> When using order-preserving encryption and the proxy database is down, updates can be made to fields using order-preserving encryption. However, the sort order will not be correct when trying to sort data based on those fields. Groups also will not work as expected. When the proxy database is again operational, schedule an order token repair job to repair missing tokens.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Encryption types

The following encryption types are listed in decreasing security quality.

Encryption type	Description
Standard AES 256	Fields cannot be filtered, sorted, or compared.
Standard AES 128	Fields cannot be filtered, sorted, or compared.
Equality preserving AES 256	Fields can be filtered using equality comparisons.
Equality preserving AES 128	Fields can be filtered using equality comparisons.
Order preserving AES 256	Fields can be sorted and equality comparison filtering can be used. Requires the use of a MySQL database in your network.
Order preserving AES 128	Fields can be sorted and equality comparison filtering can be used. Requires the use of a MySQL database in your network.

Encryption Patterns

You can secure sensitive data found in strings using encryption patterns. Once an encryption pattern is stored and activated, the Edge Encryption proxy server identifies strings that match the pattern in requests. Once located, the clear text string is stored in the proxy database and replaced on the instance with a token. Use encryption patterns to tokenize strings that match regular patterns such as social security and credit card numbers. While we recommend that encryption configurations be the primary method of encryption, use encryption patterns as a supplement to locate and secure sensitive information found outside of encrypted fields.

Note:
The Edge Encryption proxy server requires a MySQL database in your network only if using order preserving encryption or encryption patterns. Clear text values are stored in the proxy database in your network. For this reason, it is critical that you secure and regularly back up your proxy database. For recommendations, see Edge Encryption components.

Related topics

Encrypt fields using encryption configurations

Tokenize strings using encryption patterns

Installed with Edge Encryption

Edge Encryption installs tables to store encryption-related data, system properties to configure default behavior, and the edge_encryption role to administer Edge Encryption.

Tables installed with Edge Encryption

Edge Encryption adds the following tables.

Edge Encryption Configuration [sys_encryption_configuration]

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Contains encrypted fields and tables for which attachments are encrypted.

Edge Encryption Rule [sys_encryption_rule]

Contains a record for each rule. A rule has a name, the condition when it is used, a script, and an order field.

Edge Encryption Invalid Insert Log [sys_edge_encryption_invalid_insert_log]

Contains log messages created for attempts to save unencrypted data to an encrypted field.

Edge Encryption Proxy [sys_encryption_proxy]

Contains information about the encryption proxy application.

Edge Proxy Encryption Type [sys_proxy_encryption_type]

Used for enabling and disabling encryption types on the encryption form.

Encryption Job Execution [sys_encryption_job_execution]

Supports mass encryption jobs.

Encryption Job Execution Chunk [sys_encryption_job_execution_chunk]

Supports mass encryption jobs.

Scheduled Encryption Job [sysauto_encryption_job]

Lists scheduled jobs for encryption, decryption, key rotation, order token repair, and database recovery.

Encryption Key Configuration [sys_encryption_key_configuration]

Lists default encryption keys.

Encryption Key [sys_encryption_key]

Lists available keys and key attributes.

Proxy Encryption Key [sys_encryption_proxy_key]

Lists proxy encryption keys.

Properties installed with Edge Encryption

Edge Encryption adds the following properties.

Note:
To open the System Properties [sys_properties] table, enter `sys_properties.list` in the navigation filter.

glide.edge.pattern.disallowed.chars

A list of characters that are not allowed in patterns.

- **Type**: a string of a comma-separated list of values
- **Location**: System Properties [sys_properties] table

glide.edge.pattern.min.size

The minimum pattern size allowed. Allowing smaller patterns means finding more matches, which increases overhead.

- **Type**: number
- **Default value**: 5
- **Location**: System Properties [sys_properties] table

sn_edge_encryption.logging.destination

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Where messages are logged.

- **Type**: string
- **Default value**: file
- **Location**: System Properties [sys_properties] table

sn_edge_encryption.logging.verbosity

The logging level to use.

- **Type**: string
- **Default value**: info
- **Location**: System Properties [sys_properties] table

sn_edge_encryption.encryption.proxy.buildtag

The proxy version registered with your instance.

- **Type**: string
- **Location**: System Properties [sys_properties] table

sn_edge_encryption.cleartext.allowed

When true, allows clear text to be saved in an encrypted field. This happens when a user is accessing the instance without going through the Edge Encryption proxy. When false, the system prevents clear text from being saved in an encrypted field.

- **Type**: Boolean
- **Default value**: false
- **Location**: System Properties [sys_properties] table

Planning for Edge Encryption

Successful implementation of Edge Encryption requires planning and preparation.

Answer the following questions in the planning stage.

- Which fields are to be encrypted?
- Which encryption types are to be used?
- How many Edge Encryption proxies are needed? See Sizing your Edge Encryption environment for recommendations and considerations.
- If an order preserving encryption type or encryption patterns are to be used, where is the MySQL database located?
- Which key management system is to be used?

System administrators, network administrators, and security team members have different tasks to fulfill for implementing Edge Encryption.

- System administrators need the security-admin role. The system administrator must :
  - Download the Edge Encryption proxy application.
  - Set up an Edge Encryption user account for the proxies to use to connect to the instance. The user must be assigned the edge_encryption role.
  - Configure encryption keys, and set the default keys.
  - Configure Edge Encryption on the instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

  - Schedule encryption jobs.
  - Monitor Edge Encryption.
  - Create and edit encryption rules.
- Your network administrator must:
  - Install the Edge Encryption proxy application.
  - Know the network addresses for the proxy servers and the proxy database used for order-preserving encryption and encryption patterns.
  - Install the proxy database to be used for order-preserving encryption and encryption patterns.
  - Start and stop the proxy applications.
  - Perform encryption key management.
  - Determine how to map users to encryption proxy applications. This can be done with DNS settings or routing rules, and is specific to each network.
  - Manage multiple proxy servers.
  - Configure load balancer pools and settings.
- Your security administrator must determine the encryption types to be assigned to each field.

Edge Encryption system requirements

You can run the Edge Encryption proxy application on servers or virtual machines that run on Microsoft Windows or Linux operating systems. For optimum performance, ensure that your configuration meets these requirements.

Java requirements

The host machine installing or running the Edge Encryption proxy server must maintain a supported version of Java. Current supported versions are Java 11.0.6 or later in the 11.x version series

Note:
Java 8 is no longer be supported as of the Utah release. Upgrade your environment with the Edge Encryption proxy to Java 11 before you attempt to install the Utah version of the Edge Encryption proxy.

Note:
Java does not automatically allow unlimited strength keys. You must specifically enable the use of AES 256-bit encryption.

Support for OpenJDK

The ServiceNow AI Platform supports OpenJDK version 11.

Proxy server minimum configuration

A proxy server requires this minimum configuration:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- 4 GB of RAM per proxy server (6 GB is recommended for most deployments).

  Note:
  The proxy server host requires at least 1 GB of RAM more than the proxy server. The proxy server host needs the extra 1 GB for operating system services. For example, if you configure a proxy server to use 4 GB of RAM, you must install at least 5 GB of RAM on the proxy server host.

  Because the proxy server requires at least 4 GB of memory, 32-bit JREs and 32-bit operating systems are no longer supported starting with the London release.

- 3 or more GHz CPU (4-core CPU preferred for optimum performance).
- Multiple proxy servers behind a load balancer. The number of proxy servers you need depends on the number of application nodes, the number of simultaneous users, and the number of servers needed for failover. See Sizing your Edge Encryption environment for more information.
- Ability to run concurrently with other services, depending on the server utilization and resource availability.

Proxy server supported systems

The following systems are supported:

Supported System	Description
Windows Server 2012, 2012-R2, 2016, and 2019 editions	• Virtual machines or physical hardware • 64-bit systems
Linux	• Virtual machines or physical hardware • 64-bit systems On 64-bit Linux systems, you must install the 32-bit GNU C library (glibc). The installation command for CentOS is `yum install glibc.i686`.

Proxy server version requirements

Keep your Edge Encryption proxy version in sync with your ServiceNow instance version (same major release, for example Tokyo). To eliminate downtime during the upgrade process, the Edge Encryption proxy is backwards compatible. However it is important to upgrade as soon as possible to avoid ensure users can access new features and important bug fixes.

Proxy server connection requirements

The proxy server that runs the Edge Encryption application must be able to communicate with machines in your network. Make sure that the proxy server has these network privileges:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Network Privilege	Description
Firewall access	Configure any firewalls between the proxy server and the client devices to allow a connection. If your network uses a DeMilitarized Zone (DMZ) to add an extra layer of security to your Local Area Network (LAN), and if your network security protocols limit port access from within the network to the DMZ, you might have to deploy a proxy server to a machine within the DMZ.
Network access	Configure each client to enable the proxy server to connect with it. If network security prevents you from configuring new machines that can connect to the clients, install the proxy server on an existing machine with connection privileges.
Instance access	Ensure that the proxy server has network access to the instance. Make sure that you configure the proxy server network to allow traffic over TCP port 443.
Network account	Install the proxy server with either a local or domain administrator.

Order-preserving and tokenization database system requirements

Order-preserving encryption and encryption patterns require that you configure an Oracle MySQL database for the Edge Encryption proxy server. Order-preserving encryption allows any comparison operation to be directly applied on encrypted data, without first decrypting the data. Encryption patterns let you replace string patterns with tokens (called tokenization) before they are sent to and stored in the database. Because of the size of the MySQL database, use a dedicated proxy server to run the order-preserving and tokenization database.

The minimum database system requirements include:

MySQL Database	Requirement
Version	MySQL database versions 5.7 and 8.0 **Note:** MySQL versions 5.5 and 5.6 are no longer tested and have reached the end of support.
OS	64-bit systems
CPU	2 or more GHz CPU (4-core CPU preferred for optimum performance)
RAM	16 GB
Disk	Storage Area Network (SAN) or local storage (RAID 10 recommended)
Size	Determined by the number of potential records multiplied by the record size.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

MySQL Database	Requirement
	See Calculate the order-preserving and tokenization database size.
Configuration	High availability cluster. If you are unsure of how to configure your MySQL server, contact MySQL for configuration information.

Sizing your Edge Encryption environment

Choosing the number of proxy servers for your environment is an important task. Consider the number of users, redundancy needs, and acceptable latency.

Redundancy

Maintain redundant proxy servers in case of hardware failure. Proxy servers should be located behind a load balancer to provide a functional path for all users if a proxy server is unreachable. At a minimum, ensure that two proxy servers are always available.

Size

Size refers to the number of proxy servers required to avoid additional latency that the encryption of data produces. Depending on use, you may want to reduce the amount of latency by adding additional proxy servers. For example, if regular mass encryptions are run, add additional proxy servers to handle the load, or run the mass encryptions when the user load is light. In addition, the hardware that the proxy server runs on influences performance and latency. Proxy servers running on hardware with faster CPUs, more CPUs, and more RAM have higher throughput than slower, limited systems.

The following guidelines assume that your proxy server is running on at least the minimum hardware requirements. To determine the number of proxy servers:

- Consider setting up one proxy server for every two application nodes on the instance.
- For redundancy, set up a minimum of two proxy servers behind a load balancer.
- Add an extra proxy server for every 500 simultaneous users.
- Depending on the desired redundancy, add additional proxy servers for failover.

For example, for an instance with 2,000 users, you should have at least five proxy servers behind a load balancer. This calculation includes one proxy server for every 500 users, with an extra proxy server for failover. Determine ahead of time when you will approach a threshold of 500 users and place another proxy server in the load balancer pool.

Load balancers

To balance requests and improve server response time, distribute proxy servers in a load balancer pool. Configure load balancers to use the "least connections" method. This method connects requests to the proxy server with the fewest active connections, preventing the overloading of a single proxy.

CPU utilization

Because data encryption and tokenization are CPU intensive operations, CPU spikes while encrypting data are normal and expected. When CPU utilization is over 80% for several minutes at a time, it likely means that the proxy server has too much work to do. When this happens, latency increases for the period that the CPU utilization is high. If latency persists, adding another proxy server may help decrease the latency.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Memory

The proxy server must have a minimum of 4 GB of RAM available (6 GB recommended). Set the proxy server initial and upper bound memory limits to the recommended settings.

Calculate the order-preserving and tokenization database size

If using order-preserving encryption or encryption patterns, determine the size of your MySQL database by multiplying the number of potential records by record size.

Before you begin

Role required: admin

About this task

Use a dedicated machine to run the order-preserving and tokenization database. Do not run the database on the same hardware as the proxy server.

Procedure

1. Determine the potential number of records that could include fields encrypted with order-preserving encryption.
   a. Multiply the number of encryption configurations using order-preserving encryption by the number of records each configuration is applied to.
   b. To allow for growth, multiply the result by three.
2. Multiply the result of step 1 by 1,536.
   1,536 is the average size of a record in bytes.
3. If using encryption patterns, perform steps 1–2 for tokenized records and add the result to the total.

Result

The calculated value is the recommended size in bytes for your order-preserving and tokenization database.

Edge Encryption limitations

Edge Encryption impacts system functions. Carefully evaluate the impact of encrypting a field.

Field type restrictions

You can encrypt only the following field types:

- Date
- Email
- Date/Time
- HTML
- IP Address
- Journal
- Journal Input
- Multi-line text
- Single-line text
- String
- URL

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

You cannot encrypt the following field types:

- Choice fields
- Virtual fields
- Fields in system tables, except for certain fields in sys_user
- System fields in tables
- Number fields or fields associated with an auto-numbering scheme
- Any other field type not listed above

Additional restrictions:

- When a Journal field is encrypted, the **Post** button is inactive, even if there are multiple Journal fields and only one of those fields is encrypted.
- Encrypted fields aren't available in **Go to** and header filter boxes.
- When encrypting fields used as an index, you can use only order-preserving and equality-preserving encryption types. Indexed fields can't be encrypted using the standard encryption type.

For more information, see Field types.

Filtering and searching restrictions

Standard encryption

When you select a String, Date, Date/Time, or URL field with a standard encrypted field configuration as the left operand in a filter, no filtering options are available.

Equality-preserving encryption

When you select a String, Date, Date/Time, or URL field with an equality-preserving encrypted field configuration as the left operand in a filter, the following operators are available:

- **is**
- **is not**
- **is empty**
- **is not empty**

Order-preserving encryption

When you select a String field with an order-preserving encrypted field configuration as the left operand in a filter, the following operators are available, in addition to **is**, **is not**, **is empty**, and **is not empty**:

- **greater than**
- **less than**

When you select a Date or Date/Time field with an order-preserving encrypted field configuration as the left operand in a filter, the following operators are available, in addition to **is**, **is not**, **is empty**, and **is not empty**:

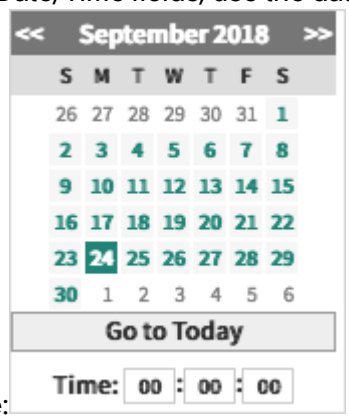
- **after**
- **before**
- **after or on**
- **before or on**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Date and Date/Time pickers

For Date fields, use the date picker to specify the date:

For Date/Time fields, use the date and time picker to specify the date and time:



List condition filters

The **Show Matching** and **Filter Out** options are supported in lists. Only exact matches are returned or filtered out.

> **Note:**
> Adding encrypted fields in condition filters is supported in scripts such as UI policies and business rules.

Configuration restrictions

Restrictions and behavior of encryption configurations:

- After you add a field to the Edge Encryption Configuration table, you can't delete the configuration record. If you no longer want a field to be encrypted, deactivate the record in the Edge Encryption Configuration table and schedule an encryption job to decrypt the data.
- If a field in a parent table is marked to be encrypted, the field is also encrypted in all inherited tables. For example, if the **Short description** field in the Task table is encrypted, then the contents of the **Short description** field in the Incident table are encrypted.
- If a field inherited from a parent table is marked to be encrypted, the field in the parent table can't be encrypted. For example, if the **Short description** in the Incident table is marked to be encrypted, then the **Short description** in the Task table can't be encrypted. In this example, you can encrypt the **Short description** in the Problem table.
- When a field with an encryption configuration defined is exported to any format, the output includes encrypted values even when exported through the proxy server.
- You can't import data to a field with an encryption configuration defined.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- You can't encrypt inherited Date and Date/Time fields. Date or Date/Time fields inherited from a parent table aren't listed on the **Column** field drop-down list, and you can't create Date or Date/Time encryption configurations for those fields.
- You can encrypt a String or URL field only from a parent table or a child table, but not both.

Instance restrictions

Impact of using Edge Encryption on the instance:

- Back-end logic can't process encrypted data. When the instance contains encrypted data, any business rule, back-end script, or back-end feature that relies on evaluating the data in the encrypted field doesn't run correctly.

  Note:
  Data encrypted with equality-preserving or order-preserving encryption still passes equivalence checks when compared against an identical encrypted value.

- Since email processing goes from the mail systems straight to the instance and can't pass through the Edge proxy, data sent in or out via email can't be encrypted or decrypted by the Edge proxy.
  - Data and attachments in inbound emails aren't encrypted.
  - Data and attachments in outbound emails remain encrypted and can't be decrypted.
- Scripts run on the server can't change encrypted data.
- Global search isn't supported. Because global search attempts to search both encrypted and clear text data, the results may not be as expected.
- Encrypted data can't be copied and pasted into a record where the field isn't encrypted.
- Depending on the type of encryption selected, the user interface functionality for the encrypted fields is reduced. For example, being able to compare, group by, sort, and search may be impacted. Generally, the stronger the encryption selected, the more functionality is reduced.
- Except for Java KeyStore, SafeNet, and Unbound Technology, no third-party software or hardware encryption key management is supported.
- Although multiple proxy servers connected to a single instance are supported, encryption proxy cluster management and monitoring aren't available. Each proxy must be managed separately.
- System configurations such as workload and the number of encrypted fields can impact the performance of encrypted fields.
- The Edge Encryption proxy server can only connect to a single instance.
- If your instance uses an Oracle database and the String field you're marking to be encrypted is greater than 2925 characters, that field can't be sorted even when order preserving encryption is selected.
- If your instance uses an Oracle database, Unicode AL32UTF8 is the only supported character set.
- Encrypted data can't be used in reports.
- Edge Encryption can't be used with Data Archiving.
- Edge Encryption proxies cannot encrypt requests that use the batch REST request API. If you are using Edge Encryption proxies, disable REST batching by setting the `glide.uxf.disable_rest_batching` system property to true.

Installing Edge Encryption

You can install an Edge Encryption proxy manually or using the Edge Encryption interactive installer.

Java requirements

The host machine installing or running the Edge Encryption proxy server must maintain a supported version of Java. Current supported versions are Java 17.0.3 or later in the 17.x version series.

Note:
Java 11 is no longer be supported as of the Yokohama release. Upgrade your environment with the Edge Encryption proxy to Java 17 before you attempt to install Yokohama or later versions of the Edge Encryption proxy.

Installing the proxy server

Installing Edge Encryption includes these steps.

- Install the Edge Encryption proxy application on a server in your network using the interactive installer or the manual installer.
- Generate the RSA key pair for digitally signing encryption configurations and encryption rules.
- Install the Java Cryptography Extension (JCE), if you plan to use AES 256 encryption.
- If you are using a secure SSL connection, obtain a server certificate and import it to the Java KeyStore.
- Set up your keystore and encryption key.
- If order preserving encryption types or encryption patterns are to be used, set up a MySQL database on a machine in your network.
- Set the desired properties. Properties are located in the `edgeencryption.properties` configuration file.
- Specify that a proxy server is a trusted source so that Edge Encryption can process requests coming from that proxy server.

Accessing the proxy server

Once installation is complete, point each user's browser to an Edge Encryption proxy using the URL format: `<host>:<port>`. Values are determined by the host and port properties in the `edgeencryption.properties` file.

As an example with the following values:

Property	Example value
edgeencryption.proxy.host	hostname.mycompany.com
edgeencryption.proxy.http.port	8081

A client will access the proxy server using the following address: `http://hostname.mycompany.com:8081/`.

Note:
DNS settings and routing rules may be used. Host and port values are determined by your network administrator.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Request Edge Encryption

The Edge Encryption plugin (com.glide.edgeencryption) is available as a separate subscription.

Before you begin

To purchase a subscription, contact your ServiceNow account manager. The account manager can arrange to have the plugin activated on your organization's production and subproduction instances, generally within a few days.

If you don't have an account manager, decide to delay activation after purchase, or want to evaluate the product on a subproduction instance without charge, follow these steps.

Role required: none

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Select **Request plugin** to open the **Activate Plugin** form on Now Support.
3. On the **Activate Plugin** form, provide the following information.

Activate Plugin form

Field	Description
What is your target instance	Select the instance that you want to activate the plugin on.
Which plugin would you like to activate	Select the name of the plugin to activate. **Note:** If the system doesn't list the plugin you want or if you're activating the plugin on an OEM or on-premise instance, select the **Plugin I'm looking for is not listed** check box and then enter the name of the plugin.
Select Maintenance Date and Time	Select the date and time to activate the plugin.

Example

For example, see the following form to activate the Event Management plugin on an instance named SNC Instance.

4. Select **Submit**.
   After the maintenance window, the system installs the plugin on your instance. To confirm the installation, go to the Installed tab in the Application Manager.

Set up an Edge Encryption user account

The Edge Encryption proxies connect to the instance as a user to obtain and update encryption configuration information. Create a user account for this purpose and give the edge_encryption role to the user.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin

The Edge Encryption plugin must be installed before you can assign the role.

Role required: admin

Procedure

1. On your ServiceNow instance, create a user account to be used by the Edge Encryption proxy applications.
2. Assign the edge_encryption role to the user.

Download the Edge Encryption proxy server

Download the Edge Encryption proxy server application from your instance, and then copy the file to each computer that is to run the Edge Encryption proxy server.

Before you begin

Before starting this procedure, the Edge Encryption plugin must be installed and activated on your instance.

Note:
The Edge Encryption proxy is officially supported only on Oracle JRE.

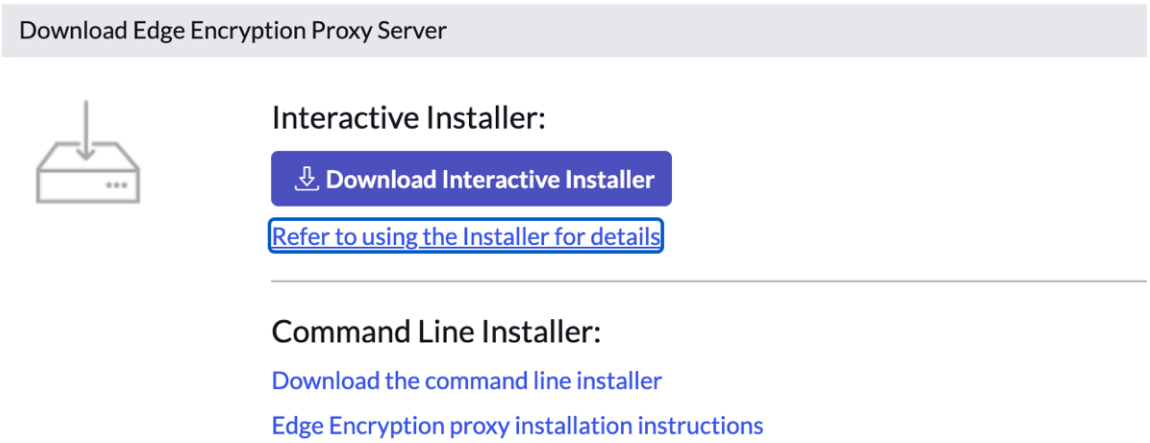
Role required: security_admin

About this task

Procedure

1. Navigate to **All** > **Edge Encryption Configuration** > **Installation & Downloads** > **Downloads**.
2. To use the interactive installer, click **Download Interactive Installer**.

   If manually installing the proxy server, select the OS version for your proxy server.



Note:
Because the proxy server requires at least 4 GB of memory to run, 32-bit JREs and 32-bit operating systems are no longer supported starting with the Washington DC release.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. Copy the installer to each computer that is to run the Edge Encryption proxy server.

> **Note:**
> If you are manually installing the Edge Encryption proxy server, copy the ZIP file to each computer that is to run the Edge Encryption proxy server.

What to do next

After downloading the Edge Encryption installer, Install the Edge Encryption proxy server using the interactive installer. If installing manually, Install the Edge Encryption proxy server using the command line installer.

Install the Edge Encryption proxy server using the interactive installer

Install the Edge Encryption proxy server on a Windows or Linux computer using the interactive installer.

Before you begin

> **Note:**
> SafeNet KeySecure keystore files are not supported by the Edge Encryption installer. To use a SafeNet KeySecure keystore, Install the Edge Encryption proxy server using the command line installer.

The Edge Encryption plugin must be installed and activated on your instance before you start this procedure. Ensure that Java version 11.0.6 or later is installed on the machine running the Edge Encryption installer.

Role required:

- security_admin on your ServiceNow instance
- local or domain administrator on a Windows host
- service user with full file system access on a Linux host

About this task

After installing a new proxy server, you can run the installer again to perform tests to detect issues with an installation or modify current settings. Your options include:

- **Install New**: Install a new proxy server.
- **Verify Installation**: Perform tests to detect and fix issues in a previous installation.
- **Reinstall Existing**: Perform tests to detect and fix issues in a previous installation and view or modify existing settings.

> **Note:**
> If installing the proxy server on a Linux machine on a privileged port (port 80 or 443), you must run the installer as a root user with full file system access. To restrict file system access after the proxy server is installed, you can use the SetUID feature in the proxy installer. To enable this feature, start the installer as root or sudo root. When prompted by the installer, provide the username and usergroup of an unprivileged user. The proxy server will install with file system privileges of the given user. You can skip this step to continue the default installation with root privileges.

Procedure

Use the installer to install multiple proxies for your instance on multiple machines, ensuring that the following criteria apply:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- All proxies must have the same encryption keys and the same RSA key pair used to digitally sign encryption configurations and rules.
- The encryption key must be the default key configured on the instance.
- When a proxy database is set up as part of the installation, all proxies must use the same proxy database.

  You may need a proxy database for equality-preserving encryption, order-preserving encryption, or tokenization. If you do not use any of these features, you do not need a proxy database.

What to do next

To use NVDA, an Assistive Technology screen reader designed to read accessibility-enabled Java applications built for keyboard users, see Configure a Windows 64-bit host to use 32-bit NVDA with Java applications.

After installing the Edge Encryption proxy server, Set the proxy server initial memory limit and upper bound memory limit.

Install the Edge Encryption proxy server (interactive installer)

Install the Edge Encryption proxy on a Windows or Linux computer.

Before you begin

Role required: admin

Procedure

1. Download the Edge Encryption proxy server installer.
2. Open the Edge Encryption proxy installer.

   Note:
   If installing on a Windows machine, you must run the installer as Administrator.

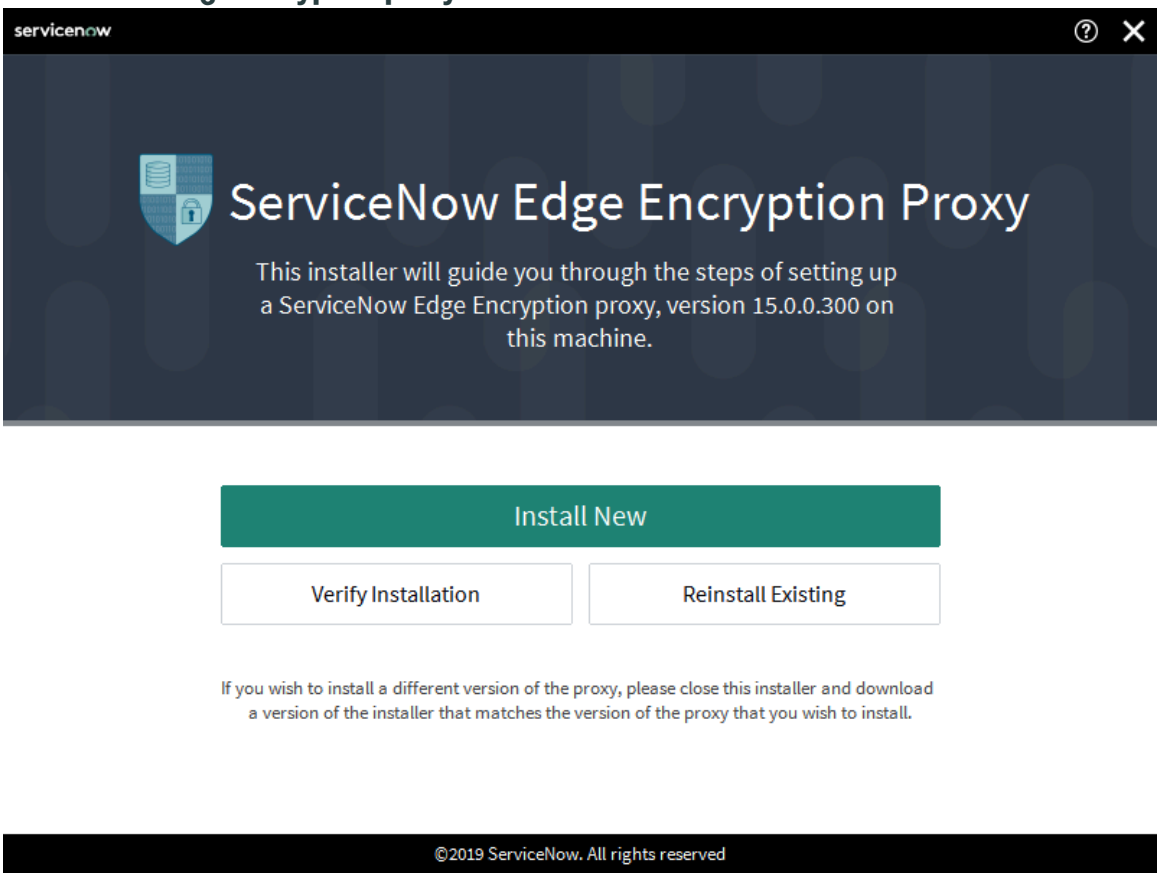
   a. To run the installer as Administrator on a Windows machine, right-click the Command Prompt and select **Run as administrator**.

   b. From the command line, navigate to the directory that contains the downloaded .jar file.

   c. Run the following command: `java -jar <file name>.jar`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

ServiceNow Edge Encryption proxy installer



3. To install a new proxy server, select **Install New**.
   If a proxy is already installed, you can run the installer to:
   - **Verify Installation**: Perform tests to detect and fix issues in a previous installation.
   - **Reinstall Existing**: Perform tests to detect and fix issues in a previous installation and view or modify existing settings.
4. Configure the **Installation Location** and **Target ServiceNow Instance**.

   a. Click **Browse** to select an installation location or manually enter an installation path.

   b. Enter the URL of the target ServiceNow instance.
   Include the protocol and port number.

   Example
   `https://example.servicenow.com:443`

   c. Enter the user name and password for a user with the edge_encryption role on the target ServiceNow instance.

5. Click **Next**.
6. Configure the **Connection Settings** and **Proxy Settings**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Setting	Description
Proxy Host	Fully qualified domain name of the machine on which you are installing the proxy server. **Note:** Click **Detect FQDN** to look up the machine's fully qualified domain name and auto-populate the **Proxy Host** field. Along with the port, this property defines the URL used by the client to access the proxy server.
HTTP Port	Port on the proxy for HTTP communication.
HTTPS Port	Port on the proxy for HTTPS communication.
Proxy Name	Name of the proxy and the service. The proxy name must be unique.
Proxy Poll Interval	Poll interval in seconds. With the default setting, it takes 5 seconds for the proxy to learn of encryption configuration changes. Larger values cause the instance to take longer to detect proxies that have come online. **Note:** Changing the default setting of the Proxy Poll Interval can result in detection delays when a proxy comes online.
Proxy Keep-Alive Ping Interval	Time in seconds between pings issued by the proxy to the instance. Pings are issued periodically to verify connectivity between the proxy and the instance. The default value is 10. The minimum value is 5.

7. Click **Install**.
   The Edge Encryption proxy server installs. The installation may take a few minutes.

Configure CyberArk properties protection

Optionally, configure CyberArk properties protection to securely store Edge Encryption passwords in a centralized and secure digital vault.

Before you begin

Role required: admin

About this task

You must purchase and configure CyberArk AIM (Application Identity Management) before you can configure CyberArk connection parameters and protected credentials for a proxy server. As part of the installation of the AIM client, the `JavaPasswordSDK.jar` file is installed in the AIM client installation directory. The CyberArk vault is installed on an independent hardened server, and the AIM clients allow secure access to that server.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
You must install the CyberArk AIM client on every host computer where an Edge proxy is installed.

In the Edge installer, you must specify the location of the `JavaPasswordSDK.jar` file to set up the CyberArk connection to the Edge proxy. You must also enter other values you defined during the AIM client installation.

Setting up CyberArk password storage is optional. If you do not want to set up CyberArk password storage, click **Skip** through the CyberArk screens.

Procedure

1. On the CyberArk Connection page of the Edge Encryption installer, enter the CyberArk connection parameters.

CyberArk connection parameters

Setting	Description
Path to PasswordSDK.jar	The path to the `JavaPasswordSDK.jar` file installed on the host Windows machine during CyberArk configuration.
App ID	The **App ID** entered during CyberArk configuration.
Safe Name	The **Safe Name** entered during CyberArk configuration.

2. Click **Next**.
3. On the CyberArk Protected Credentials page of the installer, enter the credentials to be protected by CyberArk.
   - To use a single credential name for all protected passwords, select the **Apply one Credential Name to all Credentials** check box, enter the credential name, and click **Apply**.
   - Enter the credential name for one or more of the following fields. Credential names are the usernames entered for the SSH keys during CyberArk configuration.

CyberArk protected credentials

Setting	Description
Edge Encryption User	The CyberArk credential name for an Edge Encryption user.
Signature Key Keystore	The CyberArk credential name for the signature key keystore.
HTTPS Cert Keystore	The CyberArk credential name for the HTTPS certification keystore.
Encryption Key Keystore	The CyberArk credential name for the encryption key keystore.
Database	The CyberArk credential name for the database keystore.
SafeNet HTTPS Cert Keystore	The CyberArk credential name for the SafeNet HTTPS certification keystore.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Setting	Description
SafeNet Server	The CyberArk credential name for the SafeNet server.
Forward Proxy	The CyberArk credential name for the forward proxy.

4. Click **Next**.

Configure the signature key

Configure the signature key after installing the proxy server through the Edge Encryption proxy installer.

Before you begin
Role required: admin

About this task
The signature key signs changes to configurations and properties made by the proxy server. The signature key must be an asymmetric RSA key pair in a JCEKS KeyStore.

Note:
If installing multiple proxies, each proxy must use the same signature key.

Procedure
1. On the Signature Key page of the Edge Encryption installer, select the keystore on the host machine to store the signature key.
   - **Create New Java KeyStore**: Enter the directory location, name, and password for the new keystore.
   - **Use Existing Keystore**: Enter the keystore file location and password.
2. Click **Next**.
3. Select or create a signature key.
   - **New Key**: Create a signature key for this proxy.
   - **Use Existing Key**: Use an RSA key-pair from the selected keystore.
   - **Import Existing Key**: Import an RSA key-pair from a different keystore. Browse to the keystore file, enter the password for the keystore, and select the key alias. Provide a new alias for the key.
4. Click **Next**.

Configure the HTTPS certificate

To enable clients to connect to the Edge Encryption proxy server using a secure SSL connection, import the HTTPS certificate to the proxy server.

Before you begin
Role required: admin

About this task
The Edge Encryption proxy provides the HTTPS certificate to clients trying to connect.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. On the HTTPS Certificate page of the Edge Encryption installer, select the keystore to store the certificate.
   - **Create New Java KeyStore**: Enter the directory location, name, and password for the new keystore.
   - **Use Existing Keystore**: Enter the keystore file location and password.
2. Click **Next**.
3. Select or import a certificate.
   The key alias is the given alias for the certificate.
   - **Use Existing Certificate**: Use an existing certificate in the selected keystore.
   - **Import from File or KeyStore**: Import a certificate from a different keystore or a .cer file. Browse to the keystore or .cer file, enter the password, and select the alias. You must provide a new alias for the certificate.
4. Click **Next**.

Configure the AES 128-bit encryption key

After you configure the HTTPS certificate through the Edge Encryption proxy installer, configure the AES 128-bit encryption key to encrypt your data.

Before you begin
Role required: admin

About this task
The encryption key is either a plain text file inside the `/keys` directory or a secret key inside a keystore. If you use a keystore for your AES 128-bit and AES 256-bit encryption keys, they must both use the same keystore.

If you are updating an SSL certificate on an Edge proxy server, see Update SSL certificate.

Procedure

1. Select the encryption key location.
2. Click **Next**.
3. Select or create the encryption key.
4. Click **Next**.
5. Configure the key on the instance according to the requirements defined in your installer.
   To configure the key on the instance, navigate to the instance and define a default key. See Configure encryption keys on the instance. Ensure that the key alias, size, and type match the requirements defined in the installer.

   #### Default key requirements

6. Once the key is configured on the instance, return to the installer and click **Next**.

Configure the AES 256-bit encryption key

After you configure the AES 128-bit key through the Edge proxy installer, you can optionally configure an AES 256-bit encryption key to encrypt your data.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin
Role required: admin

About this task
The encryption key is either a plain text file inside the `/keys` directory or a secret key inside a keystore. If you use a keystore for your AES 128-bit and AES 256-bit encryption keys, both keys must use the same keystore. If you don't want to configure an AES 256-bit encryption key, select **Skip** to continue installing the proxy server.

If you're updating an SSL certificate on an Edge proxy server, see Update SSL certificate.

Procedure
1. Select the encryption key location.
2. Select **Next**.
3. Select or create the encryption key.
4. Select **Next**.
5. **Optional:** If you want to use AES 256-bit encryption, see Configure the AES 256-bit encryption key.
6. To use AES 256-bit encryption, you must also configure the AES 256-bit default encryption key on the instance.

   Do this by navigating to the instance and defining a default key. See Configure encryption keys on the instance. Ensure that the key alias, size, and type match the requirements defined in the installer.
7. After the key is configured on the instance, return to the installer and select **Next**.

Update SSL certificate

When updating an SSL certificate on an Edge proxy server, you must delete the old one.

Before you begin
Role required: admin

About this task
When updating the SSL certificate on the Edge proxy server, you must also delete the old certificate. If you don't, the old certificate (in the form of an alias in the KeyStore file) continues to be used even though the Edge proxy server is configured to use the new certificate.

Procedure
1. On the Edge proxy server, list the entries in the Java KeyStore:

```
keytool -list -keystore keystore.jceks -storetype jceks
 -storepass MY_SUPER_PASSWORD
```

2. Remove the old SSL certificate:

```
keytool -delete -alias MY_OLD_ALIAS -keystore keystore.jceks
 -storetype jceks -storepass MY_SUPER_PASSWORD
```

3. Add the new SSL certificate into the Java KeyStore.

Configure the Edge Encryption proxy database

If using order-preserving encryption types or encryption patterns, you can optionally configure the Edge Encryption proxy database properties.

Before you begin
Role required: admin

About this task
To use order-preserving encryption types or encryption patterns, a MySQL database running in your network is mandatory. This task connects the proxy to the database, but it does not install or configure the database.

Note:
If using multiple proxy servers, all proxy servers must use the same proxy database. The values entered in the installer must be the same for all proxy servers.

Procedure
1. Confirm or change the database URL, which is the location of the proxy database.
2. In the **Name** field, enter the name of the proxy database.
   The default value is *edgeencryption*.
3. Enter the username and password for accessing the proxy database.
4. Click **Next**.

Launch the Edge Encryption proxy server

After an Edge Encryption proxy is installed and configured, you can start the proxy from the installer.

Before you begin
Role required: admin

Procedure
1. After configuring keys on the instance and configuring the proxy database, return to the Edge Encryption proxy installer and click **Launch**.
2. If an issue is detected, or to check the status of your proxy server, you can click **Check Status** to verify that the proxy is running.
   A message displays the proxy status.

Proxy status

What to do next
After successfully installing the Edge Encryption proxy server, Set the proxy server initial memory limit and upper bound memory limit.

Verify and troubleshoot the Edge Encryption proxy server installation

After your Edge Encryption proxy is installed, you can verify the installation to locate problems or start and stop the proxy.

Before you begin
Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Open the Edge Encryption proxy installer.
2. Select **Verify Installation**.
3. Click **Proxy Directory** and select the proxy directory.
4. Click **Run Tests**.
   Test results display.

   Edge Encryption proxy installation tests

5. Click **Next**.
   If an issue is encountered, you can move through the installer to correct the configuration. If no issues are encountered, the installer jumps to the **Launch** page. You can check the proxy status, stop the proxy, or start the proxy from the **Launch** page.

Install the Edge Encryption proxy server using the command line installer

Manually install multiple Edge Encryption proxy servers in your network.

Before you begin

Roles required: security_admin on your ServiceNow instance and local administrator on the host machine.

If order preserving encryption types or encryption patterns are to be used, set up a MySQL database on a machine in your network if not already present.

Note:
If using Unbound Technology encryption keys with Edge Encryption, install the proxy server using the command line installer on the Unbound client machine. The Edge Encryption proxy server must run on the same machine as the Unbound technology client.

About this task

First, set up a single Edge Encryption proxy server. After your first proxy server is successfully running, add additional proxy servers for one instance to ensure an optimal environment. See Sizing your Edge Encryption environment to determine the number of additional proxy servers needed.

Install the Edge Encryption proxy server (command line installer)

Install an Edge Encryption proxy on a 64-bit Windows or Linux computer.

Before you begin

Role required: admin

Java version 11.0.6 or later in the 11.x version series is required to run the installer.

About this task

Install the Edge Encryption proxy server on a machine in your network using the appropriate command for your target machine. If installing the Edge Encryption proxy server on a Windows machine, you must additionally install the proxy server as a Windows service.

When you upgrade the Edge Encryption proxy server, the system backs up the old proxy in the `backup.dist-upgrade-<timestamp>` directory under the current installation directory. The backup directory is generated during the upgrade process and stores the old proxy information.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

When you run an upgrade via the command line, a dist-upgrade.log may be generated in the directory where the command runs. The dist-upgrade.log contains logs for the upgrade process.

In case of a failed upgrade, the system creates a `failed-backup.dist-upgrade-<timestamp>` directory. In addition, `logs/wrapper.log` in the original proxy directory may also contain failure information.

Procedure

1. Create the installation directory.
2. Download the Edge Encryption proxy archive file to the installation directory.
3. Open the terminal and change to the installation directory.

> **Note:**
> If installing on a Windows machine, you must start the Windows Command Prompt with administrator privileges.

4. Run this command for the target machine and change the variables according to your configuration: `java -jar edgeencryption-<version>-all.jar -m install -n <proxy_name> --instancehost <host> -p <port> --protocol https -s <install_path>`

Option	Variable	Description
none	version	Version number of the Edge Encryption proxy being used to perform the current operation.
-m	mode	Runtime mode. Options are "install" for a new Edge proxy server or “dist-upgrade” to upgrade an existing Edge proxy server.
-n	proxy_name	Name of the installed Edge Encryption proxy server. Use a unique proxy_name to be able to identify specific proxy instances.
--instancehost	host	The host name of your ServiceNow instance (for example, `mycompany.service-now.com`).
-p	port	Port your ServiceNow instance listens on. Typically secure HTTPS connections listen on port **443** and HTTP connections listen on port **80**.
--protocol	protocol	Protocol the installed Edge proxy uses when connecting to the backend ServiceNow host. This is typically **HTTPS**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Option	Variable	Description
		(preferred for secure TLS connections) or **HTTP** (connections without TLS) depending on which protocol the host instance supports.
-s	install_path	Path to the directory or folder where the new Edge proxy is installed (the destination directory). If the directory does not already exist, this command will create it. If it does exist it must not contain an existing installation. If this option is skipped, the default folder name is derived from the proxy_name and port (for example, `EdgeProxy_443`), in the current directory.

Note:
Do not copy and paste commands from the browser. Occasionally, copy/paste operations cause unexpected characters to be pasted to the target machine and results in the command being executed incorrectly. It is best to type out the command by hand using documentation as a reference.

To see the help screen, execute this command with the `–help` option: `java -jar edgeencryption-<version>-all.jar --help`

5. If installing on a Windows machine, install the Edge Encryption proxy as a Windows service.

   a. **Optional:** Change the name of the service by opening the `conf/wrapper.conf` file on the new proxy and setting the properties in the following table.

Property	Description
wrapper.ntservice.name	Unique name of the Edge Encryption proxy service.
wrapper.ntservice.displayname	Edge Encryption proxy service display name.
wrapper.ntservice.description (Optional)	Proxy server description.

   If this step is not performed, the Edge Encryption proxy service is installed under the name **Edge Encryption**.

   b. Save and close the file.

   c. Open the Windows Command Prompt and `cd` to `ServerName_port/bin`.

   d. Execute `edgeencryption.bat install`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Result

The `ProxyName_port` directory is created in the current directory. The `edgeencryption.properties` file is updated with the host, port, and protocol values from the command line.

Create and configure the RSA key pair for the digital signature

Create an RSA key pair that the proxy server can use to create the digital signature for signing changes to the encryption properties and configuration.

Before you begin

Role required: admin

To generate and validate the digital signature, an RSA key pair must be generated and stored in the JCEKS Java KeyStore and each proxy must be configured to use this key pair. Generate an encryption key pair using the keytool command.

To use the keytool utility with a proxy installed on SElinux (CentOS), you must enable loading of shared libraries from the proxy java-installation directory. To do this, run the following command as root.

```
chcon -R -t texrel_shlib_t proxy_install_dir/java/jre /lib
```

You must use the Java 1.8 version of the keytool utility. A copy of the utility can be found in `<proxy install dir>java/jre/bin/keytool`.

Procedure

1. Change to the KeyStore directory in the proxy download directory.
2. Change the default password.

   The default password is *changeme*.

   ```
   keytool -keystore keystore.jceks -storetype jceks -storepasswd
    -new <newpassword>
   ```

3. Create an encryption key pair.

   Note:
   Do not enter a password for the key when the keytool utility prompts for one.

   Enter this command on a single line.

   ```
   keytool -genkeypair -alias <key alias> -keyalg rsa -keystore
    keystore.jceks
   -storetype jceks -storepass <keystore password> -keysize 2048
   ```

4. Update the encryption proxy property file (`edgeencryption.properties`).

   a. Change to the `<installation directory>/conf/` directory.

   b. Open the `edgeencryption.properties` file.

   c. Enter the properties for the digital signature.

      These properties must be the same for all proxies.

5. Save and close the `edgeencryption.properties` file.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Import and configure the certificate for secure SSL connection

To use a secure SSL connection, import a server certificate and add it to the Java KeyStore.

