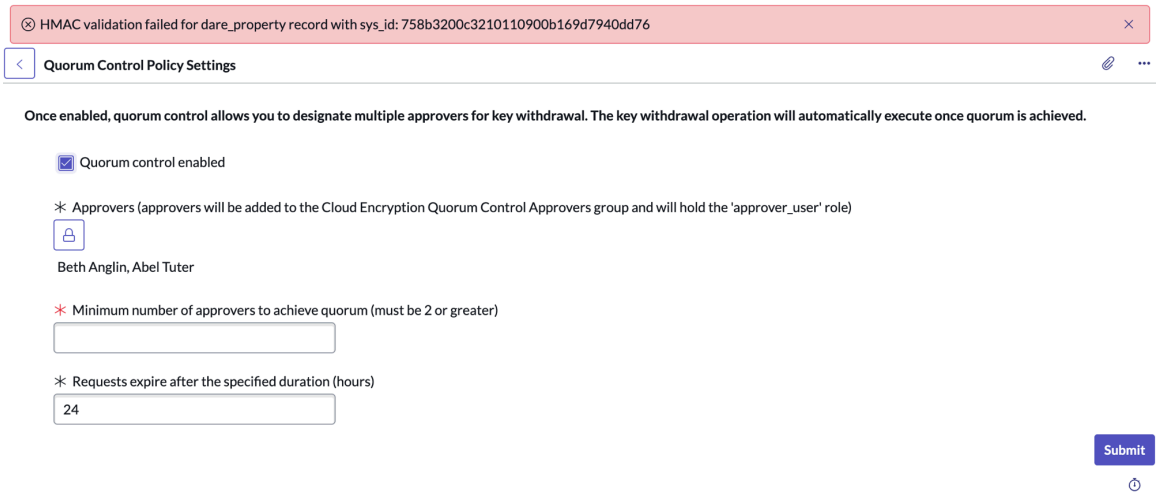
2022-06-28 13:47:35 (264) Default-thread-8
 B6FAC1F6C3D01110CF37169D7940DD6E txid=8e8cc972c310
 SEVERE HMAC_VALIDATION_FAILED:The dare_property record
 with sys_id: 758b3200c3210110900b169d7940dd76 failed
 HMAC validation
```

Logging displays information similar to these examples when validation fails. Successful validations do not appear in the logs.

Tamper detection displays a warning message on your quorum control settings page

If a quorum control setting has failed validation, you can see a warning when you view the Quorum Control Policy settings page on your instance. The warning includes the sys_id of the settings (dare_property) record that failed validation.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Tamper detection sends notifications to users with the *Security Admin* and *KMF Admin* roles

If tamper detection fails to validate any of your quorum control settings, your security admins and KMF admins receive a notification similar to this example.

Subject: IMPORTANT: Cloud Encryption Properties Tampering Detected

The following list of Cloud Encryption properties appear to have been tampered.
Contact ServiceNow support for additional information and how to correct this issue.

Tampered properties:
com.glide.dare_key_mgmt.quorum.approvers(903a3212c3210110cf37169d7940dda8)

Ref:MSG0000109_q5pzYMS7hcgHXAoUhipc

Resolving tampering issues with ServiceNow support

Important:
Tamper detection validation failures can only be resolved with assistance of ServiceNow support.

If tamper detection fails to validate any of your quorum control settings, contact ServiceNow support for assistance in resolving the issue. After a support agent has resolved the validation failure, security and KMF admins receive a notification indicating that the issue has been resolved.

Subject: IMPORTANT: Cloud Encryption Properties Reset

At your request, ServiceNow support has reset the following list of Cloud Encryption properties to their default values.
If you did not request this action, contact ServiceNow support immediately.

Reset properties:
com.glide.dare_key_mgmt.quorum.approvers(903a3212c3210110cf37169d7940dda8)

physical loss or theft of storage devices. When encrypted disk servers are powered on and providing data, the encryption provides no additional protection.

Full disk encryption

Full disk encryption may be relevant to heavily regulated organizations, but can add significant cost to a customer's ServiceNow deployment. Measures in place by ServiceNow to mitigate loss or theft of storage devices may also be a factor in its selection.

From the ServiceNow AI Platform perspective, all data flows in decrypted.