Before you begin

Role required: admin

You must obtain the server certificate and matching private key before adding it to the Java KeyStore.

Procedure

1. Generate a Certificate Signing Request (CSR) using the `openssl` command.

```
openssl req -newkey rsa:2048 -keyout PRIVATEKEY.key -out
 MYCSR.csr
```

2. Send your CSR (MYCSR.csr in the example above) to your certificate authority to have it signed.
3. Create a P12 keystore for import using the `openssl` command.

```
openssl pkcs12 -export -in MYSIGNEDCERT.pem -inkey
 PRIVATEKEY.key -name shared > MY_SERVER.p12
```

4. Store your certificate and private key into a jceks file.

```
keytool -importkeystore -destkeystore keystore.jceks
 -deststoretype jceks -srckeystore MY_SERVER.p12 -srcstoretype
 pkcs12 -alias MYALIAS
```

   The alias, shown in the example as `MYALIAS` can be any value. You will use this alias in the `edgeencryption.proxy.https.cert.alias` property in the `edgeencryption.properties` file located in the `<installation directory>/conf/` folder.
5. Stop and restart the edge proxy.

> **Note:**
> During a restart, the proxy server is offline for a short time. The amount of time is determined by your environment and how long it takes to stop and restart the proxy service.

Set up a keystore and encryption keys

Set up the keystore and encryption keys used by the Edge Encryption proxy server.

Before you begin

Role required: security_admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Carefully determine the appropriate type of keystore to use based on your organization's needs.

Supported keystore	Description
File store	Keys are stored in a file in a file system accessed by the Edge Encryption proxy server. Because encryption keys stored in a file are not encrypted, it is your responsibility to protect these files.
Java KeyStore	A Java KeyStore: ○ Stores keys in a Java JCEKS KeyStore. ○ Is password protected and more secure than storing keys in a file in the file system. ○ Can store multiple keys. A key alias represents each key, making it easier to manage multiple keys. The Edge Encryption proxy ships with the Java JCEKS KeyStore file named `keystore.jceks` in the `keystore` directory. This keystore file contains the ServiceNow public key used to validate encryption rules signed by ServiceNow.
Enterprise Key Management (EKM)	**SafeNet KeySecure** Keys are stored and retrieved with SafeNet KeySecure key management. You must secure a license with Gemalto, download the libraries, and install the SafeNet KeySecure keystore on a host machine in your network before configuring the keystore on the Edge Encryption proxy server. **Unbound Technology** The base64-encoded wrapped encryption key is stored as text file on the Edge Encryption proxy server. The Unbound Technology implementation (previously Dyadic Security) maintains control of the wrapping key. The Edge Encryption proxy server must run on the same machine as the Unbound technology client.

Note:
If using a keystore other than the base system Java JCEKS KeyStore, you must import the ServiceNow public key into your keystore. The public key alias is *`servicenow`*.

2. Set up the keystore and encryption keys in your local network.

Set up a Java KeyStore keystore

You can use a Java KeyStore keystore to store encryption keys.

Before you begin
Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

You must use the Java 1.8 version of the keytool utility. A copy of the utility can be found in `<proxy install dir>/java/jre/bin/keytool`.

About this task

The Edge Encryption proxy ships with the Java JCEKS KeyStore file named `keystore.jceks` in the `keystore` directory. This keystore file contains the ServiceNow public key used to validate encryption rules signed by ServiceNow.

Procedure

1. Set up the keystore properties.
   a. Change to the `<installation directory>/conf/` directory.
   b. Open the `edgeencryption.properties` file.
   c. Enter the properties for the Java KeyStore.
2. Save and close the `edgeencryption.properties` file.

What to do next

After setting up the Java KeyStore, Create encryption keys using the Java KeyStore keytool.

Create encryption keys using the Java KeyStore keytool

You can use the keytool shipped with the encryption proxy distribution to create AES 128-bit and AES 256-bit encryption keys.

Before you begin

Role required: admin

You must use the Java 1.8 version of the keytool utility. A copy of the utility can be found in `<proxy install dir>/java/jre/bin/keytool`.

To find out more about the keytool utility, see the Java SE Documentation.

About this task

Note:
The Java KeyStore requires that the alias name (key name, key alias) use lowercase letters and numbers.

Procedure

1. Change to the keystore directory, `<installation directory>/keystore/`.
2. To create the encryption key, run one of the following commands.

Note:
If you choose to run these commands from a directory other than the keystore directory, that is you skipped the previous step, you must change the *-keystore* option to include the path from your current directory to the keystore directory. For example, if you were in the `<installation directory>\bin` directory, the option would be `-keystore ../keystore/keystore.jceks`.

Option	Description
AES 128	`keytool -genseckey -alias 128bitkey -keyalg aes -keysize 128 -keystore keystore.jceks -storetype jceks`

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Option	Description
AES 256	`keytool -genseckey -alias 256bitkey -keyalg aes -keysize 256 -keystore keystore.jceks -storetype jceks`

You add the alias on the instance when you assign default keys.

Note:
The key password must be the same as the keystore password.

Set up a SafeNet KeySecure keystore

If you are using a SafeNet keystore, copy a set of libraries into the proxy distribution directory.

Before you begin
Role required: admin

You must install and set up the SafeNet keystore before performing this step. Secure a license with Thales in order to download the libraries.

Note:
For IngrianNAE version 8.12, you must also download the `commons-collections.jar` file

About this task

Note:
On Linux, file paths use a forward slash (/).

Procedure

1. Change to the `<installation directory>/conf/` directory, and open the `edgeencryption.properties` file.
2. Enter the properties for the SafeNet keystore.

Note:
You may configure SafeNet keystore using with username/password authentication or client certificate authentication, but not a combination of both.

Example

An example for a SafeNet keystore using username and password authentication.

```
edgeencryption.nae.retries = 3
edgeencryption.nae.enabled = true
edgeencryption.nae.server = url
edgeencryption.nae.port = 9000
edgeencryption.nae.protocol = ssl
edgeencryption.nae.keystore.path = keystore/safenet_truststore
edgeencryption.nae.keystore.password = password
edgeencryption.nae.user = safenet_user
edgeencryption.nae.password = safenet_password
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Example

An example for a SafeNet keystore using client certificate authentication. This authentication method eliminates the need to store the SafeNet server username and password in the properties file.

```
edgeencryption.nae.retries = 3
edgeencryption.nae.enabled = true
edgeencryption.nae.server = url
edgeencryption.nae.port = 9000
edgeencryption.nae.protocol = ssl
edgeencryption.nae.keystore.path = keystore/safenet_clientcert
edgeencryption.nae.keystore.password = password
edgeencryption.nae.client.certificate = cert_name
```

3. Add or create a key in the SafeNet keystore.
   You add the key name (alias) on the instance when you assign default keys.
4. Save and close the `edgeencryption.properties` file.

Upgrade from Kingston or lower to London or higher

If you use a SafeNet NAE server for key storage with Edge, before upgrading the proxy from Kingston or lower to London or higher, you must copy Gemalto SafeNet client ProtectApp JAR files and add new properties.

Before you begin

Role required: admin

About this task

Note:
On Linux, file paths use a forward slash (/).

Procedure

1. Copy the following files from `<installation directory>/lib` to the `<installation directory>/nae directory`:
   - `commons-collections<version>.jar`
   - `ingrianlog4j-api-<version>.jar`
   - `ingrianlog4j-core-<version>.jar`
   - `ingrianNAE-<version>.jar`
2. On the current version (not upgraded) of the proxy, update the `<installation directory>/conf/edgeencryption.properties` file by adding the following two properties:
   - *`edgeencryption.ekm.provider.classname`* = `com.snc.edgeencryption.encryption.CloudEdgeNaeKeyProvider`
   - *`edgeencryption.thirdparty.vendor.library.path`* = `<directory path to the directory where you copied the jar files in step 1>`

     Note:
     `edgeencryption.thirdparty.vendor.library.path` for Java 11.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. Save the changes.
4. Proceed with the upgrade to London or higher.

Set up Unbound Technology keys

Use Unbound Technology (previously Dyadic Security) keys with Edge Encryption by storing the base64-encoded wrapped encryption key as text file on the Edge Encryption proxy server and providing the wrapping key alias. The Unbound Technology implementation maintains control of the wrapping key.

Before you begin

Role required: security_admin

In your Unbound Technology implementation, identify both the wrapping key and the wrapped key. Use the RSA/ECB/OAEPWITHSHA-256ANDMGF1PADDING algorithm for wrapping and padding. Export the wrapped key in base64-encoded text format. Save the file using the key alias as the name with no file extension.

Note:
If using Unbound Technology encryption keys with Edge Encryption, install the proxy server using the command line installer on the Unbound client machine. The Edge Encryption proxy server must run on the same machine as the Unbound technology client.

Procedure

1. Add the wrapped encryption key in base64-encoded text format to the `<proxy-installation-directory>/keys` directory.
   The name of the file must be the key alias with no file extension.
2. Update the `edgeencryption.properties` file.

   a. Change to the `<proxy-installation-directory>/conf` directory.

   b. Open the `edgeencryption.properties` file.

   c. Enter the File store properties and set the value of *`edgeencryption.keyfile.directory`* to `keys`.

   This property directs the proxy server to look for the encryption key in the `<Java-home-directory>/keys` directory.

   For more information on Edge Encryption properties, see Edge Encryption proxy server properties.

   d. Uncomment the properties for the Dyadic provider configuration and set the value of *`edgeencryption.ekm.provider.rsa.wrapping.key.alias`* to the wrapping key alias in your Unbound implementation.

   e. Save and close the file.

What to do next

Add the encryption key alias to the instance. The encryption key alias is the file name of the wrapped encryption key added to the `<proxy-installation-directory>/keys` directory. For example, if the file in the directory is named `myunboundkey`, add this name to the **Key alias** field. See Configure encryption keys on the instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Create an encryption key stored in a file

You can use a simple text file as a keystore. Each file holds a single encryption key.

Before you begin
Role required: admin

About this task
This step creates both the key storage and the encryption key.

> **Note:**
> The name of the key file must match the key alias specified in the encryption keys table in the instance. See Configure encryption keys on the instance.

Procedure

1. Create a file in the `/keys` folder of the proxy server installation directory.
2. Add the encryption key to the file.

Option	Description
AES 128	Place the encryption key, exactly 16 bytes, in to the file.
AES 256	Place the encryption key, exactly 32 bytes, in to the file.

3. Update the `edgeencryption.properties` file.
   a. Change to the `<installation directory>/conf/` directory.
   b. Open the `edgeencryption.properties` file.
   c. Enter the properties for the file store.
   d. Save and close the file.

Configure encryption keys on the instance

Edge Encryption provides the tools to manage encryption keys without taking the proxy offline.

Before you begin
Role required: security_admin

Before setting up new encryption keys on the instance:

1. Create the encryption key.
2. Make the new key available to all encryption proxies. Either copy the file or Java KeyStore file to each proxy, or ensure that each proxy has access to the Java KeyStore or Enterprise Key Management (EKM) device.

About this task
Key aliases must be unique. Each key alias must have the same key size and type on each proxy, or the key cannot be assigned as the default.

Procedure

1. Navigate to **All** > **Edge Encryption Configuration** > **Encryption Key Configuration** > **Set Up Keys**.
2. On the Add New Keys section of the form, complete the following steps to add a new key.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Important:
If using SafeNet versioned keys, an additional column appears for the **Key version**. The **Key version** cannot be edited. Click the **Retrieve latest key versions** link in the Related Links to retrieve the latest version of each key from the Edge proxy.

Rows in the list with an **X** in the left column can be deleted. Keys that have been used as the default or that have a **Status** of **Available** cannot be deleted.

a. Double-click in the row that says **Insert a new row.**.

b. In the edit box, enter a name for the key, then click the check mark.

Key aliases are lowercase letters and numbers. Capital letters are changed to lowercase letters when you click **Update**. Key aliases must be unique.

Note:
If using Unbound technology keys, add the encryption key alias. The encryption key alias is the file name of the wrapped encryption key added to the `<proxy-installation-directory>/keys` directory. For example, if the file in the directory is named `myunboundkey`, add this name to the **Key alias** field.

c. In the same row, double-click in the **Key size** column.

d. In the select box, select a key size, either **128 bits** or **256 bits**, then click the check mark.

e. In the same row, double-click in the **Type** column.

f. In the select box, select a key type, either **File**, **Keystore**, **SafeNet**, or **Unbound**, then click the check mark.

g. When you are done adding keys, click **Next Step**.
You must specify an alias, key size, and key type for each key before moving on.

3. On the Keys Status section of the form, check the **State** of the key and ensure that it is **Available**.
4. When the key is **Available**, click **Next Step**.
This might take a few minutes.

Note:
If using SafeNet versioned keys, an additional column appears for the **Key version**. The **Key version** cannot be edited.

The instance tracks the status of every encryption key available to any proxy. When a key is available on all proxies, its state becomes **Available**. If the state does not change after a few minutes, check to ensure that the key is available on all proxies. If the state remains **Unavailable**, one or more of the proxies does not have the key.

Encryption key states

Status	Description
Available	All online proxies have the key.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Status	Description
Unavailable	This is a new key and the proxies have not yet loaded the key, or at least one proxy failed to load the key.

5. On the Change Default Keys section of the form, do one of the following:
   - Type in the key alias.
   - Click the magnifying glass icon and select an alias.

   Note:
   If using SafeNet versioned keys, an additional field appears for the **Key version**. The **Key version** is grayed out and cannot be edited. Choose only the most recent key version. If you choose an earlier version, the following message appears when you click **Update** or **Next Step**.

   ```
   One of the default keys chosen is not the latest version
    available for the key. Please use the latest version.
   ```

   If the default keys are not the latest versions of the SafeNet keys, an **Update default keys to latest version** link appears in the Related Links. Click the link to update the default keys to use the latest version.

6. On the Schedule Key Rotation section of the form, schedule a mass key rotation job or single key rotation job to encrypt existing data using the new encryption key.

   If you do not run a mass key rotation job or single key rotation job, existing data remains encrypted with the old key until the data is accessed again.

Configure additional properties in the Edge Encryption properties file

After installing the Edge Encryption proxy server in your network and setting up your keystore and keys, configure the additional Edge Encryption properties.

Before you begin
Role required: admin

Procedure
1. Open the `<installation directory>/conf/edgeencryption.properties` file and configure the following Edge Encryption proxy server properties:
   - Target (instance) properties
   - User account properties
   - Proxy properties
   - If using order preserving encryption types or encryption patterns, configure the Proxy database properties
   - Clear text and static IV properties
2. Save and close the file.

Configure a web proxy

If your network uses a web proxy, you can set up the Edge Encryption proxy to use the web proxy.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin
Role required: admin

About this task
If your network does not use a web proxy, leave the web proxy properties in the configuration file commented out.

The Edge Encryption proxy server supports HTTP connection to and basic authentication with the web proxy.

Procedure
1. Change to the `<installation directory>/conf/` directory.
2. Open the `edgeencryption.properties` file.
3. Configure the web proxy properties.
4. Save and close the `edgeencryption.properties` file.
5. If the web proxy is using a customer-specific server certificate, add this certificate to the JVM used by the Edge Encryption proxy server to establish trust between the web proxy and the Edge Encryption proxy server.
   a. Use the `cd` command to navigate to `<Java home directory>/jre/lib/security/cacerts`
   b. Execute the command: `keytool -keystore cacerts -importcert -alias <chooseAlias> -file <certificateFile>`

Set the proxy server initial memory limit and upper bound memory limit

Set the initial memory limit and upper bound memory limit to specify how much memory the proxy server can consume. Set these limits to avoid performance issues in your Edge Encryption implementation.

Before you begin
Role required: admin

About this task
As a guideline, set both the initial memory limit and the upper bound memory limit to the same value. On any machine, allocate 2 GB of the physical memory to the operating system (OS). Then allocate the rest of the physical memory to the heap using the initial memory limit and upper bound memory limit properties. For example, on a machine with 8 GB of memory, allocate 2 GB to the OS, and allocate the remaining 6 GB (6144 m) to the initial and upper bound memory.

Important:
If your Edge Encryption proxy server is running, you must stop and restart the proxy server after updating these properties.

Procedure
1. In your proxy server directory, open `<install dir>/conf/wrapper.conf`.
2. To set the initial memory limit, add the following line at the end of the file:

```
wrapper.java.additional.<number>=-Xms<min_memory_in_MB>m
```

   Set `<number>` to the next available `<number>` in the sequence of `wrapper.java.additional.<number>` properties defined in the `wrapper.conf` file.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Example
For example, you have the following list of `wrapper.java.additional.<number>` properties:

```
wrapper.java.additional.1=
wrapper.java.additional.2=
```

The maximum `<number>` in the above list is **2**. When you add the `wrapper.java.additional.<number>=-Xms<min_memory_in_MB>m` line, set `<number>` to **3**, the next available number.

Important:
Do not leave gaps in the numbering sequence.

Set `<min_memory_in_MB>` to the number of megabytes of memory remaining after allocating 2 GB of memory to the OS.

3. Set the upper bound memory limit.
Because an upper bound memory limit is not set in the base system, the proxy server can use all available memory. If other services are running on the server, you may want to set the upper bound memory limit.

   Add the following line at the end of the file:

   `wrapper.java.additional.<number>=-Xmx<max_memory_in_MB>m`

   Set `<number>` to the next available `<number>` in the sequence of `wrapper.java.additional.<number>` properties defined in the `wrapper.conf` file.

   Example
   For example, you have the following list of `wrapper.java.additional.<number>` properties:

   ```
   wrapper.java.additional.1=
   wrapper.java.additional.2=
   ```

   The maximum `<number>` in the above list is **2**. When you add the `wrapper.java.additional.<number>=-Xmx<max_memory_in_MB>m` line, set `<number>` to **3**, the next available number.

   Note:
   Do not leave gaps in the numbering sequence.

   Set `<max_memory_in_MB>` to the number of megabytes of memory remaining after allocating 2 GB of memory to the OS.

4. Save and close the file.

Example: Example: Setting proxy server initial and upper bound memory limits

```
wrapper.java.additional.1 = -Djava.io.tmpdir=../tmp
wrapper.java.additional.2 = -Dcloudedge.home.dist=..
# must ensure UTF8 encoding when running on Windows
wrapper.java.additional.3 = -Dfile.encoding=UTF8
# additional properties for heap settings
wrapper.java.additional.4 = -Xms6144m
wrapper.java.additional.5 = -Xmx6144m
```

© 2026 ServiceNow, Inc. All rights reserved.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

What to do next
Start the Edge Encryption proxy.

Start the Edge Encryption proxy

After an Edge Encryption proxy is installed and configured, you can start the proxy from the command line.

Before you begin
Role required: admin

Before starting the encryption proxy, verify the following:

- The Edge Encryption plugin is activated on the instance.
- The `edgeencryption.properties` file on this machine has been configured.
- If using an order preserving encryption type or encryption patterns, the proxy database is running.

Note:
The first time you set up the `edgeencryption.properties` file or change properties, you may not want to set the password encryption property. After you have verified that everything is working, you can set the password encryption property, shut down the proxy, and then restart the proxy.

Procedure

1. Run the proxy server.

Option	Description
On a Linux machine	**a.** cd to `ServerName_port` **b.** Execute `./startup.sh`
On a Windows machine	Perform the following steps from the com mand line as admin: **a.** cd to `ServerName_port/bin` **b.** Execute `edgeencryption.bat start`

2. Check the log on the proxy server to verify that the proxy is running.

Obfuscate passwords in the properties file

Obfuscate passwords in the `edgeencryption.properties` file to be able to share the properties file without revealing clear text passwords.

Before you begin
Role required: admin

Make sure that the Edge Encryption proxy server is set up and successfully running before you set this property. Before setting this property, Stop the Edge Encryption proxy.

About this task
Setting this property may make it difficult to debug connection and access issues during initial startup. Only set this property in production environments after the proxy has been set up and tested successfully.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Change to the `<installation directory>/conf/` directory.
2. In the `conf` directory, create a text file containing a complex string or phrase that can be used as a passphrase which the proxy uses to obfuscate the passwords in the `edgeencryption.properties` file.
   This passphrase should be a random and complex phrase not related to the passwords themselves.
3. Open the `edgeencryption.properties` file.
4. Set the password encryption property.
5. Save and close the `edgeencryption.properties` file.

What to do next
After setting this property, you can Start the Edge Encryption proxy.

Manually add an additional proxy

After the first Edge Encryption proxy is properly configured and tested, you can set up additional proxies on a Linux or Windows machine. Installing multiple proxies on the same machine is not recommended.

Before you begin
Role required: admin

About this task
Add additional proxy servers on additional machines to ensure an optimal environment. See Sizing your Edge Encryption environment to determine the number of additional proxies needed.

Note:
Make sure that all proxies have the same encryption keys and the same RSA key pair used to digitally sign encryption configuration and encryption rules. If a proxy database was set up as part of the installation, all proxies must use the same proxy database.

Procedure

1. Install the proxy using the appropriate command.
   For more information, see Install the Edge Encryption proxy server (interactive installer).
2. Copy all the encryption keys and the `edgeencryption.properties` file from the first proxy to the new proxy.
   Encryption keys may be located in the proxy keystore, in the `/keys` directory, or in a SafeNet KeySecure keystore.
3. Open the `edgeencryption.properties` file on the new proxy.
4. Change the following properties:

Property	Description
edgeencryption.proxy.name	Unique name of the proxy server
edgeencryption.proxy.host	The server name, IP address, or fully-qualified domain name of the computer running the proxy.
edgeencryption.proxy.http.port	Port on the proxy for HTTP communication. Must be unique across all processes on the machine.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property	Description
edgeencryption.proxy.https.port	Port on the proxy for HTTPS communication. Must be unique across processes on the machine.

5. If installing the proxy server on a Windows machine, you must change the name of the service. by opening the `conf/wrapper.conf` file on the new proxy and adding the properties listed in the following table.

Note:
You must perform this step before launching the proxy server.

Property	Description
wrapper.ntservice.name	Unique name of the Edge Encryption proxy service.
wrapper.ntservice.displayname	Edge Encryption proxy service display name.
wrapper.ntservice.description (Optional)	Proxy server description.

6. Save and close the file.
7. Launch the proxy using the appropriate command.
For more information, see Start the Edge Encryption proxy.

Authenticate an Edge Encryption proxy server

Specify that a proxy server is a trusted source so that Edge Encryption can process requests coming from that proxy server.

Before you begin

If a proxy server is not authenticated, the console log includes the following message:

```
WARN This Edge Encryption proxy has not yet been authenticated
 by the instance.
Please navigate to the matching Proxy record on your ServiceNow
 instance and authenticate it.
```

If you attempt to access the proxy, you receive the following message: `This site can't be reached`.

To maintain the proxy in an operational state during the upgrade process, authentication is not required until after the proxy update is successful.

Role required: admin

Procedure

1. Navigate to **All** > **Edge Encryption Configuration** > **Proxies**.
2. Select the proxy and click **Authenticate**.

Result

The proxy moves from **Unauthenticated** to **Pending** to **Authenticated**. The status changes from **Unauthenticated** to **Pending** when you start the authentication. When authentication is

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

complete, the status changes from **Pending** to **Authenticated**, and you can access the proxy and Edge Encryption can accept requests from the proxy.

Note:
If you stop and restart the proxy, the proxy remains **Authenticated** and restarts successfully.

Stop the Edge Encryption proxy

You can stop an Edge Encryption proxy from the command line.

Before you begin
Role required: admin

Procedure

1. Stop the proxy server.

Option	Description
On a Linux machine	Execute `./shutdown.sh`
On a Windows machine	Execute `edgeencryption.bat stop` To remove the Windows service, execute `edgeencryption.bat remove`

2. Check the log on the proxy server to verify that the proxy has stopped.

Uninstall the Edge Encryption proxy on Linux

You can uninstall the Edge Encryption proxy. If you are upgrading the proxy, it is not necessary to shut down and uninstall the current version.

Before you begin
Role required: admin

You must have access to the computer running the Edge Encryption proxy.

About this task
Before shutting down the Edge Encryption proxy, ensure that no users are connected to the instance using the proxy.

The encryption proxy running on Linux operates as a single process. You can end this process to accommodate such tasks as redeploying the encryption proxy to another host machine, updating the proxy version, updating the Java version, or changing the unique name of the encryption proxy when deploying the encryption proxy on multiple proxy servers.

Procedure

1. You may want to save the `edgeencryption.properties` file before deleting the distribution directory.
2. Execute the `shutdown.sh` shell script.
3. Check the log on the proxy server to verify that the proxy server is shut down.
4. Delete the files in the distribution folder.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Uninstall the Edge Encryption proxy on Windows

You can uninstall the Edge Encryption proxy. If you are upgrading the proxy, it is not necessary to shut down and uninstall the current version.

Before you begin

Role required: admin

You must have access to the computer running the Edge Encryption proxy.

Before shutting down the Edge Encryption proxy, ensure that no users are connected to the instance using the proxy.

Procedure

1. You may want to save the `edgeencryption.properties` file before deleting the distribution directory.
2. Execute `edgeencryption.bat stop`
3. Execute `edgeencryption.bat remove`
4. Check the log on the proxy server to verify that the proxy server is shutdown.
5. Delete the files in the distribution folder.

Set up multiple provider SSO with Edge Encryption

Set up multiple provider SSO to enable logging in through the Edge Encryption proxy server URL or the instance URL. If you are implementing multiple provider single sign-on (SSO) with Edge Encryption enabled, some users might need to log in to your instance through the Edge Encryption proxy server, while other users might not.

Before you begin

- Enable the Integration - Multiple Provider Single Sign-On Installer plugin (com.snc.integration.sso.multi.installer).
- Enable the Edge Encryption plugin (com.glide.edgeencryption) and ensure that one or more proxy servers are set up in your network.
- Determine the URL for the Edge Encryption proxy server that users will log in through using multiple provider SSO. To determine the URL of an Edge Encryption proxy server, see Installing Edge Encryption.

Role required: admin

About this task

The user logging in will need to use the appropriate URL to log in, either using the Edge Proxy or not using the Edge Proxy.

- If routing all users through the Edge Encryption proxy server, set up your identify provider record and define the proxy server URL in the **ServiceNow Homepage**, **Entity ID / Issuer**, and **Audience URI** fields.
- To route some users through the proxy server and some users to the instance, create two identify provider records. Both records use the same value in the **Identity Provider URL** field. However, one of the records routes through the proxy server, while the other routes to the instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Login via instance name: `https://<instance name>.service-now.com/login_with_sso.do?glide_sso_id=<sys_id` of IdP record for non-Edge Proxy
- Log in via Edge Proxy: `https://<edge hostname>:<port>/login_with_sso.do?glide_sso_id=<sys_id` of the IdP record for the Edge Proxy

Procedure

1. Enable the duplication of identity provider URLs in identity provider records.
   A unique constraint prevents duplication of the identity provider URL in two different identity provider records. You can enable duplication of the identity provider URL in multiple IdP records by setting a field to false.
   a. Navigate to **System Definition** > **Dictionary**.
   b. Open the definition record for the **idp** field of in the Identity Providers table [saml2_update1_properties].
   c. Configure the form to add the **Unique** field.
   d. Ensure that the value of the **Unique** field is set to **false**.
2. Navigate to **Multi-Provider SSO** > **Identity Providers**.
3. Create two identity provider records for the same identity provider: one using the instance URL and one using the Edge Encryption proxy server URL.
   To create an identity provider record, see Create an external identity provider.

   a. For the Edge Encryption proxy server URL, complete the form using these values.

Field	Value
Identity Provider URL	Imported from IdP metadata.
ServiceNow Homepage	The URL for your proxy server homepage. For example: `https://<proxy hostname>:<port>/navpage.do`
Entity ID / Issuer	`https://<proxy hostname>:<port>`
Audience URI	`https://<proxy hostname>:<port>`

   b. Click **Submit**.

   c. For the instance URL, complete the form using these values.

Field	Value
Identity Provider URL	Imported from IdP metadata.
ServiceNow Homepage	`https://<instance>.service-now.com/navpage.do`
Entity ID / Issuer	`https://<instance>.service-now.com/navpage.do`
Audience URI	`https://<instance>.service-now.com/navpage.do`

   d. Click **Submit**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. **Optional:** If using more than one identity provider, modify the MultiSSO installation exit.

   a. Navigate to **System Definition** > **Installation Exits**.
   The system displays the current list of installation exits.

   b. Open the **MultiSSO** installation exit.

   c. Locate the following statement in the **Script** field.

```
var samlResponseTxt = request.getParameter("SAMLResponse");
if (!GlideSession.get().isLoggedIn() &&
 GlideStringUtil.notNil(samlResponseTxt)) {
    var idpRecord = this.getIdPRecord(request);
    if (idpRecord) {
        SSO_Helper.debug("IdP found based on SAML response: "
 + idpRecord.getUniqueValue());
        return new SSO_Helper(idpRecord.getUniqueValue(),
 false, null, true);
    }
}
```

   d. Replace the statement with the following code.

```
var samlResponseTxt = request.getParameter("SAMLResponse");
if (!GlideSession.get().isLoggedIn() &&
 GlideStringUtil.notNil(samlResponseTxt)) {
   /* // You have two profiles that use the same IdP entity
 id it cannot use
   // the IdP issuer / entity id from the response otherwise
 it may result in the
   // wrong IdP profile. IdP initiated login will not work
   var idpRecord = this.getIdPRecord(request);
   if (idpRecord) {
      SSO_Helper.debug("IdP found based on SAML response: " +
 idpRecord.getUniqueValue());
      return new SSO_Helper(idpRecord.getUniqueValue(),
 false, null, true);
      }*/
   return new SSO_Helper(null, true);
   }
```

   Note:
   IdP initiated login does not work in this configuration.

   e. Click **Update**.

5. **Optional:** If using more than one company, configure users for multi-provider SSO and update sys_id of the identity provider record depending on the user.

   (Optional) For more information, see Configure users for Multi-Provider SSO.

   - To configure a user to log in through the Edge Encryption proxy server, use the sys_id of the identity provider record that uses the Edge Encryption proxy server URL.
   - To configure a user to log in to the instance, use the sys_id of the identity provider record that uses the instance URL.

Login URLs

URL	Login destination
`https://<proxy hostname>:<port>/login_with_sso.do?glide_sso_id=<sys_id of the IdP record for the proxy server URL>`	Logs in through the proxy server.
`https://<instance name>.service-now.com/login_with_sso.do?glide_sso_id=<sys_id of IdP record for the instance URL>`	Logs in through the instance.

Edge Encryption proxy server properties

The `edgeencryption.properties` configuration file located in the `<installation directory>/conf/` folder contains properties used to configure your environment.

You must restart the proxy server after making changes to any proxy server properties.

Clear text and static IV properties

edgeencryption.customer.assigned.known.cleartext	Clear text to let the instance verify that all proxies are using the same keys. At startup, the proxy encrypts the clear text and sends the encrypted text to the instance. The instance does not know the clear text, nor are keys sent to the instance. This property must be the same for all proxies.
edgeencryption.encrypter.static.iv	Static IV (initialization vector) used in equality-preserving and order-preserving encryption. This property must be the same for all proxies and must be exactly 16 bytes (16 ASCII characters).

Digital signature properties

edgeencryption.proxy.signature.keystore.path	Path and Java KeyStore file name.
edgeencryption.proxy.signature.keystore.password	Password. The default password is <changeme>. Change the password after installing the Java KeyStore.
edgeencryption.proxy.signature.keystore.keyalias	The key alias given as the -alias argument when the RSA key pair is generated.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

File store property

edgeencryption.keyfile.directory	The directory specifies where key files are stored. If using the Java KeyStore or a SafeNet KeySecure keystore, leave this property commented out. Example: `edgeencryption.keyfile.directory=keys` If using Unbound Technology keys, uncomment this property and set the value to the keys directory.

General configuration properties

edgeencryption.config.poll.interval	Poll interval in seconds. The default setting means that it takes 5 seconds for the proxy to learn of encryption configuration changes. Larger values cause the instance to take longer to detect an offline proxy. **⚠ Warning:** Do not change this property. Changing the default setting of the Proxy Poll Interval can result in detection delays when a proxy comes online.
edgeencryption.rules.dir	Folder where the encryption rules are stored on the proxy.
edgeencryption.encryption.order_preserving.caching.enable	Setting determines whether caching is used to support order-preserving encryption types.
edgeencryption.encryption.order_preserving.cache.size	Maximum cache size, in bytes.
edgeencryption.jobs.concurrency	Maximum number of mass encryption jobs that can run concurrently on this proxy.
edgeencryption.jobs.requests_per_second	Number of http job requests per second that can be sent to the instance by this proxy.
edgeencryption.attachments.request.timeout.seconds	Attachment upload request timeout in seconds.
edgeencryption.request.buffer.size	Size of an encryption request. If an encryption request is larger than this size, the excess is saved to disk. **⚠ Warning:** Do not change this property.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

edgeencryption.httpclient.request.buffer.size	Size of the client request. If the client request is larger than this size, the excess is saved to disk. **⚠ Warning:** Do not change this property.
edgeencryption.httpclient.header.size	Size of the request/response header. • Minimum value: 8K • Maximum value: 32K **⚠ Warning:** Do not change this property.
edgeencryption.proxy.idle.timeout	Time in seconds after which a transaction times out. Default value: 300 (seconds)
edgeencryption.proxy.keepalive.interval	Time in seconds between pings issued by the proxy to the instance. Pings are issued periodically to verify connectivity between the proxy and the instance. • Default value: 10 (seconds) • Minimum value: 5 (seconds)
edgeencryption.register.retry.count	Maximum number of times the proxy pings the instance to try to register. Default value: 0 (no limit)
edgeencryption.tokenization.exclusion.list	Encryption patterns cannot tokenize strings found in these fields.

Java KeyStore properties

edgeencryption.keystore.path	Path to the Java KeyStore. If using a file store or a SafeNet KeySecure keystore, leave this property commented out. Example: `edgeencryption.keystore.path = keystore/keystore.jceks`
edgeencryption.keystore.password	Password the proxy uses to connect to the Java KeyStore. If using a file store or a SafeNet KeySecure keystore, leave this property commented out.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Logging properties

Logging properties are found in the lo4gj2.properties file found in the `<installation directory>/conf/` directory. These properties are only changed for troubleshooting or when directed by ServiceNow support. For details see How to increase debug logging for the Edge Encryption proxy.

NAE device keystore properties

edgeencryption.nae.retries	Number of retries to make.
edgeencryption.nae.enabled	Setting indicates whether an NAE device is available.
edgeencryption.nae.server	Name of the NAE server.
edgeencryption.nae.port	Port used by the NAE server.
edgeencryption.nae.protocol	Protocol used by the NAE server.
edgeencryption.nae.keystore.path	Path to the keystore on the NAE server.
edgeencryption.nae.keystore.password	NAE keystore password.
edgeencryption.nae.username	User name to use to authenticate with the NAE device.
edgeencryption.nae.password	Password to use to authenticate with the NAE device.
edgeencryption.nae.client.certificate	Certificate located in the keystore on the NAE server. Set this property to authenticate using a certificate instead of a username and password.

Password property

edgeencryption.encrypter.properties.password	Name of the file in the `conf` folder that contains a string used within a secure process to obfuscate passwords in the `edgeencryption.properties` file. **Note:** Name of the file in the `conf` folder that contains a string used within a secure process to obfuscate passwords in the `edgeencryption.properties` file.

Proxy properties

edgeencryption.proxy.host	Server name, IP address, or fully qualified domain name of the computer running the proxy. Along with the port, this property defines the URL used by the client to access the proxy server.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

edgeencryption.proxy.name	Proxy name. Must be unique for each proxy.
edgeencryption.proxy.http.port	Port on the proxy for HTTP communication.
edgeencryption.proxy.https.port	Port on the proxy for HTTPS communication.

Proxy configuration locked property

edgeencryption.proxy.locked	When true, the proxy does not accept encryption configuration changes or encryption rule changes from the instance. Set this property on the production instance after all encryption configurations and rules are final.

Proxy database properties

edgeencryption.db.url	Proxy database location. Must be the same for all encryption proxies connecting to the same instance.
edgeencryption.db.user	User name for accessing the proxy database. Must be the same for all encryption proxies connecting to the same instance.
edgeencryption.db.password	Password to access the proxy database. Must be the same for all encryption proxies connecting to the same instance.
edgeencryption.db.name	Proxy database name. Must be the same for all encryption proxies connecting to the same instance. The default for this property is `edgeencryption`.
edgeencryption.db.bootstrap.file	Bootstrap file for the proxy database. The file is relative to the `sql/` directory. Must be the same for all encryption proxies connecting to the same instance. **⚠ Warning:** Under normal circumstances, do not change this parameter.

Proxy server performance properties

Proxy server performance properties are not present in the configuration file by default. To change the default values, you must add the properties and restart the proxy server. For more information, see Edge Encryption diagnostics and performance.

edgeencryption.stat.collection.enabled	Enables the collection of statistics used by the Edge Encryption proxy server performance dashboard. Default value: true

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

	Add this property and set the value to false to disable the collection of statistics used by the Edge Encryption proxy server performance dashboard.
edgeencryption.stat.collection.interval	Interval length in seconds during which the Edge Encryption proxy server collects statistics. The value cannot be less than 30 seconds. Default value: 30 (seconds)

SSL certificate properties

Restart your proxy if you change the value of any SSL certificate property. The system uses the HTTPS keypair on startup to establish the proxy server connection and determine how the proxy answers client requests.

edgeencryption.proxy.https.cert.alias	Alias of the certificate provided by the proxy server to connecting clients.
edgeencryption.proxy.https.keystore.path	Path to the keystore that contains the HTTPS certificate.
edgeencryption.proxy.https.keystore.password	Password for the keystore that contains the HTTPS certificate.

Target (instance) properties

edgeencryption.target.host	Host name for the instance. Must be the same for all encryption proxies connecting to the same instance. This property is set when the proxy is installed. For example, `instancename.servicenow.com`
edgeencryption.target.port	Instance port. Must be the same for all encryption proxies connecting to the same instance. This property is set when the proxy is installed.
edgeencryption.target.protocol	Instance protocol. Must be the same for all encryption proxies connecting to the same instance. This property is set when the proxy is installed. Options include: • http • https

Unbound Technology provider properties

edgeencryption.ekm.provider.classname	Internal class name for the implementation.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

	Warning: Do not change this property.
edgeencryption.thirdparty.vendor.library.path	Path to the Unbound API JAR file on the Unbound client machine.
edgeencryption.ekm.provider.rsa.wrapping.key.alias	Wrapping key alias in the Unbound Technology implementation. Must be the same for all proxies.

User account properties

edgeencryption.target.username	User name that the proxy uses to log in to the instance. The user must have the edge_encryption role. See Set up an Edge Encryption user account.
edgeencryption.target.password	Password that the proxy uses to log in to the instance.

Web proxy properties

edgeencryption.webproxy.host	Web proxy name or IP address.
edgeencryption.webproxy.port	Port on the web proxy.
edgeencryption.webproxy.user	User name used to connect to the web proxy. If your web proxy does not use authentication, leave this property commented out.
edgeencryption.webproxy.password	Password to use to connect to the web proxy. If your web proxy does not use authentication, leave this property commented out.

Deprecated proxy encryption properties

edgeencryption.encrypter.default.key128

Specifies the name of the current AES 128 key. An AES 128 key must be available even if it is not used. Must be the same for all proxies.

Perform maintenance of these keys on the instance.

edgeencryption.encrypter.default.key256

Specifies the name of the current AES 256 key. Must be the same for all proxies.

Perform maintenance of these keys on the instance.

edgeencryption.encrypter.key

Specifies the key name for each key and is used to specify the default keys. This is the key alias integrated with the metadata that is included with each encrypted item and, therefore, is stored on the instance. The key name must use lowercase letters.

edgeencryption.encrypter.type

Specifies the type of encryption keystore system.

edgeencryption.encrypter.file

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Specifies the path and file name of the text file associated with the key.

edgeencryption.encrypter.password

Specifies the password for accessing the keystore.

CyberArk integration with the Edge proxy server

Use CyberArk to store passwords in a centralized and secure digital vault to secure passwords that were previously stored in clear text and secured by file access, or that were previously encrypted via a second file.

CyberArk AIM (Application Identity Management) prevents unauthorized access by eliminating hard-coded and visible passwords. AIM stores passwords in a digital vault on an independent hardened server, where the passwords are represented as digital credentials. The AIM clients (the Edge proxy servers) use CyberArk digital credentials and access the independent server to retrieve the secured passwords. No passwords are stored on the Edge proxy servers or in the instance.

CyberArk digital vault credentials

You must purchase and configure CyberArk before you can set up CyberArk integration with the Edge proxy server.

To add a credential to CyberArk (which is read by the Edge proxy), set the **Platform Name** of the credential to **Unix via SSH** and make sure you either create a **Custom** credential **Name** or write down the **Auto-generated** credential **Name**. When you configure the Edge proxy to use this credential, the proxy server matches this credential **Name** to the setting in the proxy.

Each credential entry holds a **Password** that is being secured, as well as a credential **Name** used by an application to access that password.

Note:
CyberArk credentials are not encryption keys.

Adding CyberArk during an Edge proxy installation

The proxy installer includes a new configuration page for a CyberArk integration. This page is optional if you do not want to include CyberArk when installing your proxy with the proxy installer. You can also manually set up and configure CyberArk integration in the configuration file.

The proxy installer also includes a new page for CyberArk protected credentials. This page allows configurations of different properties using a single credential name or multiple credential names. This page is optional if you do not want to include CyberArk when installing your proxy with the proxy installer.

CyberArk password protection

Any password field in the Edge proxy installer that has a CyberArk credential configured in the CyberArk vault and specified on the CyberArk Protected Credentials page of the installer is grayed out and contains the message `Protected by CyberArk`.

Using a load balancer with the Edge proxy server

You can use a load balancer to balance the load across the proxy servers in your Edge Encryption proxy setup. If the load balancer and proxy servers are using different ports, specify

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

the host name and HTTPS port of the load balancer to enable users to view responses on their browser.

Important:
All production environments should include at least two Edge Encryption proxy servers for redundancy.

Edge request processing without a load balancer

If you are not using a load balancer, a request is processed as described below.

1. The user issues a request from a browser.
2. The browser sends the request to the Edge proxy server.
3. The proxy server sends the request to the ServiceNow instance.
4. The ServiceNow instance returns the response to the proxy server.
5. The proxy server adds its own port number in the response header before returning the response to the user's browser.

The request is completed successfully because the user can view the response from the proxy server at the port number specified in the response header.

Edge request processing with a load balancer

However, if you are using a load balancer, the user's browser communicates directly with the load balancer, not with the proxy server. A request is processed as described below.

Note:
The following example uses 1025 as the proxy server port number.

1. The user issues a request from a browser.
2. The browser sends the request to a load balancer Virtual IP (VIP), also known as a Virtual Server.
3. The VIP is configured to point to the proxy server (for example, `10.2.200.148:1025`), so the load balancer forwards the request to the proxy server.
4. The proxy server sends the request to the ServiceNow instance.
5. The ServiceNow instance returns the response to the proxy server.
6. The proxy server rewrites the location header in the response with values configured in the properties for `risk-servicenow.dev.echonet:1025`.
   - **Host**: `edgencryption.proxy.host`
   - **HTTP port**: `edgeencryption.proxy.http.port`
   - **HTTPS port**: `edgeencryption.proxy.https.port`
7. The proxy server forwards the response to the load balancer with the location header pointing to the proxy server port.

The outcome depends on whether the load balancer and proxy servers are using the same port.

- If the load balancer and proxy servers are using the same port, the request succeeds because the user receives the response from the same port identified in the response header.
- If the load balancer and proxy servers are using different ports, the request fails because the user's browser communicates only with the load balancer, but the response is on the proxy server.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Solution

You could resolve the issue by simply using the load balancer and all Edge proxy servers on the same port, but this is not an ideal solution. A better solution is to enable the system to know which port the load balancer uses.

The following properties enable the Edge proxy server to reroute response messages to the load balancer if the proxy server and load balancer are using different ports.

- *`edgeencryption.proxy.rewrite.location.host`* specifies the host name used to access ServiceNow through the load balancer.
- *`edgeencryption.proxy.rewrite.location.https.port`* specifies the HTTPS port used to access ServiceNow through the load balancer.

Configure the load balancer

If the load balancer and proxy servers are using different ports, specify the host name and HTTPS port of the load balancer to enable users to view responses on their browser.

Before you begin

Roles required:

- local or domain administrator on a Windows host
- service user with full file system access on a Linux host

Procedure

1. Login to the proxy server host as admin, domain admin, or a service user.
2. Navigate to the installation directory for the Edge proxy and select `conf/edgeencryption.properties`.
3. Set the following properties:

Property	Description
edgeencryption.proxy.rewrite.location.host	If your Edge configuration includes a load balancer to balance the load among proxy servers, rewrites responses to the load balancer so requests can be completed. ○ If there is a load balancer in the proxy setup, specify the host name used to access ServiceNow through the load balancer. ○ Optional: If there is no load balancer in the proxy setup, you can set this value to the host name used by the proxy server.
edgeencryption.proxy.rewrite.location.https.port	If your Edge configuration includes a load balancer to balance the load among proxy servers, specifies the HTTPS port used to access ServiceNow through the load balancer.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property	Description
	○ If there is a load balancer in the configuration, specify the HTTPS port used to access ServiceNow through the load balancer. ○ Optional: If there is no load balancer in the configuration, you can set this value to the HTTPS port used by the proxy server.

4. Save the file.

Result
Requests can be completed because users can now view responses on their browser.

Upgrading Edge Encryption

Both instance upgrades and proxy server upgrades require special consideration in an Edge Encryption environment.

Instance upgrades

Instance upgrades in an Edge Encryption environment require caution to ensure that Edge controls work properly after the instance upgrade.

During an instance upgrade, you should not add, edit, or delete the following:

- Edge Encryption configurations
- Edge Encryption rules
- Edge Encryption tokenization patterns
- Edge Encryption scheduled jobs
- Edge Encryption key configurations
- Edge Encryption scheduled upgrades
- Edge Encryption denylist IP configurations

Any scheduled job running during the instance upgrade will not complete. To complete the interrupted job, rerun the job once the instance is upgraded. When you reschedule the job, the processing that occurred before the instance upgrade is not lost, and the job continues to process only the data that has not yet been processed.

Proxy server upgrades

Schedule a proxy upgrade to enable the instance to upgrade the Edge Encryption proxy server, or manually upgrade the proxy server at any time.

Warning:
For an upgrade on Windows, you may encounter file lock issues and the upgrade may fail. For the upgrade to succeed, you should not have any files open under the installation directory. Also, there should be no existing shell in the installation directory. In particular, if you start the proxy from the command line (via `bin\edgeencryption.bat install/start`) while in the installation directory, you should close that shell or move it out of the installation directory afterward. No files under the installation directory should be opened by an editor or by any other application.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Third party libraries

Third party libraries, such as Gemalto, are lost during instance and proxy server upgrades if they are kept in the same directory. You can perform the following to prevent the loss of third party libraries during upgrades:

1. Manually add the following property to edgeencryption.properties:

   ```
   edgeencryption.ekm.provider.classname =
   com.snc.edgeencryption.encryption.CloudEdgeNaeKeyProvider
   ```

2. Add the *edgeencryption.thirdparty.vendor.library.path* vendor library location property and set it to `/path/to/jars`.

   For example:

   ```
   edgeencryption.thirdparty.vendor.library.path = /app/servicenow/
   libs
   ```

3. Copy the SafeNet JARs into that path.

After you install the third party libraries outside of the Edge Encryption installation, they are no longer lost during upgrades.

Scheduled upgrades

Important:
During ServiceNow Instance upgrades, also upgrade your proxy server version to align with your Instance version and reduce the chance of compatibility issues.

Schedule an upgrade to allow the instance to upgrade the proxy server at the scheduled time. This functionality is available by default after upgrading. A scheduled upgrade includes these events:

1. The proxy server checks with the instance to see if there is a new version available for upgrade. New versions generally become available when the instance is upgraded.
2. The administrator receives a notification upon logging in when a new version of the proxy server is available.
3. The administrator can Schedule an Edge Encryption proxy server upgrade for each proxy server.

   Note:
   Only users with the security_admin role can create an upgrade schedule through the proxy server.

4. Once the upgrade is scheduled, the proxy server automatically upgrades at the scheduled time. During the upgrade, the proxy server is offline for only a short time.

   Note:
   Because the proxy server restarts during the upgrade, it is offline for a short time. The amount of time is determined by your environment and how long it takes to stop and restart the proxy service.

5. During the scheduled upgrade, a new proxy directory is created and your configuration files are copied to the new directory. New properties are written to your existing properties file. The following files or directories in your old proxy directory are copied to the new proxy directory.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- `/conf` directory
- `/keys` directory
- `/keystore` directory
- `java/jre/lib/security/cacerts` file

As a result, your keys, keystores, settings, and certificates are preserved.

Note:
Only the above files are copied to the new proxy directory. Any other customized files in the proxy server directory are not preserved during a scheduled upgrade. The upgrade log file can be found in the original proxy directory in the following folder: `<original-proxy-directory>/tmp/upgrade-wrapper/bin`.

Prerequisites for scheduled upgrades

Before scheduling an upgrade for an Edge Encryption proxy, ensure the following:

1. The *JAVA_HOME* environment variable points to a java installation on the machine that is outside the Edge Encryption proxy's directory structure.
2. The *JAVA_HOME* environment variable points to a java installation that is at version 1.8_u144 or higher.
3. The *-Djava.io.tmpdir* parameter in the wrapper.conf file of the Edge Encryption proxy points to a directory that is OUTSIDE the Edge Encryption proxy's directory structure, and the proxy has read/write/execute permissions on the directory. Optionally, you could comment out the parameter entirely so that Java uses its default tmp location.

Manual upgrades

Instead of creating an upgrade schedule, you can manually upgrade each proxy server through the command line. See Manually upgrade an Edge Encryption proxy server running on Linux or Manually upgrade an Edge Encryption proxy server running on Windows.

Proxy build status

You can easily identify whether a proxy server is out of date by navigating to **Edge Encryption Configuration** > **Proxies** > **All**. The status of your proxy build is indicated in the **Proxy build** column by the following colors:

Green

Your proxy server is up-to-date.

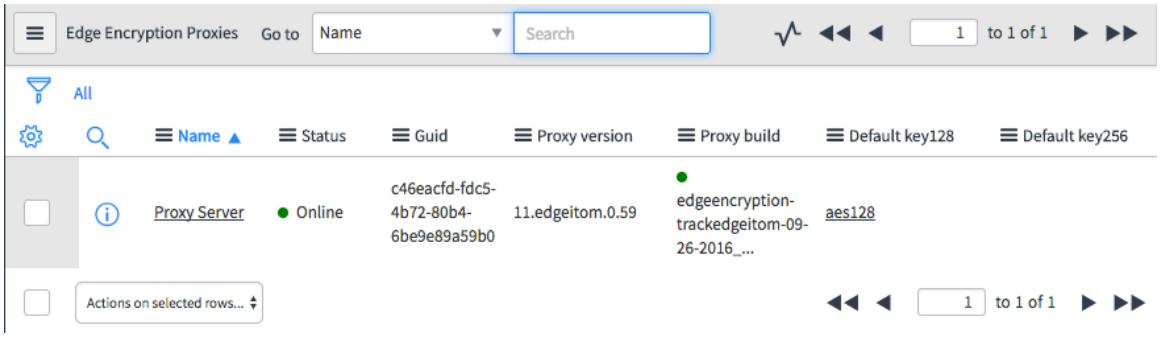
Yellow

Your proxy server is out-of-date and an upgrade is needed.

Orange

Upgrade failed. Your proxy server reverts to the old version to ensure that there is no downtime.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Troubleshoot a failed scheduled proxy upgrade

When a scheduled proxy upgrade fails, the proxy server reverts to the version you are upgrading from. All original data, keys, and configuration files are preserved. This process may take several minutes. Contact Customer Service and Support to ensure a successful upgrade.

To determine the reason for the failure, you can check the **Failure Reason** in the upgrade schedule. In addition, the installation directory for the failed upgrade is maintained so that log files are available for troubleshooting.

Note:
Before deleting any extra proxy directories, always confirm which directory is current by reviewing the log files. If the log files have recent activity, the proxy might be connected to your instance.

If a scheduled proxy upgrade fails repeatedly, you can manually upgrade your proxy server. See Manually upgrade an Edge Encryption proxy server running on Linux and Manually upgrade an Edge Encryption proxy server running on Windows.

Java minimum requirements

The host machine installing or running the Edge Encryption proxy server must maintain a supported version of Java. Current supported versions are Java 17.0.3 or later in the 17.x version series.

Note:
Java 11 is no longer be supported as of the Yokohama release. Upgrade your environment with the Edge Encryption proxy to Java 17 before you attempt to install Yokohama or later versions of the Edge Encryption proxy.

If using AES 256-bit encryption with Java 8 update 141 (8u141) or lower, you must install the Java Cryptography Extension (JCE) jurisdiction policy files by copying them into the system Java home directory of each Edge Encryption proxy server host. Add these files to the `<Java-home-directory>/jre/lib/security` folder before performing a scheduled or manual upgrade. To install the AES 256-bit encryption policy files, see Configure the AES 256-bit encryption key.

Mixed proxy-version environments

Although an environment running old versions of the proxy server with up-to-date versions of the proxy server is not recommended, it is supported if all proxy servers are within the same version family as your instance. For example, if you have an instance on the Zurich release, your environment supports proxy servers from any Zurich patch or hot fix. However, the following limitations apply.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- If one proxy server supports functionality that another proxy does not support, you will see inconsistent behavior, depending on which proxy server is used.
- If a proxy server is out-of-date, it may not include recent security enhancements.

If a proxy server from a previous release is registered with a newer release of the instance, you will receive regular notifications that the proxy server is out-of-date. To ensure an optimal and secure environment, ServiceNow recommends always upgrading your proxy server to the most recent version of the software supported by your instance.

Schedule an Edge Encryption proxy server upgrade

Create an upgrade schedule to enable the instance to upgrade an out-of-date proxy server.

Before you begin

To schedule an upgrade, you must be logged in to your instance through the proxy server.
If using AES 256-bit encryption with Java 8 update 141 (8u141) or lower, you must install the Java Cryptography Extension (JCE) jurisdiction policy files by copying them into the system Java home directory of each Edge Encryption proxy server host. Add these files to the `<Java-home-directory>/jre/lib/security` folder before performing a scheduled or manual upgrade. To install the AES 256-bit encryption policy files, see Configure the AES 256-bit encryption key.

Role required: security_admin

About this task

Once the upgrade is scheduled, the proxy server automatically upgrades at the scheduled time. During the upgrade, the proxy server is offline for only a short time.

Note:
Because the proxy server restarts during the upgrade, it is offline for a short time. The amount of time is determined by your environment and how long it takes to stop and restart the proxy service.

During the scheduled upgrade, a new proxy directory is created and your configuration files are copied to the new directory. New properties are written to your existing properties file. The following files or directories in your old proxy directory are copied to the new proxy directory.

- `/conf` directory
- `/keys` directory
- `/keystore` directory
- `java/jre/lib/security/cacerts` file

As a result, your keys, keystores, settings, and certificates are preserved.

Note:
Only the above files are copied to the new proxy directory. Any other customized files in the proxy server directory will not be preserved during a scheduled upgrade. The upgrade log file can be found in the original proxy directory in the following folder: `<original-proxy-directory>/tmp/upgrade-wrapper/bin`.

If multiple proxy servers are out-of-date, you must schedule an upgrade for each proxy server individually.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
Avoid hosting multiple proxy servers on the same machine. However, if your environment includes this configuration, do not schedule upgrades to multiple proxies on the same machine at the same time.

Procedure

1. Navigate to **All** > **Edge Encryption Configuration** > **Proxies** > **Upgrade Schedules**.
2. Click **New**.
3. Complete the form.

Edge Encryption Proxy Upgrade Schedule form

Field	Description
Proxy server	Proxy server being upgraded.
Target version	Version to which you are upgrading your proxy server. This value is read-only and set to the most up-to-date proxy version available for your instance.
Scheduled Start Time	Date and time on which to start the upgrade.
Active	Whether the scheduled upgrade is active. If this field is not selected, the upgrade will not perform on the scheduled date and time.
Status	The status of the upgrade. This value is read-only. Possible statuses include: ○ Pending ○ Running ○ Complete ○ Failed

4. Click **Submit**.

What to do next

The typical time for an upgrade is less that 15 minutes. After an upgrade is executed, you can review the upgrade details to learn more about it. If your upgrade failed, review the **Failure Reason** to determine next steps.

Upgrade details

Field	Description
From Version	The version that the server was upgraded from.
To Version	The version that the server was upgraded to.
Actual Start Time	Time that the upgrade began.
End Time	Time that the upgrade ended.
Failure Reason	Reason that the upgrade failed.

Manually upgrade an Edge Encryption proxy server running on Linux

Update a proxy running on Linux.

Before you begin

If using AES 256-bit encryption with Java 8 update 141 (8u141) or lower, you must install the Java Cryptography Extension (JCE) jurisdiction policy files by copying them into the system Java home directory of each Edge Encryption proxy server host. Add these files to the `<Java-home-directory>/jre/lib/security` folder before performing a scheduled or manual upgrade. To install the AES 256-bit encryption policy files, see Configure the AES 256-bit encryption key.

Role required: security_admin or local administrator on the host machine

Procedure

1. Download the Edge Encryption proxy-update archive file to the installation directory.
   a. Navigate to **Edge Encryption Configuration** > **Installation & Downloads** > **Downloads**
   b. Select the **Download the command line installer** link.
   c. When the download begins, select the your installation directory as the download location.
2. Change to the installation directory.
3. Run the following command:

```
java -jar edgeencryption-dist-<version>-linux-x86-64.jar -m
dist-upgrade -c <proxy directory>
```

Option	Description
proxy directory	The directory in the installation directory where the proxy was initially installed. This directory is created by the install.

If you want to see the help screen, execute this command without arguments: `java -jar edgeencryption-dist-<version>-linux-x86-64.jar`

A new proxy directory is created with a current timestamp. A backup of the old proxy directory is maintained as backup.dist-upgrade_timestamp in the new proxy installation directory. The old proxy shuts down and the new proxy starts up. Any open connections/transactions on the old proxy server are terminated.

4. Check the proxy log in the new directory and the instance to verify that the new proxy is running.

Manually upgrade an Edge Encryption proxy server running on Windows

Update a proxy running on Windows.

Before you begin

If using AES 256-bit encryption with Java 8 update 141 (8u141) or lower, you must install the Java Cryptography Extension (JCE) jurisdiction policy files by copying them into the system Java home directory of each Edge Encryption proxy server host. Add these files to the `<Java-home-directory>/jre/lib/security` folder before performing a scheduled or manual upgrade. To install the AES 256-bit encryption policy files, see Configure the AES 256-bit encryption key.

Role required: security_admin or local administrator on the host machine

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Download the Edge Encryption proxy-update archive file to the installation directory.
   a. Navigate to **Edge Encryption Configuration** > **Installation & Downloads** > **Downloads**
   b. Select the **Download the command line installer** link.
   c. When the download begins, select the your installation directory as the download location.
2. Start the Windows cmd terminal program with administrator privileges.
3. Change to the installation directory.
4. Run the following command:

```
java -jar edgeencryption-dist-<version>-all.jar -m dist-upgrade
-c <proxy directory>
```

Option	Description
proxy directory	The directory in the installation directory where the proxy was initially installed. This directory is created by the install.

   If you want to see the help screen, execute this command without arguments: `java -jar edgeencryption-dist-<version>-all.jar`

   A new proxy directory is created with a current timestamp. A backup of the old proxy directory is maintained as backup.dist-upgrade_timestamp in the new proxy installation directory. The old proxy shuts down and the new proxy starts up. Any open connections/transactions on the old proxy server are terminated.
5. Check the proxy log in the new directory and the instance to verify that the proxy has been updated and is running.

Roll back an Edge Encryption proxy server upgrade

If a proxy upgrade is unsuccessful, you can go back to the earlier version.

Before you begin

Role required: admin

About this task

If an upgrade fails when using the scheduled upgrade feature in the Zurich release, the proxy server will automatically roll back to the old version. The old proxy server is stored unmodified in a backup directory.

If you would like to roll back a manual upgrade, you can follow these steps.

Procedure

1. Shut down the proxy.
2. Delete the new proxy directory.
3. Rename the backup directory to the proxy name.
   The backup directory is in the proxy installation directory with the name `<proxy name>_backup`
4. Start the proxy.
5. Check the proxy log and the instance to verify that the proxy is online.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Configuring Edge Encryption

After the Edge Encryption proxy server is installed and running, manage Edge Encryption through the proxy server.

You must complete all the steps in Installing Edge Encryption before creating encryption configurations and encryption patterns on the instance.

Note:
To access the Edge Encryption configuration, you must log in through the proxy server and elevate to the security_admin role.

Rotate encryption keys

Perform encryption key rotation from the instance. Add a new key, change the default key assignment, and then schedule a mass key rotation or a single key rotation.

Before setting an encryption key as the default key, make the key available to each proxy. This ensures that the proxies have the key to encrypt data when the key is assigned as the default key. All proxies must have access to a key before that key can be assigned as the default key.

Warning:
Before deleting a key from the proxy, set up and run a mass key rotation job to ensure that no data on the instance uses the key. If any information is still encrypted with that key, you cannot decrypt the information after you delete the key.

Edge filtering and sorting behavior

Whenever you change default keys, be sure to perform a key rotation (either mass or single key rotation). Otherwise, you may receive unexpected results when sorting and filtering records. For example, consider the following scenario:

1. You create encrypted records using one encryption key.
2. You create a new key and set it as default.
3. You create a new set of encrypted records using the new encryption key.

If you filter by any encrypted field when connected through the Edge proxy, all records may not be filtered out correctly, or records may appear unexpectedly. The filter works only for records encrypted using the current default key. The records encrypted using the previous default key still appear in the list view.

If you sort by any encrypted field when connected through the Edge proxy, you see two groups of records with the same human readable text in the encrypted field.

Schedule a single key rotation job

Schedule a job to find data encrypted using a specified key alias and then re-encrypt the data with the current default encryption key. The data is decrypted before it is re-encrypted with the default key.

Before you begin

Role required: security_admin
Before scheduling this job, update the default key in **Edge Encryption Configuration** > **Encryption Key Configuration** > **Set Default Keys**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **Edge Encryption Configuration** > **Maintenance** > **Schedule Single Key Rotation**.
2. Fill in the fields on the form as appropriate.

Field	Value
Name	Enter a descriptive name.
Job Type	Select **Single Key Rotation**.
Key	Enter the key to be retired. Verify that this key is no longer the default key in **Edge Encryption Configuration** > **Encryption Key Configuration** > **Set Default Keys**.
Estimate record count	Total estimated number of records to process. Not available when running a single key rotation.
Process Historical Records	Select to process historical records in the Audit table if the field is audited. When encrypting historical records for a field in the Audit table, both new values and old values are encrypted. This field is read only and active. To learn more about audited fields, see Auditing.
Estimate Maximum Audit Record Count	Estimated maximum number of audited records to process. Not available when running a single key rotation.
Active	Clear this check box if you want to deactivate this job.
Run	Select the period between job executions.
Starting	Enter the date and time to run the job for the first time.

3. Click the menu icon in the form header and select **Save**.
   Estimate Record Count is not supported when processing audited fields.

Schedule a mass key rotation job

Schedule a job to find data encrypted with any previous key, and then re-encrypt the data with the current default encryption keys. The data is decrypted before it is re-encrypted with the current default key.

Before you begin

Role required: security_admin

Procedure

1. Navigate to **All** > **Edge Encryption Configuration** > **Maintenance** > **Schedule Mass Key Rotation**.
2. Fill in the fields on the form as appropriate.

Field	Value
Name	Enter a descriptive name.
Job Type	Select **Mass Key Rotation**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Value
Estimate record count	Total estimated number of records to process. Not available when running a mass key rotation.
Process Historical Records	Select to process historical records in the Audit table if the field is audited. When encrypting historical records for a field in the Audit table, both new values and old values are encrypted. This field is read only and active. To learn more about audited fields, see Auditing.
Estimate Maximum Audit Record Count	Estimated maximum number of audited records to process. Not available when running a mass key rotation.
Active	Clear this check box to deactivate this job.
Run	Select the period between job executions.
Starting	Enter the date and time to run the job for the first time.

3. Click the menu icon in the form header and select **Save**.
   Estimate Record Count is not supported when processing audited fields.

Schedule an attachment key rotation job

Schedule a job to find attachments encrypted using a specified key alias, and then re-encrypt the attachments with the current default encryption key. The attachment is decrypted before it is re-encrypted with the default key.

Before you begin

Role required: security_admin

Procedure

1. Navigate to **All** > **Edge Encryption Configuration** > **Maintenance** > **Schedule Attachment Key Rotation**.
2. Fill in the fields on the form as appropriate.

Field	Value
Name	Enter a descriptive name.
Job Type	Select **Attachment Key Rotation**.
Active	Clear the check mark if you want to deactivate this job.
Table	Select a table.
Run	Select the period between job executions.
Starting	Enter the date and time to run the job for the first time.

3. Click the menu icon in the form header and select **Save**.
4. To see an estimated count of records to be updated, click **Estimated Record Count**.
5. To run the job immediately, click **Execute Now**.

Encrypt fields using encryption configurations

Encrypt fields by creating encryption configurations.

To configure Edge Encryption, you must be connected to the instance through the proxy. Test all changes on a non-production instance before applying them to the production instance.

Define encryption keys

After setting up one or more proxies and configuring a default encryption key, the instance verifies that the keys are available to all proxies. You can't make an encryption key the default key unless all proxies have the key. After a default key is defined, you can create encryption configurations.

Assign fields and attachments to be encrypted

Assigning fields and attachments to be encrypted means assigning an encryption type to the field or attachment. Before marking a field as encrypted, evaluate these issues.

- Determine what system features might be impacted.
- Examine all scripts for use of the field.
- Make any desired adjustments to the field size. After a field has been configured for encryption, the field size can't be changed.

Marking a field to be encrypted expands the field size to store the encrypted data. The process of expanding the field size can take a long time, depending on the number of records in the table.

API support

Field Encryption updates the `setDisplayValue()` and `setValue()` APIs so they can insert encrypted data for encrypted fields. It also enables `getDisplayValue()` and `getValue()` to return cleartext values.

The following script illustrates these API changes when the Incident short description is encrypted:

```
var gr = new GlideRecord('incident'); //creates a new incident
gr.setValue('short_description','test123'); //sets the value to
 test123
var sys_ID = gr.insert(); //inserts the record in the Incident
 table.
gs.info(gr.getValue('short_description')); //displays the
 unencrypted value
```

When using `getValue()` to get encrypted text, your script no longer returns the ciphertext. Your script returns the plaintext, assuming that the user has access to the cryptographic module. `getValue()` returns the ciphertext if the user doesn't have access to the cryptographic module.

Create a field encryption configuration

Select the fields to be encrypted and identify the encryption type.

Before you begin
Role required: security_admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Edge Encryption Configuration** > **Encryption Configurations** > **Create New**.
2. Complete the form.

Field	Description
Table	The table that contains the field to be encrypted.
Type	Whether to encrypt a table column or attachments for the table. Select **Column**.
Column	The field to be encrypted. Appears only when the **Type** is **Column**. Only String, Date, Date/Time, Journal, Journal Input, and URL fields are supported. ○ **String and URL fields**: You can add an encryption configuration to either a parent table or a child table. ○ **Date and Date/Time fields**: You can add an encryption configuration to a parent table only. You cannot add a new encryption configuration to a child table. **Note:** Depending on the number of records affected by the Date and Date/Time fields you are encrypting, it may take up to a few minutes to create the encryption configuration. Make sure that you create the encryption configuration for Date and Date/Time fields when transaction volume on the instance is low.
Encryption type	The encryption type to use.

Note:
A specific table and field combination can have only one active configuration at a time.

3. Click **Submit**.

What to do next

After you add the encryption configuration record, you can create an encryption job to encrypt existing data. If you do not run an encryption job, Edge encrypts the existing data the next time the data changes. For details, see Schedule an encryption job.

Create a variable encryption configuration

Select service catalog variables to be encrypted and identify the encryption type.

Before you begin

Role required: security_admin

Procedure

1. Navigate to **All** > **Edge Encryption Configuration** > **Variable Encryption Configuration**.
2. In the **Edge Encryption Variable Configurations** list, click **New**.
3. Complete the form.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Variable	The variable to be encrypted.
Encryption type	The encryption type to use.

4. Click **Submit**.

What to do next
After you add the encryption configuration record, you can create an encryption job to encrypt existing data. If you do not run an encryption job, Edge encrypts the existing data the next time the data changes. For details, see Schedule an encryption job.

Deactivate an encryption configuration

After configuring a field or a table's attachments to be encrypted, you can stop encryption by deactivating the encryption configuration. After deactivating encryption, you can run a Decryption job for fields or an Attachment Decryption job for attachments to remove the encrypted data from the instance.

Before you begin
Role required: security_admin

About this task

Warning:
Deactivating an encryption configuration does not delete the encryption record and the encryption type cannot be changed.

Procedure

1. Navigate to **Edge Encryption Configuration** > **Edge Encryption Configurations** > **All**.
   The **Edge Encryption Configurations** list is shown.
2. Click on the encryption configuration to be deactivated.
   The **Edge Encryption Configuration** form is shown.
3. Click on the **Active** box.
   The **Active** box is clear.
4. Click **Update**.
   The **Edge Encryption Configurations** list is shown.

What to do next
You can run a Decryption or Attachment Decryption job to decrypt data on the instance. If you do not run a job, the encrypted data is decrypted the next time it is changed.

Schedule an encryption job

You can schedule a job to find and encrypt any unencrypted data in a specified field, using the default encryption key configured for the field. If you do not create an encryption job after configuring a field for encryption, only new values are encrypted.

Before you begin
Role required: security_admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **Edge Encryption Configuration** > **Encryption Configurations** > **All** to create a job for a field or **Edge Encryption Configuration** > **Variable Encryption Configuration** to create a job for a variable.
2. Click the field that you want to schedule an encryption job for.
3. Under **Related Links**, click **Schedule Mass Encryption Job**.

   The **Scheduled Encryption Job** form is shown with all fields populated. The bottom of the form shows records for any previous job executions.
4. Fill in the fields on the form, as appropriate.

Field	Value
Name	Enter a descriptive name.
Active	Clear this check box if you want to deactivate this job.
Job Type	Select **Encryption**.
Table	Select a table.
Column	Select a column.
Estimated record count	Total estimated number of records to process. Populates after selecting **Estimate Record Count**.
Process Historical Records	Select to process historical records in the Audit table if the field is audited. When encrypting historical records for a field in the Audit table, both new values and old values are encrypted. To learn more about audited fields, see Auditing.
Estimate Maximum Audit Record Count	Estimated maximum number of audited records to process. Populates after selecting **Estimate Record Count**. This field is only visible when **Process Historical Records** is selected. **Note:** The estimate may be larger than the actual number of records processed.
Run	Select the period between job executions.
Starting	Enter the date and time to run the job for the first time.

5. Click the menu icon in the form header and select **Save**.
6. To see an estimated count of records to be updated, click **Estimate Record Count**.
7. To run the job immediately, click **Execute Now**.

Schedule a decryption job

You can schedule a job to decrypt data in an encrypted field, to store clear data in the instance.

Before you begin

Note:
You must mark the encryption record for the field as inactive (clear the **Active** box) in order to run the decryption job.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Role required: security_admin

Procedure

1. Navigate to **Edge Encryption Configuration** > **Encryption Configurations** > **All** to create a job for a field or **Edge Encryption Configuration** > **Variable Encryption Configuration** to create a job for a variable.
2. Click the field that you want to decrypt.
3. Under **Related Links**, click **Schedule Mass Decryption Job**.

   The **Scheduled Encryption Job** form is shown with all fields populated. The bottom of the form shows records for previous job executions.
4. Fill in the fields on the form, as appropriate.

Field	Value
Name	Enter a descriptive name.
Job Type	Select **Decryption**.
Active	Clear this check box if you want to deactivate this job.
Table	Select a table.
Column	Select a column.
Estimated record count	Total estimated number of records to process. Populates after selecting **Estimate Record Count**.
Process Historical Records	Select to process historical records in the Audit table if the field is audited. When encrypting historical records for a field in the Audit table, both new values and old values are encrypted. To learn more about audited fields, see Auditing.
Estimate Maximum Audit Record Count	Estimated maximum number of audited records to process. Populates after selecting **Estimate Record Count**. This field is only visible when **Process Historical Records** is selected. **Note:** The estimate may be larger than the actual number of records processed.
Run	Select the period between job executions.
Starting	Enter the date and time to run the job for the first time.

5. Click the menu icon in the form header and select **Save**.
6. To see an estimated count of records to be updated, click **Estimate Record Count**.
7. To run the job immediately, click **Execute Now**.

Encrypt attachments using standard encryption

You can encrypt attachments for specific tables.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

All attachments to a table use the same encryption type. Encrypted attachments are not searched when performing a text search. Only the standard encryption types are allowed for attachments. The order preserving or equality preserving encryption types are not allowed.

For a session bypassing the Edge Encryption proxy:

- On a record with attachment encryption activated:
  - The user can see that there are attachments and the attachment names.
  - The user cannot add new attachments.
- On a record without attachment encryption activated:
  - The user can open and download existing attachments.
  - The user can add new attachments.

For a session using the encryption proxy, the user can open and download existing attachments and add new attachments.

Configure attachment encryption

Select the tables whose attachments are to be encrypted and identify the encryption type.

Before you begin

Role required: security_admin

Procedure

1. Navigate to **All** > **Edge Encryption Configuration** > **Edge Encryption Configurations** > **Create New**.
2. Fill in the fields on the form, as appropriate.

Edge Encryption configuration

Field	Description
Table	Select a table whose attachments are to be encrypted.
Type	Whether to encrypt a table column or attachments for the table. Select **Attachment**.
Column	The table field to be encrypted. This field appears when the **Type** is **Column**, and not when **Type** is **Attachment**.
Encryption type	The encryption type to use. For attachments, only Standard AES128 and Standard AES256 are allowed.

3. Click **Submit**.

What to do next

After the encryption record has been added, you can create an attachment encryption job to encrypt existing attachments. If you do not run an attachment encryption job, the system encrypts new attachments when you attach them.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
If you mark the *edge_encryption_clear_attachment_allowed attribute* as **True** in the table's Collection Dictionary entry, unencrypted attachments are added to a table using Edge Encryption to encrypt attachments. If enabling this attribute, you should setup an 'Attachment Encryption Job so that any unencrypted attachments added will be encrypted.

Schedule an attachment encryption job

You can schedule a job to find and encrypt any unencrypted attachments for a specified table, using the default encryption key configured for the table.

Before you begin
Role required: security_admin

Procedure

1. Navigate to **Edge Encryption Configuration** > **Encryption Configurations** > **All**.
2. Click the table you want to schedule an encryption job for.
3. Under **Related Links**, click **Schedule Mass Encryption Job**.

   The **Scheduled Encryption Job** form is shown with all fields populated. The bottom of the form shows records for previous job executions.
4. Fill in the fields on the form, as appropriate.

Field	Value
Name	Enter a descriptive name.
Active	Clear this check box if you want to deactivate this job.
Job Type	Select **Attachment Encryption**.
Table	Select a table.
Run	Select the period between job executions.
Starting	Enter the date and time to run the job for the first time.

5. Click the menu icon in the form header and select **Save**.
6. To see an estimated count of records to be updated, click **Estimate Record Count**.
7. To run the job immediately, click **Execute Now**.

Schedule an attachment decryption job

You can schedule a job to decrypt any encrypted attachments for a specified table, to store clear attachments in the instance.

Before you begin

Note:
You must mark the encryption record for the table as inactive (clear the **Active** box) before the decryption job runs, otherwise, nothing happens.

Role required: security_admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **Edge Encryption Configuration** > **Encryption Configurations** > **All**.
2. Click the table with the attachments that you want to decrypt.
3. Under **Related Links**, click **Schedule Mass Attachment Decryption Job**.

   The **Scheduled Encryption Job** form is shown with all fields populated. The bottom of the form shows records for previous job executions.
4. Fill in the fields on the form, as appropriate.

Field	Value
Name	Enter a descriptive name.
Job Type	Select **Attachment Decryption**.
Active	Clear the check mark if you want to deactivate this job.
Table	Select a table.
Run	Select the period between job executions.
Starting	Enter the date and time to run the job for the first time.

5. Click the menu icon in the form header and select **Save**.
6. To see an estimated count of records to be updated, click **Estimate Record Count**.
7. To run the job immediately, click **Execute Now**.

Change a field or attachment's encryption type

You can change a field or attachment's encryption type by selecting a new encryption type in the existing encryption configuration record. A specific table and field combination can only have one active configuration at a time.

Before you begin

Role required: security_admin

Procedure

1. Navigate to **Edge Encryption Configuration** > **Encryption Configurations** > **All**.
   The **Edge Encryption Configurations** list is shown.
2. Open the record for the encryption configuration to be changed.
3. Click the **Encryption type** dropdown and select a new encryption type.

   Note:
   For attachments, only Standard AES128 and Standard AES256 are allowed.
4. If needed, run an encryption or attachment encryption job.
   It is not necessary to run an encryption job. If you do not run an encryption job, the field or attachment is encrypted using the new encryption type the next time the field or attachment is changed.

Tokenize strings using encryption patterns

You can replace string patterns with tokens before they are sent to and stored in the instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin

To use encryption patterns, you must install and set up a MySQL database in your network. This is the same database used for order-preserving encryption. To create or edit encryption patterns, you must be connected to the instance through the proxy.

Role required: security_admin

About this task

You can use base system patterns, or create your own patterns. Base system patterns are advanced patterns. Encryption patterns include the following limitations.

- A pattern of all alpha characters is not allowed.
- The minimum pattern size is five characters. You can change this setting using a system property.
- The * and + quantifiers are forbidden in encryption patterns.
- Encryption patterns match complete words, not parts of strings embedded in a larger string. Words are defined by spaces and characters not available for inclusion in a pattern.
- If the same string is sent to the instance multiple times, it is replaced with the same token.
- Text search on exact matches is supported. The query string is exchanged with a token when sent to the instance, the search is performed on tokens, and when the search results are returned to the proxy server, the tokens are replaced with the clear text. Features such as stemming are not supported.

When using patterns, the clear text never leaves your network. When the proxy server matches a pattern in a request going to the instance, the proxy replaces the string with a token of the same size. The token is sent to instance instead of the clear text string. When the response is sent from the instance to the proxy server, the proxy replaces the token with the string. When viewed through the proxy server, the string displays as clear text.

Note:
Encrypted fields are not checked for encryption patterns.

Procedure

1. Navigate to **All** > **Edge Encryption Configuration** > **Encryption Patterns** > **Create New**. Alternatively, you can navigate to **Advanced Patterns** to activate or edit a preconfigured pattern.
2. Enter the pattern name.
3. Define the **Edge pattern input type**.

Option	Description
Basic	A series of character types. In the **Basic Pattern Input** tab, click **Add** and select a character type. The **Sample pattern** displays the pattern as characters are added. Click **New Block** to move the next character to the next line. This enables you to group characters in a long pattern. Click **X** to delete the last character in the pattern.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Option	Description
Advanced	A Java RegEx expression. If advanced is se lected, you cannot change the input type back to basic. In the **Sample match** field, enter a sample pattern to test the RegEx expression. In the **Pattern** field, enter a Java RegEx expression. Click **Validate** to verify that the expression matches the sample pattern.

The input type defines how you are going to enter the pattern. It does not impact how the pattern is used.

4. Click **Submit**.

Repair or recover order-preserving encrypted data

If you have the security-admin role, you can schedule jobs performed by the Edge Encryption proxy to repair or recover fields that use order preserving encryption.

Schedule jobs to:

- Repair order tokens.
- Recreate the proxy database.

Running these jobs can be a time-consuming operation that might impact the performance of the Edge Encryption proxy. Schedule these jobs at a time when no users or a minimum set of users are using the system, such as midnight on the weekend.

Schedule an order token repair job

You can schedule a job to find and repair fields where the order token is missing.

Before you begin
Role required: security_admin

About this task
Use these jobs to repair individual fields in a table or to repair all fields using order preserving encryption. Run this job when the proxy database has been offline while the instance has been running, which results in order preserving fields that are missing order tokens.

Procedure

1. Navigate to **All** > **Edge Encryption Configuration** > **Maintenance** > **Schedule Order Token Repair**.
2. Fill in the fields on the form, as appropriate.

Field	Value
Name	Enter a descriptive name.
Job Type	Select **Order Token Repair**.
All fields	Select this check box to repair all tables.
Table	Select a table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Value
Column	Select a column.
Active	Clear this check box if you want to deactivate this job.
Run	Select the period between job executions.
Starting	Enter the date and time to run the job for the first time.

3. Click the menu icon in the form header and select **Save**.
4. To see an estimated count of records to be updated, click **Estimated Record Count**.

Schedule a proxy-database recovery job

Run this job when the proxy database has lost data. This job finds all records that have been encrypted with a token (order preserving encryption type) and sends them to the proxy so that the proxy database can be rebuilt.

Before you begin

Role required: security_admin

Procedure

1. Navigate to **All** > **Edge Encryption Configuration** > **Maintenance** > **Schedule Database Recovery**.
2. Fill in the fields on the form, as appropriate.

Field	Value
Name	Enter a descriptive name for this job.
Job Type	Select **Database Recovery**.
Active	Clear this check box if you want to deactivate this job.
Run	Select the period between job executions.
Starting	Enter the date and time to run this job for the first time.

3. Click the menu icon in the form header and select **Save**.
4. To see an estimated count of records to be updated, click **Estimate Record Count**.

Configure the IP address deny list

Prevent an IP address in your network from sending requests to your instance

Before you begin

Role required: security_admin

Because the Edge Encryption proxy server resides in your network, it may be subject to vulnerability scans by your network software. To prevent IP scanner or other requests from being forwarded to your ServiceNow instance, you can add IP addresses, IP ranges, or network masks to a deny list. Any connection to the proxy server from a deny listed address is terminated and is not forwarded to your instance.

To place an IP address on a deny list, you must be logged in to your instance through the proxy server.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Important:
Ensure that you understand your network topology before adding IP addresses in your network to a deny list. If an IP address is added to the deny list, any user with that IP address will be blocked from accessing the Edge Encryption proxy server.

Procedure

1. Navigate to **All** > **Edge Encryption Configuration** > **Maintenance** > **Denylist IP Addresses**. The Encryption Proxy IP Denylists [edge_encryption_ip_blacklist] list view opens.
2. Click **New**.
3. Complete the form.

Field	Description
Proxy server	The Edge Encryption proxy server that is prevented from forwarding requests from addresses on the deny list.
IP, IP range, or net-mask	Requests from this IP address, range, or network mask are not forwarded to your ServiceNow instance. Example values include: ○ IP address: 10.10.10.5 ○ IP range: 10.10.10.1-15 ○ Network mask: 10.10.10.0/24 **Note:** You may use either IPv4 or IPv6 addresses
Active	Whether the record is active. Only IP addresses from active records are prevented from sending requests to the instance.
Description	Description of the deny list record.

4. Click **Submit**.
5. Repeat these steps for all other proxies for which an IP address should be denied.

Result
The Edge Encryption proxy server terminates any connection from IP addresses, ranges, or network masks on the deny list and cannot forward the request to the instance.

Encrypt data from a record producer

Configure your Edge Encryption proxy server to allow inserts from a record producer by creating encryption rules from the record producer record.

Before you begin
Role required: security_admin
Record producers allow end users to create task-based records, such as incident records, from the Service Catalog and Service Portal. If a record producer attempts to insert data into a field marked for encryption, an invalid insert message displays and the data is not saved to the field.

Encrypting data from a record producer requires an encryption configuration defined for the target field. Check that you have created an encryption configuration for the target field and table before creating an encryption rule from a record producer. See Create a field encryption configuration. To encrypt attachments from a record producer, Configure attachment encryption.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Log in to your instance through the Edge Encryption proxy server.
2. Navigate to **Service Catalog** > **Catalog Definitions** > **Record Producers**.
3. Create a record producer record or open an existing record producer record.
4. Under **Related Links**, select **Create Edge Encryption Rule**.
   Two inactive encryption rules are automatically created to encrypt data sent from the record producer to the field marked for encryption.

Encryption rule	Description
<RecordProducerName>	Rule created to process POST parameters from the Service Catalog and map variables to fields in the instance.
<RecordProducerName>Json	Rule created to process a JSON payload from the Service Portal and map variables to fields in the instance.

5. Activate the necessary encryption rules created by the record producer.

   a. Navigate to **Edge Encryption Configuration** > **Rules** > **All**.

   b. Depending on where the record producer will be used, open the associated encryption rule created by the record producer and select the **Active** flag.
   If using the record producer in the Service Catalog, activate the <RecordProducerName> encryption rule. If using the record producer in the Service Portal, activate the <RecordProducerName>Json encryption rule.

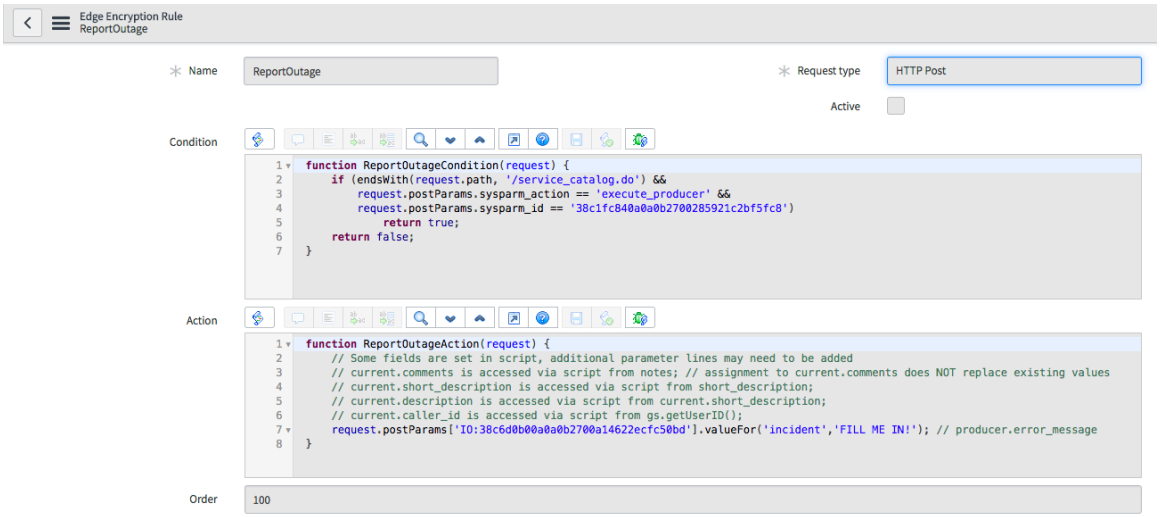
6. **Optional:** Examine the Encryption rule **Action** field and add any necessary field names or statements.

   (Optional) If a record producer directly maps a variable to a field in a table, the encryption rule automatically maps the variable to the correct field. However, if a variable is indirectly mapped through various scripts on the platform, you may need to update the rules to map each variable to the correct field.

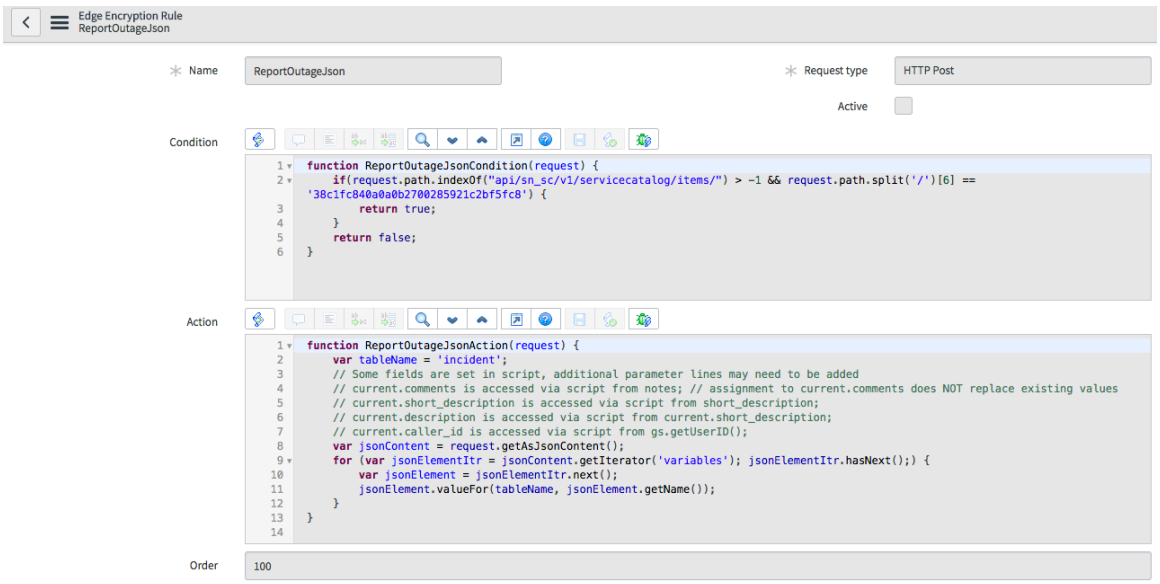
   Example

   (Optional) The below encryption rule was created from the Report Outage record producer and processes POST parameters from the Service Catalog to map variables to fields in the instance. Replace `'FILL ME IN'` with the target field.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



The below encryption rule was created from the Report Outage record producer and processes a JSON payload from the Service Portal to map variables to fields in the instance. Add additional statements to map any scripted variables to the target fields.



When the payload from the record producer is examined, the error_message element contains the value for the short_description field. By adding the following statement, you can map the scripted variable error_message to the short_description field.

```
if (jsonElement.getName() == 'error_message')
        jsonElement.valueFor(tableName, 'short_description');
```

The value of the **Action** field becomes:

```
function ReportOutageJsonAction(request) {
 var tableName = 'incident';
 // Some fields are set in script, additional parameter lines
 may need to be added
 // current.comments is accessed via script from notes; //
 assignment to current.comments does NOT replace existing
 values
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
// current.short_description is accessed via script from
short_description;
// current.description is accessed via script from
current.short_description;
// current.caller_id is accessed via script from
gs.getUserID();
var jsonContent = request.getAsJsonContent();
for (var jsonElementItr =
jsonContent.getIterator('variables');
jsonElementItr.hasNext();) {
 var jsonElement = jsonElementItr.next();
 if (jsonElement.getName() == 'error_message')
  jsonElement.valueFor(tableName, 'short_description');
            } else {
        jsonElement.valueFor(tableName,
jsonElement.getName());
 }
}
```

Result
The two encryption rules enable the record producer to insert values into fields marked for encryption from either the Service Catalog or Service Portal.

Define a custom encryption rule

It may be necessary to identify and encrypt sensitive information in HTTP requests on the way to your instance. You can write encryption rules to identify, interpret, and encrypt data in such requests, mapping fields in the request to table-field names on your instance.

What is an encryption rule

Encryption rules are scripts executed on the Edge Encryption proxy server to map fields in a request to fields in a table on your ServiceNow instance. An encryption rule tells the Edge Encryption proxy server how to encrypt data in custom payloads.

Note:
Encryption rules only support ECMAScript 3 and below.

When to use custom rules

A set of encryption rules is included as part of the Edge Encryption plugin. These rules handle many core platform use cases, such as:

- Editing a field from the list edit form
- Updating a record from the record form
- Managing direct web service
- Processing data from the REST Application Program Interface (API)

Applications created using standard forms and lists should work without custom encryption rules.

If you develop scripts that contain data that should be encrypted, create encryption rules to find and map that data to Glide table-field names. For example:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Scripted processors
- Scripted web services
- Scripted REST APIs, UIs, or Ajax scripts

Format of an encryption rule

Rules include three parts:

- **Condition**: Identifies the type of request.
- **Action**: Maps fields in the request to fields in a table, encrypting values that map to fields with encryption configurations defined.
- **Order**: Priority of the rule. The lowest priority rule with a satisfied condition is the only rule that runs. Like business rules, rules run from lowest to highest.

Except for attachment requests, HTTP requests are evaluated by the Edge Encryption proxy server. The Edge Encryption proxy server evaluates all encryption rule conditions in priority order until either all conditions return false, or one condition returns true. When a condition returns true, the action is executed on the request, and the result is forwarded to the instance. No other conditions are evaluated. As a result, encryption rule conditions should be as specific as possible. A generic rule might evaluate as true for a request meant to be processed by another rule, causing the request to be processed by the wrong action. If a generic condition is unavoidable, the rule should be marked with a high-order value so that more specific rules are evaluated first.

Guidelines for creating encryption rules

Creating efficient, optimized encryption rules can reduce processing time for script validation.

Overall guideline: When rules get long, do your best to minimize the number of blocks and break the rules apart whenever possible. Ideally, custom rules should apply to specific use cases, rather than encompassing several cases, with `if`s or switch statements in the action script.

1. Split rules whenever possible. For example,
   - Create different rules for different tables and ensure that each rule runs only on its respective table.
   - Create different rules for each record producer that you're targeting, or at least for each subset of record producers. Instead of one rule targeting dozens of `sys_ids`, you could create several different rules targeting smaller subsets of record producers, or even create one rule per `sys_id`.

     Note:
     Creating multiple rules requires more maintenance. The trade-off is that multiple, simpler rules can be validated more efficiently than longer, more complex rules.

2. Minimize the number of blocks. Because the processing engine scans each block while evaluating scripts, a large number of blocks causes delays in validation. For example,
   - Replace all `if` blocks with an array lookup, and replace all blocks in the array lookup with just one `if` block.
   - Combine `if` blocks whenever it's possible to group them.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Encryption rule APIs

Encryption rules are written in JavaScript and utilize Edge Encryption APIs to locate and encrypt sensitive information in the body of a request. The API uses expressions similar to xPath to navigate through both JSON and XML content.

Edge Encryption APIs process the request off the stream as it is being written to the output stream. Stream parsing enables encryption rules to be network performant. However, fetching and parsing content from the body multiple times could lead to unexpected results. To void this potential problem, requests should be processed by the action in a single pass.

When creating encryption rules, you can't use Glide APIs, script includes, business rules, or any global parameters such as `current`. Because the rules are created for HTTP objects, a global `request` object is available.

When creating encryption rules, you can't use APIs from the allow list manager or scoped applications.

Error handling

If an encryption rule condition or action throws an exception, check the proxy log for troubleshooting information.

Inspect the client request

Before creating a custom encryption rule, you must determine the format of the client request entering the Edge Encryption proxy server.

Before you begin
Role required: admin

About this task
Because encryption rules iterate over client requests and determine what, if anything, needs to be encrypted, you must understand the type of request you are creating a rule for. The format of the client request determines the structure of your encryption rule and the APIs available for use in the rule.

Procedure

1. Inspect the client request.

   Depending on the source of the request, the following tools are available to inspect the request and determine the format.

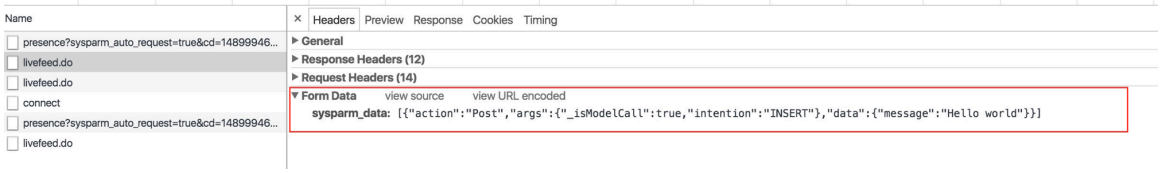
Source of request	Available tools
Client browser	Use the developer console in your browser to inspect the client request. Useful tools include: ○ Firefox Network Monitor ○ Chrome Network Panel

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Source of request	Available tools
Third-party/external source	Use an HTTP protocol analyzer to inspect the request. Useful tools include: ○ Wireshark ○ HTTP Scoop Alternatively, you can often use documentation for the external source to determine the format of the request.

2. From the client request, inspect the packet and determine:
   - The client request method
   - The URL path of the request
   - The URL parameters
   - The POST parameters, if any
   - The format of the request body, if included

Example



Result
Inspecting the request provides an understanding of the fields you need to filter for and iterate over in your encryption rule. To understand the fields in the `request` object, see request.

Create an encryption rule

Encryption rules are used by the proxy to find content in HTTP requests that should be encrypted.

Before you begin
Role required: security_admin
Before creating an encryption rule, you must Inspect the client request to determine the format.

About this task
To create or edit encryption rules, you must be connected to the instance through an encryption proxy.

Procedure

1. Navigate to **All** > **Edge Encryption Configuration** > **Rules** > **Create New**.
2. In the **Name** box, enter a name.
3. In the **Request Type**, select an HTTP method.
   - **HTTP Post**
   - **HTTP Get**
   - **HTTP Put**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **HTTP Patch**
- **HTTP Delete**

> **Note:**
> Pre-Jakarta instances allow only **HTTP Get** and **HTTP Post** methods.

4. In the **Condition** box, enter a JavaScript statement defining when the rule should run.
5. In the **Action** box, enter a JavaScript function to be executed when the condition is true.
6. In the **Order** box, enter the relative priority of the rule.
7. Click **Submit**, or save the form.

Encryption rule conditions

Encryption rule conditions determine if the rule should be executed.

An encryption rule condition must return true if the rule is to handle the HTTP request; otherwise, it must return false.

As you build your condition, keep in mind that only one rule is executed per request. As a result, the condition must be as general or specific as needed to run under the intended circumstances.

> **Note:**
> Be careful when performing checks on content in the condition. Excessive checks can be expensive for the proxy server and may cause increased latency when handling complex requests.

The condition can use the method type, content type, URL path, or any URL query string parameters to determine if the rule should handle the request. The condition has access to these fields via the request object. Be sure that, prior to creating an encryption rule condition, you have inspected the client request and understand the conditions needed to trigger the rule.

> **Note:**
> To build efficient rules, consider easy ways to rule out requests that you do not want to be evaluated by a rule. Build your condition to return false for those requests first. This method increases performance and quickly routes the request to the correct rule faster.

Encryption rule objects and APIs are available to encryption rule conditions.

Example using path and postParams

```
/*This condition checks if the request coming in has a path
 ending in
"/sample_processor.do" and if a post parameter exists in that
 request called myPostParam */

function SampleCondition(request) {
   if (endsWith(request.path, "/sample_processor.do") &&
 request.postParams.myPostParam) {
       return true;
   }
   return false;
}
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Example using urlParams and contentType

```
/* This condition checks if a url parameter exists in the query
 called
myUrlParam and if the content type contains 'xml'
(if so, you can expect the body to be an XML payload).
Then, it checks if the xml payload contains myXmlTag */

function SampleCondition2(request) {
   if (request.urlParams.myUrlParam &&
 request.contentType.indexOf('xml') > -1 &&
 request.xmlContains('myXmlTag')) {
       return true;
   }
 return false;
}
```

Encryption rule actions

An encryption rule maps fields in a client request to fields in a table on your instance and identifies fields marked for encryption.

An encryption rule action only runs when the encryption rule condition returns true. An encryption rule identifies the data to be encrypted in your request payload. Because the rule iterates over the content in the request object, you must understand the form and structure of your request body and determine what in the request must be encrypted. The data to be encrypted might be located within:

- A POST or URL parameter.
- JSON or XML content within a POST or URL parameter.
- A JSON payload.
- An XML payload.

Before writing an encryption rule action, be sure to:

- Inspect the client request.
- Identify where the sensitive data is located in the request object.
- Determine the field and table name to insert data into, or understand how to dynamically pull this from the request.

Encryption rule objects and APIs are available to encryption rule actions and conditions.

Encryption rule objects and APIs

Use encryption rule APIs to parse and encrypt values in requests moving through the Edge Encryption proxy server to the instance.

The APIs available for your encryption rule depend on the format of the request object. For example, if the contentType parameter of the request object is XML, you can use the XML APIs to parse and encrypt values in the payload. After you determine the type of object in your request, you can build an encryption rule using the available APIs.

Encryption rule APIs are available in both encryption rule condition and action scripts.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

request

The `request` object is a global object available in Edge Encryption rule action and condition scripts.

The `request` object is a JavaScript object that represents the client request coming in to the Edge Encryption proxy server. You must build your encryption rule to parse the `request` object, map `request` object values to fields in a table on the instance, and encrypt any sensitive data in the `request` object.

The `request` object includes the following attributes and data from the client request:

Request object fields

Field	Description
path	The path portion of the URL.
requestMethod	GET, POST, PUT, PATCH, DELETE.
contentType	The Content-Type header field.
urlParams	The parameters in the query string. This can also be evaluated to a String.
postParams	If this is a form post, this contains the post parameters.

request - getAsJsonContent()

Returns the request as an iterable object of type `JsonNode`.

This method is available only in an Edge Encryption rule if the request body is a valid JSON payload. If you are not sure what format the request body includes, check the contentType field on the `request` object.

Once the request is returned as a `JsonNode` object, you can use the JSON APIs to iterate over the object and encrypt fields.

Parameters

Name	Type	Description
None		

Returns

Type	Description
JsonNode	The request as an iterable `JsonNode`.

request - getAsXmlContent()

Returns the request content as an iterable object of type `XMLContent`.

This method is available only in an Edge Encryption rule if the request body is a valid XML payload. If you are not sure what format the request body includes, check the contentType field on the `request` object.

Once the request is returned as an `XMLContent` object, you can use the XML APIs to iterate over the object and encrypt fields.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Parameters

Name	Type	Description
None		

Returns

Type	Description
XMLContent	The request as an iterable object of type *XMLContent*.

request - XMLContains(String path)

Returns true if the given path exists in the XML DOM.

This method is available only if the request body is a valid XML payload. If you are not sure what format the request body includes, check the contentType field on the *request* object.

Parameters

Name	Type	Description
path	String	XPath statement you are searching for.

Returns

Type	Description
Boolean	Whether the given path exists in the XML DOM.

POST and URL parameter APIs

POST and URL parameters can be accessed as properties of the *request* object using `request.postParams` and `request.urlParams`.

Any single parameter can be accessed as a property of the *postParams* and *urlParams* parent objects by calling `request.postParams.myParam`. Any parameter accessed this way is an object of the underlying class *ParameterValue*. Any APIs in this class can be called on any parameter.

After inspecting the client request, it may be necessary to access and encrypt parameter values from the *request* object. Depending on the data in the client request, you can encrypt values and map them to fields on the instance in multiple ways.

Encrypt the value of a known table and field

If you know the name of the instance table and field that will hold the encrypted data, you can explicitly define them in the encryption rule. For example, you may know that the request will be processed on the instance to create an incident and you want to encrypt the **text** parameter in the description field. In this case, you can create the following action.

```
function SampleAction1() {
    request.postParams.text.valueFor('incident', 'description');
}
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Encrypt the value of a dynamically defined table and field

If, conversely, you do not know the name of the field that the encrypted data will populate, you can dynamically define them using **tableName** and **fieldName**.

The below example processes a generic request that might store data in different task tables (such as incident, problem, and change_request) on the instance.

```
function SampleAction2() {
    var tableName = request.urlParams.table;
    for (var parameter in request.postParams) {
        var currentParam = request.postParams[parameter];
        var fieldName = currentParam.toString();
        if (fieldName == 'text') {
            currentParam.valueFor(tableName, 'description')
        } else {
            currentParam.valueFor(tableName, fieldName);
        }
    }
}
```

This action:

- Gets the destination table from the URL parameters.
- Iterates over the URL parameters.
- Asks the Edge Encryption proxy server to encrypt any URL parameter with a name that matches a field marked for encryption.
- Looks for a specific parameter called *text* and asks the Edge Encryption proxy to encrypt the value based on the encryption configuration for the description field on the incident table.

In this example, the valueFor() method is not actually performing any encryption. Rather, the method asks the Edge Encryption proxy server to check whether the table/field pair in the request object is marked for encryption with an encryption configuration and, if applicable, encrypt it.

Encrypt JSON or XML within a parameter

A POST or URL parameter might include JSON or XML content. In this case, you can process the content within the parameter, iterate over the values, and encrypt required fields. In this example, the **tableName** is still accessed from a POST parameter, but the value of the field is the JSON object **data**.

```
function SampleAction3() {
    var tableName = request.postParams.table;
    var data = request.postParams.data;
    var dataIterator = data.getAsJsonContent().iterator();
    while (dataIterator.hasNext()) {
        var jsonElement = dataIterator.next();
        var fieldName = jsonElement.getName();
        if (fieldName == 'text') {
            jsonElement.valueFor(tableName, 'description');
        } else {
            jsonElement.valueFor(tableName, fieldName);
        }
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
    }
}
```

An example of an encryption rule action that processes XML within a POST parameter.

```
function SampleAction4() {
    var tableName = request.postParams.table;
    var data = request.postParams.data;
    var dataIterator =
 data.getAsXmlContent().getIteratorOverAllChildren();
    while (dataIterator.hasNext()) {
        var jsonElement = dataIterator.next();
        var fieldName = jsonElement.getName();
        if (fieldName == 'text') {
            jsonElement.valueFor(tableName, 'description');
        } else {
            jsonElement.valueFor(tableName, fieldName);
        }
    }
}
```

Encrypt a query

You might encounter an encoded query within a parameter in the client request that contains sensitive data. To match a field in a query to an encrypted value in the instance database, you must create an encryption rule that asks the proxy to check whether a field in the query is marked for encryption. The encodedQueryFor() method parses an encoded query on a given table, and checks if any fields in the query have encryption configurations.

In this example, the rule iterates over the parameters looking for the **filter** parameter, which is expected to be a Glide encoded query.

```
function SampleAction5() {
    var tableName = request.urlParams.table;
    for (var parameter in request.postParams) {
        var currentParam = request.postParams[parameter];
        var fieldName = currentParam.toString();
        if (fieldName == 'filter') {
            currentParam.encodedQueryFor(tableName);
        } else {
            currentParam.valueFor(tableName, fieldName);
        }
    }
}
```

For example, if the value of **filter** is: `short_description=My sensitive information^number=INC000056^category=Outage`, the query would become `short_description=<Encrypted(My sensitive information)>^number=INC000056^category=Outage` on the instance.

ParameterValue - toString()

Converts the POST or URL parameter value to a string.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Parameters

Name	Type	Description
None		

Returns

Type	Description
String	The parameter value as a string.

ParameterValue - getAsJsonContent()

Returns the request as an iterable object of type `JsonNode`.

This method is available only in an Edge Encryption rule if the request body is a valid JSON payload. If you are not sure what format the request body includes, check the contentType field on the `request` object.

Once the request is returned as a `JsonNode` object, you can use the JSON APIs to iterate over the object and encrypt fields.

Parameters

Name	Type	Description
None		

Returns

Type	Description
JsonNode	The request as an iterable `JsonNode`.

ParameterValue - getAsXmlContent()

Returns the request content as an iterable object of type `XMLContent`.

This method is available only in an Edge Encryption rule. This method assumes that the request body is a valid XML payload. You can check the contentType to make sure.

Once the request is returned as an `XMLContent` object, you can use the XML APIs to iterate over the object and encrypt fields.

Parameters

Name	Type	Description
None		

Returns

Type	Description
XMLContent	The request as an iterable object of type `XMLContent`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

ParameterValue - encodedQueryFor(String tableName)

Specifies that the value of the element is an encoded query on the specified table.

Calling this function on a parameter tells the proxy that the value of the parameter is an Encoded query strings for the specified table. The proxy parses the encoded query and encrypts the fields in the encoded query that must be encrypted.

Parameters

Name	Type	Description
tableName	String	The table that you expect the query to run on.

Returns

Type	Description
void	

ParameterValue - valueFor(String tableName, String fieldName)

Specifies that the value of the element maps to the specified field in the specified table.

Calling this method on an element value tells the proxy that the value for this element maps to the specified field in the specified table. The proxy then checks if the field must be encrypted.

Parameters

Name	Type	Description
tableName	String	The table name.
fieldName	String	The field name.

Returns

Type	Description
void	

XML APIs

XML APIs can be used after calling `getAsXmlContent()` on either the `request` object or a `ParameterValue` property.

When using XML APIs to write your encryption rule, you can follow a general format:

1. Call `getAsXmlContent()` on the `request` object or `ParameterValue` property. This returns an iterable object of the `XMLContent` underlying class.
2. Call `getIterator()` or `getIterator(String xPath)` on the `XMLContent` object. This returns an `XMLElementIterator` object that can be used to iterate over XML elements.
3. Call the `hasNext()` method on the `XMLElementIterator` object to determine whether another element is available.
4. Call `next()` on the `XMLElementIterator` object to return the next XML element. You cannot call `next()` without first calling `hasNext()`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

5. Call *valueFor(String tableName, String fieldName)* on the XML element. This method tells the proxy that the value for this element maps to the specified field in the specified table. The proxy then checks if the field must be encrypted.

Note:
To determine if you want to call *valueFor(String tableName, String fieldName)* on an XML element, you can use the *getName()* method to return the name of the element.

Mapping to a known table-field on the instance

In this example, the XML payload will be processed on the instance to insert records in the incident table. The description field will populate short_description on the incident.

```
<data>
    <record>
        <name>'Test Record 1'</name>
        <description>'Test Record 1 Description'</description>
        <tag>critical</tag>
    </record>
    <record>
        <name>'Test Record 2'</name>
        <description>'Test Record 2 Description'</description>
        <tag>security</tag>
    </record>
</data>
```

The following encryption rule action can apply:

```
function sampleXmlAction1() {
    var xmlContent = request.getAsXmlContent();
    // This loop iterates over all description tags that match
 the given path
    var xmlElementIterator =
 xmlContent.getIterator('data/record/description');
    while (xmlElementIterator.hasNext()) {
        var xmlElement = xmlElementIterator.next();
        xmlElement.valueFor('incident', 'short_decription');
    }
}
```

This action iterates through the **description** tags and asks the proxy server to encrypt the values and insert them into incident.short_description on the instance.

Note:
This rule finds all **description** tags within all **record** tags in the XML payload. If there is only one occurrence of a tag to encrypt, the rule still uses the xPath and iterator structure. However, it iterates only once in the loop.

Mapping to an unknown table-field on the instance

In this example, the rule iterates over the **record** tags, but does not know what tags to expect within the **record** tag. The only known is that the tags within the **record** tags match the names of the columns specified in the table URL parameter.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The rule also specifies that, if the table is incident, then the data in the **description** tag should be encrypted and stored in the short_description field on the instance.

```
function sampleXmlAction2() {
    var xmlContent = request.getAsXmlContent();
    var tableName = request.urlParam.table;
    // This first iterator will iterate over all record elements
    var xmlElementIterator =
 xmlContent.getIterator('data/record');
    while (xmlElementIterator.hasNext()) {
        encryptFieldsInRecord(xmlElementIterator.next());
    }
}
function encryptFieldsInRecord(xmlElement) {
    //Then, iterate over all tags representing fields in the
 table
    var fieldIterator = xmlElement.getIteratorOverAllChildren();
    while (fieldIterator.hasNext()) {
        var field = fieldIterator.next();
        var fieldName = childElement.getName();
        //if table is incident, then description is encrypted
 for the short_description field
        if (tableName == 'incident' && fieldName ==
 'description') {
            field.valueFor(tableName, 'short_description');
        } else {
            //if table is not incident, ask the proxy to check
 if the given field is encrypted for the given table
            field.valueFor(tableName, fieldName);
        }
    }
}
```

In the *encryptFieldsInRecord()* function, the *valueFor()* method is called on a table and a field that are dynamically assigned based on the request. Even though the table and field names can change, the rule asks the proxy to check whether the field in the table must be encrypted based on the encryption configurations defined.

If the field is not configured for encryption, or if the tag does not match a field in the table, the proxy skips that tag. If the tag matches a field marked for encryption, then the Edge Encryption proxy server encrypts the value.

Using an encoded query

In this example, all tags have the **filter** attribute, which indicates whether the tag contains an encoded query.

```
<data>
    <record>
        <name filter="false">'Test Record 1'</name>
        <description filter="false">'Test Record 1
 Description'</description>
        <query filter="true">category=1^name=edge</query>
    </record>
    <record>
        <name filter="false">'Test Record 2'</name>
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
        <description filter="false">'Test Record 2
 Description'</description>
        <query filter="true">category=2^severity=3</query>
   </record>
</data>
```

The following encryption rule action can apply:

```
function sampleXmlAction3() {
   var xmlContent = request.getAsXmlContent();
   var tableName = request.urlParam.table;
   // This first iterator will iterate over all record elements
   var xmlElementIterator =
 xmlContent.getIterator('data/record');
   while (xmlElementIterator.hasNext()) {
       encryptFieldsInRecord(xmlElementIterator.next());
   }
}
function encryptFieldsInRecord(xmlElement) {
   //this time we want to iterate over all tags representing
 fields in the table
   var fieldIterator = xmlElement.getIteratorOverAllChildren();
   while (fieldIterator.hasNext()) {
       var field = fieldIterator.next();
       var fieldname = childElement.getName();
       //let's look at the filter attribute, if true, then
 encrypt as encoded query
       if (field.getAttributeValue('filter') == 'true') {
           field.encodedQueryFor(tableName);
       } else {
           //if it is false then check if the field should be
 encrypted
           field.valueFor(tableName, fieldName);
       }
   }
}
```

If the **filter** attribute value is true, the rule asks the proxy server to encrypt the values in the encoded query. If false, the rule asks the proxy to check whether the field should be encrypted.

XMLContent

A global object that provides methods to iterate over the XML content.

You can access an *`XMLContent`* object by calling getAsXmlContent() on a *`request`* object.

You access XML data in a POST or URL parameter by calling `request.postParams.<parameter name>.getAsXmlContent()` or `request.urlParams.<parameter name>.getAsXmlContent()`.

XMLContent - getIterator()

Returns an *`XMLElementIterator`* object for the XML content.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Parameters

Name	Type	Description
None		

Returns

Type	Description
XMLElementIterator	An object that can be used to iterate over elements in the `XMLContent` object.

XMLContent - getIterator(String xPath)

Returns an `XMLElementIterator` object for the XML content based on the specified parameter.

Parameters

Name	Type	Description
xPath	String	An xPath-like expression that specifies where in the `XMLContent` object to start.

Returns

Type	Description
XMLElementIterator	An object that can be used to iterate over elements in the `XMLContent` object.

XMLElementIterator

Provides methods for iterating over XML elements.

You get an `XMLElementIterator` object by calling the `getIterator()` method of the `XMLContent` class.

XMLElementIterator - hasNext()

Determines if there is another element available.

Parameters

Name	Type	Description
None		

Returns

Type	Description
Boolean	True if another element is available.

XMLElementIterator - next()

Returns the next element in the iterator.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

You cannot call `next()` without first calling `hasNext()`.

Parameters

Name	Type	Description
None		

Returns

Type	Description
XMLElement	The next XML element.

XMLElement

Provides methods for iterating through XML elements and mapping values to fields in a table.

You get an `XMLElement` object by calling the `next()` method of an `XMLElementIterator` object.

XMLElement - getIterator(String xPath)

Returns an `XMLElementIterator` object for the XML element based on the specified parameter.

Parameters

Name	Type	Description
xPath	String	An xPath-like expression that specifies where in the `XMLElement` object to start.

Returns

Type	Description
XMLElementIterator	An object that can be used to iterate over elements in the `XMLElement` object.

XMLElement - getIteratorOverAllChildren()

Returns an `XMLElementIterator` object that includes all sub-elements for the XML element based on the specified parameter.

Parameters

Name	Type	Description
None		

Returns

Type	Description
XMLElementIterator	An object that can be used to iterate over elements in the `XMLElement` object.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

XMLElement - valueFor(String tableName, String fieldName)

Specifies that the value of the element maps to the specified field in the specified table.

Calling this method on an element value tells the proxy that the value for this element maps to the specified field in the specified table. The proxy then checks if the field must be encrypted. If the table and field names are unknown, you can call the `valueFor()` method on a table and a field that are dynamically assigned based on the request.

Parameters

Name	Type	Description
tableName	String	The table name.
fieldName	String	The field name.

Returns

Type	Description
void	

XMLElement - encodedQueryFor(String tableName)

Specifies that the value of the element is an encoded query for the specified table.

Calling this function on an element tells the proxy that the value of the element is an Encoded query strings for the specified table. The proxy parses the encoded query and encrypts the fields in the encoded query that must be encrypted.

Parameters

Name	Type	Description
tableName	String	The table that you expect the query to run on.

Returns

Type	Description
void	

XMLElement - getName()

Returns the element name.

Parameters

Name	Type	Description
None		

Returns

Type	Description
String	The element name.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

XMLElement - getAttributeValue(String attribute)

Returns the value of the specified attribute.

Parameters

Name	Type	Description
attribute	String	Attribute name.

Returns

Type	Description
String	The attribute value.

JSON APIs

JSON APIs can be used after calling `getAsJsonContent()` on either the `request` object or a `ParameterValue` property.

When using JSON APIs to write your encryption rule, you can follow a general format:

1. Call `getAsJsonContent()` on the `request` object. This returns an iterable object of the `JsonNode` underlying class.
2. Call `iterator()` or `getIterator(String xPath)` on the `JsonNode` object. This returns a `JsonNodeIterator` object that can be used to iterate over nodes in the JSON object.
3. Call the `hasNext()` method on the `JsonNodeIterator` object to determine whether another element is available.
4. Call `next()` on the `JsonNodeIterator` object to return the next JSON element. You cannot call `next()` without first calling `hasNext()`.
5. Call `valueFor(String tableName, String fieldName)` on the JSON element. This method tells the proxy that the value for this element maps to the specified field in the specified table. The proxy then checks whether the field must be encrypted.

Note:
To determine if you want to call `valueFor(String tableName, String fieldName)` on a JSON element, you can use the `getName()` method to return the name of the element.

Mapping to a known table-field on the instance

In this example, the JSON payload is processed on the instance to insert records in the incident table. The description field populates short_description on the incident.

```
{
    data: {
        records: [
            {
                "name": "Test Record 1",
                "description": "Test Record 1 Description",
                "tag": "security"
            },
            {
                "name": "Test Record 1",
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
                "description": "Test Record 1 Description",
                "tag": "security"
            }],
        "query":
 "assigned_to=3D4860165813e63a00d00abd322244b092^category=vulner
ability"
    },
    "source": "10.11.13.14"
}
```

The following rule can apply:

```
function sampleJsonAction1() {
    var jsonContent = request.getAsJsonContent();
    // This loop iterates over all description elements in the
 records array
    var jsonNodeIterator =
 jsonContent.getIterator(’/data/records/description’);
    while (jsonNodeIterator.hasNext()) {
        var jsonNode = jsonNodeIterator.next();
        jsonNode.valueFor('incident', 'short_decription');
    }
}
```

This action iterates through the **description** nodes and asks the proxy server to encrypt the values and insert them into incident.short_description on the instance.

Note:
This rule finds all **description** nodes within the JSON payload. If there is only one occurrence of a node to encrypt, the rule still uses the xPath and iterator structure. However, it iterates only once in the loop.

Mapping to an unknown table-field on the instance

In this example, the rule iterates over **records**, but is not sure what nodes to expect. The only known is that for each object within **records**, the nodes match the names of the columns specified in the table URL parameter.

The rule also specifies that, if the table is incident, then the data in the **description** node should be encrypted and stored in the short_description field on the instance.

```
function sampleJsonAction2() {
    var jsonContent = request.getAsJsonContent();
    var tableName = request.urlParam.table;
    // This first iterator will iterate over all record elements
    var jsonNodeIterator =
 jsonContent.getIterator('data/records');
    while (jsonNodeIterator.hasNext()) {
            encryptFieldsInRecord(jsonNodeIterator.next());
    }
}
function encryptFieldsInRecord(jsonNode) {
    //this time we want to iterate over all nodes
    var fieldIterator = jsonNode.iterator();
    while (fieldIterator.hasNext()) {
            var field = fieldIterator.next();
            var fieldname = childElement.getName();
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
            if (fieldName == 'description') {
                field.valueFor(tableName, 'short_description');
            } else {
                field.valueFor(tableName, fieldName);
            }
    }
}
```

In the *encryptFieldsInRecord()* function, the *valueFor()* method is called on a table and a field that are dynamically assigned based on the request. Even though the table and field names can change, the rule asks the proxy to check whether the field in the table must be encrypted based on the encryption configurations defined.

If the field is not configured for encryption, or if the node name does not match a field in the table, the proxy skips that node. If the node name matches a field marked for encryption, then the proxy encrypts the value.

Using an encoded query

```
function sampleJsonAction3() {
    var jsonContent = request.getAsJsonContent();
    var tableName = request.urlParam.table;
    // This first iterator will iterate over all record elements
    var jsonNodeIterator = jsonContent.getIterator('data');
    while (jsonNodeIterator.hasNext()) {
        var jsonNode = jsonNodeIterator.next();
        if (jsonNode.getName() == 'records')
            encryptRecors(jsonNodeIterator.next());
        else if (jsonNode.getName() == 'query')
            jsonNode.encodedQueryFor(tableName);
    }
}
function encryptRecords(jsonNode) {
    //we iterate over all fields in the node
    var recordIterator = jsonNode.iterator();
    while (recordIterator.hasNext()) {
        encryptFieldsInRecord(recordIterator.next());
    }
}
function encryptFieldsInRecord(jsonNode) {
    //this time we want to iterate over all nodes
    var fieldIterator = jsonNode.iterator();
    while (fieldIterator.hasNext()) {
            var field = fieldIterator.next();
            var fieldname = childElement.getName();
            field.valueFor(tableName, fieldName);
    }
}
```

In this example, the rule iterates over **data**. As it finds **records**, it performs the same logic as in the second example, iterating over fields in each node. When it finds the **query** node, it calls *encodedQueryFor()* to encrypt values that should be encrypted in the query.

JsonNode

A global object that provides methods to iterate over the JSON content.

You can access a *JsonNode* object by calling getAsJsonContent() on a *request* object.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

You access JSON content from a POST or URL parameter by calling `request.postParms.<parameter name>.getAsJsonContent()` or `request.urlParms.<parameter name>.getAsJsonContent()`.

JsonNode - getIterator(String xPath)

Returns a *`JsonNodeIterator`* object for the JSON content.

This method can only be used on the root node, but can be used to traverse deep into the JSON object. Subsequent traversals must use the *`iterator()`* method.

Parameters

Name	Type	Description
xPath	String	An xPath expression.

Returns

Type	Description
JsonNodeIterator	An object that can iterate over nodes in the JSON object.

JsonNode - iterator()

Returns a *`JsonNodeIterator`* object that iterates over all child nodes of the current node.

Parameters

Name	Type	Description
None		

Returns

Type	Description
JsonNodeIterator	An object that can iterate over nodes in the JSON object.

JsonNode - getAsString()

Returns the current node value as a string.

Parameters

Name	Type	Description
None		

Returns

Type	Description
String	The current node value.

JsonNode - getAsString(String propertyName)

Returns the string value of the specified property.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Parameters

Name	Type	Description
propertyName	String	Name of the property.

Returns

Type	Description
String	The property value.

JsonNode - getName()

Returns the name of the current JSON node.

Parameters

Name	Type	Description
None		

Returns

Type	Description
String	Name of the current JSON node.

JsonNode - valueFor(String tableName, String fieldName)

Specifies that the JSON property maps to the specified field in the specified table.

Calling this method on a JSON property tells the proxy that the value for this property maps to the specified field in the specified table. The proxy then decides if the field must be encrypted. If the table and field names are unknown, you can call the `valueFor()` method on a table and a field that are dynamically assigned based on the request.

Parameters

Name	Type	Description
tableName	String	The table name.
fieldName	String	The field name.

Returns

Type	Description
void	

JsonNode - encodedQueryFor(String tableName)

Specifies that the value of the JSON property is an encoded query for the specified table.

Calling this function on a JSON node tells the proxy that the value is an Encoded query strings for the specified table. The proxy parses the encoded query and encrypts the values for fields in the encoded query that must be encrypted.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Parameters

Name	Type	Description
tableName	String	The table that you expect the query to run on.

Returns

Type	Description
void	

JsonNodeIterator

You get a `JsonNodeIterator` object by calling the `getIterator()` or `iterator()` methods of the `JsonNode` class.

JsonNodeIterator - hasNext()

Determines if there is another property available.

Parameters

Name	Type	Description
None		

Returns

Type	Description
Boolean	True if another property is available.

JsonNodeIterator - next()

Returns the next property in the iterator.

You cannot call `next()` without first calling `hasNext()`.

Parameters

Name	Type	Description
None		

Returns

Type	Description
JsonNode	The next `JsonNode`.

print(String message)

Prints a message to the wrapper log file: `<proxy server directory>/logs/wrapper_<date>.log`.

This method is available only in an Edge Encryption rule action script.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Parameters

Name	Type	Description
message	String	The message to be written to the wrapper log file.

Returns

Type	Description
void	

Prohibited keywords

The Edge Encryption proxy validates encryption rule scripts before saving the rule. Many JavaScript keywords aren't allowed in encryption rule scripts.

Edge Encryption dictionary attributes

Add dictionary attributes to tables and fields to control how they work with Edge Encryption.

To set a dictionary attribute to true, you must enter `attribute=true` in the **Attributes** field. To add a dictionary attribute to a record, see Altering tables and fields using dictionary attributes.

Edge Encryption Excluded [edge_encryption_excluded]

Determines whether the field is excluded from encryption.

When set to `true`, the field or table can't be encrypted. When set to `false`, the field can be encrypted.

- Value: true/false
- Target element: field or table
- Default value: false

Edge Encryption Enabled [edge_encryption_enabled]

Determines whether the field is eligible for encryption through an encryption configuration.

When set to `true`, the field is eligible for encryption. When set to `false`, the field isn't eligible for encryption. Because this attribute is used by the system and can't be modified, it isn't displayed to the user.

> **Note:**
> This attribute doesn't indicate that a field is encrypted, nor does it trigger any encryption logic on the field. Rather, the attribute determines the possibility of the field being encrypted by a user.

- Value: true/false
- Target element: field
- Default value: true for String fields

Edge Encryption Clear Text Allowed [edge_encryption_clear_text_allowed]

Determines whether server-side scripts may append non-encrypted data to an encrypted string within the field for user actions performed through the proxy server, or any server-side automated scripts, such as scheduled jobs.

When set to `true`, appending data is allowed. When set to `false`, appending data isn't allowed.

- Value: true/false
- Target element: field
- Default value: false

Domain separation and Edge Encryption

Domain separation is supported in limited circumstances with Edge Encryption. Edge Encryption provides the ability to encrypt data from within the customer's environment through the use of specific configurations, rules, and keys defined on the Edge Encryption proxy. The Edge Encryption proxy is not domain aware and cannot support domain-specific settings. Domain separation enables you to separate data, processes, and administrative tasks into logical

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: No support

- The domain field may exist on data tables but there is no business logic to manage the data.
- This level is not considered domain-separated.

For more information on support levels, see Application support for domain separation.

How domain separation works in Edge Encryption

Edge Encryption can be used where domain-specific keys, configurations, and rules are not required.

Related topics

Domain separation for service providers

Data integration with Edge Encryption

To integrate third-party data with an instance using Edge Encryption, you must route the data through the Edge Encryption proxy server using supported integrations. Supported integrations use base system encryption rules that map data in each payload to fields in a table.

Upload data to fields marked for encryption

Edge Encryption does not support importing data from or exporting data to Excel, CSV, XML, or other file types to or from fields with encryption configurations defined.

ODBC driver

Encrypt requests and query data through the Edge Encryption proxy server using the ODBC driver.

Learn more: Edge Encryption ODBC driver integration

MID Server

You can configure the MID Server to route data through an Edge Encryption proxy server. However, some restrictions apply.

Learn more: Edge Encryption MID Server integration

REST/SOAP web services

Use REST/SOAP web services to update or retrieve record data through the Edge Encryption proxy server.

Learn more: Web services

JSONv2 web service

Use JSONv2 web service APIs to update or retrieve record data through the Edge Encryption proxy server. Base system encryption rules support data retrieval and data modification APIs.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- To insert a single record using the data modification API, use the `insert()` or `insertMutiple()` methods.
- To insert multiple records using the data modification API, use the `insertMultiple()` method.

Learn more: JSONv2 Web Service

To encrypt data from custom third-party integrations not listed above, create custom encryption rules. See Define a custom encryption rule.

Upload attachments to records marked for encryption

Attachments can be uploaded to tables with attachment encryption configured using REST and SOAP web services.

Edge Encryption ODBC driver integration

Configure your ODBC driver to query data encrypted by Edge Encryption. The Edge Encryption proxy server encrypts ODBC driver requests to the ServiceNow instance when Edge Encryption is integrated with the ODBC driver.

Encrypted responses from the instance are decrypted through the Edge Encryption proxy server before passing to the ODBC driver in your network.

For a successful integration, the ODBC driver must trust the Edge Encryption proxy server certificate. If the Edge Encryption proxy server certificate is signed by a Certificate Authority trusted by the ODBC driver, the Edge Encryption proxy server is automatically trusted. However, if a Certificate Authority trusted by the ODBC driver has not signed the Edge Encryption proxy server certificate, you must import the self-signed certificate to the ODBC truststore.

Import a self-signed certificate to the ODBC truststore

If a Certificate Authority trusted by the ODBC driver has not signed the Edge Encryption proxy server certificate, you must import a self-signed certificate to the ODBC truststore. You can export the certificate from the Edge Encryption proxy server and import it into the ODBC truststore.

Before you begin
Role required: admin

To determine whether a Certificate Authority trusted by the ODBC driver has signed the Edge Encryption proxy server certificate, run the following command in the keystore directory in the proxy home directory to view a list of Certificate Authorities trusted by the ODBC driver:

```
keytool -keystore "<ODBC
 directory>\ip\Java\jre\lib\security\cacerts" -list
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:

In most cases, the client connects to the Edge Encryption proxies through a load balancer, so the certificate would be the certificate configured in the load balancer.

In the case where there is no load balancer between the client and the Edge proxy server, the certificate is the certificate presented by the Edge proxy and is configured in the *edgeencryption.properties* file.

```
edgeencryption.proxy.https.port = 9090
edgeencryption.proxy.https.keystore.path = keystore/keystore
edgeencryption.proxy.https.keystore.password = password
edgeencryption.proxy.https.cert.alias = jetty
```

For details on editing properties, see Configure additional properties in the Edge Encryption properties file

Procedure

1. Change to the keystore directory in the proxy home directory.
2. Check the keystore for the self-signed certificate.
   a. To check the keystore for the certificate, you can run the following command to list all the items in the keystore.

   ```
   keytool -list -keystore keystore.jceks -storetype jceks -v
   ```

   b. Locate the key alias in the list of items.
3. Using the key alias, export the certificate to a .cer file.

   ```
   keytool -export -alias <key alias> -keystore keystore.jceks
    -storetype jceks -rfc -file <file name>.cer
   ```
4. Change to your ODBC truststore directory: `ODBC\ip\Java\jre\lib\security\cacerts`.
5. Import the certificate to your ODBC truststore.

   ```
   keytool -keystore cacerts -importcert -alias $<key alias> -file
    <file name>.cer
   ```

Set the ODBC driver properties

Set the ODBC driver properties to route requests through the Edge Encryption proxy server.

Before you begin

Role required: admin

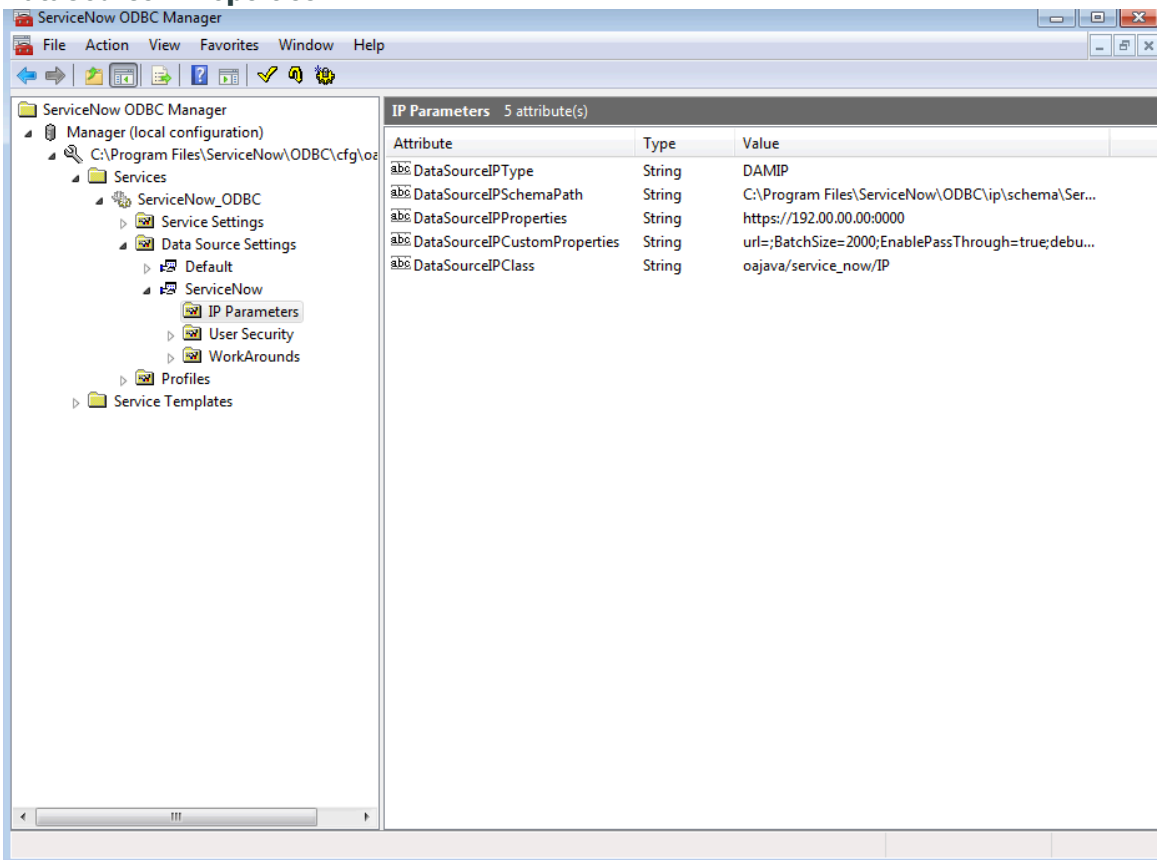
Procedure

1. In Windows, navigate to **Start** > **Programs** > **ServiceNow ODBC Management Console**.
2. Expand the console tree root to: `ServiceNow ODBC Manager\Manager\<installation location>\Services\ServiceNow_ODBC\Data Source Settings\ServiceNow\IP Parameters`.
3. Double-click the **DataSourceIPProperties** attribute.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Change the **Value** to the URL of your Edge Encryption proxy server, such as `https://<IP address>:<port>`

DataSourceIPProperties



5. Click **OK**.

What to do next

The ODBC driver is now configured to route requests to the instance through the Edge Encryption proxy server.

Edge Encryption MID Server integration

Configure the MID Server to route data through an Edge Encryption proxy server.

When integrated with the MID Server, the Edge Encryption proxy server acts as the MID Server's endpoint. The Edge Encryption proxy server then encrypts and decrypts data passing between the ServiceNow instance and the MID Server.

Limitations when integrating with the MID Server

When MID Server data is configured to pass through the Edge Encryption proxy server, the following limitations apply:

- Encryption of ECC Queue fields is not supported.
- Encrypted data cannot be used with Discovery or Service Mapping.

Point the MID Server to the Edge Encryption proxy server

To pass data from the MID Server through the Edge Encryption proxy server, update the MID Server configuration file to point the MID Server to the Edge Encryption proxy server.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin
Role required: admin

About this task
When configuring the MID Server to pass through the Edge Encryption proxy server, you cannot use the web proxy properties in the MID Server configuration file to route traffic through the Edge Encryption proxy server to your instance. Instead, you must set the Edge Encryption proxy server as the MID Server's endpoint.

Procedure
1. Navigate to your local MID Server directory and open the `config.xml` file.
2. Find the element `<parameter name="url" value="https://YOUR_INSTANCE.service-now.com" />` and change the value property to the URL of your Edge Encryption proxy server.
   For example, `http://hostname.mycompany.com:8081`
   This step directs the MID Server to pass traffic to the Edge Encryption proxy server instead of the instance. The Edge Encryption proxy server in turn encrypts any necessary fields and passes the payload to the instance.
3. Save and close the file.
4. If running, restart the MID Server.

Edge Encryption diagnostics and performance

Monitor Edge Encryption proxy server performance trends and drill into errors generated by the Edge Encryption proxy server.

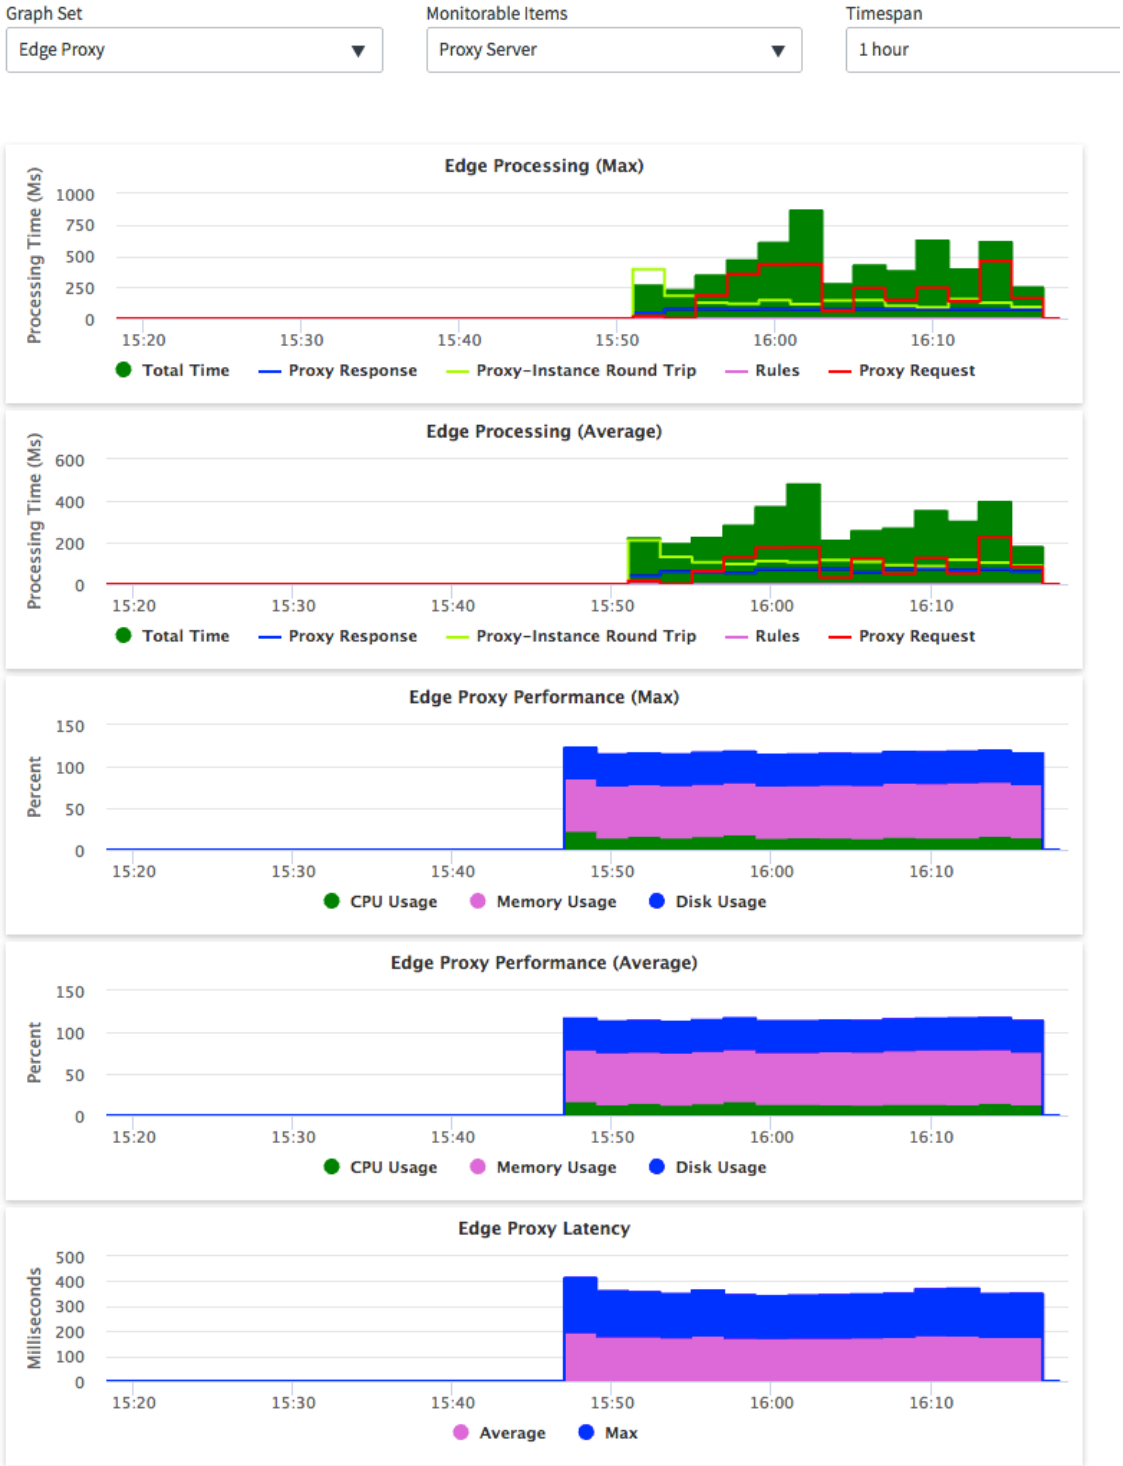
Edge proxy performance

View key Edge Encryption proxy server performance trends using the Edge Proxy graph set on the ServiceNow Performance homepage. Monitored trends include:

- Maximum and average response times between the client, proxy server, and instance.
- CPU, disk space, and memory usage of the host machine.
- Maximum and average network latency between the proxy server and the ServiceNow instance.