Commercial environments use full disk encryption (FDE) with FIPS 140 validated hardware or storage devices that are in the process of validation along with a ServiceNow dedicated hardware option at extra cost. FDE applies to the hardware itself, and therefore provides encryption at rest for all data stored in every instance assigned to you.

For further details on selecting FDE and dedicated hardware options, contact your ServiceNow representative.

Edge Encryption

ServiceNow® Edge Encryption ™ encrypts sensitive data on your company premises before sending it over the Internet to your ServiceNow instance (encrypted in flight), where it remains encrypted at rest.

Important:

Starting with the Zurich release, Edge Encryption and Edge Encryption Core are being prepared for future deprecation. They will be hidden and no longer activated on new instances but will continue to be supported. Field Encryption and Field Encryption Enterprise provide the latest experience for this functionality.

For details, see the Deprecation Process [KB0867184] article in the Now Support knowledge base.

Configure

Understand how to configure the Edge Encryption.

Exploring Edge Encryption

Edge Encryption is a network encryption system that resides on your network and that encrypts and decrypts sensitive data as it travels between your data center and the ServiceNow cloud.

What is Edge Encryption

Also referred to as 'client-side' encryption, Edge requires all bi-directional user traffic to pass through proxies that are maintained on your infrastructure. You have the full control over your key management because the keys are stored within your proxy on your infrastructure. The ServiceNow AI Platform can't decrypt your ciphertext to access your keys.

The Edge Encryption feature is an additional cost option that provides you with the ability to control the end-to-end encryption of your data and key management. Edge Encryption uses a proxy application, provided by ServiceNow and installed by you within your own network. This proxy application tokenizes specified data patterns or encrypts string fields, Date fields, Date/Time fields, and attachment data before it's sent from your environment to your instance. The proxy application also decrypts the same data, again only within your own network, using keys stored only within your own network.

The relevant encryption keys and configuration exist only on the Edge proxy within your network and aren't visible to ServiceNow. The data is encrypted from the moment that it leaves your environment and is only decrypted upon retrieval. At no point is the data accessible in plaintext by ServiceNow systems or personnel.

Who uses Edge Encryption

Only a user logged in to the instance through a proxy server on your network can view encrypted data in clear text. Likewise, only a security_admin user logged in to an instance through a proxy server in your network can configure and administer Edge Encryption.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Because the proxy server resides in your network, you own and manage the encryption keys, and they're never sent to the instance. As a result, ServiceNow never shows sensitive data in clear text.

In addition to the Edge proxy configuration and management of rules, you're responsible for the usual requirements of operating a server within your environment (including hosting, routing, backup, DNS configuration, and so on) to enable and support your Edge proxies.

Encryption and tokenization

Edge Encryption supports both encryption (through encryption configurations) and tokenization (through encryption patterns) as a means of protecting your sensitive information.

Encryption configurations

You can encrypt individual fields using encryption configurations. Edge Encryption supports AES 128-bit and AES 256-bit encryption keys. Edge Encryption supports standard, equality-preserving, and order-preserving encryption types.

In addition to attachments, you can encrypt the following field types:

- Date
- Email
- Date/Time
- HTML
- IP Address
- Journal
- Journal Input
- Multi-line text
- Single-line text
- String
- URL

Note:

If a Journal field marked for encryption is added to the activity stream, all user input to the field is encrypted in the activity stream.

Multi-byte characters within supported field types can be encrypted.

You can also encrypt the following service catalog variable types:

- String Types
  - Single-line text
  - Multi-line text
  - Wide single-line text
- Date
- Date/Time
- URL
- Email

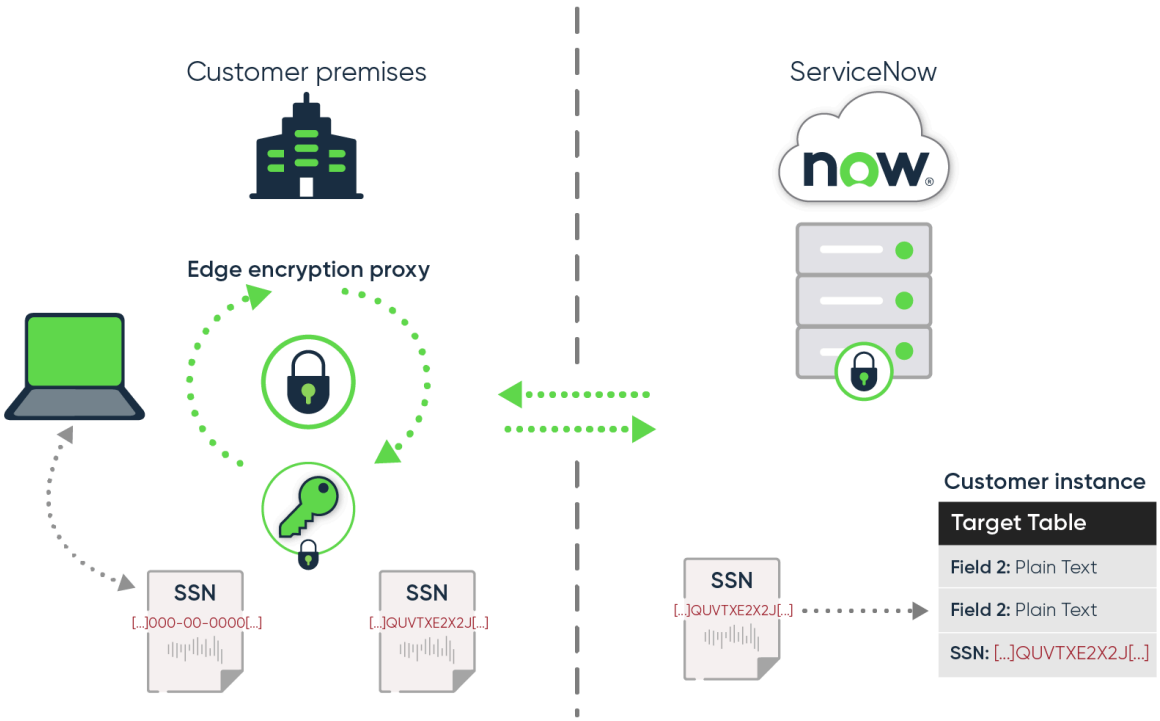
- HTML
- IP Address

Encryption patterns

You can use encryption patterns to tokenize strings that match regular patterns such as social security and credit card numbers. While encryption configurations should be the primary method of encryption, use encryption patterns as a supplement to secure sensitive information found outside of encrypted fields.

Note:
The Edge Encryption proxy server requires a MySQL database in your network only if using order preserving encryption or encryption patterns. Clear text values are stored in the proxy database in your network. For this reason, it is critical that you secure and regularly back up your proxy database. For recommendations, see Edge Encryption components.



Edge Encryption on the ServiceNow AI Platform

Edge Encryption acts as a gateway between your browser and your ServiceNow instance. Traffic from your browser passes through the gateway on its way to the ServiceNow instance. The gateway, in turn, is configured to encrypt outbound data that is marked for encryption. Inbound traffic is decrypted through the gateway, and the end user sees clear text in the browser. The advantage of this implementation from a security control perspective is that the encryption and key management are handled externally from ServiceNow.

Pros and cons

As with Field Encryption Enterprise and Field Encryption, Edge Encryption imposes some functional limitations within an instance as a result of the additional security. The local Edge proxy does, however, also provide some additional functionality relating to sorting when compared to column-level encryption.

Pros:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Edge Encryption provides absolute control of who sees your information and prevents data breaches.
- Information remains on your proxy server and never leaves your network unencrypted.
- Information is encrypted in transit, before it even reaches the ServiceNow instance.
- You hold and manage all your own encryption keys. No one else, not even ServiceNow personnel, can access your keys.
- You can choose the strength of the encryption algorithm: AES-128 or AES-256.
- Edge Encryption includes the ability to encrypt String text, Date and Date/Time fields, attachments, URLs, and journals.
- Edge Encryption provides Standard, Equality Preserving, and Order Preserving encryption of data at rest within the database and instance.
- Encryption rules enable you to write custom scripts that tell the proxy server specifically what to encrypt and where to put that encrypted information in the instance. These scripts are useful when the data structure doesn't exactly match the ServiceNow instance.
- Encryption patterns enable you to tokenize information such as passwords.

Cons:

- Edge Encryption requires an extra network hop through the Edge proxies cluster, and extra processing, which can add delay to traffic. The added processing delay of the Edge Encryption application is negligible compared to the network hop.