Note:
Edge Encryption proxy servers with duplicate names do not report performance trends.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Edge Processing (Max and Average)

Maximum and average time in milliseconds to process a request. These data points are general trends over time.

- **Total Time**: Time for the proxy server to receive a request from a client and send a response. This data point is the sum of the subsequent data points.
- **Proxy Response**: Time for the proxy server to process a response from the instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **Proxy-Instance Round Trip**: Time for the proxy server to send a request to the instance and receive a response. Includes network latency between the proxy server and the instance and time spent by the instance to process the request.
- **Rules**: Time for the proxy server to evaluate a request using defined encryption rules.
- **Proxy Request**: Time for the proxy server to process a client request and forward it to the instance.

Edge Proxy Performance (Max and Average)

Maximum and average percentage of resources used on the host machine.

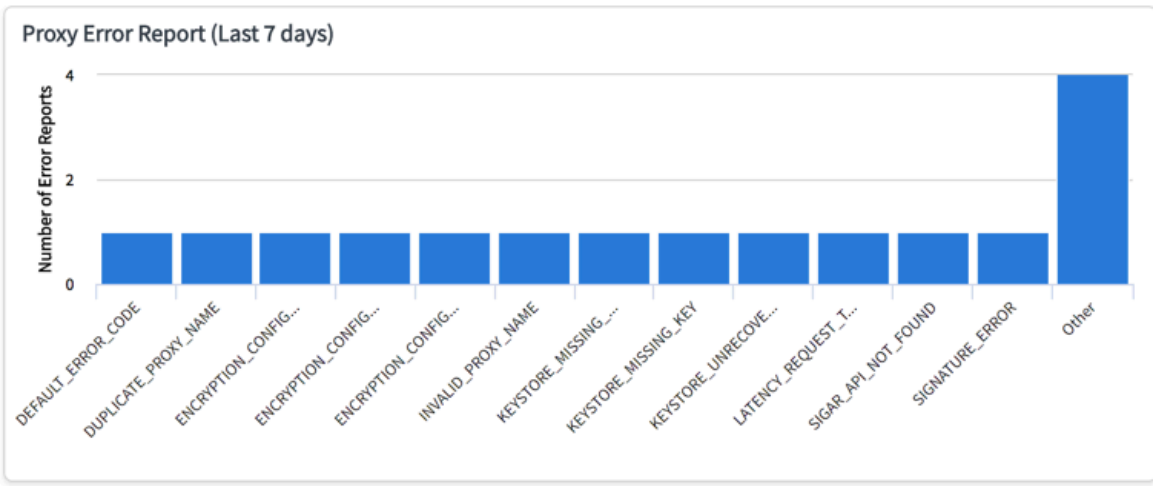
- CPU Usage
- Memory Usage
- Disk Usage

Edge Proxy Latency

Maximum and average network latency in milliseconds at a given point in time. Latency is determined by round-trip time for a proxy server to send a simple ping to the instance and receive a response.

Proxy Error Reports

Navigate to **Edge Encryption Configuration** > **Diagnostics and Troubleshooting** > **Proxy Error Reports** to view all proxy server errors collected over the past seven days.



Errors are collected over a one-minute period. Each minute, an error report is generated. The vertical axis displays the number of error reports over the last seven days that include each error. For example, even if the DEFAULT_ERROR_CODE error is thrown multiple times over a one-minute report period, the DEFAULT_ERROR_CODE bar will only reach one on the **Number of Error Reports** axis.

From this view, you can:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Click each proxy error code bar to see the report on a single error for each proxy server. From this view, you can click the bar again to view the error text in the Edge Encryption Proxy Stat table [edge_encryption_stat]. Follow links in the error text to see more information and possible remediation steps.
- Click **Other** to see page two of the error report.

Note:
If you have more than one proxy server with the same name, a single DUPLICATE_PROXY_NAME error appears in the Proxy Error Report. No other errors are reported for proxy servers with duplicate names. If you encounter this error, make sure that all proxy servers have unique names.

Additional monitoring resources

The instance tracks all encryption proxies. Each Edge Encryption proxy server registers when it starts up. The instance is notified when:

- A new Edge Encryption proxy server starts up.
- An Edge Encryption proxy server is intentionally shut down.

If an Edge Encryption proxy server attempts to register with an instance that does not have Edge Encryption installed, the proxy does not start.

All encryption configuration files are audited. Deleted records are audited on all encryption configuration files. Audit records are put in the sys_audit table. To view the history of a specific configuration record, view the record, and click **History** > **List** in the menu. The Mass Encryption Job is not audited.

Use the following additional resources to monitor you proxy servers.

Table	Description
Invalid Insert Attempts [sys_edge_encryption_invalid_insert_log]	List of attempts to save the following data to encrypted fields: • Unencrypted data. • Data that did not come from an Edge Encryption proxy. The instance rejects and then logs any attempts to save this data. If you have the security-admin role, you can view the logs in the Invalid Insert Attempts list.
Job Failures [sys_encryption_job_execution]	A list of jobs that did not execute successfully.
System logs	The instance periodically checks for messages from each registered proxy server. If a proxy server has not sent a message in the required time frame, an error is logged. The log message contains information about the encryption proxy and the last time the proxy pinged the instance. If the instance determines that none of the encryption proxies are online, it logs a message. These messages are added to the system log.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Disable or reduce Edge Proxy statistic collection

Prevent the Edge Encryption proxy server from sending Edge Proxy Graph Set statistics to the ServiceNow Performance homepage, or reduce the frequency of statistic collection.

Before you begin
Role required: admin or security_admin

About this task
By adding properties in the `edgeencryption.properties` configuration file, you can:

- Disable the Edge Proxy graph set.
- Change the interval during which statistics are collected by the Edge Encryption proxy server. By default, statistics are collected every 30 seconds.

Procedure

1. In your proxy server installation directory, open the `edgeencryption.properties` configuration file located in the `<installation directory>/conf/` folder.
2. Add one of the Edge Encryption proxy server properties.
3. Restart the proxy server.

Increase debug logging for the Edge Encryption proxy

Increase the level of logging to interpret the logs and debug issues with the proxy.

There are currently three options for increasing debug logging in the Edge Encryption proxy. Increase the level of logging to debug issues provide technical support with information to look into the issue with the benefit of more verbose log statements.

Depending on the issue being debugged, set up debug logging in one of three ways:

- Debugging issues other than SSL connectivity
- Logging timing metrics for requests through the proxy
- Debugging issues with SSL connectivity between the Edge Encryption Proxy and the instance

For all debug cases, you may view and interpret the logs in your own or open an incident to get an interpretation from ServiceNow technical support providing the description of the issue and how it's reproduced.

Debugging issues with the Edge Encryption application other than SSL connectivity

Use this method to debug issues with the Edge Encryption application, without stopping and restarting the proxy. These steps increase logging level and help troubleshooting the root cause with more verbose log statements.

Before you begin
Role required: admin

Note:
Changes made to the `$proxy_installation_location/conf/log4j2.properties` file are taken up by the proxy within about 60 seconds after you make your changes. You don't have to restart the proxies.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. In the `$proxy_installation_location/conf/log4j2.properties` file find the following line.

```
logger.edge.level=info
```

2. Change the above line to the following:

```
logger.edge.level=debug
```

3. Save the change.
   It may take up to 60 seconds for the change to take effect, but this doesn't require a proxy restart.
4. Reproduce your issue.
5. Check for debug log statements related to the application in the `$proxy_installation_location/logs/edgeencryption.log` file.

Result

After making the property change, you can see additional detail in your `$proxy_installation_location/logs/edgeencryption.log` file. When you have finished debugging, revert the change made to the `$proxy_installation_location/conf/log4j2.properties` file.

Logging timing metrics for requests through the proxy

Enable timing metric logging to add a metric statement for each request handled by the Edge Encryption proxy. Each of these timing metric log statements contains useful information about the request, such as processing times and which encryption rule was used.

Before you begin

Role required: admin

Note:

The additional logging settings are added to the `$proxy_installation_location/conf/log4j2.properties` file. Changes made are taken up by the proxy dynamically within about a minute after the changes to the file are made, so you do not have to restart the proxies.

Procedure

1. Modify the `$proxy_installation_location/conf/log4j2.properties` file by adding the following lines at the end of the file

```
appender.timinglog.type=RollingFile
appender.timinglog.name=TimingLog
appender.timinglog.fileName=../logs/edgenetwork.log
appender.timinglog.filePattern=../logs/$
${date:yyyy-MM}/edgenetwork-%d{yyyy-MM-dd-HH}-%i.log.gz
appender.timinglog.layout.type=PatternLayout
appender.timinglog.layout.pattern=%d [%t] %-5p %m%n
appender.timinglog.policies.type=Policies
appender.timinglog.policies.size.type=SizeBasedTriggeringPolicy
appender.timinglog.policies.size.size=500MB
appender.timinglog.strategy.type=DefaultRolloverStrategy
appender.timinglog.strategy.max=4
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
logger.timing.name=com.snc.edgeencryption.metrics.EdgeEncryptio
nTimingMetricCache
logger.timing.level=debug
logger.timing.additivity=false
logger.timing.appenderRef.rolling.ref=TimingLog
```

2. Save the file.

Result

After the `log4j.properties` file is saved, the following types of messages appear in the `$proxy_installation_location/logs/edgenetwork.log` log file for network times.

```
2022-07-21 12:56:15,783 [qtp1971991758-7700] DEBUG
 com.snc.edgeencryption.metrics.EdgeEncryptionTimingMetricCache
 -
 request_uri=/api/now/ui/presencesysparm_auto_request=true&cd=16
58433375754 request_method=POST
 client_request_received="2022-07-21 12:56:15,015"
 proxy_request_processing_time=6 all_rules_processing_time=0
 rule_executed="REST JSON" rule_execution_time=1
 proxy_instance_round_trip=14 proxy_response_processing_time=1
 total_time_from_proxy=21 reponse_code=201
 glide_user=SCv3_1:BAz1ZK7ee9XoroG2nvMlixHpgTvsT4fY2bwQvnH2WdU=:

5a33be04be441 jsessionid_suffix=037A66
```

The values in the log messages are as follows:

```
request_uri: The URI being requested

request_method: The HTTP method being used, for example, GET,
 POST, PUT, PATCH, DELETE

client_request_received: The timestamp noting when the HTTP
 client request arrived at the Edge proxy

proxy_request_processing_time: How long the Edge proxy took to
 process the request in milliseconds

all_rules_processing_time: Total time it took to execute all of
 the Edge Encryption rules for the request in milliseconds

rule_executed: The name of the encryption rule that was executed

rule_execution_time: How long it took to execute listed
 rule_executed in milliseconds

proxy_instance_round_trip: The time from when the Edge proxy
 sent the request to the instance until the instance sent the
 response and was received by the edge proxy in milliseconds

proxy_response_processing_time: How long the Edge proxy took to
 process the response in milliseconds
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
total_time_from_proxy: The total time from when the Edge proxy
 received the request from the client and returned the response
 to the client in milliseconds

response_code: HTTP response code

glide_user: The glide_user cookie value

jsessionid_suffix: The JSession cookie suffix associated with
 the request
```

Debug issues with SSL connectivity between the Edge Encryption proxy and the instance

Use this method to debug issues with SSL connectivity between the Edge Encryption proxy and your instance, such as access to the instance fails via the proxy. These steps increase logging and help find the verbose log statements.

Before you begin

Role required: admin

Note:
SSL connectivity debugging is only relevant when troubleshooting TLS connectivity type issues. In practice, this is not common and rarely needed.

Procedure

1. Stop the proxy server.
2. Add the following line to the file `$proxy_installation_location/conf/wrapper.conf`, which is a Java startup property:

   ```
   wrapper.java.additional.<next available number in sequence> =
    -Djavax.net.debug=all
   ```

   For example:

   ```
   For example: wrapper.java.additional.4 = -Djavax.net.debug=all
   ```

3. Save the change and restart the proxy server.
4. Reproduce your connectivity issue.

Result

After reproducing the issue debug log statements related to the SSL exchange can be found in the `$proxy_installation_location/logs/wrapper_<current date>.log` file. When you are finished debugging. You can remote the additional logging by removing or commenting out the line created in the previous steps.

Database Encryption

ServiceNow® offers database encryption (DBE) and full-disk encryption methods for customers with statutory obligations for data protection which may require at-rest protection for all data.

Important:
Starting with the Washington DC release, Database Encryption is being prepared for future deprecation. Cloud Encryption is the replacement solution for data at rest encryption. For details, see Cloud Encryption with Key Management

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Explore	Request	Reference
Learn the key features and business value of Database Encryption.	Learn more about how to request database key rotation.	Database Encryption with Customer-Controlled Switch (DBE-CCS) is an encryption solution that encrypts all data-at-rest when not in use in the database.

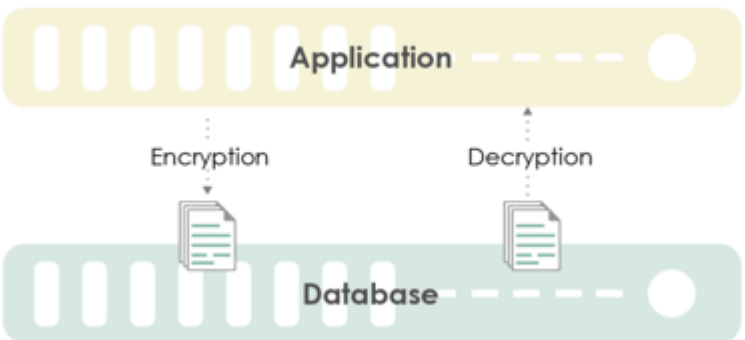
Exploring Database Encryption

ServiceNow® offers database encryption (DBE) and full-disk encryption methods for customers with statutory obligations for data protection which may require at-rest protection for all data.

Important:
Starting with the Washington DC release, Database Encryption is being prepared for future deprecation. Cloud Encryption is the replacement solution for data at rest encryption. For details, see Cloud Encryption with Key Management

Database Encryption enables all data to be protected with symmetric AES-256 encryption, whether the database is online or offline. From the ServiceNow AI Platform perspective, all data flows in decrypted.

- Database Encryption supports all stored data to be encrypted in real time providing protection for data online and offline with no loss of functionality.
- Full disk encryption protects offline data if there is disk loss or theft.



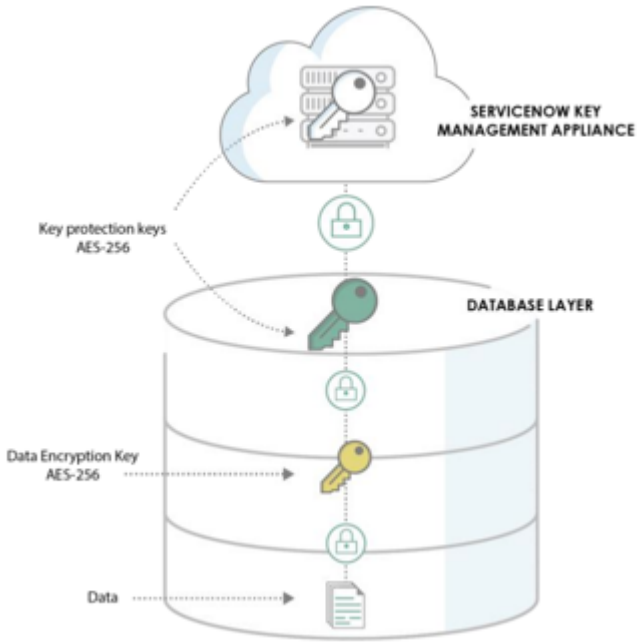
With Database Encryption, all stored data is encrypted and individual records or tables are decrypted in memory while being accessed. New or changed data is encrypted as it is entered into a table and associated activity log files (bin, redo, undo, and error) are also encrypted.

Database Encryption is transparent to users, with no loss of functionality. When using this feature, all instances are encrypted, along with replication traffic and backups. Instance cloning is still available with a minor performance impact for using Database Encryption of up to 5%.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Both new and existing instances on supported releases of the ServiceNow AI Platform can take advantage of database encryption.

As illustrated, ServiceNow stores and manages keys using a three-level key hierarchy:



1. A customer specific AES-256 key is created by the database engine and is used to encrypt the data.
2. A second customer specific AES-256 key is created by the database engine and is used to protect the first-level key.
3. A third AES-256 key is created by and stored within FIPS 140 validated key management appliances in the ServiceNow datacenters. This key protects the second-level key and is unique per customer instance.

The ServiceNow AI Platform also supports database encryption with a customer supplied switch, DBE with CCS. This is an encryption solution that encrypts all data-at-rest when not in use in the database. It uses industry standard AES encryption with no impact to functionality. The database encrypts data as it is written to the disk, and decrypts data as it is read from the disk. That means that applications always have the data in an unencrypted state to perform the necessary logic and functions without impact.

Note:
Database Encryption is not supported for on-premise instances.

If you are using your own keys for database encryption, see Database Encryption with Customer Controlled Switch.

Requesting database key rotation

Rotate the database key annually or as needed by submitting a request to support.

Before you begin
Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Important:
Starting with the Washington DC release, Database Encryption is being prepared for future deprecation. Cloud Encryption is the replacement solution for data at rest encryption. For details, see Cloud Encryption with Key Management

About this task
Key rotation occurs at night within 24 hours prior to the expiration date and does not interrupt service for the instance.

Note:
Currently, key rotation is only available in ServiceNow Commercial, Government Community Cloud (GCC), France, and Singapore environments.

Procedure

Contact Customer Service and Support to request any of the following key rotation actions:

- Enroll to perform annual key rotation on all designated instances.
- Obtain a historical report of the last three key rotations containing the following:
  - Instance name.
  - Key name and version.
  - Dates and times of rotation.
- Schedule an early key rotation outside of the annual scheduled rotation.

Database Encryption with Customer Controlled Switch

Database Encryption with Customer-Controlled Switch (DBE-CCS) is an encryption solution that encrypts all data-at-rest when not in use in the database.

Important:

Database Encryption with Customer Controlled Switch has begun its End of Life process, and has reached the End Of Sale and End of Renewal milestones as of the Yokohama release. For data-at-rest encryption support, see Cloud Encryption with Key Management.

Overview

Database Encryption with customer controlled switch uses industry standard AES encryption, with no impact to functionality. The database encrypts data as it is written to the disk and decrypted by the database as it is read from the disk. Applications always have the data in an unencrypted state to perform the necessary logic and functions.

DBE-CCS utilizes technology native to the database, often called Tablespace Encryption or Transparent Data Encryption. For more details on the technology, refer to the MariaDB website under "Tablespace Encryption."

DBE-CCS requires you to set up an HTTPS REST service endpoint that periodically provides the secret key to the ServiceNow instance. The CCS endpoint then returns the customer secret key encrypted with the public key of the database instance.

Customer endpoint

Important:
Your organization is solely responsible for setting up and maintaining your CCS endpoint. The customer endpoint specification is provided in KB0789788.

© 2026 ServiceNow, Inc. All rights reserved.

Access Management

Access Management enables you to have access to ServiceNow® instance securely.

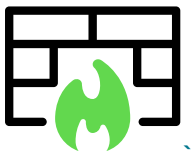
Zero Trust Access

Zero Trust Access ensures that all access to applications and data is granted on a least privilege basis, only after the user's identity verification and risk assessment.

Access Analyzer

Access Analyzer is a ServiceNow® Store App which is an access diagnostic tool. It helps to determine who has access to a resource.

Authentication

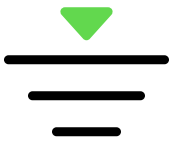


ServiceNow's authentication validates the identity of a user who accesses an instance, and then authorizes the user to features that match the user's role or job function.

ACL

Rules for access control lists (ACLs) restrict access to data by requiring users to pass a set of requirements before they can interact with it.

Data Filtration



Use data filtration to control access to tables and records based on subject attributes when performing read queries.

Security Roles

Security Roles provide added security, every user must have at least one role so that the instance can distinguish between internal and external users.

Connections and Credentials

ServiceNow Access Control

Domain Separation

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Credentials and connection information are required to gain access to a computer or network device for Discovery, Service Mapping, and Cloud Management or to perform work using Orchestration.

The SNC Access Control plugin enables you to control which Customer Service and Support employees can access your instance, and when.

With the ServiceNow AI Platform, service providers (SPs) can provide their customers with faster onboarding, meet compliance, and protect their data using domain separation.

Zero Trust Access (ZTA)

Zero Trust Access (ZTA) is a security model that assumes no user or device is trusted by default.

Zero Trust Access (ZTA) is a security model that assumes that no user or device is trusted by default.

ZTA ensures that all access to applications and data is granted on a least privilege basis, only after the user's identity verification and risk assessment.

Zero Trust - Policy Based Session Access

ServiceNow Zero Trust - Policy Based Session Access (Session Access) enables organizations to dynamically reduce user privilege in a web session based on a variety of factors, including IP address, location, authentication method, user’s role, group, user having MFA and attributes shared by the Identity Provider (IDP). This can help protect organizations from unauthorized

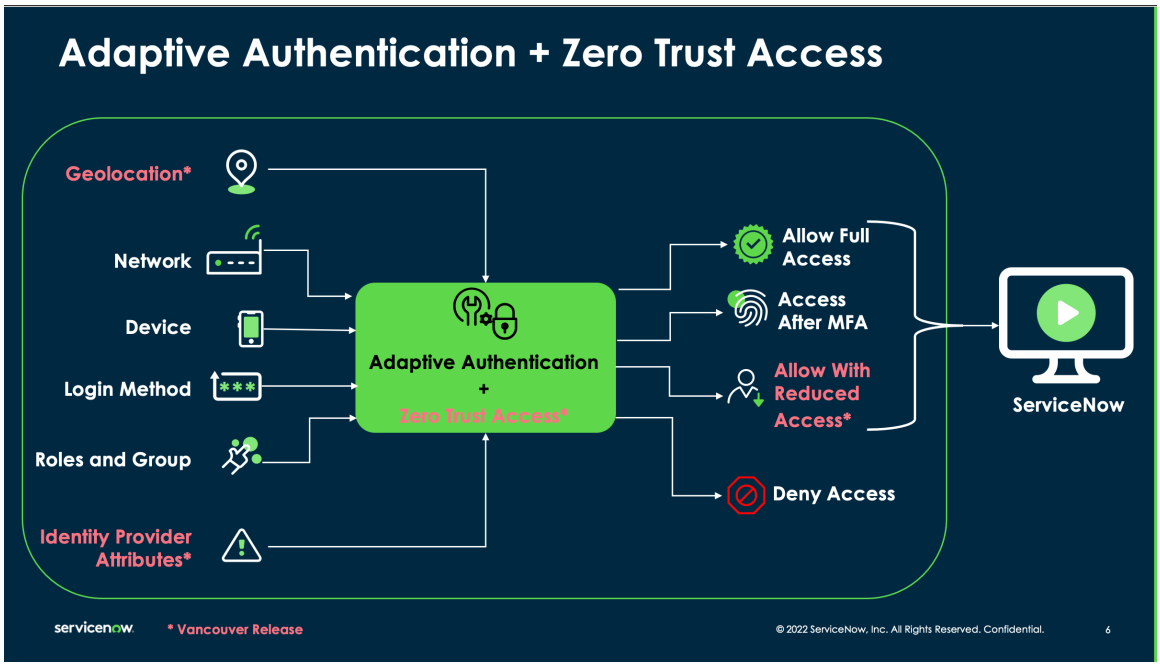
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

access and data breaches, even when high-privileged users access applications from untrusted devices or locations.

Zero Trust - Policy Based Session Access

It enables the security admins to reduce or limit user access in a session based on IP address, location, Identity Provider attributes, and user attributes using adaptive authentication policies.



Note:

- Session Access configurations can only be performed with `security_admin` role. You must elevate your role to `security_admin`.
- Session Access doesn't support integrations.
- Session Access has no impact if the reduced or limited role isn't assigned to a user. In this case, there are no changes to the logged in session. The user continues to access the instance with the assigned privileges.
- Session Access has no impact while the user is already logged in to the instance and simultaneously the admin configures the policy. The user has to log out from the session for the policy to be effective.
- Session Access has no impact when the user is in a trusted network and later switches to a VPN (change in location or network) within a session.
- Session Access is enforced at the time of login. Any change in risk parameters during the session won't result in reduced access. For example, a user switching from the corporate network to an untrusted network after establishing the session won't result in reduced access unless the user logs out and logs in again.
- Session Access (Zero trust access - ZTA) feature, roles like `snc_internal` and `snc_external` cannot be removed.
- Session Access (Zero trust access - ZTA) feature does not remove a role from the `sys_user_has_role` or the user group membership table. Based on the ZTA policy, it establishes the user session with reduced or limited roles.
- The scripts running in the system context will not honor the ZTA session roles.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Use case

Following are some of the use cases of Zero Trust Access:

- Reduce privileges based on the risk associated with the session. For example, a fulfiller role user logging from outside the trusted network can be configured to have only the requester role for the session.
- Reduce access based on IDP response for a user session, if the user is using an untrusted device. For more information, see Configure Identity Provider attribute for Session Access.

This role relegation ensures that the user doesn't have any other existing privileges in a session. When the user is logging in from a trusted network, all the existing privileges are assigned for a session.

Multiple IP conditions and multiple role or group assignments can be defined as part of the policy.

Zero Trust Access - Mobile

You can use the Zero Trust Access - Session Access policy within the Adaptive Authentication policy to reduce the roles or privileges of the particular session in mobile.

Zero Trust Access - Session Access mobile can be enabled by enabling the **glide.authenticate.session_access.mobile.enabled** from the system properties table.

To use Zero Trust Access - Session Access mobile with the IDP attributes you can configure the **glide.authenticate.session_access.mobile.refresh_token_interval** field. This enables the administrators to effectively control the session access based on refresh token.

For more information, see Configure Zero Trust Access for mobile.

Activate Zero Trust Access

Activate the **Zero Trust - Policy Based Session Access** `com.snc.zero_trust_session_access` plugin to enable security admins to reduce or limit user access in a session based on IP address, location, Identity Provider attributes, and user attributes using adaptive authentication policies.

Before you begin

Role required: admin

Plugin type: Paid and requires license.

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the **Zero Trust - Policy Based Session Access** (`com.snc.zero_trust_session_access`) plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Configure Session Access role

Configure Session Access to reduce user access in a session based on IP, location, Identity Provider attributes, and user attributes using adaptive authentication policies.

Before you begin

Role required: security_admin

Note:

- Session Access configurations can only be performed with `security_admin` role. You must elevate your role to `security_admin`.
- Session Access doesn't support integrations.
- Session Access has no impact if the reduced or limited role isn't assigned to a user. In this case, there are no changes to the logged in session. User will still continue to access the instance with their assigned privileges.
- Session Access has no impact while the user is already logged in to the instance and simultaneously the admin configures the policy. The user has to log out from the session for the policy to be effective.
- Session Access is enforced at the time of login. Any change in risk parameters during the session won't result in reduced access. For example, a user switching from the corporate network to an untrusted network after establishing the session, won't result in reduced access unless the user logs out and logs in again.
- Session Access (Zero trust access - ZTA) feature, roles like `snc_internal` and `snc_external` cannot be removed.
- Session Access (Zero trust access - ZTA) feature does not remove a role from the `sys_user_has_role` or the user group membership table. Based on the ZTA policy, it establishes the user session with reduced or limited roles.
- The scripts running in the system context will not honor the ZTA session roles.

Procedure

1. Navigate to **All** > **Zero Trust Access** > **Session Access Role Configurations**.
2. To create a Session Access role configuration, select **New**.
3. On the form, fill the fields:

Session Access Role Configuration

Field	Description
Name	Name of the configuration
Description	Short description of the configuration.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Policy	Choose the adaptive authentication policy. Use the look-up icon to view the list of policy.
Action	**Remove Roles** or **Limit to Roles**. ○ **Remove Roles**: When the configured user logs in, the list of roles provided in the Role or Group List are removed for the session. ○ **Limit To Roles**: When the configured user logs in, only the selected roles are provided to the user and all other roles are removed for the session.
Role List	Choose roles from the Role List.
Group List	Choose the roles from the Group List that you want to remove or limit to the user.

4. Select, **Submit**.

   The login for users based on the configured countries is as follows:

   - In **Remove Roles**, the users from the configured countries with the selected roles no longer have those roles for the session.
   - In **Limit To Roles**, the users from the configured countries with the selected roles only have those roles for the session.

   To know more about how to remove or limit roles for a session explained with a sample use-case, see Tutorial: Use Zero Trust Access.

Zero Trust Access system properties

Use system properties to enable and customize Zero Trust Access to meet your security requirements.

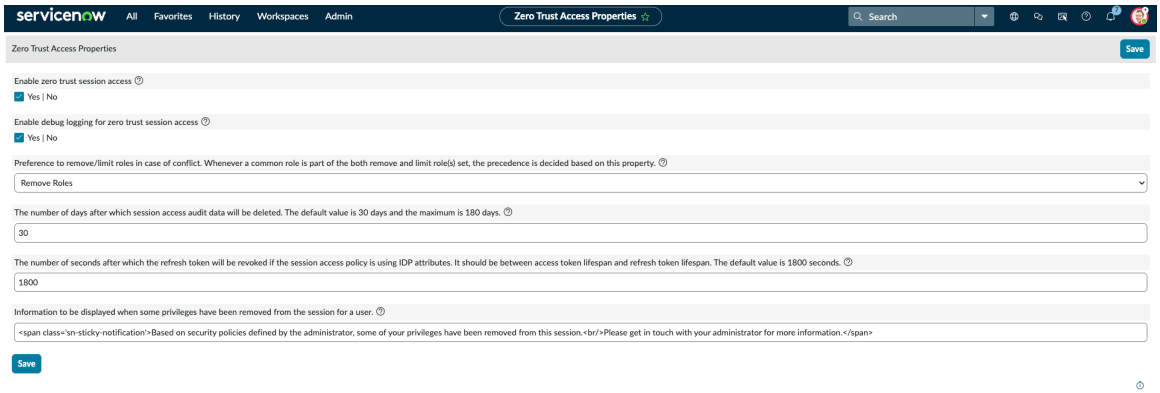
Properties



Zero Trust Access system properties

Property	Description
Enable Zero Trust Session Access	Option that enables administrators to use the Zero Trust Session Access feature. By default the value is `false`.
Enable debug logging for Zero Trust Session Access	Option to enable debug logging for Zero Trust Session Access.
Preference to remove/limit roles in case of conflict. Whenever a common role is part of both remove and limit role(s) set, the precedence is decided based on this property.	**Remove Roles** or **Limit Roles**
The number of days after which session access audit data will be deleted. The default value is 30 days and the maximum is 180 days.	By default, it's 30 days.
The number of seconds after which the refresh token will be revoked if the session access policy is using IDP attributes. It should be between access token lifespan and refresh token lifespan. The default value is 1800 seconds.	By default, it's 1800 seconds.
Information to be displayed when some privileges have been removed from the session for a user.	Description that you want to display to your users regarding limiting or removal of privileges. Sample Description: `Based on security policies defined by the administrator, some of your roles have been removed from this session. Please get in touch with your administrator for more information.`

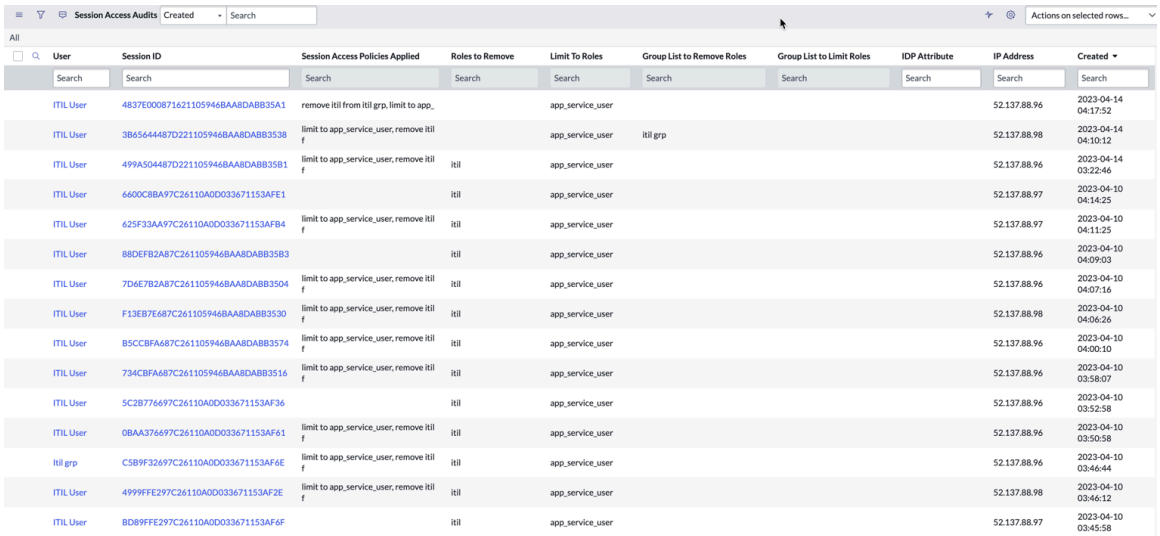
Session Access Audits

The Session Access Audits displays the Session Access logs and information related to a user's session.

Audits

The Session Access audit displays audit information as follows:

Note:
Use the `glide.authenticate.session_access.log_audit_event` property to populate the audit information.



Session Access Audits

Field	Description
User	Details of the user.
Session ID	Details about the session displayed as a unique ID.
Mobile Client	The mobile client details. **ServiceNow Agent** (Now Agent) and **ServiceNow Request** (Now Mobile).
Session Access Policies Applied	The Session Access policy that is applied.
Roles to Remove	Roles that were removed from the user while logging.
Limit To Roles	Roles that were limited to the user while logging.
Group List to Remove Roles	Information about the group that has removed roles for the user.
Group List to Limit Roles	Information about the group that has limited roles for the user.
Mobile Client	Details of the user logged-in through mobile with reduced or removed access.
IDP Attribute	The IDP that was used for that session.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Session Access Audits (continued)

Field	Description
IP Address	Details of the IP address used by the user to log in.
Created	Details of the created user record's date and time.

Tutorial: Use Zero Trust Access

Procedure to use Zero Trust Access feature with an end-to-end use case.

Before you begin

Role required: security_admin

Enable the **Enable Session Access property**.

Note:

- Session Access configurations can only be performed with `security_admin` role. You must elevate your role to `security_admin`.
- Session Access doesn't support integrations.
- Session Access has no impact if the reduced or limited role isn't assigned to a user. In this case, there are no changes to the logged in session. User will still continue to access the instance with their assigned privileges.
- Session Access has no impact while the user is already logged in to the instance and simultaneously the admin configures the policy. The user has to log out from the session for the policy to be effective.
- Session Access is enforced at the time of login. Any change in risk parameters during the session won't result in reduced access. For example, a user switching from the corporate network to an untrusted network after establishing the session, won't result in reduced access unless the user logs out and logs in again.
- Session Access (Zero trust access - ZTA) feature, roles like `snc_internal` and `snc_external` cannot be removed.
- Session Access (Zero trust access - ZTA) feature does not remove a role from the `sys_user_has_role` or the user group membership table. Based on the ZTA policy, it establishes the user session with reduced or limited roles.
- The scripts running in the system context will not honor the ZTA session roles.

Session Access is a feature that enables the administrators to dynamically reduce or restrict a set of roles to the user, when the user is trying to log in to the instance from different environments such as log in from the untrusted network, log in from a different device, and so on.

Session Access can be controlled by the created policy and selected action when performing the configuration. Some of the scenarios are as follows:

- If the Policy is true, and the roles action is set to **Remove Roles**, then the selected roles and its associated child roles are removed for the user when trying to log in to the instance.
- If the Policy is true, and the roles action is set to **Limit To Roles**, then only the selected roles and its associated child roles are assigned to the user when trying to log in to the instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The following procedure explains an end-to-end configuration of session access configuration based on which the role is limited to the user who is logging in to the instance. Similarly you can also remove roles by selecting the **Remove Roles** option during the configuration.

Procedure

1. Navigate to **All** > **Session Access** > **Session Access Role Configurations**.
2. On the Session Access Role Configurations page, select **New**.
3. To limit any role for the user, on the form, fill the fields:
   - Name
   - Description
   - Policy
   - Action
   - Role List
   - Group List

   a. Choose **Limit To Roles** to limit roles for the user.
   For example, **itil**.

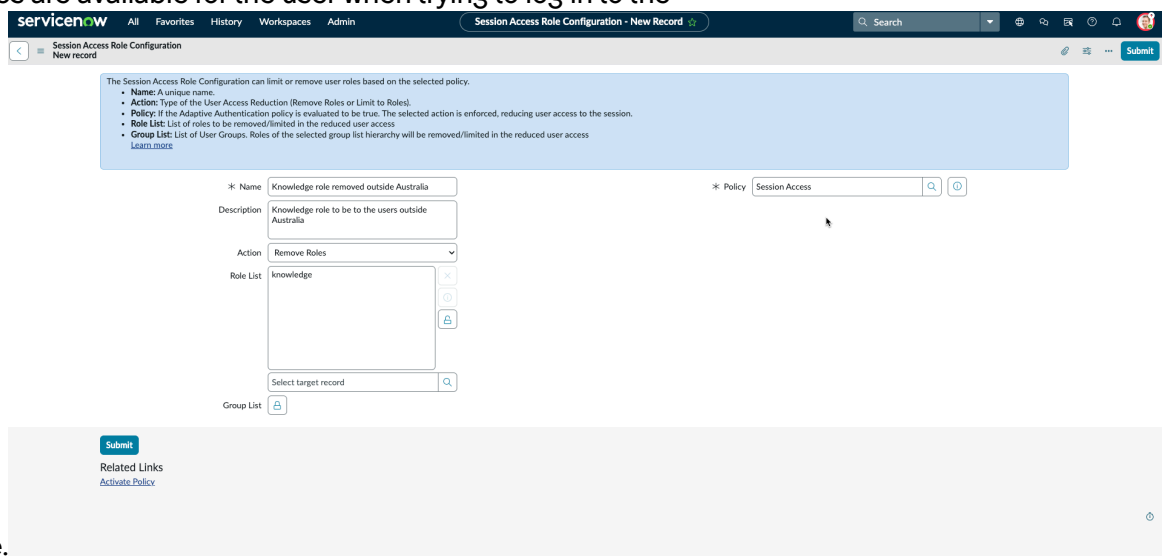
   b. Choose **knowledge** role from the Role List.

   c. Choose the **Policy**.

   You can create the Session Access policy using an authentication policies and filter criteria (Role, Group, IP, Location) with policy inputs and conditions.

   Use the policy in the Session Access configuration. For example, you want to limit the role (knowledge) to the user logging in outside the Location (Australia).

   d. Choose Action as **Limit To Roles**.
   If the Policy is true, then only the selected roles and their associated child roles are available for the user when trying to log in to the instance.



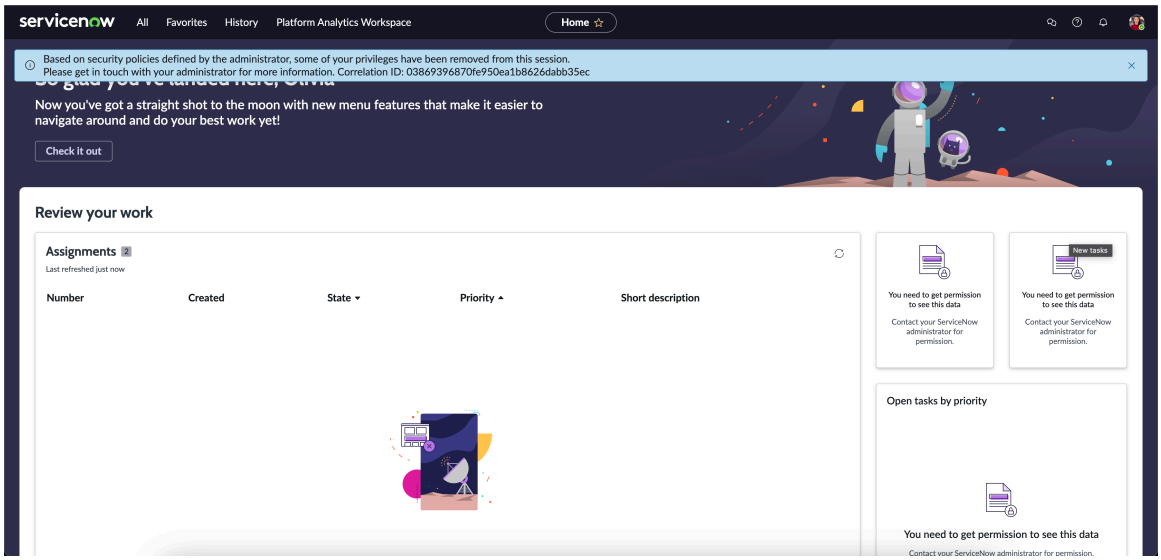
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

e. Select **Submit**.

Similarly, you can choose the group from the Group List to restrict or remove roles for the users within the group.

When the user logs to the instance outside Australia, only the **Knowledge** role and its associated child roles are assigned for the logged session and other roles to the user are restricted.

After logging in, the user is displayed with the following error message on the platform in their profile section:



The user can contact the administrators and provide the Correlation ID for investigation.

Note:
The correlation ID is the sys_id of the corresponding audit record in the session access audit table.

Configure Identity Provider attribute for Session Access

Use Identity Provider (IDP) attribute created from the Security Assertion Markup Language (SAML) response and OpenID Connect (OIDC) for removing or restricting user session access to the instance.

Before you begin

Role required: security_admin

Enable the **Enable Session Access property**.

Note:
To use the Session Access role configuration, you must elevate your role to `security_admin`.

Session Access can be controlled by the created policy and selected action when performing the configuration. Some of the scenarios are as follows:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- If the Policy is true, and the roles action is set to **Remove Roles** along with the IDP attribute input and condition, then the selected roles and its associated child roles are removed for the user when trying to log in to the instance.
- If the Policy is true, and the roles action is set to **Limit To Roles** along with the IDP attribute input and condition, then only the selected roles and its associated child roles are assigned to the user when trying to log in to the instance.

The following procedure shows steps to configure the IDP attribute from the SAML response a policy input to control session access.

Procedure

1. Navigate to **All** > **Session Access** > **Session Access Role Configurations**.
2. On the Session Access Role Configurations page, select **New**.
3. For removing any role for the user, on the form, fill the fields:
   - Name
   - Description
   - Policy
   - Action
   - Role List
   - Group List

   a. Choose **Remove Roles** to remove roles for the user.
   For example: **itil**.

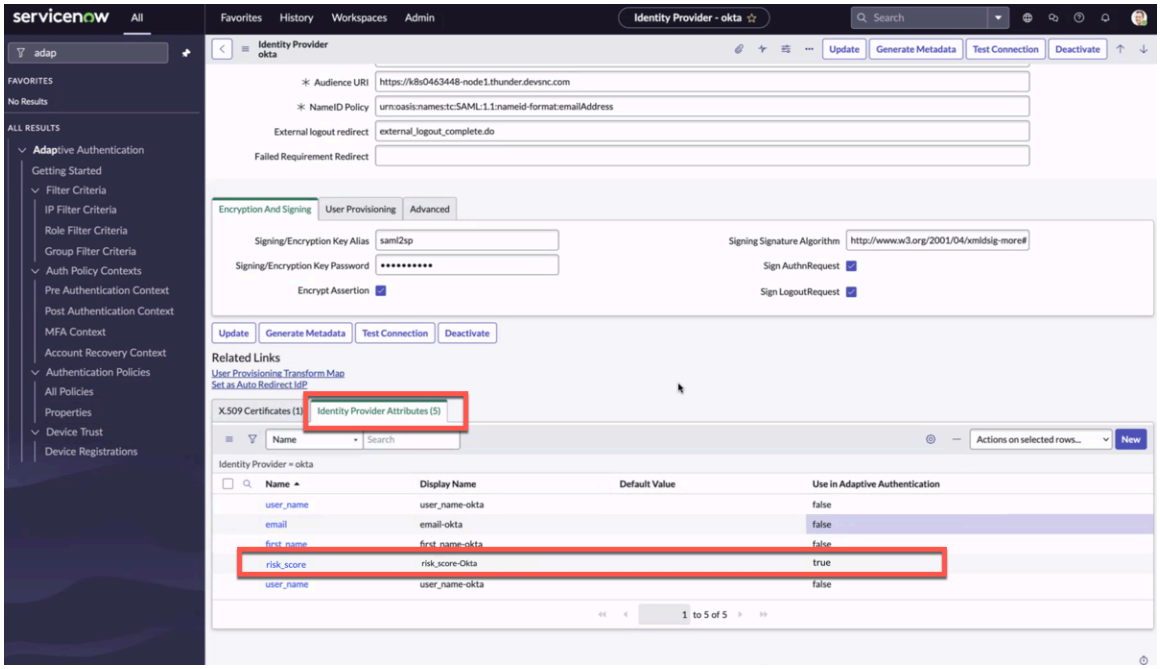
   b. Choose **itil** role from the Role List.

   c. Choose the **Policy**.
   To know more on how to create policy using different filter criteria using Adaptive Authentication policy creation, see Filter criteria.

   d. Choose Action as Remove Roles.
   If the Policy is true, and the roles action is set to **Remove Roles**, then the selected roles is removed for the user when trying to log in to the instance.

   e. In the Policy Input, create the Policy Input and Policy Condition.
   For example:
   - **Policy Input**: Risk score attribute from Okta (IDP).
   - **Policy Conditions**: Risk score from 60 through 80 as a condition.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Based on this configuration, when the risk score attribute value from the Okta (IDP) beyond 80, the user isn't authenticated with the roles (**employee**) and its child roles that were removed to the instance, the user is only authenticated with other roles assigned. If the risk score is from 60 through 80, the user is authenticated to the instance with all the roles.

For more information on how to create Post Authentication Context's Policy with Policy inputs and Condition, see Post-authentication context.

> **Note:**
> If the **Enable Session Access** property is inactive, then the configuration for Session Access doesn't restrict or remove the roles of the user.

f. Select **Submit**.

Zero Trust Access for Mobile

Zero Trust Access (ZTA) is a security model that assumes that no user or device is trusted by default.

You can use the Zero Trust Access - Session Access policy within the Adaptive Authentication policy to reduce the roles or privileges of the particular session in mobile for users.

To enable Zero Trust Access on mobile, you must perform the following tasks:

- Session Access configurations can only be performed with `security_admin` role. You must elevate your role to `security_admin`.
- Activate the **Zero Trust - Policy Based Session Access** `com.snc.zero_trust_session_access` policy.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Enable the **glide.authenticate.session_access.mobile.enabled** from the system properties

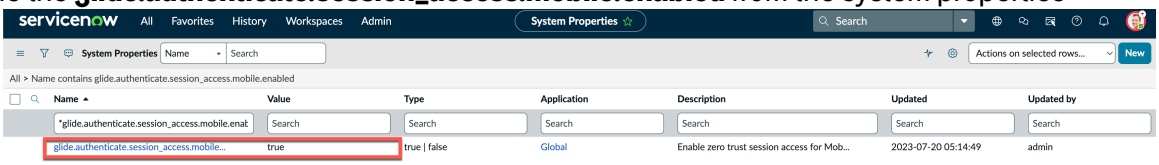


table.

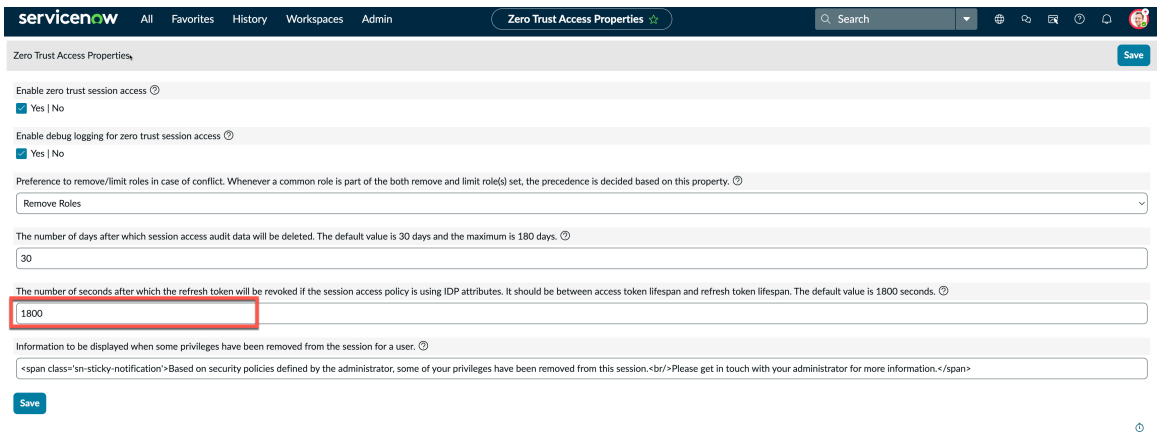
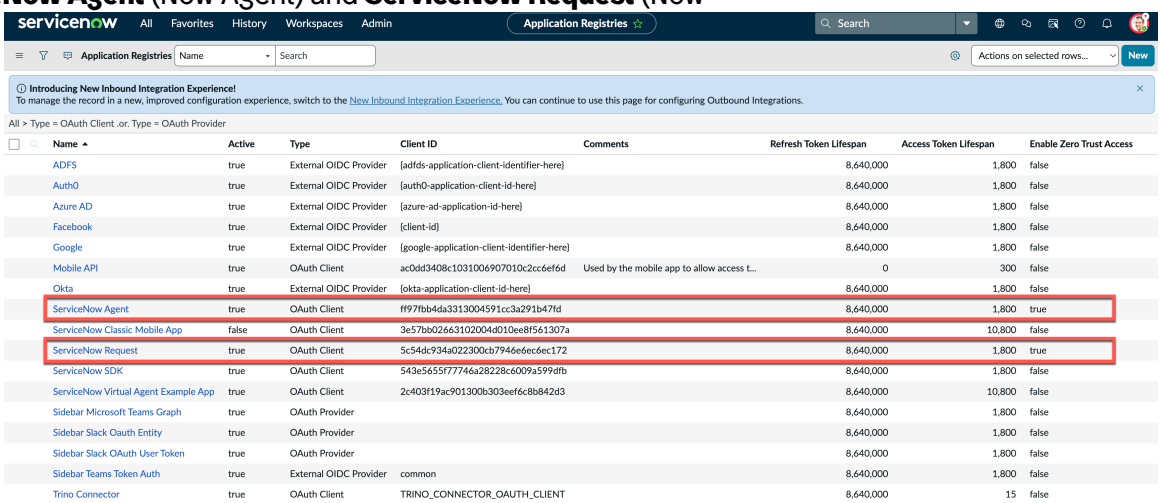
- Configure the **glide.authenticate.session_access.mobile.refresh_token_interval** field to control session access on mobile based on the refresh



token.

> **Note:**
> You must configure the refresh token seconds when using an IDP for Mobile App logins. By default, users are logged out from the mobile apps after 1800 seconds (30 minutes).

- Set Enable Zero Trust Access to true under **Application Registries** for the mobile client application (OAuth client). In this case, **ServiceNow Agent** (Now Agent) and **ServiceNow Request** (Now



Mobile).

- Configure Session Access role to either reduce or remove roles for the users logging based on the policy inputs and conditions. To learn more about the configuration, see Configure Session Access role.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The configuration evaluates the login to reduce or remove the roles of the users who access your ServiceNow® instance based on the policy filters and conditions. For more information, see Configure Zero Trust Access for mobile.

Continuous Authentication (CA)

ServiceNow's continuous authentication enables you to reverify and authenticate a user if they access resources that are protected by you.

Explore Learn the features and business value of Continuous Authentication.	Activate Understand how to Activate Continuous Authentication.
Configure Configure Continuous Authentication.	Reference - Properties Know about the properties in Continuous Authentication.

Explore Continuous Authentication

ServiceNow's continuous authentication (CA) enables you to reverify and authenticate a user if they access resources that are protected by you.

ServiceNow's continuous authentication is a security mechanism designed to verify a user's identity not just at the initial login, but throughout the user's entire session. CA is built on ServiceNow's zero trust access security architecture that aims to enhance security by ensuring that the user remains who they claim to be, even after the initial authentication process.

CA works on the following zero trust access principles:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **Verify explicitly**: No implicit trust for any user, device, or system within a network, regardless of location. Every user and device must be explicitly authenticated and authorized, regardless of location or past access.
- **Use least privilege access**: Grant only the minimum access or permissions needed to perform specific tasks and limit potential damage from compromised accounts or systems."
- **Assume breach**: Instead of relying only on prevention, assume breach and focus on proactive detection, containment, and response.

CA provides the ability to enforce step-up authentication or re-authentication based on the data users are accessing and activities they are performing. It be opted by administrators for creating security policies at a table or data class level.

You can enforce step-up authentication (MFA) or re-authentication (SSO - SAML or OIDC) within a logged-in session whenever there is an attempt by the user to access Personally Identifiable Information (PII) and sensitive data.

Note:
You must install the **Zero Trust - Continuous Authentication** (`com.snc.zero_trust_continuous_authentication`) for opting CA which requires a license.

Benefits

Following are the some of the benefits of using CA:

- **Enhanced Security**: By continuously verifying the user's identity, the system can detect and respond to potential security threats more quickly.
- **Reduced Risk of Account Takeover**: Even if an attacker gains access to a user's session, continuous authentication can help prevent them from accessing confidential data.

Use cases

Following are some of the use cases for using CA:

- Enforce re-authentication before allowing access to sensitive data using different policies.
- Enforce periodic re-authentication or step-up authentication using different policies:
  - Use re-authentication that can include IdP's MFA, IdP's SSO.
  - Use step up authentication with ServiceNow's MFA.

Roles in CA

CA has the following roles:

- CA Admin (ca_admin): Ability to create, edit, and view CA policies. Configure CA properties and view dashboards (Metrics) of CA.
- Policy Admin (ca_policy_admin): Ability to create, edit, and view CA policies..
- Auditor (ca_auditor): Ability to view dashboards (Metrics) of CA. And policies, and logs of CA.

To configure CA you must elevate your role to **ca_admin** and perform the policy configurations.

Note:
All these 3 roles are elevated roles.

Following are the different system properties for CA:

Continuous Authentication system properties

Property	Description
General Properties	
Continuous Authentication (*glide.zta.continuous_authentication.feature.enabled*)	Enable to use Continuous Authentication feature
Enable Debugging (*glide.zta.continuous_authentication.debug.enabled*)	Enable to view the debugging information related to continuous authentication.
High Assurance	
High Assurance session length (*glide.zta.high_assurance.session.timeout*)	Specify the high assurance session length, after which the end-users should re-authenticate. Default: 10 mins. **Note:** The value must be between 1 and 480.
Default high-assurance session length upon login (*glide.zta.default.high_assurance.session.timeout*)	Specify the duration in minutes for the default high-assurance session length upon user login. Default value: 5 mins. **Note:** The property is only applicable for local login.
Configure end-user display message (*glide.zta.high_assurance.session.message*)	Specify the message that is displayed to the end-user for re-authentication. Default message: `One or more resources require additional authentication due to a policy created by your administrator.`

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Continuous Authentication system properties (continued)

Property	Description
Total times failed authentication before user account lock-out (*glide.zta.high_assurance.session.max.login.failed attempts*)	Set the maximum failed authentication attempts before the users are logged out. **Note:** The value must be between 3 and 10.
Audit properties	
Total no of days to keep audit records (*glide.zta.continuous_authentication.audit.records.lifespan*)	Specify the no of days you want to save the audit records for CA. **Note:** The value must be between 1 and 180.
Total no. of days after which policies will be deleted after deactivated (*glide.zta.continuous_authentication.policy.lifespan*)	Specify the no of days after which the CA policies are deleted.

Important:

- By default, high-assurance sessions are not required for mobile app sessions, even when a continuous authentication policy is active on source. To change this behavior and block access from mobile app sessions, update the **glide.zta.high_assurance.mobile.session.allowed** property value to `false`.
- The **sys_properties**, **sys_continuous_auth_policy**, **sys_user** tables are excluded for CA and cannot be added to the CA policy configuration.

Metrics

Pre-work for Continuous Authentication

Pre-work for Continuous Authentication

Ensure to perform the following pre-work before using Continuous Authentication (CA).

CA is built on ServiceNow's zero trust access security architecture that aims to enhance security by ensuring that the user remains who they claim to be, even after the initial authentication process.

Note:
You must install the **Zero Trust - Continuous Authentication** (`com.snc.zero_trust_continuous_authentication`) for opting CA which requires a license.

CA configuration can be performed based on the following:

- LDAP or Local login (Username and Password)
- SSO login (SAML or OIDC).

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

CA for Local login

When the users are performing local login and to verify the Identity of the users, MFA is used as an authentication mechanism. If the users haven't setup MFA, it is compulsory to complete the setup.

Note:

- From Yokohama, MFA is enforced to users for every login to ServiceNow performing local login.
- Make sure the MFA properties are Active and configured based on your requirement. To know more about MFA properties, see Multi-factor Authentication system properties.

To know more, see High Assurance session for non-SSO login.

CA for SSO login

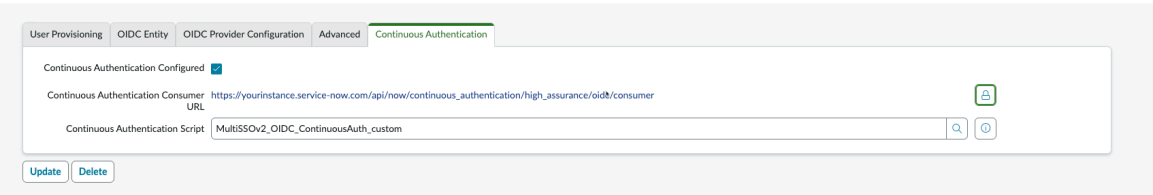
When the users are performing SSO based login (SAML or OIDC). To verify the Identity of the users, the same SSO used during initial login is shown as the re verification with re-authentication or IdP's MFA.

Note:

- You must install the **Zero Trust - Continuous Authentication** (`com.snc.zero_trust_continuous_authentication`) for opting CA which requires a license.
- Activate the Integration - Multiple Provider Single Sign-On Installer (*`com.snc.integration.sso.multi.installer`*) plugin.

You must configure the IDP for CA as follows:

- Enable the check box that is required to be set on a given multi SSO record to validate that set ready for using CA.



- For OIDC, CA relies on redirecting back to the `api/now/continuous_authentication/high_assurance/oidc/consumer` endpoint, which must be configured on the IDP. Both re-authentication and IdP's MFA options are available.
- For SAML, the SSO records use the default re-athentication script for all Identity Providers (IdP) to support re-authentication.

Note:

- To configure step up for **Okta** you can use the **ContinuousAuth_Okta_StepUp_Script** in the IdP record. To know more, see this documentation.
- To configure step up for **Entra ID** or **Azure** you can use the **ContinuousAuth_Azure_StepUp_Script** and add the required claim. To know more, see this documentation.

To know more, see High Assurance for SSO login.

- Configure Continuous Authentication

Activate Continuous Authentication

For activating the Continuous Authentication feature on your instance, install the **Zero Trust - Continuous Authentication** (`com.snc.zero_trust_continuous_authentication`) plugin.

Before you begin

Role required: admin

This plugin enables security administrators to define security policies that require step-up authentication (MFA) or re-authentication (SSO) within a logged-in session, based on the data the user is accessing and the activities they are performing.

You must install the **Zero Trust - Continuous Authentication** (`com.snc.zero_trust_continuous_authentication`) for opting CA which requires a license.

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the **Zero Trust - Continuous Authentication** (`com.snc.zero_trust_continuous_authentication`) plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

   Note:
   When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

   You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin

- Role required: Admin (ca_admin)

> **Note:**
> You must elevate your role to **ca_admin**.

- You must install the **Zero Trust - Continuous Authentication** (`com.snc.zero_trust_continuous_authentication`) for opting CA which requires a license.
- Enable the Continuous Authentication (*`glide.zta.continuous_authentication.enabled`*) system property. For more information, see System properties.
- Activate the Integration - Multiple Provider Single Sign-On Installer (*`com.snc.integration.sso.multi.installer`*) plugin.
- Understand the pre-work that is required before configuring CA for the instance. For more information, see Pre-work for Continuous Authentication.
- CA policies can be configured for Data Class or Table.

Procedure

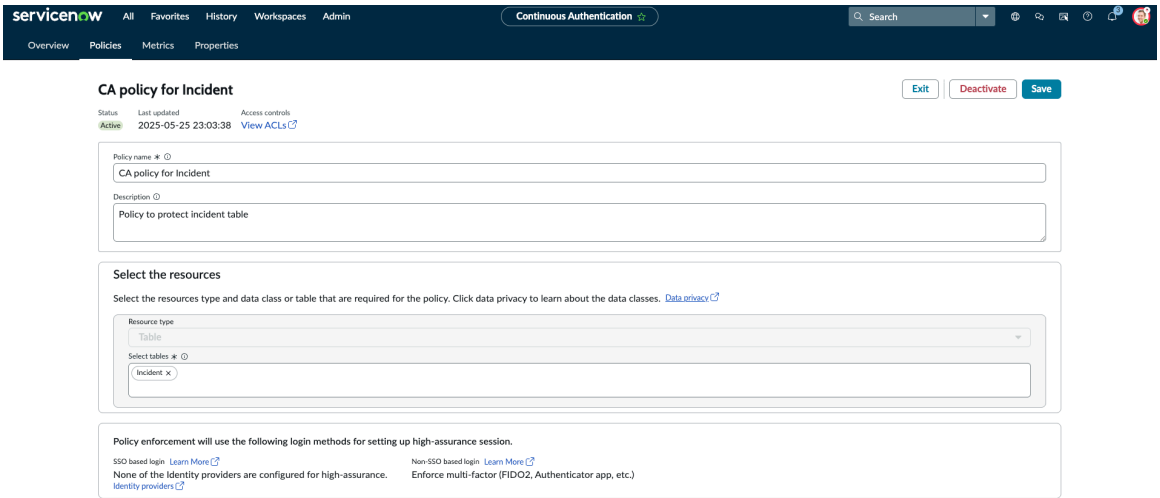
1. Navigate to **All** > **Continuous Authentication**.
2. Select **Policies** tab.
3. Select **New**.
4. On the form, fill the fields:

Continuous Authentication

Field	Description
Policy Name	Name of the policy
Description	Generic description to the policy
Select the resources	Options: ○ **Data Class**. You can create data class and use it for CA policy configuration. **Note:** To know more about how to create data class, see Data Classification. ○ **Table**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Note: ○ Table selected with metadata displays an error. ○ You need to check if you actually want to restrict access to the metadata table, since it can impact configuration access to your users. ○ The **sys_properties**, **sys_continuous_auth_policy**, **sys_user** tables are excluded for CA and cannot be added to the CA policy configuration.



Note:
You can use either of the login methods for the CA policy:

- **SSO based login**: Specify the fields in the **Continuous Authentication** tab within the Identity Provider record and the set the Identity Provider record as **Active**.

  To know more about Identity Providers configuration, see OIDC and SAML.

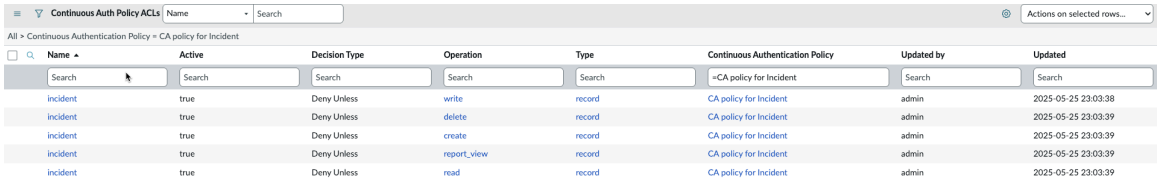
- **Non-SSO based login**: By default, if there are no Identity Provider with Continuous Authentication configuration, Multi-factor Authentication (MFA) is used as a login method. Make sure the MFA properties are Active and configured based on your requirement. To know more about MFA properties, see Multi-factor Authentication system properties.

5. Select **Save & Activate**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

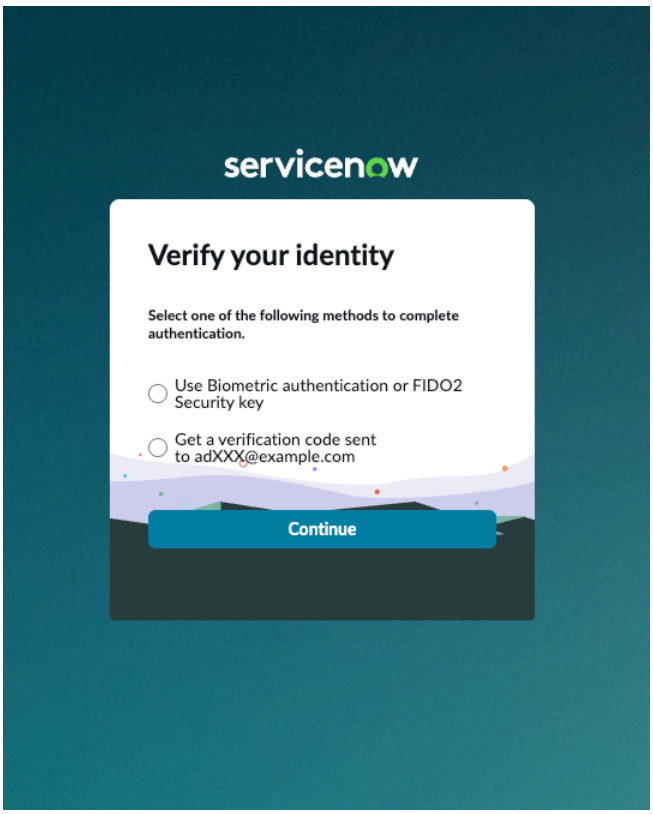
Result

Based on the details provided for the configuration, CA policy is created with Access Control List (ACLs) for the selected table or data class. You can view the details of the ACLs that are created by selecting the **View ACLs** on the policy page.



The CA policy created, prompts the user for authentication to access table or data class that you've protected using the policy, based on the following scenarios.

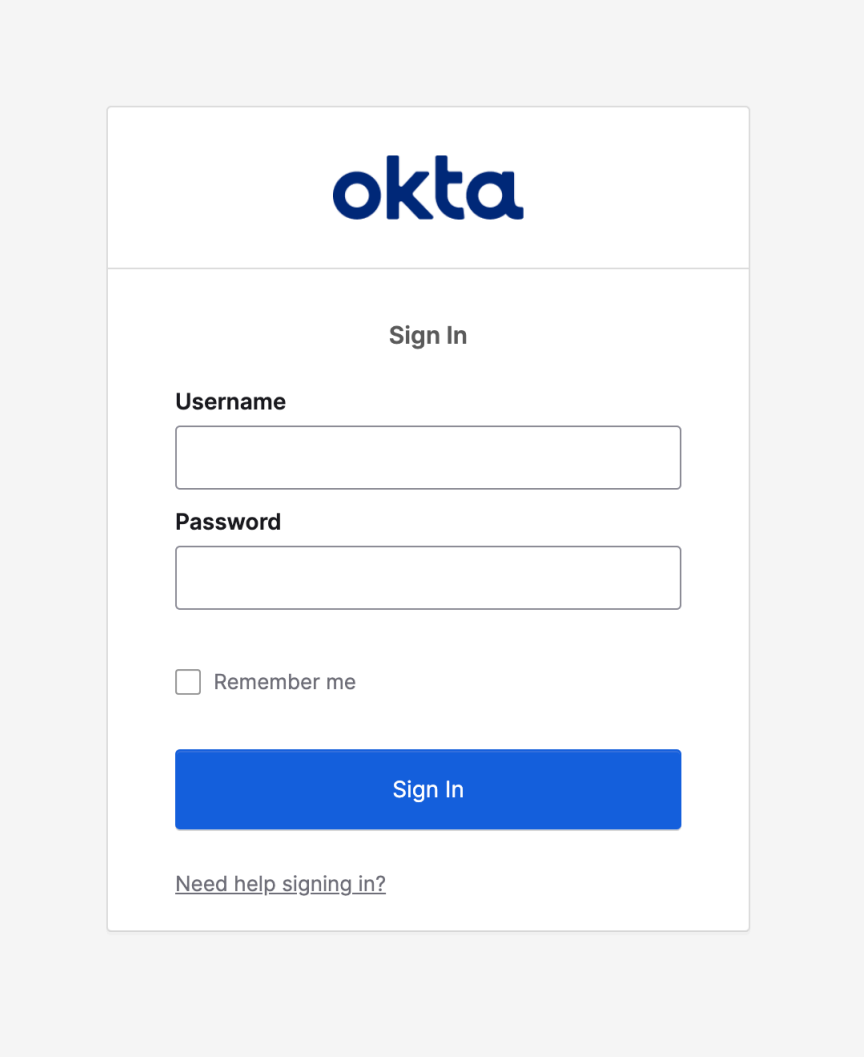
- User who had performed local login to log in to the instance, is displayed with platform MFA for step-up authentication.



Note:
The users recently used MFA factor is displayed for authentication.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- User who had performed SSO login (OIDC or SAML) to log in to the instance is displayed with the SSO for re-authentication.



An high assurance session is now established for the user. High assurance session is limited to the High Assurance session length (*glide.zta.high_assurance.session.timeout*) system property. If the high assurance session time exceeds the property length, the user is prompted for re-authentication or step up authentication.

To know more about the end to end configuration of continuous authentication for table or data, see:

Explore Continuous Authentication

High Assurance session with Continuous Authentication

Establish high assurance session for with ServiceNow's continuous authentication.

A high assurance session is a security measure to establish a secure and trusted connection with the identities (users) who access data and are verified with a high degree of confidence.

ServiceNow's High assurance is achieved through robust authentication methods which enforces re-authentication using methods such as Multi-factor Authentication (MFA) and Single Sign On (SSO) while the users try to access data that are sensitive.

When the user re-authenticates or perform step-up authentication (MFA), there's a high assurance session that is established, which provides the ability for the users to access the data protected by the CA administrator based on the CA policy configuration.

Following are the re-authentication methods used to establish High-assurance based on the type of login:

- High Assurance for SSO login
- High Assurance for non-SSO login

High assurance session created by the user is valid based on the High Assurance session length (*glide.zta.high_assurance.session.timeout*) determined by the CA administrator.

The high assurance session can be customized based on your requirement by setting the **High Assurance** system properties:

High Assurance system properties

Field	Description
High Assurance session length (*glide.zta.high_assurance.session.timeout*)	Specify the high assurance session length, after which the end-users should re-authenticate. Default: 30 minutes. **Note:** The value must be between 1 and 480.
Default high-assurance session length upon login	Specify the duration in minutes for the default high-assurance session length upon user login. Default value: **5** minutes. **Note:** This property is only applicable for non-sso logins.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

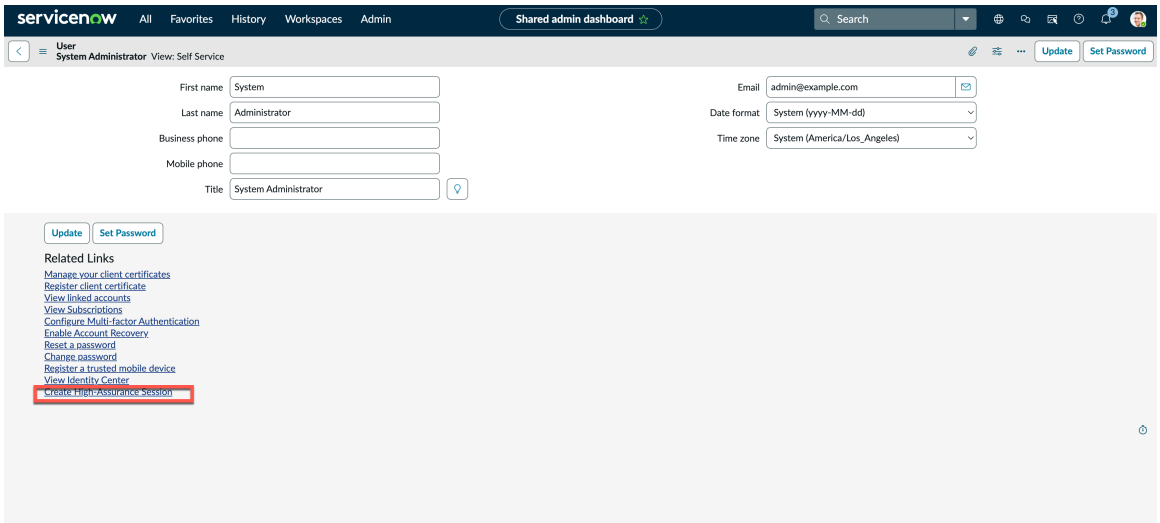
High Assurance system properties (continued)

Field	Description
Configure end-user display message (*glide.zta.high_assurance.session.message*)	Specify the message that is displayed to the end user for re-authentication. Default message: `One or more resources require additional authentication due to a policy created by your administrator.`
Total times failed authentication before user account lock-out (*glide.zta.high_assurance.session.max.login.failed attempts*)	Set the maximum failed authentication attempts before the users are logged out. **Note:** The value must be between 3 and 10.

High assurance session as a Preemptive measure

Users who work with high privilege data such as financial transactions, government information, PII, can establish high assurance session as a preemptive measure to avoid frequent authentication notification during their logged in session.

High assurance session can be created by the themselves. To create a high assurance session, select **User Profile** > **Profile**. In the **Related Links** section, select **Create High-Assurance Session**. Verify your identity to create a high assurance session.



Related topics

High Assurance for SSO login

Establish high assurance session for SSO login using ServiceNow's continuous authentication.

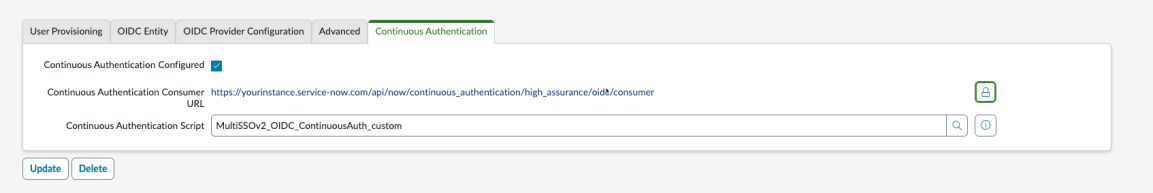
A high assurance session is a session that requires a user to verify their identity and authenticate with a specific identity or Identity Providers for a specific time frame.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

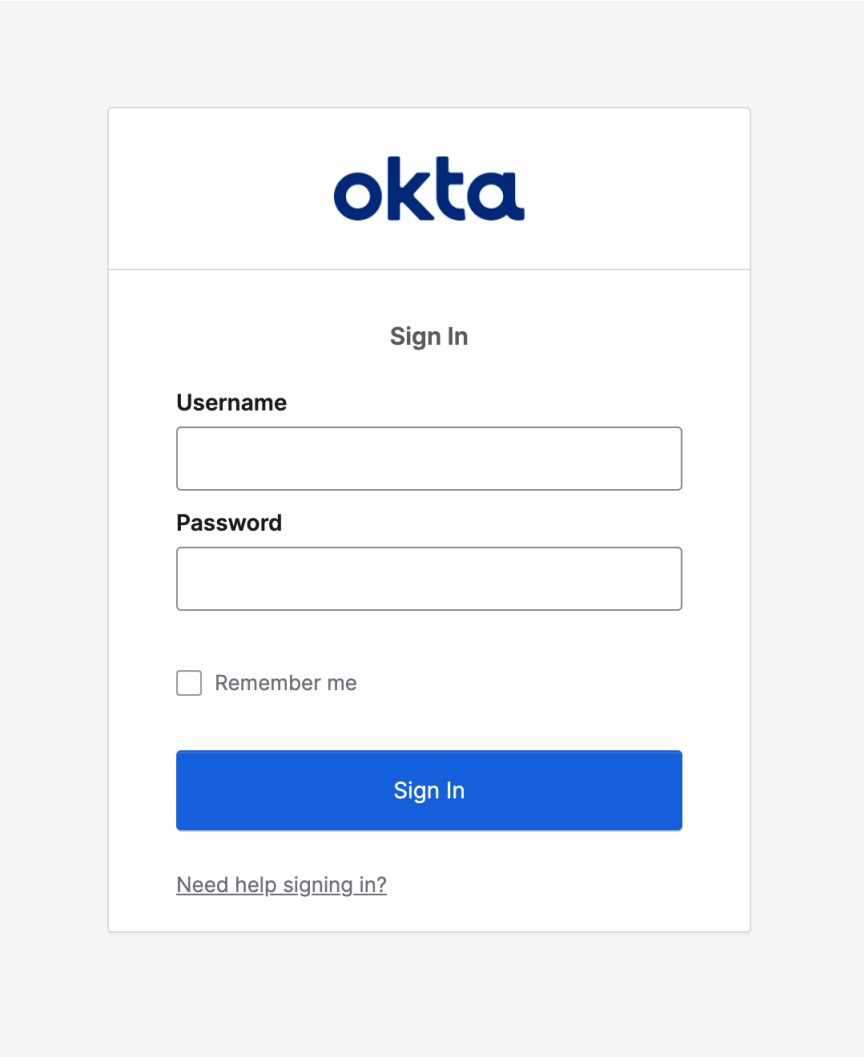
ServiceNow's continuous authentication (CA) feature enables you to create policies that creates a high assurance session to the users who access Personally Identifiable Information (PII), sensitive data, or restrict the access to explicit data that you want to protect.

When the user re-authenticates, there's a high assurance session that is established, which provides the ability for the users to access the data protected by the CA administrator based on the CA policy configuration.

You can create CA policies to verify the users identity and authentication the users to access the data that you've protected. You can configure the CA policy and provide the Identity Providers details in the Identity Providers record to establish high assurance session.



The users who are performing SSO based login (SAML or OIDC) and whenever there is an attempt to access the protected data, re-authentication screen is prompted with the same SSO that was used by the user during the initial login.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

After successful SSO authentication, the protected data is displayed to the users for a certain time frame. You can configure the properties to change the time limit based on your requirement. To know more, see High Assurance session with Continuous Authentication.

Performing re-authentication with SSO login (SAML or OIDC), creates a high assurance session establishing a secure and trusted connection with the identities (users) who are accessing the protected data.

An high assurance session established for the user is limited to the High Assurance session length (*glide.zta.high_assurance.session.timeout*) system property. If the high assurance session time exceeds the property length, the user is prompted for re-authentication or step up authentication.

Related topics

- High Assurance session with Continuous Authentication

The log page displays information about the authentication method, correlation ID, with other details related to the user's session.

Domain separation for service providers

With the ServiceNow Platform, service providers (SPs) can provide their customers with faster onboarding, meet compliance, and protect their data using domain separation. You can separate client data, processes, and reports into logical groupings called domains. SPs control who sees and accesses what content.

Explore Learn about Domain Separation.	Configure Configure Domain Separation.
Reference Get details about Domain Separation.	Analyze Learn more about how to analyze Domain Separation

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Exploring domain separation

With domain separation you can separate data, processes, and administrative tasks into logically defined domains.

Domain separation is best for those customers who:

- Need to enforce absolute data segregation between business entities (data separation).
- Customize business process definitions and user interfaces for each domain (delegated administration).
- Maintain some global processes and global reporting in a single instance.
- Separate data between service providers, customers, partners, or sub-organizations.
- Have minor or moderate process differences among customers.

Domain separation compared to separate instances

While domain separation provides multi-tenancy support, multi-tenancy is still contained within a single instance. Some global properties, data, and processes are shared across all domains. For example, having the system *Remember me* on the login page of the system is global and cannot be specified per domain.

If you need complete and total separation of all system properties and do not require global reporting or global processes, then separate instances are the best option.

Data separation

Members of a domain see only the data contained within their domain or the child domains that are lower in the domain hierarchy. By default, all users and all records are members of the global domain unless an administrator assigns them to a particular domain. Once you assign a user or a record to a domain, the instance compares the user's domain to the record's domain to determine whether the user can view the record.

ServiceNow applications are defined with the following incremental support levels. These levels are based on the perspective of actual use cases and personas.

Data Separation: Tenants see only data that they have permissions to see. Tenants can be granted access to other tenant data, but cannot query tenant data if they don't have access.

UI Separation: Supports a tenant-specific experience for UI elements such as views, lists, labels, and so on.

Business Logic Separation: You can create tenant-specific system policies such as email notifications, business rules, client scripts, UI policy, and UI actions.

Hierarchical Modeling: Nested-multi-tenancy so parent tenants can access child tenant resources. Business logic for parent tenants runs automatically for child tenants, and can be overridden at any level.

Cross-Tenant Intelligence (Domain Scope): Handles automatically the data, metadata, business logic, and processing context for tenants that have access to additional tenant data.

In general, data defined at a higher level in the domain hierarchy is not visible at lower levels in the hierarchy.

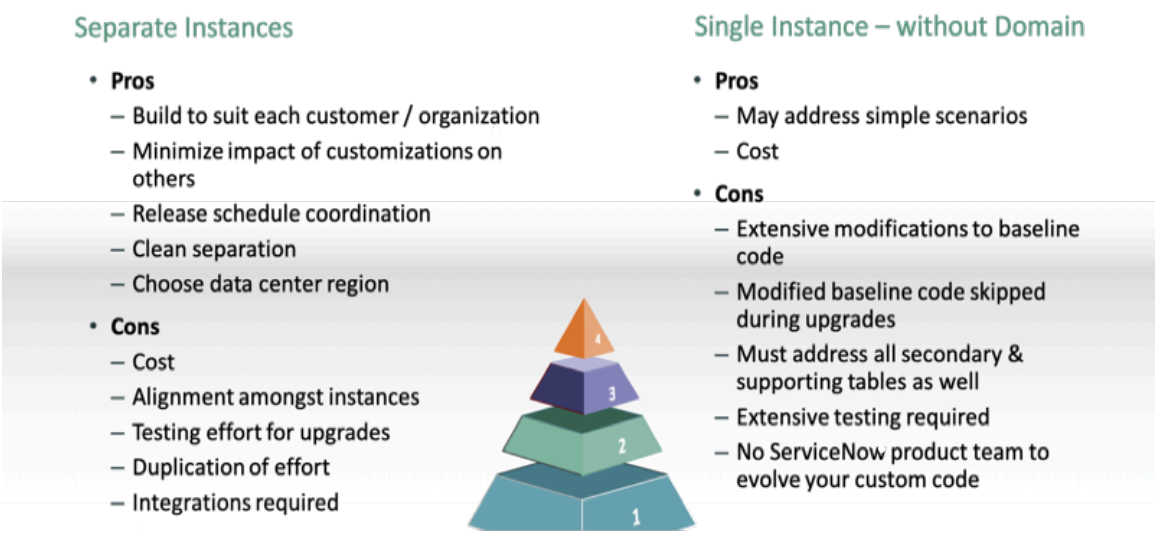
Domain path migration

Domain paths are used for all customers. Domain numbering is not used. Customer Service and Support can assist in the upgrade.

Alternatives to domain separation

Separate instances are a common alternative to domain separation. This provides a great degree of flexibility in meeting the requirements for customers and stakeholders with little to no impact on others.



Warning:
Before activating domain separation, consult your representative to verify that it is suitable for your environment. Domain separation adds a level of administration overhead. Although it can be disabled, it cannot be removed from an instance.

Configuration that can be delegated to internal or external customers

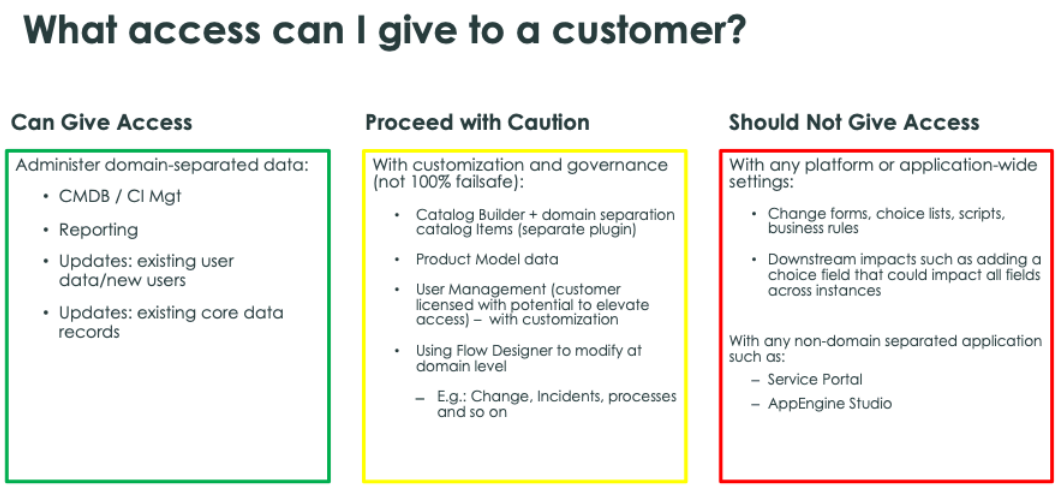
Domain separation is designed to give ServiceNow® service providers (SPs) the ability to configure the services they offer to their customers. It is not designed to enable their customers to administer those services themselves, except in a few areas that this topic details.

overview

It is safe for SP customers, on their own, to manage data contained within their domain that does not affect licensing or other customers. For example, it is safe for a customer to create new reports or manage configuration items, but it's not safe for them to customize fields, choices, business rules, and other processes where they can impact other customers on the same instance.

The ServiceNow base system administrative roles and their access controls on the ServiceNow platform are designed for a single admin team per instance. For example, the domain_admin role is granted to one of the SP's resources to manage all domain setting for the instance, and to create new domains. For any domain-specific admin tasks, the SP should create new "customer admin" roles and access controls as needed to grant specific access to their customers.

The following image is an overview of common admin functions in varying categories of what is safe for a customer to do.



Can give access

Examples:

- CI data management in the CMDB
- Report creation
- Updates to existing user data, or new users without roles
- Updates to existing core data records such as department, group, location,cost center, or new groups without roles, and new departments/ cost centers/ location.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Proceed with caution

Examples:

- Catalog Items: To create customer-specific catalog items that can be updated by the customer, two capabilities can be used together: Domain separation for catalog items (Domain separation and Service Catalog) enables the instance owner to create items in the customer's domain. The instance owner can create a role to allow customers to update safe fields such as price, description, and images. The Catalog Builder (new in the Quebec release), gives the SP admin team the ability to create item templates that are safe to distribute to customers to create new items within their domain from within a prescriptive UI experience.
- User/Group Management: It's safe to create a "customer admin" role that can create and modify user records, but adding and removing roles can affect security and licensing. There is no way in the base system to subdivide roles that are safe for a customer to be able to grant them. The same goes for the creation and modification of groups. While the group itself can be modified, the addition or subtraction of roles should be controlled.
- Flow Designer: ServiceNow Workflow Studio is the building tool used to create process (workflow) for tables. The flow_designer role gives customers script-free access to build flows. They can read and clone every flow in domains above them in the hierarchy. They can create and modify flows in their domain. This cannot happen in a silo, however. Anyone who can affect process must be added to the global admin team for governance so processes do not cancel out each other or cause other conflicts.

Do not give access

Understanding how choice fields work is helpful to understand why only the SP admin team should be managing them.

- Structure of a choice field: Choice field values are stored in the sys_choice table and grouped based on: Table, Domain, and Language.

  For example, the **State** field in a Task is available to every table that extends a Task. That means that each table can have its own values, those values can be multiplied by domain, and the domain values can be multiplied by language.

  All of the values for **State** across all tables, domains and languages are considered the values for the **State** field.

- How changes to choice fields work: When a choice field is updated, a payload is created with all values for that field (Tables, Domains, Languages). When you install this payload on an instance, all existing values for the field are deleted and the new values are loaded. This ensures that there are no duplicate entries or leftover values that are no longer valid.

  For this reason, it's impossible to give a customer in a domain-separated instance the ability to update choice fields directly because that would affect the entire instance. In addition, you can't update choices directly in a production instance because any imported update sets that affect that field would overwrite the existing choices. In some cases, choice fields can drive processes themselves, which would break if a customer were to change those fields.

- Domain separation release notes

Domain assignment

By default, domain separation adds a domain field to tables and their extensions.

You can also extend domain separation to any new tables you create by adding a **sys_domain** field to the table's dictionary definition. By default, the system only domain-separates platform and baseline application tables where appropriate.

> **Warning:**
> ServiceNow does not recommend domain-separating platform tables (any table with the sys_ prefix such as the Dictionary Entry [sys_dictionary] and Dictionary Entry Override [sys_dictionary_override] tables) because it can produce unexpected results.

Each record is assigned a single domain. That domain is stored in the **sys_domain** field. Several tables, by default, have the **sys_domain** column and are already domain separated.

The value of the **sys_domain** field contains the domain assigned to the record by any of the following:

- Company to which the user belongs
- Business rule when creating record
- Module used when creating record
- Form template used when creating record
- Domain of the parent record
- Domain assigned to User record
- Domain of the user who creates it

The system prevents the following tables from being domain separated:

- Access Control `[sys_security_acl]`
- Script Include `[sys_script_include]`
- System Property `[sys_properties]`
- Security Exclusion/Inclusion List Entities `[sys_security_restricted_list]`
- Dictionary Entry `[sys_dictionary]`
- Dictionary Entry Override `[sys_dictionary_override]`

Assigning users to companies

Administrators can quickly assign users to a domain by assigning them to a company. After users are assigned to a domain, records automatically inherit the user's domain.

For example, assigning Bow Ruggeri to the ACME company automatically assigns him to the ACME domain. Assigning Don Goodliffe to the Initech company automatically assigns him to the Initech domain. Any records they create are automatically added to the appropriate domain.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Using business rules to assign domains

Administrators can use a business rule to automatically set a domain value when creating a record. The business rule must set a value in the **sys_domain** field. Administrators must ensure there is a **sys_domain** column available for the record's table. To learn more see Domain separation recommended practices for service providers.

Using modules to assign domains

Administrators can use the **sysparm_domain** URL parameter to automatically assign new records to a particular domain from a module. Administrators must create a module with an **Argument** value of: `sysparm_domain=sys_ID of domain`.

Using form templates to assign domains

Administrators can use a form template to automatically assign new records to a particular domain. Administrators must add the **sys_domain** field to the form and select a domain value. For example, setting the **sys_domain** field to **TOP/ACME domain** automatically assigns all records from this template to the TOP/ACME domain.

Domain inheritance on tables

By default, related records inherit the domain of the parent record. For example:

- A change task record inherits the domain of the parent change request record.
- A problem record inherits the domain of the parent incident record.

Automatic domain assignment based on user domains

If no other domain conditions apply, a record automatically inherits the domain of the user who creates it.

Visibility domains and Contains domains

Visibility domains control what a specific user or group of users can see. "Contains" domains control what an entire domain of users can see.

Visibility domains

The "Visibility domains" element determines whether users from one domain can access records from another domain. Associate this element with User [sys_user] and Group [sys_user_group] records in related lists on those records. Groups grant their members the visibility domains of the group. When a user leaves a group, they lose the group's visibility domains. Granting users a visibility domain grants all the rights to the records in that domain based on ACL (access control list) rules.

A visibility domain:

- Is a user-to-domain relationship and is explicitly granted.
- Is not a child domain.
- Is not controlled by the selection in the domain picker. Users with access to a visibility domain always see data in that domain and its child domains.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
Using visibility domains excessively is not recommended. Although visibility is one method to allow users to access records, it's best to use contains domains for more robust control.