- Maintaining your own encryption keys can be complex and time-consuming.
- A maximum of two encryption keys can be active at any given time. You cannot assign different keys to specific subsets of columns, data categories, user roles, or access scopes. However, one key can encrypt certain columns while a different version of the same key can be used to decrypt others.
- Edge Encryption has the side effect that the server or platform can't decrypt the data to perform any manipulation of the decrypted data. As a consequence, functionality and data processing on the ServiceNow AI Platform may be restricted when encrypting columns with Edge Encryption.

What to know before you begin

Because encryption and tokenization change the nature of your data, Edge Encryption can affect other instance processes. Before using Edge Encryption, carefully consider the impact on your instance.

Because the proxy server is installed and maintained in your network, Edge Encryption requires network administration and management. Review the network requirements to ensure a smooth implementation.

Review the following topics to understand the impact of Edge Encryption on your instance:

- Planning for Edge Encryption
- Edge Encryption system requirements
- Sizing your Edge Encryption environment
- Calculate the order-preserving and tokenization database size
- Edge Encryption limitations
- Key management for Edge Encryption

Edge Encryption components

Edge Encryption is composed of the Edge Encryption proxy server that runs on a server in your network, and the Edge Encryption plugin that must be installed on your ServiceNow instance. If using order-preserving encryption types or encryption patterns, a proxy database must also be installed in your network.

Proxy application

When going through the Edge Encryption proxy server, the Edge Encryption plugin enables you to specify which fields, patterns, and attachments should be encrypted. You can also manage encryption rules to encrypt specific requests and can schedule mass encryption jobs.

Proxy server

The Edge Encryption proxy server uses encryption rules to identify in an HTTP request what, if anything, must be encrypted and encrypts it before forwarding the request to the instance. For decryption, the Edge Encryption proxy server looks at the HTTP responses for any encrypted data and decrypts it before sending the response back to the client. For this decryption to happen, all HTTP requests and responses must go through the Edge Encryption proxy server. These HTTP requests include any requests originating from a browser, as well as any SOAP or REST requests.

Proxy database

If using order preserving encryption or encryption patterns, your proxy servers rely on a MySQL database located in your network. All proxy servers in your network must use the same database.

The proxy database contains these tables.

Proxy database tables

Name	Description
db_id	Unique database ID
edge_token_map	Encryption pattern data
token_map	Order-preserving encryption data

Backing up your proxy database

Because encryption patterns rely on tokenization, clear text values are stored in your proxy database. If the database is lost, clear text values can't be restored. It's critical that you maintain regular backups. To avoid data loss, back up your proxy database according to ServiceNow recommendations.

- Back up your database every 24 hours.
- Retain MySQL database binary log files for at least two days. After a backup has been restored, use the binary log to regenerate any data lost since the most recent backup.

Edge Encryption clients

Edge Encryption uses three clients to inform the instance that the proxy is running, to synchronize requests between the proxy and the instance, and to forward all end user requests to the instance after any potential encryption.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Client	Description
heartbeat/keepalive client	In charge of sending a request to the ServiceNow instance every 5 seconds to let the instance know that this proxy is up and running. The requests drive the last_response_on field on the Edge proxy table, and as a consequence drive the state of the proxy. If your system has issues sending the requests, or if the request or request processing is delayed, the instance may mark the proxy as unresponsive, even if the other clients (including the one for user traffic) are up and running. This client also controls the online status of the proxy on the instance. The *edgeencryption.proxy.keepalive.interval* property controls the polling rate for this client. The default is 5 (seconds).
polling/sync client	In charge of various requests the proxy sends to the instance to synchronize on the Edge Encryption configuration (for example, which table, column, or attachment to encrypt, keys, jobs, rules, and tokenization patterns). The *edgeencryption.config.poll.interval* property controls the polling rate for this client. **⚠ Warning:** Do not change this setting. Changing the default setting of the proxy poll interval may result in synchronization delays when updating Edge Encryption settings on the instance.
default/user traffic client	For everything else, this client handles all end user requests and forwards them to the ServiceNow instance after any potential encryption. This client also handles responses from the instance, forwarding them to the end user after any potential decryption.

Key management for Edge Encryption

You are responsible for providing and managing the encryption keys used by Edge Encryption.

This topic refers to keys for the Edge Encryption product. If you are looking for information on the Key Management Framework, which can be used with Field Encryption, see Key Management Framework.

When obtaining and creating encryption keys to support the encryption types used by Edge Encryption, consider the following:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Whether to use AES 128-bit or AES 256-bit. You must define a default AES 128-bit encryption key, even if it is not used.
- Whether to use file system, Java KeyStore, or Enterprise Key Management (EKM).
- When to rotate encryption keys.
- When and if to use a mass encryption job to re-encrypt data using the new key.

Before removing a key from the proxy configuration files and the keystore, it is critical that you decrypt all data on the instance that uses the key. You can do this by adding a new encryption key and scheduling a mass key rotation job.

Keystores

Edge Encryption supports the following types of key storage.

File store

Keys are stored in a file in a file system that is accessible by the Edge Encryption proxy. Encryption keys stored in a file are not encrypted, so it is your responsibility to protect these files.

Java KeyStore

Keys are stored in Java's JCEKS KeyStore. A Java KeyStore is protected by a password, so it is more secure than storing keys in a file in the file store. A single Java KeyStore can store multiple keys, and the keys are identified by a key alias, making it easier to manage multiple keys.

Enterprise Key Management (EKM)

Keys are stored and retrieved with the SafeNet KeySecure or Unbound Technology key management systems.

The Edge Encryption proxy ships with the Java JCEKS KeyStore file named `keystore.jceks` in the `keystore` directory. This keystore file contains the ServiceNow public key used to validate encryption rules signed by ServiceNow.

Note:
If using a keystore other than the base system Java JCEKS KeyStore, you must import the ServiceNow public key into your keystore. The public key alias is *`servicenow`*.

In addition to the encryption keys, the Java JCEKS KeyStore is used to store the RSA key pair for digitally signing the encryption configuration and encryption rules that are stored in the instance, and the digital certificate that the Edge Encryption proxy uses to establish a secure connection with the browsers and any other clients.

SafeNet key versioning for Edge Encryption

Use SafeNet key versioning to simplify changing keys. Instead of creating an alias for every new key, SafeNet key versioning keeps the same alias and increments the version.

You must set up key versioning in SafeNet before you can configure SafeNet key versioning on the Edge proxy server.

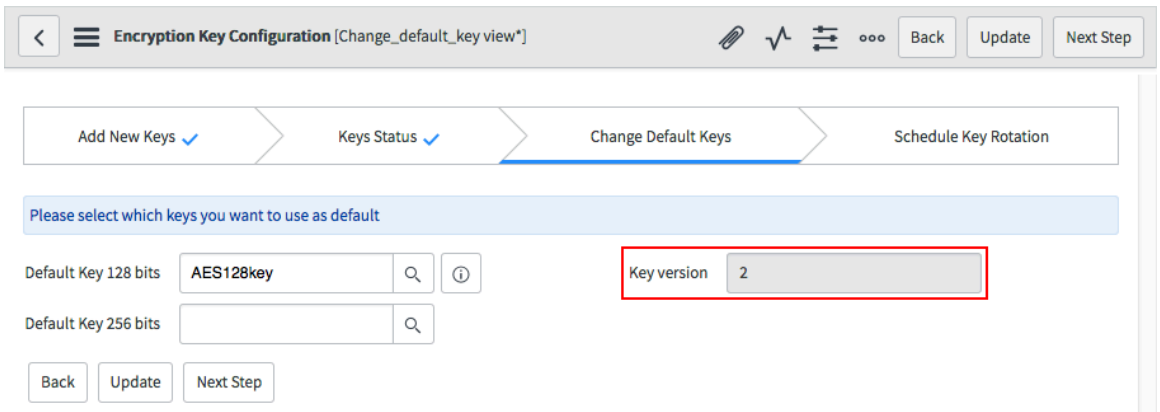
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
Edge proxies installed before the London release support SafeNet keys, but do not support SafeNet key versioning. If you mistakenly use a versioned key on a Kingston or earlier proxy, when you upgrade to a London or later release, the London or later proxy detects this problem, and to prevent potential data loss the proxy does not start.

You must first schedule a mass key rotation job or a single key rotation job to replace the old SafeNet versioned key with a non-versioned key, and then create a new SafeNet versioned key, if needed. This new versioned key is safe to use with the London or later proxy, and you can restart the proxy.