Contains domains

Normally parent-child relationships define the domain hierarchy. A contains domain lets you relate domains on an as-needed basis, independent of parent-child relationships. However, contains domains grant visibility only to domain data. Processes remain unaffected by contains relationships.

A contains domain:

- Is a many-to-many, domain-to-domain relationship.
- May have child domains. When a domain is selected, you can see the data from that domain and its children.
- Is controlled by the selection in the domain picker.

Note:
When you open the domain record, the scope is set to that record's domain, so you can see only child domains. Choose **Toggle Domain Scope** from the menu to populate the related list.

Contains domain example

When a user's home domain is A, and the A domain contains domains B and C, they all become peer domains. That means the user sees data from domains A, B, and C while in their home domain A. If users change domains with the domain picker to Domain B, they see only data in Domain B. When users interact with a record from Domain B or Domain C directly, they see only data for that domain.

Visibility domain example

Using domain visibility, if Don Goodliffe is in the Database domain, and Bow Ruggeri is in the Network domain, and no incidents are in the global domain, then Don cannot access Bow's incidents because of data separation.

Inheriting visibility domains based on group membership

If you set the domain table to the Group [sys_user_group] table, users can inherit visibility domains based on their group membership.

Contains queries and domain access

Domain separation recommended practices for service providers

Domain scope

Domain scope defines what users can and cannot access.

Every user has two domain scopes when establishing a session in a domain-separated instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- *Session scope* is set upon session establishment to the domain listed in the user's user record. Users can manually change their session domain scope from the domain picker.
- *Record scope* uses the domain of the record and is active when viewing the form of any record.

By default, the record scope takes precedence over the session scope so that users in higher level domains adhere to each record's data and process constraints. However, these users can choose to expand or collapse the domain scope to show or hide data from other domains. For example, a user in the Service Provider (SP) domain also has visibility into child domains such as the ACME domain. When looking at an incident record from the ACME domain, the user can choose to expand the domain scope to show values from the SP domain or collapse the domain scope to show only record values that match the record's ACME domain.

Note:
Users always have access to data from domains that have been explicitly granted to them by domain visibility.

Users with the domain_expand_scope user role can select the domain scope from the **Toggle Domain Scope** UI action on the form. When record scope is in effect, click the UI action to expand to session scope and display all data available based to the user's domain and child domains. When session scope is in effect, click the UI action to collapse to record scope and display only data that matches the current record's domain.

Note:
A record does not display the UI action to toggle the domain scope if the record is in the global domain or if the user's domain matches the record's domain.

Record value selection from other domains

Users who can see multiple domains have the option to select record values from a domain that is different than the record's domain.

For example, service desk agents working for a service provider might want to assign certain incidents to themselves to resolve issues on behalf of their customers. When they do this, the incident **Assigned to** field might contain a user from the SP domain, even though the incident record itself is associated with a child domain such as ACME.

Selecting a record value from another domain does not change the record's domain. The record retains its original domain. When a user views a record with values from multiple domains, the user's domain visibility determines what they see.

Record value selection

When these conditions are met	The user has access to these UI elements
The user has access to the domain of the current record referenced in a field.	The user can: • See reference field display value. For example, sees the user name in the **Assigned to** field. • See the related record from reference icon. For example, sees the user record for the user in the **Assigned to** field. • Select values from any visible domain. For example, can select users from either the SP and ACME domains.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Record value selection (continued)

When these conditions are met	The user has access to these UI elements
The user does not have access to the domain of the current record referenced in a field.	The user can: • Not see reference field display values. (This is the case if domain separation was activated in Madrid or later releases and the user doesn't have access to the domain of that record.) • Only select values from the record's domain. For example, can only select users from the ACME domain.

Domains and associated companies

With domain separation you can cascade changes you make to a company record to the domain and other records associated to the company.

By default, the system automatically assigns users to the same domain as their company. For example, all users of the ACME company automatically become members of the TOP/ACME domain.

Note:
Users with the admin role can change their own user records and therefore change domains. Service Providers may want to either disable delegated administration or set up an approval process to verify that the user needs the admin role.

When you change a company's domain, the instance automatically changes the domain of the following associated records to match the company's new domain.

- Locations
- Departments
- Groups
- Users

Note:
The instance does not automatically change the domain of any record where you have selected the **Managed domain** checkbox.

Domain deactivation and associated companies

When you deactivate a domain, the instance also automatically completes the following actions.

- Deactivates all companies in the domain.
- Prevents all users assigned to the inactive company from logging in.

Note:
When a user from an inactive company attempts to log in, the user sees an error message similar to `Company inactive - your access to this instance is not authorized`.

For example, if you deactivate the ACME domain from the sample data, the instance also deactivates the ACME company, and the three sample users are locked out.

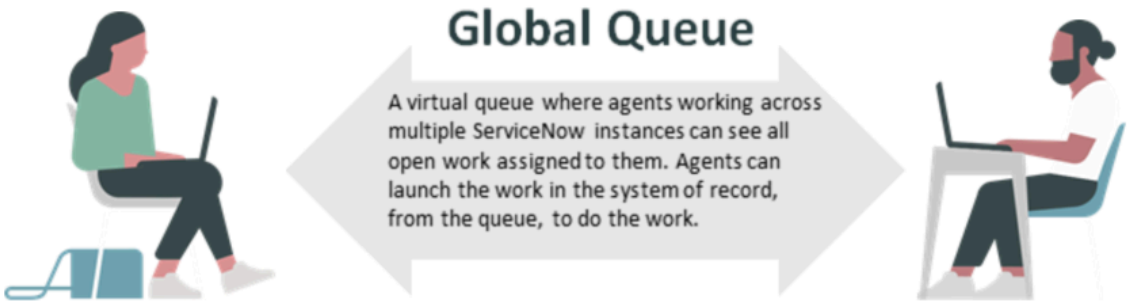
Concepts for service providers

These concepts work with the existing ServiceNow platform capabilities to help you solve for common use cases.

Global queue v.2

The global queue concept provides a single virtual view of tasks that reside in multiple instances. The concept creates a custom application to provide a fulfiller view of work that resides in multiple instances without having to replicate tasks or data.

Overview



Service Providers with agents working on tasks from multiple systems tend to integrate the data back to a central instance, or a "swivel chair" between instances. While this method might be appropriate in some cases, it can be expensive and time-consuming to build and maintain. This method also opens the provider up to potential auditing and data requirement considerations such as General Data Protection Regulation (GDPR) in all of the instances where the data now lives.

Global queue v.2 is an alternative: With this method, agents can see data assigned to them from a single instance without sovereign data persisting on the instance they are logged into. For example, in cases where clients have data residency requirements, but allow access by agents from other countries, the provider could use a "follow-the-sun" Help Desk using global queue v.2.

Learn more about the Global Queue v.2 Proof of Concept on the ServiceNow Knowledge site.

Note:
In the Quebec release forward, the Global Queue Proof of Concept has been upgraded to Global Queue v. 2.

Service provider connector

The service provider connector application is a reference design for creating a ServiceNow Store application for your customers to use to integrate with your systems. Service provider applications help you speed on-boarding and create standardized integrations.

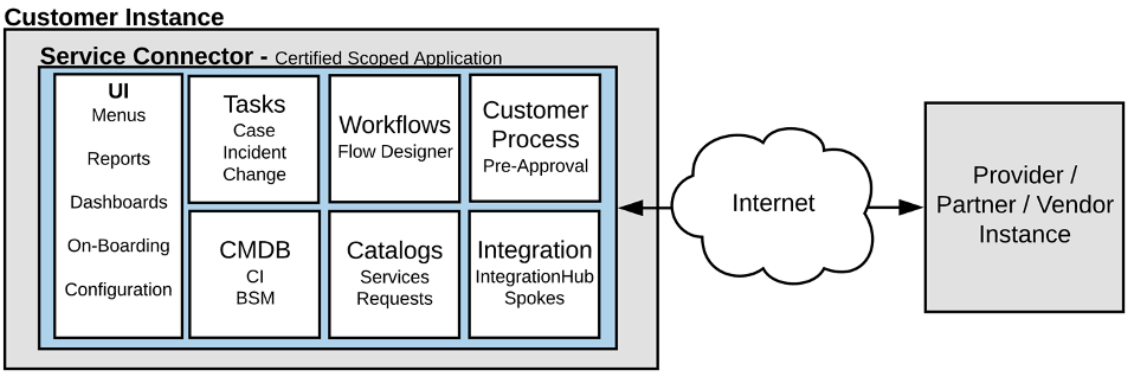
Benefits of service connectors

When service providers (vendors, suppliers, partners) publish connectors, customer on-boarding is faster, which means faster billing. Integrated instances increase productivity, greater visibility in the ServiceNow ecosystem, and partner program benefits. Specific benefits are:

- Eliminates custom integrations, including the cost of services required to deliver and maintain them.
- Services are provider-defined within their ServiceNow instances and remove the need for the complexity and cost of custom integrations.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Workflows and catalog requests can be synchronized, with the customer's processes and approvals preceding the provider's processes, so customers can follow their own processes.
- Any data created or modified (e.g. CIs) for the customer on the provider's instance can be synchronized back into the customer's instance for their visibility and use in processes.



Key features

Feature	Description
User Interface	A service connector should include the following UI components at a minimum: • Reports/Dashboards – Reports and dashboards pre-defined by persona help with visibility. • Menu and modules – The customer should be able to find the application via descriptive Menu **Provider XYZ Services**. • Roles – Every connector requires user and admin roles to ensure access can be controlled by the customer. For example, "x_snc_xyz_user" or "x_snc_xyz_admin". • On-boarding – Rapid on-boarding is essential to a good customer experience and should be included via playbook, guided setup, or catalog item in such a way that no professional services are required for the customer to go live. (Professional services are available, but on-boarding can be achieved without it). • Configuration – Data points should be built into processes to account for most of the normal process configuration a customer needs to achieve. This eliminates professional services as much as possible. • Documentation – Thorough documentation increases customer satisfaction and ease of use.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Feature	Description
	• Support integration or contact info – The customer needs an easy way to stay in contact with the service provider for any issues, questions, or requests.
Tasks	Use the application for tasks, such as incidents, case, changes, problems, and so on, should be predefined in the connector. These integrations are built using Workflow Studio and Integration Hub to ensure the highest level of resiliency and performance.
CMDB	Core data synchronize such as the CIs required for proper ITIL processes should be kept in sync between provider and customer instances.
Workflows	All workflows should be designed in Workflow Studio to ensure resiliency and performance.
Catalogs	The provider's catalog that the customer requests from should be included in the application as a record-producing catalog. The request generated by the item in the customer's instance should be eBonded with the provider's instances. The provider's workflows keep the request updated and synchronize back to the customer's instance.
Customer Processes	Any mechanisms for syncing requests with the provider's instance should allow for customer processes to interact with the requests before they are sent to the provider's instance. During provider processing, approvals can be sent to the customer's instance as needed.
Integration	Integrations should be built using Workflow Studio and Integration Hub to ensure the highest level of resiliency and performance.

Possible components you can include in a Service Connector

Component	Description
Instance data replication (IDR)	When replication is the goal: • Can be used for process integration, but can be too rigid depending on the complexity integration logic based on state transition • To learn more, see Instance Data Replication
IntegrationHub	When process integration is the goal:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Component	Description
	• Easier to inject in the middle of a process, as part of complex or conditional step in the middle of a flow • To learn more, see IntegrationHub
Global Work Queue (Virtual)	When task federation is the goal, and storing data externally is not acceptable: • Used where agents are working across multiple ServiceNow instances and need to see all open work assigned to them • Rows returned should be limited to less than 1000 • To learn more, see Global work queue
Remote Tables	When external data usage without storage is the goal: • Used to connect an instance to third-party sources, or to another instance, to retrieve external data and optionally cache it in the memory. The data is treated as a table in the instance for read-only purposes such as group, sort, aggregate, and filter. • To learn more, see Retrieving external data using remote tables and scripts
Flow Designer	When process design is the goal • Used for automating processes in a single design environment. Process owners can use natural language to automate approvals, tasks, notifications, and record operations without coding. • To learn more, see Flow Designer

Learn more about the Service Connector proof of concept on the ServiceNow Knowledge site.

Installed with domain separation

Several platform components are added or modified with domain separation.

Roles

Role	Description
domain_admin	Can create, edit, and delete domains.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.

Additions to [sys_domain] fields

The sys_domain field is added to the following tables:

Tables with the sys_domain field

Tables
sys_attachment
sys_user_has_role
sys_group_has_role
sys_email
sys_user_group
core_company
cmn_location
cmn_department
sys_gauge
sys_report
kb_feedback
sysapproval_approver
sys_user_grmember

Field for the Task Table

MSP Extensions add a task_for field to the Task table. This reference field refers to the User table.

Options for the Group Type

MSP Extensions add several new default options to the type field of the Group table. Add to or update these types as needed to support your domains.

Tables
Security
Support
Visibility

Business rules

Name	Table	Description
Domain - Activate/ Deactivate	core_company	Activates the related domain if at least one of its companies is active. Deactivates the related domain if all related companies are inactive.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Name	Table	Description
Domain - Cascade Company	core_company	Keeps a company's domain in sync with its users, groups, departments, and locations.
Domain - Cascade Domain - Email	sys_email	Keeps an email's domain in sync with its attachments.
Domain - Cascade Domain - Group	sys_user_group	Keeps a group's domain in sync with its inherited roles (sys_group_has_role records).
Domain - Cascade Domain - Knowledge	kb_knowledge	keeps a knowledge article's domain in sync with its related feedback.
Domain - Cascade Domain - Task	task	Keeps the domain in sync with related tasks for wf_context, wf_executing, wf_history, attachments, emails, task_sla and its workflow, sysapproval_approver and its workflow, and sysapproval_group and its workflow.
Domain - Cascade Domain - User	sys_user	Keeps a user's domain in sync with its group membership (sys_user_grmember) and role (sys_user_has_role) records.
Domain - Cascade Domain - Version	wf_workflow_version	Keeps domains in sync with related workflow versions for wf_activity and wf_transition.
Domain - Deactivate Companies	domain	Deactivates related companies if a domain is deactivated.
Domain - Default - Task	task	Sets the task domain based on the Task for user's domain. If this domain would be global, sets domain to Default instead.
Domain - Default - User	sys_user	Sets a user's domain to Default if the domain otherwise would have been global.
Domain - Disallow Global Domain Record	domain	Prevents creation of a domain with the name global.
Domain - Override Copy	sys_app_application	When an application is overridden for a domain, creates a copy of its modules for the new application.
Domain - Override Copy	sys_data_policy2	When a data policy is overridden for a domain, creates a copy of its data policy rules for the new data policy.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Name	Table	Description
Domain - Override Copy	sys_gauge	When a gauge is overridden for a domain, creates a copy of its gauge counts for the new gauge.
Domain - Override Copy	sys_ui_action	When a UI action is overridden for a domain, creates a copy of its UI action views for the new UI action.
Domain - Override Copy	sys_ui_list_control_embedded	When an embedded list control is overridden for a domain, creates a copy of its client and server scripts for the new embedded list control.
Domain - Override Copy	sys_ui_policy	When a UI policy is overridden for a domain, creates a copy of its UI policy actions for the new UI policy.
Domain - Set Domain - Approvals	sysapproval_approver	Sets the domain based on that of the record being approved.
Domain - Set Domain - Attachment	sys_attachment	Sets the domain based on the parent record's domain.
Domain - Set Domain - CMDB_CI	cmdb_ci	Sets a CI's domain to that of its company.
Domain - Set Domain - Department	cmn_department	Sets a department's domain to that of its company.
Domain - Set Domain - Domain	domain	Sets a domain's domain to itself.
Domain - Set Domain - Email	sys_email	Sets the domain based on the parent record's domain. An email's parent record is the record specified in the instance field.
Domain - Set Domain - Feedback	kb_feedback	Sets a knowledge feedback's domain to that of its knowledge article.
Domain - Set Domain - Group	sys_user_group	Sets a group's domain to that of its company.
Domain - Set Domain - Group Approvals	sysapproval_group	Sets the domain based on that of the record being approved.
Domain - Set Domain - Group Role	sys_group_has_role	Sets a group role's domain to that of its group.

Name	Table	Description
Domain - Set Domain - Location	cmn_location	Sets a location's domain to that of its company.
Domain - Set Domain - Task SLA	task_sla	Sets a task SLA's domain to that of its task.
Domain - Set Domain - User	sys_user	Sets a user's domain to that of its company.
Domain - Set Domain - User Role	sys_user_has_role	Sets a user role's domain to that of its user.
Domain - Set Domain - WF Activity Hist	wf_history	Sets the workflow activity history domain based on the parent workflow context's domain.
Domain - Set Domain - WF Context	wf_context	Sets the workflow context domain based on the referenced record's domain, if it has one.
Domain - Set Domain - WF Exec Activity	wf_executing	Sets the workflow executing activity domain based on the parent workflow context's domain.
Domain - Set task for - Change	change-request	When converting a ticket to a change request, sets the Requested by field to the ticket's Task for value.
Domain - Set task for - Incident	incident	When converting a ticket to an incident, sets the Caller field to the ticket's Task for value.
Domain - Validate Default	domain	Ensures only one domain has the Default check box selected.
Domain - Validate Primary	domain	Ensures only one domain has the Primary check box selected.
Business Rules Installed with Domain Support Plugin		
Change Domain Set	sys_dictionary	Sets the domain set to the current domain.
Domain support properties	sys_properties	Sets the system properties to match the domain query method (domain paths or domain numbering).

Client scripts

Client script	Description
Domain - Set Company and Location (sys_script)	Monitors the incident caller field for changes. If the company and location fields do not already have a value, the script adds this information from the caller record. If the company and location fields already have a value, the script retains the existing values.
Deactivated script	
(BP) Set Location to User	Monitors the incident location field and sets the location field to the caller's location.

Related topics

Domain separation recommended practices for service providers

Application support for domain separation

Many ServiceNow applications support domain separation in the base system but not all. Some supported applications include limitations on the data and administrative settings that can be domain-separated. These definitions delineate the domain separation support levels from the perspective of actual use cases and the people who use them.

Domain separation support levels

ServiceNow applications that support domain separation may support the separation of data and data routing only, have advanced business logic separation, or support tenant (customer) level administration of the application. ServiceNow applications are defined with the following incremental support levels.

No support

- The domain field may exist on data tables, but no logic exists to manage data.
- This level is not considered domain-separated.

Basic

- Business logic: Ensure data goes into the proper domain for the application's service provider (SP) use cases.
- In the application, the user interface, cache keys, reporting, rollups, aggregations, and so on, all use domain at production run time.
- The owner of the instance must be able to set up the application to function across multiple tenants.

Sample use case: When an SP uses chat to respond to a tenant-customer's message, the client must be able to see the SP's response.

Standard

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Includes **Basic** level support.
- Business logic: Processes can be created or modified per customer by the service provider (SP). The use cases reflect proper use of the application by multiple SP customers in a single instance.
- The owner of the instance must be able to configure the minimum viable product (MVP) business logic and data parameters per tenant as expected for the specific application.

Sample use case: An admin must be able to make comments mandatory when a record closes for one tenant but not for another.

Enhanced

- Includes **Basic** and **Standard** levels.
- Data-driven process enables service provider customers to modify business logic that is based on defined use cases. These configurations are UI-based and fail-safe so that configurations by one customer cannot affect another.
- Tenants of the instance must be able to configure minimum viable product (MVP) business logic and data parameters for themselves. This logic and parameters would be expected for the application's normal function.

Sample use case: Tenant-customers of a shared environment must be able to change to the impact, urgency, or priority matrix to set priority within their domain.

Note:
Effective Domain (*)

Sometimes, a platform feature or application may effectively support SP use cases even without the domain framework. If so, the use cases must detail its support of domain separation. An asterisk (*) after the support level indicates this kind of configuration.

Supported feature	Basic	Standard	Enhanced
Domain column is present for base system application tables.	●	●	●
Domain-specific configuration is managed by instance owner.	●	●	●
Tenant domains can manage their own application data.		●	●
Application properties are domain aware when needed.		●	●
Business logic and processes can be domain-separated by instance owner.		●	●
Business logic and processes can be administered by the tenant domain.			●

Domain separation recommended practices for service providers

You can create, implement, and maintain domain separation for your applications and services.

Domain basics

With domain separation (also known as ServiceNow Multitenant Platform Architecture), you can segregate the application data, user interface, and business logic in a single customer instance that supports hierarchical modeling with cross-tenant intelligence. Business logic describes how the domain separation is configured and what rules are affecting the configuration.

Before you set off on the domain separation journey, here are some good practices to follow. Select topics as you want or follow them in order by clicking the links below the image.

Domain separation explained

With domain separation, you can segregate application data, UI, and business logic, such as rules or workflows, in a single customer instance. Separating these elements into logically defined domains supports specific hierarchies for all customers using your applications.

Domain basics

Domain separation, also known as ServiceNow multitenant platform architecture, adds considerable overhead to the management of an instance. If you use domain separation correctly though, it can improve efficiency, add greater security, and increase the performance of your customers' instances.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

You can't separate some global standards and properties, such as system properties and table schema, per tenant.

Before you start separating domains, read the following guidelines.

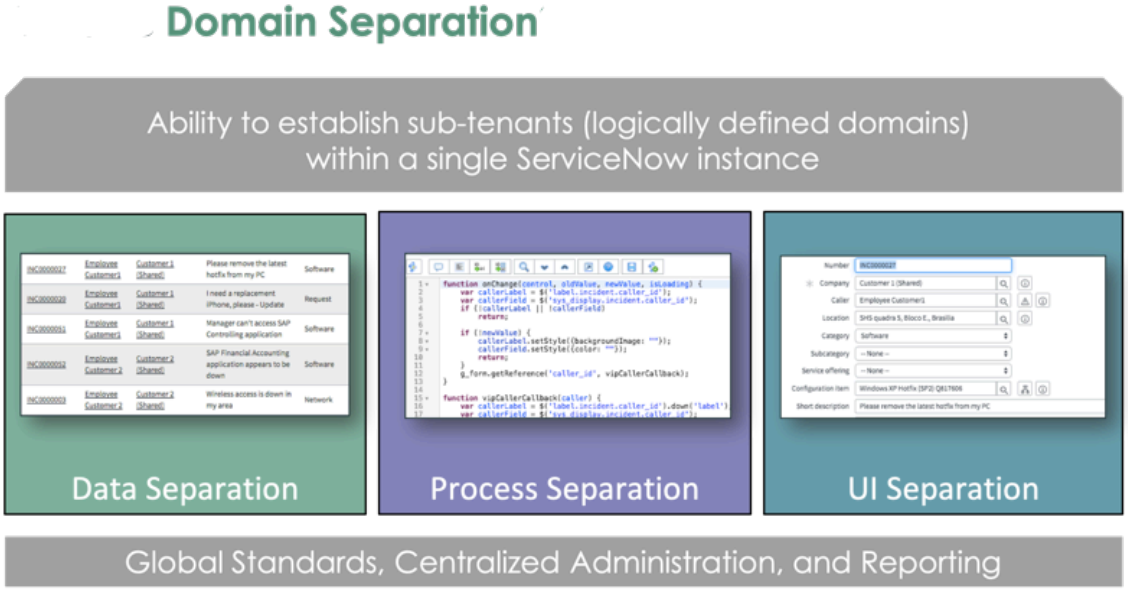
What you can do with domain separation

- Data separation: Enables tenants of the domain to see only data that they have permissions to see. Tenants can be granted access to other tenant data but can't query tenant data that they don't have access to.
  - When you update data records, they do not generate Update Set records.
  - Users, including the customer accounts that are used for integrations, see only the data in the domains they have permission to access.
  - Customers, agents, and fulfillers see data that pertains to the customers and organizations that they support.
- UI separation: Supports a tenant-specific experience for UI elements such as views, lists, labels, and so on.
  - You can override the browser-based user interface, including application menus, lists, forms, and dashboards. You can also customize them for a specific domain or set of domains while preserving your basic process logic.
  - Service providers can alter the displayed branding and UI elements to meet individual customer needs.
- Business logic separation: Creates tenant-specific system policies such as email notifications, business rules, client scripts, UI policy, and UI actions.
- Hierarchical modeling: Nests your multiple tenants so that parent tenants can access child tenant resources. Business logic for parent tenants runs automatically for child tenants, which you can override at any level.
- Cross-tenant intelligence: Automatically handles data, metadata, business logic, and processing context for tenants with access to additional tenant data.

Domain separation at a glance

The following graphic shows the division of data, process, and UI separation. These concepts are discussed in depth in the Recommended Practices section.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

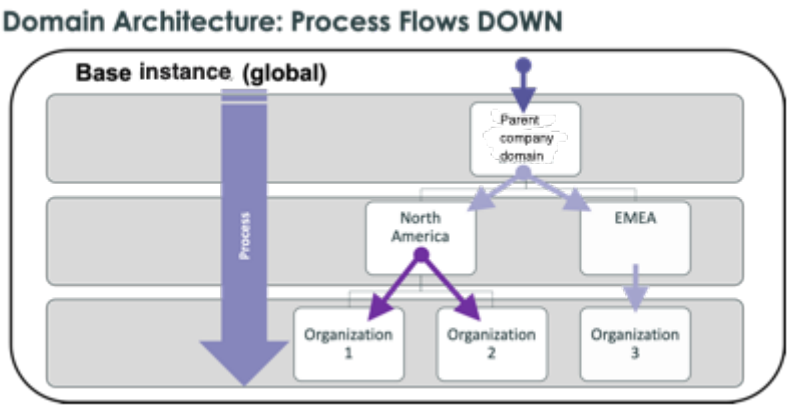


Domain architecture

User records are assigned a domain value that represents the user's home domain. Users have no access to data in parent domains, peer domains, or domains in other branches of the hierarchy.

See Contains queries and domain access for advanced options to grant additional domain visibility.

The following diagram shows how the architecture process flows down to the child



domains.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Domain separation value proposition

With domain separation, service providers can have a multitenant instance architecture that delivers offerings efficiently and securely to their clients. Strong universal process standards, data-driven process design, strict governance, and centralized administration help to maximize these benefits.

Benefits of domain separation

The tenants of a domain benefit from a quick return on investment, lower administrative overhead, and leverage of business services provided by instance owners.

Here is an quick view of these benefits.

Instance Owner	Domain Tenants
Service provider employee productivity	Increased security
Only process deltas maintained	Pre-built processes and features
Administration efficiencies	Reduced staff required
Fewer client integrations	Faster onboarding
Upgradability and scalability	Leverage of the latest releases
Data segregation	Services provided by the instance owner
Global reporting	

Definition of domain separation

With domain separation (also known as the ServiceNow® Multitenant Platform Architecture), you can segregate application data, UI, and business logic in a single customer instance that supports hierarchical modeling with cross-tenant (customer) intelligence.

Properties of domain separation

Domain-separated ServiceNow applications are defined with the following properties:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Data separation

Enables customers to see only the data that they have permissions to see. Customers can be granted access to other customer data but cannot query customer data if they don't have access.

UI separation

Supports a customer-specific experience for UI elements such as views, lists, labels, and so on.

Business logic separation

Supports customer-specific system policies such as email notifications, business rules, client scripts, UI policy, and UI actions.

Hierarchical modeling

Supports nested-multitenancy so parent tenants (customers) can access child customer resources. The business logic for parent customers runs automatically for child customers and can be overridden at any level.

Cross-customer intelligence (domain scope)

Handles automatically the data, metadata, business logic, and processing context for tenants that have access to additional tenant data.

Domain separation hierarchies

Create a hierarchy when defining a domain architecture to track your processes and workflows.

Sample domain separation hierarchies

The following diagram is a good starting point for defining domain architecture. It demonstrates the relationship between the TOP and lower domains and how the process, data, and business rules impact parent and child domains.

- In the following example, TOP is a process domain. It should never contain users. Rather, TOP should contain the new processes that instance owners develop and the overrides to these processes from the global domain.
- Only the service provider (SP) has access to the default domain. This domain never contains active users. It contains only the "lost" data that you need to reassign to the correct domain.

  Note:
  When data is not assigned to a specific domain, it moves to the default domain. It is temporarily "lost" and needs to be assigned to its correct domain.

- Tasks and users without a domain are placed in the default domain automatically when you create or update domains. You can override that action by either clearing the **Default** option on this record or selecting the **Default** option on another domain record. If you have not set a default domain yet, tasks and users with no domain move to the global domain.
  - Don't move data between domains while you are using the instance.
  - If any data ends up in the default domain, that means you have a configuration or procedural problem to address.

You don't see the word "Global" in this diagram because there is no global domain. Remember that "global" is the absence of a domain on a record.

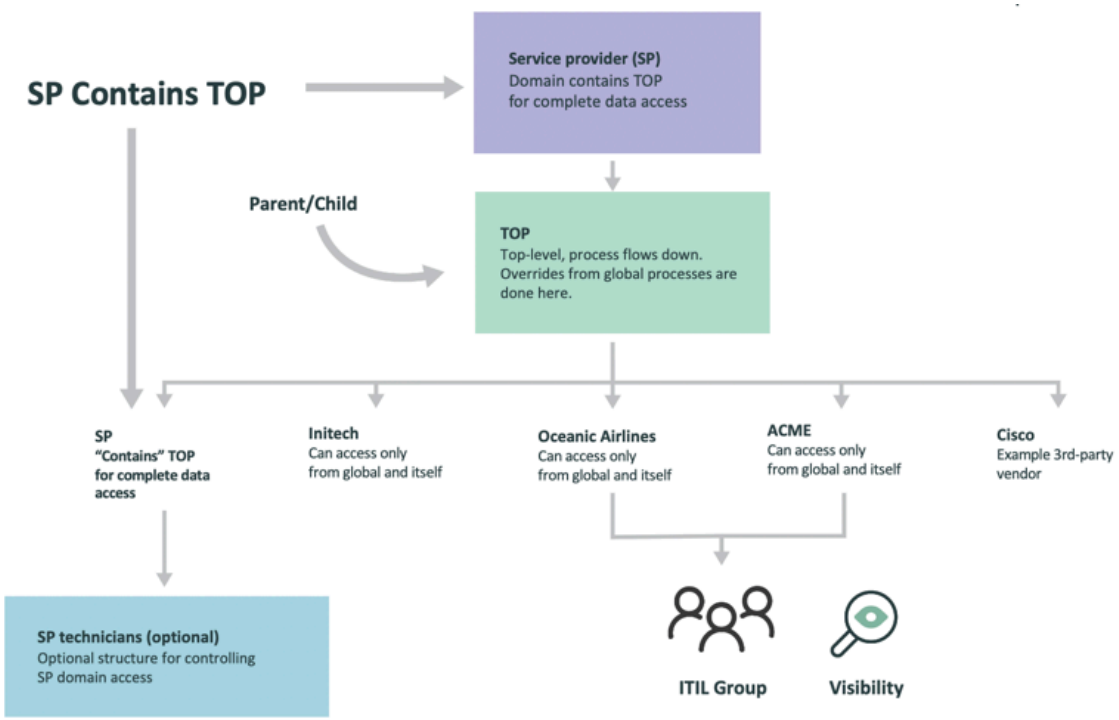
For example, a table that has no domain field means that the table contains all global records. A table that has a domain field means that any record without a domain is a global domain.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The word "global" is in the domain field. It is placed there automatically when the record has no domain.

Global records are available to all users of the instance unless they are restricted by security configurations.

- Use the default domain to make sure that records do not end up in the global domain on tables that should never have global records.
- Instance owners must then triage the records in the default domain and move them to the correct domain.



Domain hierarchies

- Parent/child: Process and data affected
  - Design that is based on a process flow.
  - Remember that the parent domains can access all data in the child domains.
- "Contains" domain: Only data is affected. For example, making SP in the diagram contain TOP does not make processes in SP run in the TOP domain and downward.
  - Grants data access rights to individuals in groups that require dedicated access to certain domains.
  - Contains causes or conditions to be added to database queries that can cause performance issues with large domain and data sets.
- Visibility: Hierarchy that is always visible to users once you provide access. Only the data is affected, not the processes.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Grants data access of a domain to another domain that did not have that access when the parent-and-child hierarchy was built.
- Enables users to see all the data in the domains that they have visibility access for, all the time, regardless of the record they are working on.

Note:
Use sparingly, as Visibility can allow complete access that you may not intend.

Basic principles of defining a domain hierarchy

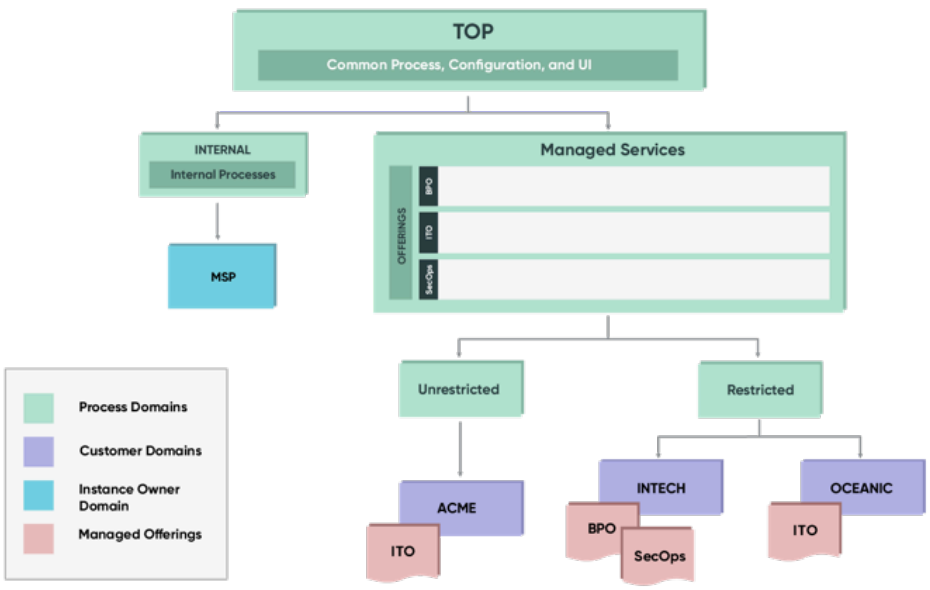
Unrestricted and restricted use cases for domain separation.

Many SPs have customers who implicitly state that access to their domains must be tightly regulated, which constrains the use of the “contains” function at the TOP domain. The following diagram explains how to mitigate that regulation by dividing domains into Restricted and Unrestricted domains.

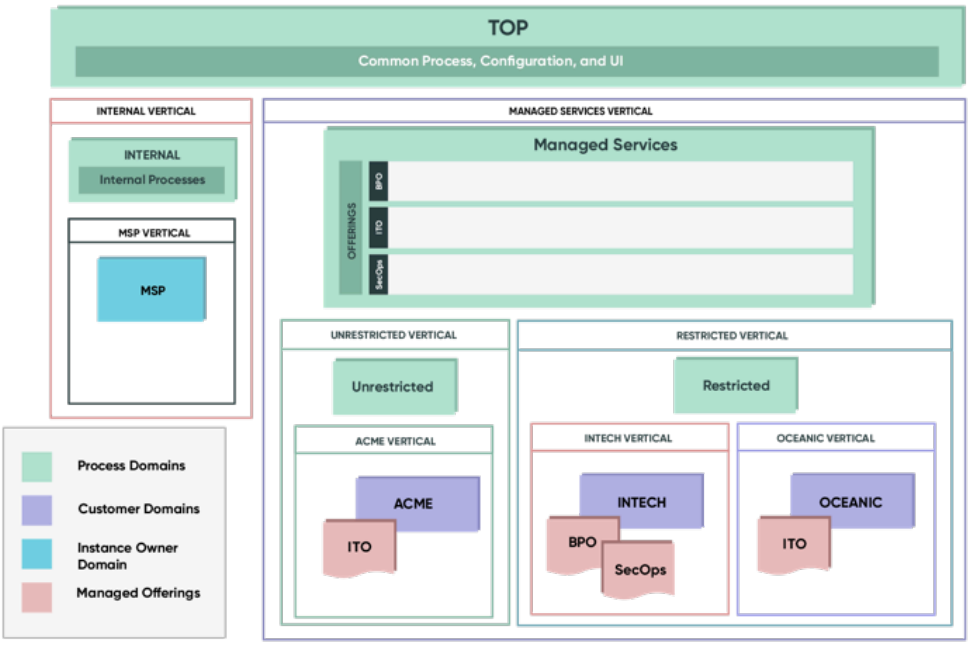
1. Customers exist in a specific "vertical" of the domain separation hierarchy. This means they only consume processes defined in their domain and all parent domains above theirs in the hierarchy. Any processes defined in domains that are not in their linear parent-child hierarchy do not apply.

   Note:
   Customers or "tenants" are entities that are segregated from each other completely, not like departments or business units that share resources with each other.

2. Super verticals (restricted, manager services, and so on) are allowed as long as the customers only ever belong to one of them.
3. Services, products, or offerings that need to be horizontally available to all customers are not defined within separate domain hierarchies.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Here are some sample use cases:

- Under TOP, you might create two domains, Unrestricted and Restricted.
  - Place customers and their domains that don't have SP visibility restraints under Unrestricted.
  - Place customers and their domains that do have that requirement under Restricted.
- System admins can then use “contains” and “visibility” functions in an efficient, targeted manner.
  - Apply "contains" to Unrestricted, so a single “contains” can grant visibility to most customers.
  - Apply domain visibility using ”domain visibility groups” to specific domains as needed.

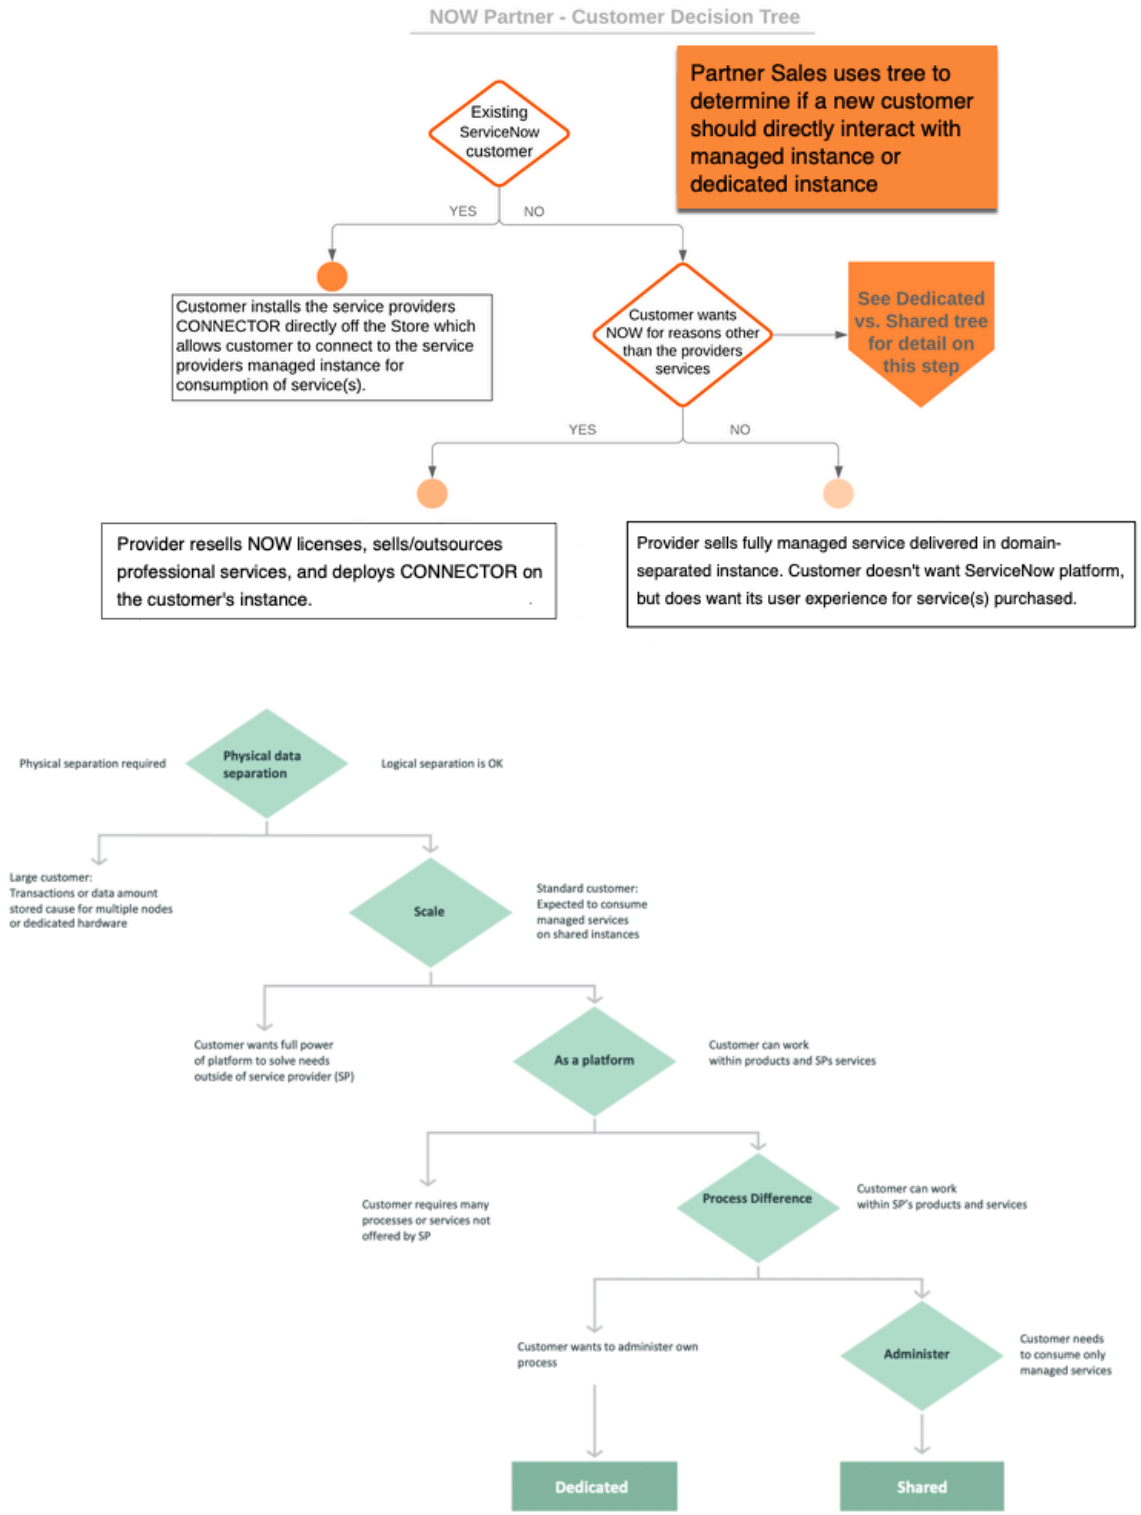
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Customer Decision Trees

The following diagram delineates how to choose which hierarchy model is right for you. You can choose separate hierarchies, hybrid, or shared hierarchies depending on which processes and functionality you want in your domain structures.



To learn more about hierarchy architecture, see Service provider reference architecture.

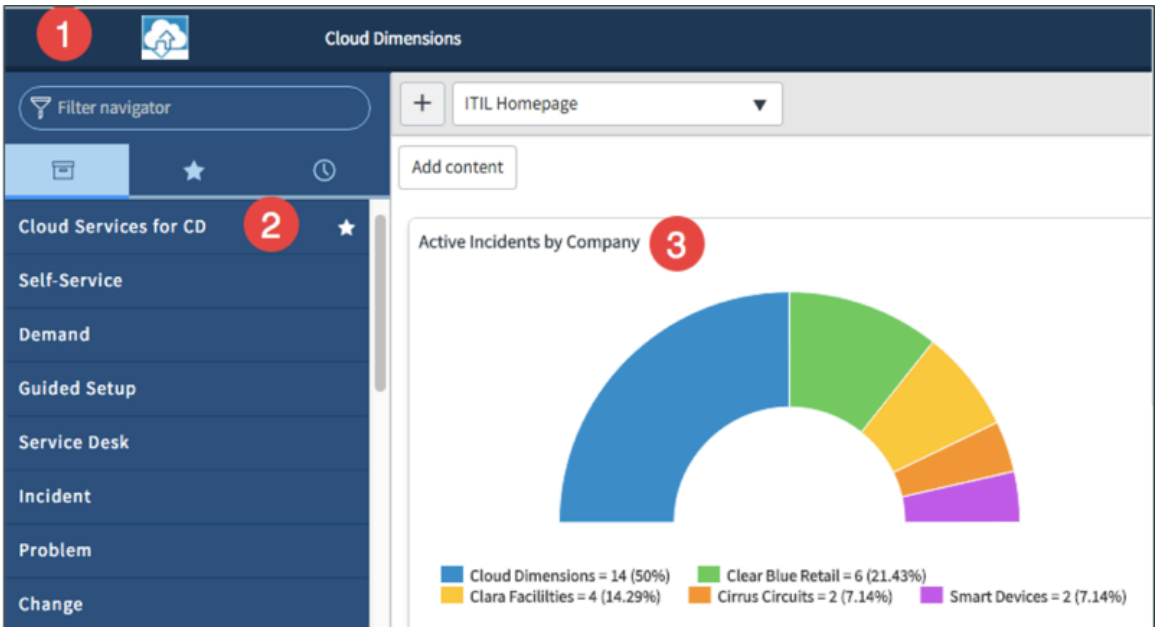
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Context and domain separation

The context of a user's session determines the processes, data, and user interface (UI) as the user browses through list views, home pages, reports, and knowledge articles. The context is determined by the processes that you create, the business rules that you set, your workflows, and other factors.

User session context

Many factors determine the context of a user session, such as user profiles, groups, company criteria, and so on. In the following diagram, you see that the incidents that a company has created are part of the context.



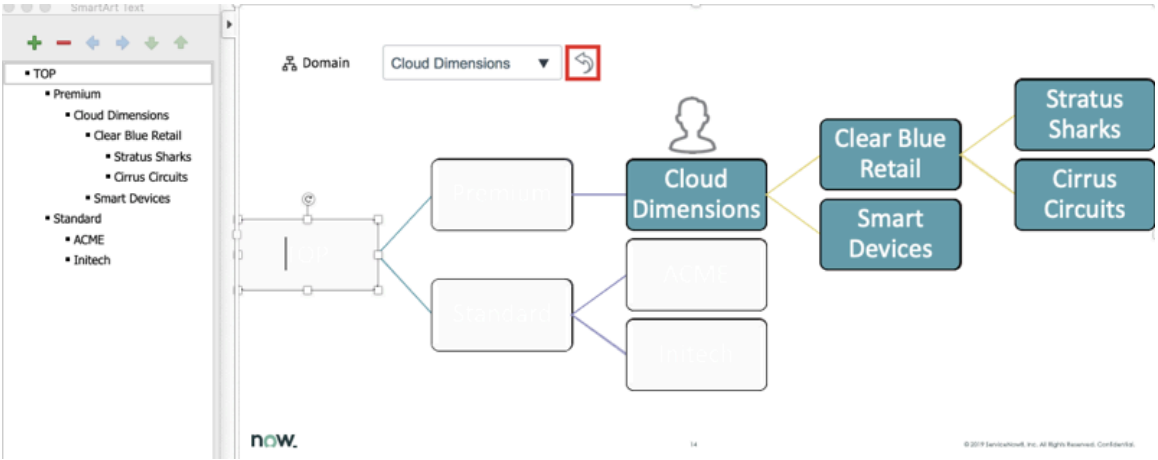
The user in this example has a home domain of Cloud Dimensions.