Encryption key configuration

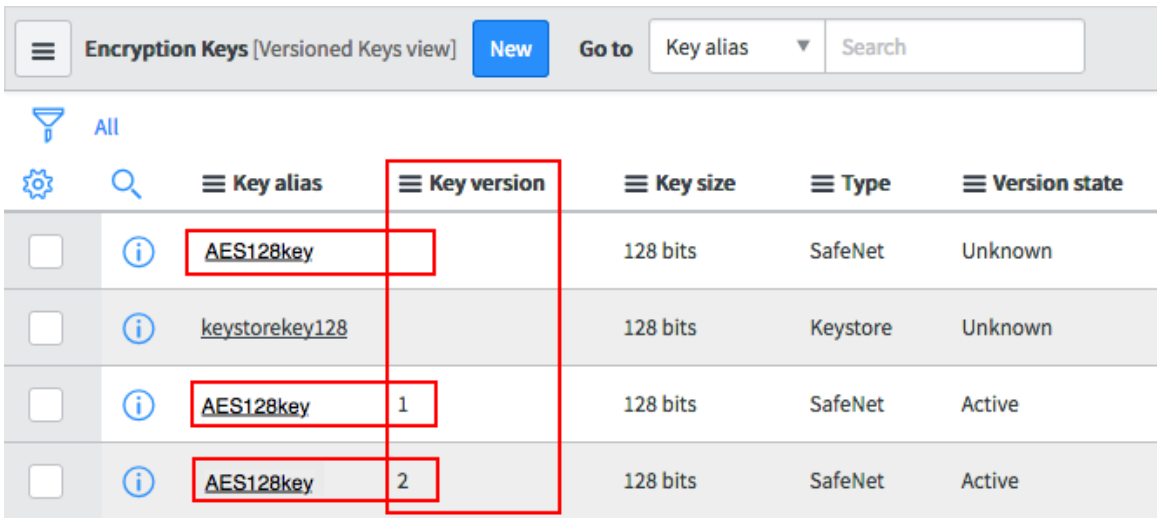
If using SafeNet versioned keys, the Change Default Keys section of the Encryption Key Configuration form includes new fields for the **Key version** of the default 128-bit and 256-bit keys. **Key version** fields are grayed out and cannot be edited.



For procedures, see Configure encryption keys on the instance.

Versioned keys

If using SafeNet versioned keys, when you navigate to **Edge Encryption Configuration** > **Encryption Key Configuration** > **All Keys**, versioned keys include the **Key version**.



A version number does not appear for the initial entries you make in the Change Default Keys section of the Encryption Key Configuration form. When the proxy server requests a key from SafeNet, the system adds a new line for the alias and adds the **Key version**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

In the above example, **AES128key** is listed three times:

- The first listing, with no **Key version** indicated, is the initial entry.
- The second listing, with **1** in the **Key version** column, is the first version of the key returned from SafeNet.
- The third listing, with **2** in the **Key version** column, is the second version of the key returned from SafeNet.
- As other versions of the key are returned from SafeNet, new lines are added to record the **Key version** now in use.

Encryption configurations and patterns

With Edge Encryption, you can encrypt fields and tokenize strings.

Encryption configurations

You can encrypt individual fields using encryption configurations. Edge Encryption supports AES 128-bit encryption keys. If the Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy files are installed, Edge Encryption supports AES 256-bit encryption keys for each encryption type. Edge Encryption supports the following types of encryption configurations.

Standard encryption

The encrypted value of a field is different each time the field is encrypted, even when the field value remains the same. Standard encryption is the most robust form of encryption. Fields using standard encryption cannot be sorted, grouped by, or filtered on.

Equality-preserving encryption

The encrypted value of a field is the same when the field value remains the same. Supports equality comparisons and group by operations on a field.

> **Note:**
> When equality-preserving encryption is selected for a field that already contains data, performing a group by action on the field may not group fields with the same value if one is encrypted and the other is not.

Order-preserving encryption

Uses tokens and encryption to secure data in your proxy database. Supports equality comparisons, group by operations, and the ability to sort data. The order preserving encryption type is only supported if there is a MySQL database configured for the Edge Encryption proxy server.

> **Note:**