1. The branding reflects the settings in the Cloud Dimensions domain and company record.
2. The application navigator shows the items that are inherited from higher-level domains as well as the modules that are defined in the Cloud Dimensions domain.
3. The home pages and list data reflect the data that is visible to the user. This data is based on the user's session context. In this case, the user in the Cloud Dimensions domain can see the data in Cloud Dimensions, child domains, and the global domain.

User session context starts in the home domain

In the following diagram, you can see the elements of the context.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



The system administrator sets users' home domains on their user records. Typically, a user's home domain is set to the same domain as their company's domain. When the user logs in, the domain picker sets automatically to the user's home domain. Users can return to their home domain at any time by clicking the arrow icon on the domain picker.

The domain picker's list includes domains within the user's session context. Users may further limit their session context by selecting child domains with the picker.

The context of the user session includes the user's home domain and any child domains. This set of domains in the user's session context is appended automatically to every query that is sent to the database. That way, the results are limited to just the data in these domains and global data. This process is embedded in the compiled code that is not accessible.

Service accounts that are used for integrations also have user session context. There is user context and records context, each with its own data in its own domain. These contexts affect the integrations. Database queries (records) are limited in the same way as interactive users (users), meaning that they work as normal but are limited by whatever constraints the developer has configured.

You can learn about additional ways to add domains to a user's session context in Service provider reference architecture.

Record context

As a user drills into individual records, record context is activated. The record context determines the UI elements and processes to apply to the record.

A record's domain dictates the process, data, and the availability of UI elements within the record.

Note:

- Record context persists even if the user's domain changes.
- Users can view records concurrently in multiple browser tabs, while maintaining their own record context.

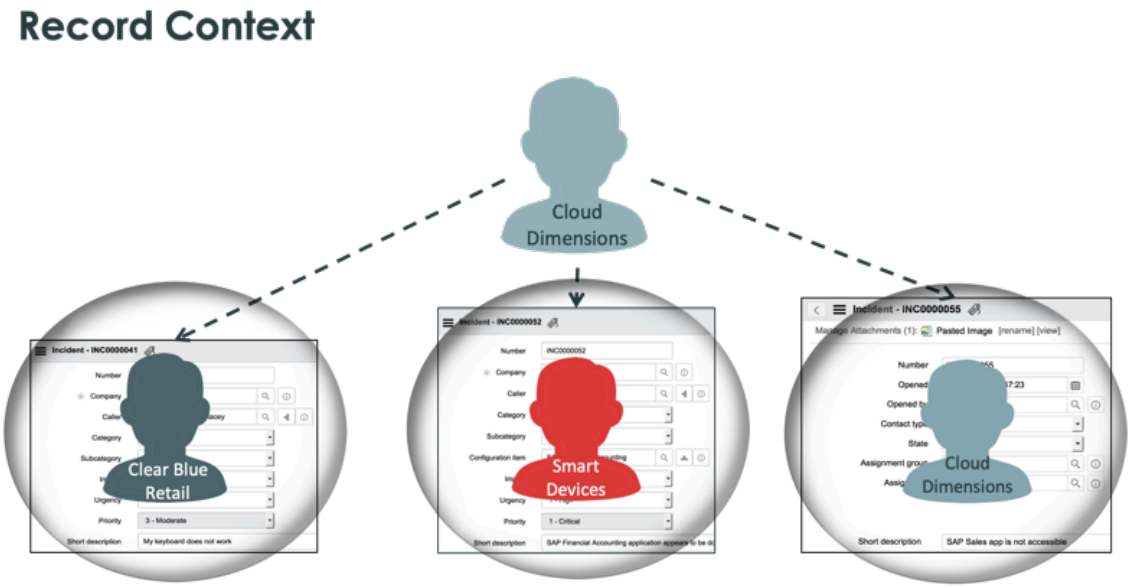
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

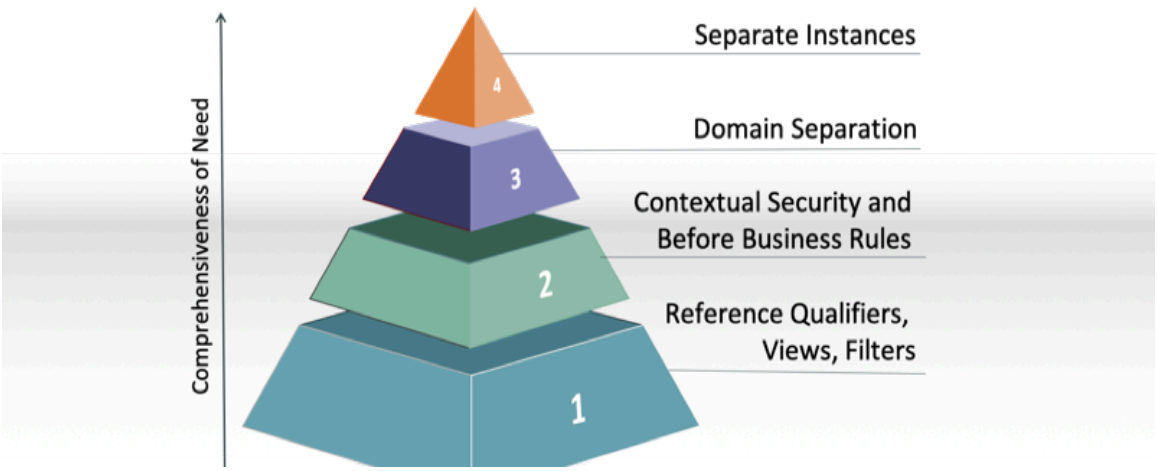


Segregating and securing data with domain separation

You can segregate and secure data on the ServiceNow platform in multiple ways, depending on your customer's needs.

Segregating data in multiple ways

The following diagram shows four ways that you can segregate data. You can use separate instances, domain separation, contextual security and business rules, and the reference architecture itself as ways to segregate data.



You can segregate data in these four ways:

1. Customizing the reference architecture with qualifiers and filters so that departments and groups within a company can focus on their own work. By segregating the data between these departments or groups, a department or group can't see another department or group's records.
2. Adding contextual security and Before Query business rules as additional layers of security to guard against data breaches. See Context and domain separation and Before Query business rules to learn more about domain separation and business rules.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. Adding another level of security in a company by using domain separation. The data from every database query is limited to the data that is visible in a domain before contextual security and business rules are executed.
4. Using separate instances to segregate the data at the database and application layer.

Separate instances, domain separation, contextual security and business rules, and the reference architecture are ways to segregate data. These four ways relate to each other as indicated by the Comprehensiveness of need arrow in the diagram. How each layer interacts with the other layers depends on how you set up your domain separation configuration.

Not all organizations require domain separation. You might find other alternatives, such as separate instances or a single instance without a domain. To learn more about these alternatives, see Evaluating the need for domain separation.

Cross tenant intelligence

A multi-tenant architecture is where you have a single instance serving multiple tenants. Data, metadata, business logic, and processing context for tenants is automatically handled with access to additional tenant data.

Single versus multiple tenants

Single-tenant instance

You're a ServiceNow customer, you bought the licenses, and it's up to you to decide what services you want. You can upgrade when you want, see previews of all the great new features, and configure your instance right away. Being a single tenant has these benefits and restrictions:

- You have higher upfront costs and administrative overhead, but you have more freedom to remodel and expand.
- You have higher costs to obtain and maintain the instance and supply administration staff. Although you are free to build out the environment as required, you must comply with the ServiceNow recommended practices and standards.

Multiple-tenant instance

Someone else owns the instance, possibly a service provider with multiple customers. They upgrade when they want and put new services on the instance when they want. If you are a customer of a service provider, you are most likely on their instance because you wanted what they offer. Multiple tenants have these benefits and restrictions:

- A centralized staff administers configurations, integrations, and upgrades.
- The instance owner provides added services.
- Domain tenants have lower upfront costs to use the ServiceNow platform, have lower monthly costs because they are sharing it with many tenants, and do not have to employ a staff to administer the environment.
- Benefits shared from requests or changes that are initiated by other tenants.

Alternatives to domain separation

You can use a separate instance as an alternative to domain separation for your customers. A separate instance allows you the flexibility to meet the requirements for data separation within the groups and departments in an organization with little to no impact on others.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Separate instances

Pros and cons of separate instances

Separate instance	Single instance - without domain
Pros	**Pros**
Built to suit each customer/organization	May address simple scenarios
Minimize impact of customization on others	Cost
Release schedule coordination	**Cons**
Clean separation	Extensive modifications to baseline code
Choose DATACENTER region	Modified base system code skipped during upgrades
Cons	Must address all secondary and supporting tables as well
Cost	Extensive testing required
Alignment of instances	No ServiceNow product team to evolve your custom code
Testing effort for upgrades	
Duplication of effort	
Integrations required	

You can time upgrades and releases separately for each instance. However, if you choose to use separate instances, you need to do a lot of coordination with other people who are administering instances. By configuring an instance with contextual security, form views, reference qualifiers, filters, and robust conditions, you don't have to use domain separation in your company.

With a separate instance, you may address data and process separation but your instance owners must maintain and keep up with the extensive customizations that is required for separate instances.

Evaluating the need for domain separation

You may find that domain separation doesn't always work for your customers' organizations. It's best that you base your decision to go with domain separation by looking at your customers' needs.

Evaluating the need for domain separation

Reasons for domain separation

These factors may help you decide to choose domain separation for your customers' organizations:

- Your customers have moderate alignment of processes and general platform requirements.
- Your customers plan to work on tasks as fulfillers rather than as requesters.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Your customers have a contractual agreement that requires that data records be isolated, but your instance owner has determined that the requirement may be addressed somewhere else in the configuration.
- Your company's instance owners have entire entities that operate as physically separate organizations and do not share data, but full reporting is still required. Separate domains would allow data visibility when configured correctly.

Reasons for no domain separation

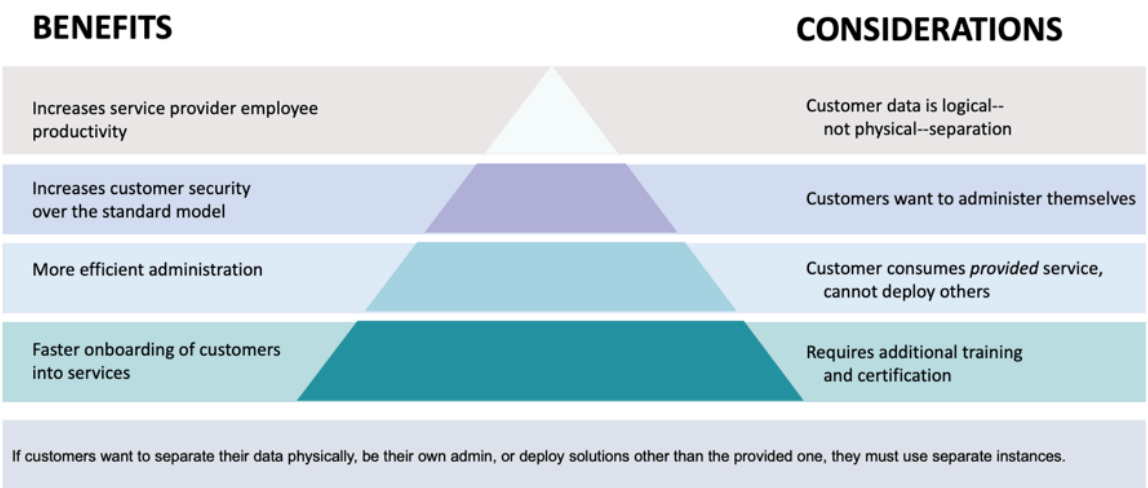
These factors can point to reasons why your customers' organizations might not want to set up domain separation:

- Your customers want to administer their environment, have full ownership of it, and set the roadmap for expansion.
- Your customers require that the data and process at the physical or database level be completely isolated.

Note:

Domain-separated instances contain a shared database so this undermines the isolation requirement.

- Departments in your customers' organization want to isolate records. (Access controls may suffice.)
- Your customers all want their own processes, business rules, and workflows.
- The corporate culture is one of non-collaboration between your customers' organizations.
- Your customers interact with the platform as end users only.



Benefits of domain separation

Domain separation may work better for your customers' organizations than any other method for separating the data between groups and departments.

Domain separation benefits at a glance

You can enable domain separation with a ServiceNow plugin that has functionality built into the core platform. The separate domains configuration is managed by a product manager who is supported by a development team. Enhancements and fixes for domain separation functionality are included with ServiceNow releases and ready to be used by customers. For assistance with

domain separation, your instance owners can use Customer Service and Support resources, such as the Service Portal.

How a database query works with domain separation

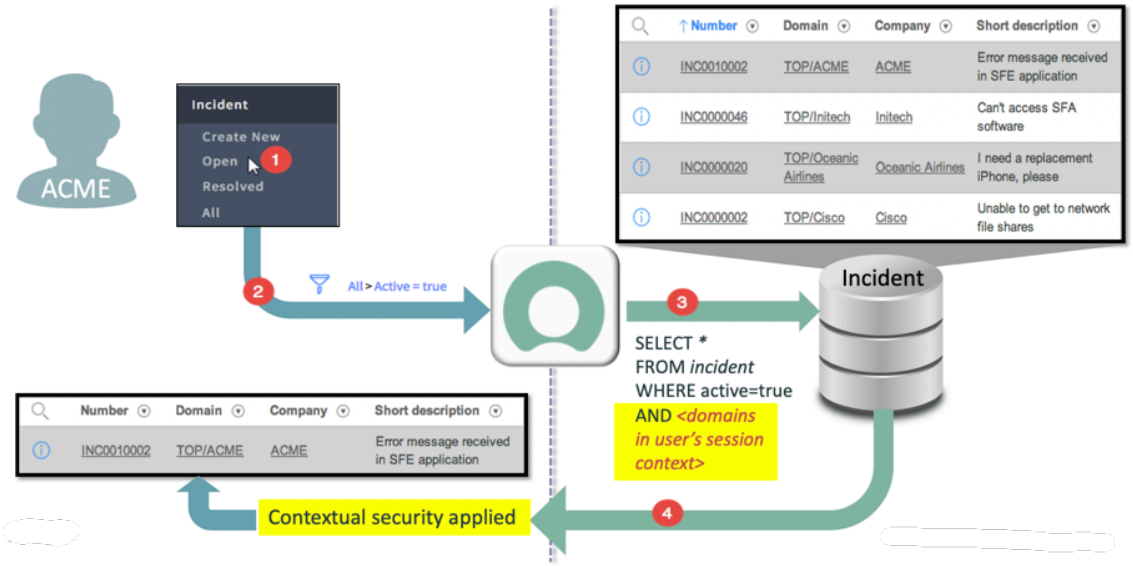
Using database queries with domain separation in your customers' applications help them protect their data. These queries then speed up the configuration and build processes.

How domain separation protects data

In the following figure, the Incident table [incident] has a domain field that is inherited from the incident's task. When you see this domain field, you know that the records in the table can have domain assignments.

When users log in, their home domain appears with the set of domains they may access. This is known as the user's session context. For more information about session contexts, see Context and domain separation.

Database query with domain separation



1. In a browser, the user from one of the companies, Acme, selects the Open Incidents module to view all incidents where active=true.
2. The active=true filter is submitted to the application.
3. The application then sends a query to the database by appending a WHERE clause to active=true. The WHERE clause limits the incident records that are returned to those records that are in the user's domain or the domains that the user may access. Only the records in these domains are returned to the application for processing.
4. Contextual security is applied, further limiting the data that is returned to the user. The incident records appear in the Open Incidents list.

Note:

When you apply contextual security, you create limits to the data that are returned to the user. These limits protect other content that you may not want users to see.

To learn more about contextual security, see Context and domain separation.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
This processing logic applies for all queries to the database, including those queries that are triggered using integrations.

Domain separation levels of support

Choose from three categories for domain separation of an application for your customers' organizations.

Applications that support domain separation may support the separation of data and data routing only, have advanced business logic separation, or support tenant (customer) level administration of the application. These definitions delineate the support levels from the perspective of actual use cases and the people who implement them.

Incremental ServiceNow support levels

Level	Type	Summary
No support		• The domain field may exist on data tables, but no business logic exists to manage the data. • This level isn't considered domain-separated.
Basic	Customer data management	• Business logic: Ensures that data goes into the proper domain for the application's service provider use cases. • In the application, user interface, cache keys, reporting, rollups, aggregations, and so on, all consider the properties of the domain at run time. • Your instance owners must be able to set up the application to function normally across multiple tenants. Use case: When a service provider uses chat to respond to a customer's message, the client must be able to see the response.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Level	Type	Summary
Standard	Customer process management	• Includes the Basic level • Business logic: Processes can be created or modified per customer by the service provider. The use cases reflect how the application is used by multiple service provider customers in a single instance. • Your instance owners must be able to configure minimum viable product (MVP) business logic and data parameters per customer for the specific application. Use case: Admin must be able to make comments required when a record closes for one customer, but not for another customer.
Enhanced	Customer self-managed configuration	• Includes Basic and Standard levels • Enables service provider customers to modify business logic that is based on defined use cases. These configurations are UI-based and fail-safe so that configurations by one customer can't affect another customer. • The instance customers must be able to configure MVP business logic and data parameters themselves. Use case: Customer of a shared environment must be able to make changes according to impact, urgency, or priority within a domain.
Effective domain*		In some cases, a platform feature or application may support service provider use cases even if the domain framework isn't being used. The use cases must be detailed to support domain separation. An asterisk (*) after the support level indicates this kind of configuration. Use case: Before the New York release, Service Catalog had no domain support but the instance owners could configure separate catalogs and items for each tenant in a domain-separated instance by using user criteria. The result was that each tenant could use Service Catalog at a Standard level.

To view all applications listed by their support level see Application support for domain separation.

Summary

Domain separation is a framework that you must use to make your applications aware of its customers.

Consider the domain framework capabilities, your applications' business use cases, what the personas are, and how they use the application before you can use the framework to make your application supportable.

Service provider reference architecture

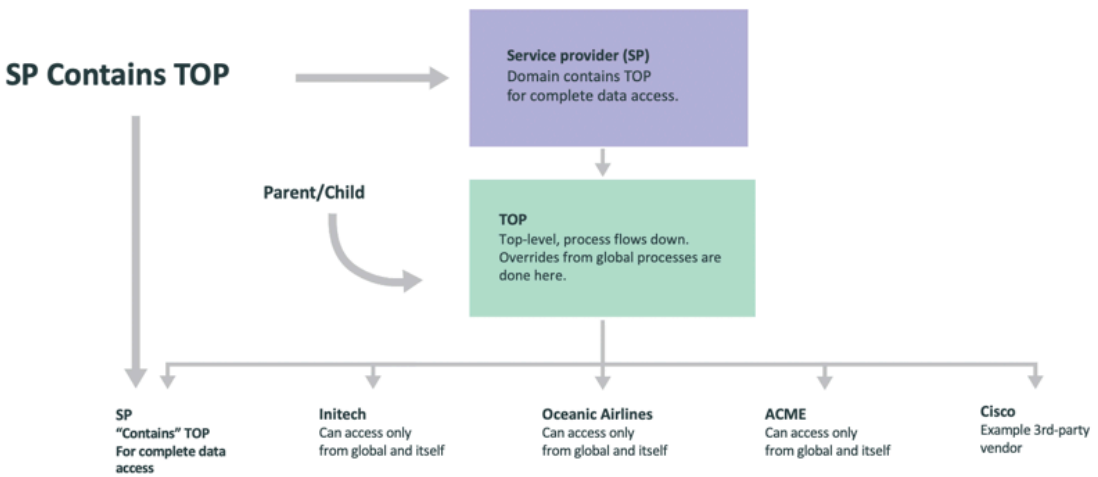
Your customers can access service provider (SP) services by using a portal that is designed for them to reach their domain-separated instance.

Basic attributes of service provider reference architecture

- You do not assign fulfillers to a domain. Instead, you share them across domains. This makes it harder to audit how many fulfillers you have per domain.
- You can share and leverage domain administration. This means that there is no overhead and you can optimize licenses.
- The number of users on the instance can change when you get a new customer. A new customer can result in tens or even hundreds of thousands of new users on the system. The number of total users is virtually unlimited in one shared environment.

The portal for SP services is dedicated or shared to the SP shared instance. Service providers use ServiceNow shared instances to manage their service delivery.

Reference hierarchy for domain-separated instances



Service provider reference architecture decision trees

You can use decision trees and a comparison chart to determine if a new customer should be added to a shared instance or to their own dedicated instance.

Decision trees

Use these decision trees to help your customers decide whether to use a managed or dedicated instance.

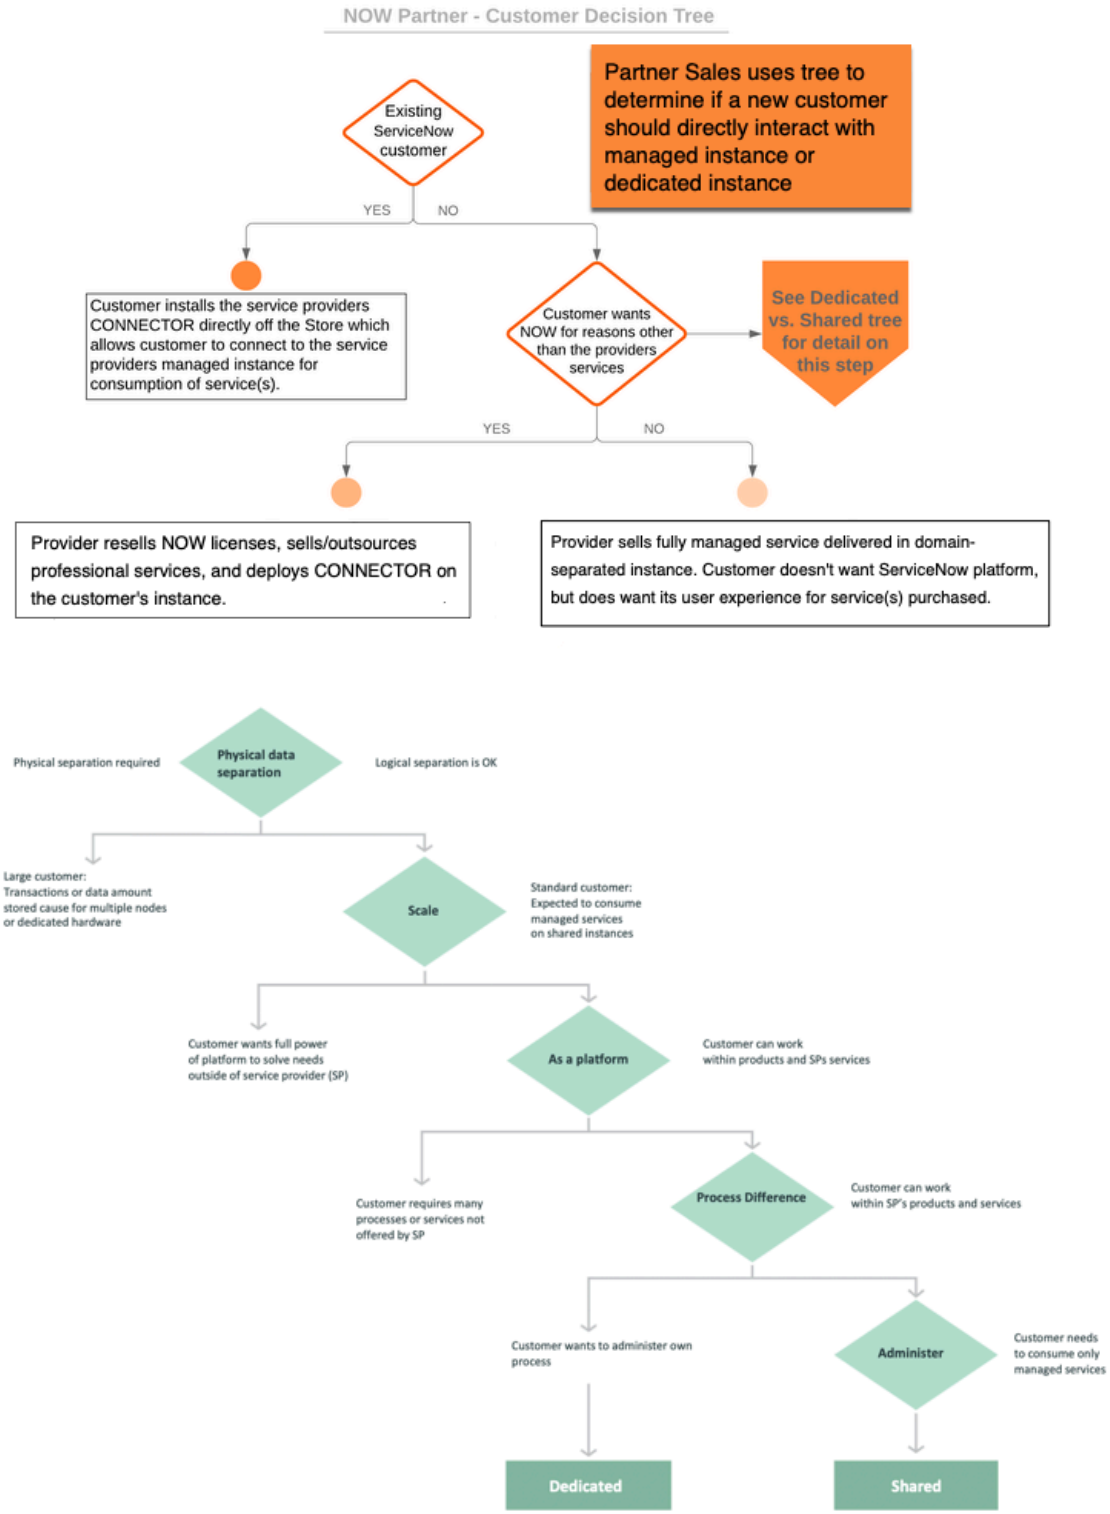
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Customer decision tree



SP reference architecture comparison

Service provider reference architecture for dedicated instances

Service provider (SP) customers can access SP services by using a portal to a dedicated instance. SPs use these dedicated instances to manage their service delivery.

Dedicated instances

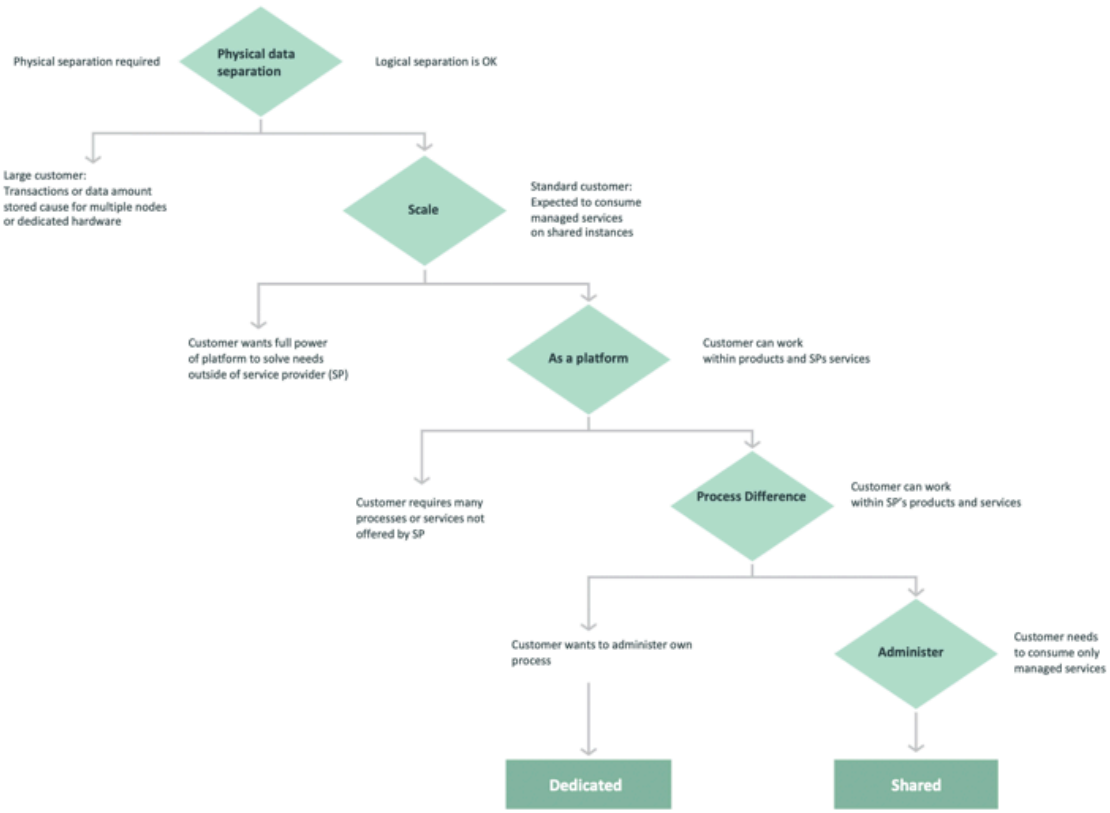
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Attributes

- Dedicated instances require that you have separate administration and dedicated teams. You need multiple licenses for the administrators and developers who log in to multiple instances.
- Each instance has a finite number of requesters and fulfillers. When you get a new customer, you must procure an instance that is based on the size and scale of your customer's company.

Shared instance

Dedicated vs. shared instance



SP reference architecture comparison

Service provider reference architecture for hybrid

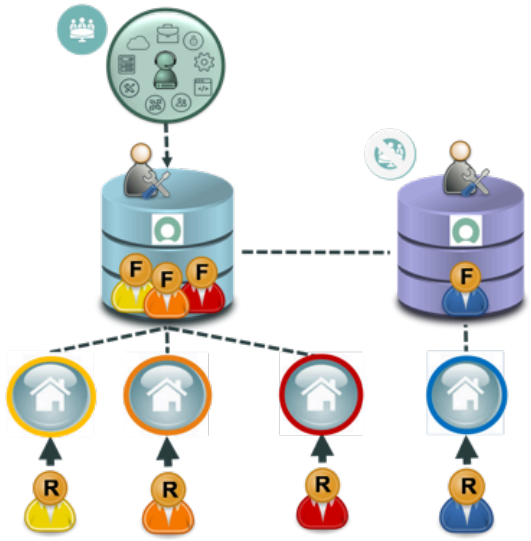
Use the hybrid service provider (SP) reference architecture for a customized solution. Your customers require a dedicated instance for a specific service. They can still use the shared SP instance for other services, but it requires integration of each instance.

Hybrid architecture

Your customer may be responsible for delivering this additional service directly. You need to build a hybrid solution of several attributes for your customer to provide.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

SP Reference Architecture - Hybrid



- Some customers require a dedicated instance
  - Service may be for the sole use of that customer
  - Offering Industry or Vertical Solution
  - Government or Regulatory Requirements
  - Application does not support Domain Separation
- Customers can consume some shared services from the SP instance and some via integration with the customers dedicated instance
- SP or customer owns and manages the dedicated instance. The SP could provide operational management of the dedicated instance as a service

Legend:

- Centralized governance at the SP for instances managed by the SP
- Dedicated instance managed independently or governance maintained via a SP "Gold Blueprint"
- Administration (shared or dedicated) can still be owned by the SP
- Fulfillers and requestors are on the shared instance and on the dedicated instance
- Customer requesters on each instance

Attributes

- You can share and leverage the administration of the instance. This means that there is no overhead, and you can optimize licenses.
- If there is a new instance for a decentralized environment, the program team is responsible and funded accordingly as dedicated administrator users for that instance. In a centralized environment where all instances stem from a blueprint, you need duplicate administration licenses.
- You do not assign fulfillers to a domain. Instead, you can share them across domains.
- If a customer is sharing both a shared environment and a dedicated environment, they require a fulfiller in both environments. This means more work for each team because the processes for shared and dedicated instances require different work for each instance.
- The number of users on the instance can change when you get a new customer. A new customer can result in tens or even hundreds of thousands of new users on the system. The number of total users is virtually unlimited in one shared environment.
- Each instance has a finite number of requesters and fulfillers. When you get a new customer, you must procure an instance that is based on the size and scale of your customer's company.

SP reference architecture comparison

Standalone (SA)		Multi-Tenant (MT)		Hybrid (MT+SA)		SIAM (Multi-Vendor)	
Platform as a Service	Enterprise scale	Processes simplified	Cost reduction	Managed Services (MT)	Custom Services (SA)	Service Integration	Multi-supplier governance
Customer wants full power of platform to Solve own needs outside those offered by SP.	Large customer: Transactions or data amount stored cause for multiple nodes or dedicated hardware.	Global governance & admin for business use case & process can be developed & maintained on the instance. Best when used w/ minor-to-moderate process differences among customers or sub-entities.	Lower administration, transaction, & onboarding costs, & ongoing operational costs for resources & licensing. Faster onboarding = more revenue.	Standardized re-usable services. procedures. processes, & resources delivered on a single ServiceNow instance to multiple Customers.	Services for sole use of customer, offerings specific to industry or vertical solutions, government, or regulatory requirements, applications that do not support Domain Separation.	Multiple best in class Service providers for individual services bringing together tooling, reporting, SLAs, strategy, & design for unified customer experience.	Unified governance across all providers to ensure organization requirements are met & that all providers cooperate on behalf of the customer.

Service provider reference architecture for Service Integration Management (SIAM)

The Service Integration Management Service Integration and Management (SIAM) for service provider (SP) architecture integrates services for a unified customer experience.

Attributes of SIAM architecture

- Customers access SP services on a dedicated or shared portal to the SP shared instance.
- SPs use ServiceNow shared instances to manage their service delivery.

Domain separation terms

With a ServiceNow instance, you can improve efficiency, add greater security, and increase performance for your customer organizations. It's helpful to understand some of the most common terms as you create your configurations.

Managed domain

In a managed domain, the **Managed domain** field allows domain administrators to manually select a domain for the user, group, department, location, or CI record, rather than using the domain that is assigned automatically from the company record.

If you want to change those properties, you can override them to further customize the functions of the applications in each of your domains.

Process tables

In process tables, if you see a value in the **Overrides [sys_overrides]** field, a process override record exists. That means that delegated administration, which is how administrators can set domain-specific policies, is in effect. Admins in the global domain can use the **Expand/Collapse Domain Scope** related link to see override records.

Note:
Reports are separated into domains and contain an **Overrides** field. To view all reports from the global domain, use the **Expand Domain Scope** related link.

When you view process tables from a domain, you see only the relevant process records for the selected domain. When you view a process table from the global domain, the **Expand Domain Scope** related link is displayed to let you see all process records, including overrides. To view only the relevant process records for global again, use the **Collapse Domain Scope** related link.

The domain scope feature is used only for process tables and causes the visibility of data on the table to shift in the opposite direction. For example, a record in the parent domain can be seen in the child, but a parent cannot see a child record. This allows the process to flow down to child domains.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Types of domains

Different types of domains can help you organize your processes and data and how they function in the application or feature.

Customer Domain

In the customer's domain is the user interface, as well as the process that controls how the data Is used.

The ACME domain in the following image is a customer domain.

Process Domain

You create processes for how the data is used and what it does in the domain. These processes must have these attributes:

- Specific processes and UI settings for a set of domains
- No core data of any kind (such as specific user data).
- The TOP domain in the following image is a process domain.

Data Domain

The data domain holds data that is relevant to multiple customers. That data can be shared without sharing the actual customer domains. Each customer has its own data domain and can access it.

Note:

This kind of domain is not common and can cause performance issues if overused. Consult with an SP architect before use.

Example: The domain may hold tasks that ACME, Cisco, and the SP all need to interact with.

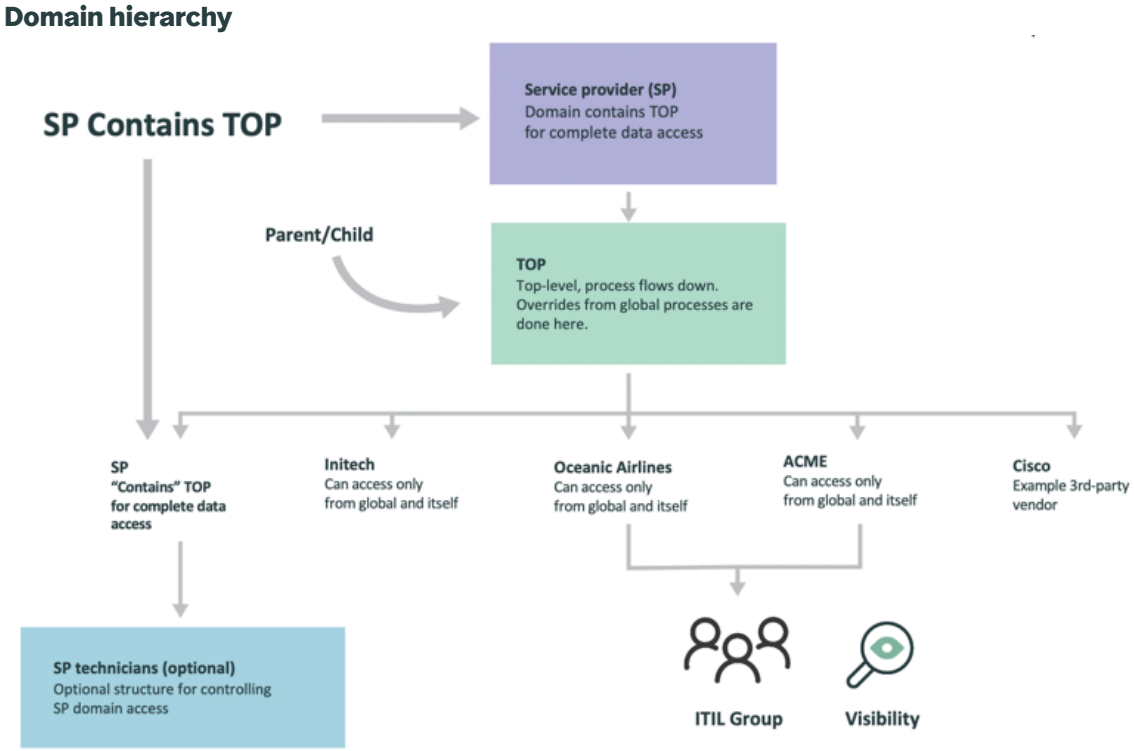
The Default domain in the following image is a data domain.

User Data

User record data never belongs in the global domain or any of the process domains. Users are primarily created in customer domains and can on occasion be created in data domains.

Admin accounts are special as they should not be used as everyday users of the instance and should be in the global domain to facilitate administrative functions.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Lists, admin, global process

Lists

From the global domain, if you right-click any choice field's label, select **Configure Choices**, and then add a new choice, the choice pushes automatically to all domain-specific lists for that field. If the new option is marked as **Selected**, it is added as active. If the new option is marked as **Available**, it is added as inactive.

Instance Administration

The instance owner's administrators must handle all normal process creation, modification, and maintenance in a domain-separated instance. Individual domain managers can maintain some parts of data-driven processes. The types of domain managers maintain user administration, support group memberships, and locations, or manage applications that are designed with tenant administration in mind.

Global process/parameters

You can create and maintain the process that affect the global domain as well as set the parameters. These properties are common for all users of a domain-separated instance.

Examples: System properties, dictionary overrides, `sys_documentation` (field labels), the data model (classes, CI types, and so on), tables and fields `[sys_dictionary]` (access can be restricted), indexing (text indexes as well as database), ACLs, installation exits, inbound actions, public pages, and interceptors.

Domain-separate a custom table

You may need to create custom tables in separate domains. This topic covers both the procedure and the concept behind domain-separating a custom table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

1. Create a sys_domain field

Note:
If a system table or a table has not been domain-separated by the Domain Separation plugin, it's best not to domain-separate it.

Use these points as a guideline to create a sys_domain field.

- Create a new field as a *domain_id* type.
  - Column Name: sys_domain
  - Other attributes: Defined automatically
- The Sys_domain_path is created automatically.

The column name **sys_domain** is reserved in the ServiceNow AI Platform, which means that the system recognizes it and automatically applies the appropriate field type and attributes for you. This automatic configuration also creates a corresponding **sys_domain_path** field.

- Set the column name to `sys_domain` rather than using the label.
- Domain separation is not appropriate for every table. In general, if a table is part of the base instance and that table does not have a **sys_domain** field, you should leave it that way.

A **sys_domain** field is created automatically when you create a domain_id type field with the name “sys_domain."

2. Add a business rule to set the domain

Without business rules

The domain is set to the current domain of the user who creates the record.

With business rules

The domain is assigned using scripted logic, typically based on the Company field.

In addition to a `sys_domain field`, custom tables need a business rule similar to **Domain - Set Domain – Task**to set the value of the domain field. In addition, you will need **Domain – Default – Task**, which moves records without a domain to the default domain if the first rule fails to assign a domain.

On the task table, review the business rules for Domain. Pay particular attention to the Order field. The priority of execution is given by the Order field from low to high.

The first rule that runs, **Domain – Set Domain – Task**, attempts to set the domain of the record based on the record’s Company’s Domain.

If the first rule fails to find an appropriate domain, the second rule, **Domain – Default – Task**, executes. This rule sets the domain of the record to the default domain.

Finally, if the domain of a task record changes, the **Domain – Cascade Domain – Task** business rule changes the domain on all records related to the task, such as workflows, metrics, SLAs, and attachments.

3. Add a business rule if Step 2 failed

If the initial business rule fails to set a domain and the domain is still empty or global, a second business rule runs. This rule examines the `task_for` field that is based on the caller or

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

`requested_for` field. This rule is checking to see if you can set the domain of the record based on the user's domain. If not, the business rule sets the domain to the default domain.

Following is a sample script for the business rule:

```
/* essentially
If (task_for is set)
  set the domain to the user's domain
ELSE
  set the domain to the default domain
*/
```

4. Domain – cascade domain – task

Tasks can have many related tables that work together for business objectives. These related records include workflow, SLA, approvals, attachments, and email. If the domain of a task changes, the related records domain must change, too, so they remain visible to users in the new domain.

This Cascade rule is commonly triggered when you clear records out of the default domain.

The related records for a Cascade domain contained in the Script are shown similar to the example:

```
/*
* Keep domains in sync w/related records for:
* workflow context
* workflow history
* approver tables and related workflows
* attachments
* emails
*/
```

Customizing domain properties and themes

You can customize your customers' company properties and themes within the domains that you have configured. Customization makes their instances fit in with their companies' overall look and feel.

Customizing company themes and logos

On the company record, you can customize specific design themes and logos for each company.

Customize the domain

By default, when you have the service provider plugin installed, the standard business rules contained in the core tables cause the record's domain to be set to the domain of the company that is associated with the record. The company can control the tables such as Task, User, Group, Location, Department, and so on.

With all of these tables, except the Task table, you can override the domain that a record is created in. This gives you more customization options.

Managing domain separation for specific uses

You can set up separate domains for email notifications and customize the properties of catalog, tables, users, groups, and views. This enables you to provide more specific behavior in each domain, giving your customers more flexibility.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Emails

You can use separate domains for email notifications and overrides. When you use separate domains for notifications, you can do an override that is based on the domain of just the attached record, not the user's whole domain.

Service Catalog

The Service Catalog is now domain-separated so that your customers can see and access the catalog. Items are processed as OR conditions when multiple items are used. Service providers should administer the categories and Items themselves so they fit their own criteria specifically.

Users and groups

Only use admin accounts in the global domain because admins need access to all domains. Do all your application testing from an actual domain, not in the global domain. Overrides don't process properly in the global domain. Admins should also be given user accounts in production if they are to use the application.

Working with fields

There are several points to consider when you work with fields. Pay close attention to these fields because they can have many variations that affect your configurations.

Lists

There are personal, global, and domain lists, as well as multiple views of each.

Forms

There are global and domain lists as well as multiple views of each.

One database

Any fields that you create exist for all users, in one database. Consider the global impact before you create one.

Note:
ACL scripts cannot keep a field from being viewed in a list because they do not run. You can add a READ ACL to hide a field from users if the ACL is only role-based.

Creating tables

When you create a table, you should add a `sys_domain` or an `sys_overrides` field. Any table that contains data that your instance users need to access, needs the `sys_domain` field. Tables that extend or support processes and that need to flow down to children domains also need the `sys_domain` field.

Configuring domain separation with the domain picker

Use the domain picker wisely, and remember the 80/15/5 approach so that you do not customize too much and impact the performance of your instance.

Verify your domain before making changes

The domain picker gathers all the domains into a list for you to choose from.

If your session times out and even if you don't get logged out, your session falls back to the domain on your user record. You also lose any elevated roles at the same time. In this case, your domain picker could still show the last domain that you selected if the top frame of the list hasn't

© 2026 ServiceNow, Inc. All rights reserved.

been reloaded. For this reason, you should reload your list completely if you have been away from the instance for any time.

Configuring at the TOP domain or the global domain

Domain separation works best when you are providing services to customers that are mostly standard in their configuration and user and group definition. The more that you customize and create "one-off" solutions, the more you create a margin for error. When you create your processes and business logic, any variations should be in properties that work automatically for each customer. While processes can still be adjusted as needed, use great care when you decide when, and to what degree, to create a unique configuration for a single customer.

You need to use an "80-15-5" approach in configuring your domains to avoid too large a margin for customization, and therefore error.

- Recommended approach for configuration:
  - **80%** or more **Standard**
  - **15%** or more **Parametric**
  - Less than **5% Configuration**
- Determine if a suggested change should be a global or a configurable property.
- Do not overbuild by adding more and more customization that needs to be managed. Instead, do the following:
  - Start with the base system features and verify any gaps before you make any changes.
  - Look for no-code solutions.
  - Use server-side scripts, build modular APIs, and build in domain-separated properties.
  - If you must use client scripting, use only ServiceNow APIs. Limit "synchronous" calls (those that go back and forth from client to server, also called AJAX).
  - Write all scripts logically to keep them simple and effective. Enforce peer reviews of code changes and make sure everyone is following the Domain separation recommended practices for service providers in this section.

Domain separation performance considerations

As you configure domain separation in your application and services, make sure that you consider the number and properties of domains you create. Too many property-heavy domains can impact the performance of your instance.

Limiting property-heavy domains

You can create as many domains as needed, but make sure that you don't create unnecessary domains on the instance. Weighing too many domains on the instance with a lot of properties can impact the performance of your instance.

The number of domains is not what impacts performance but rather what's in them. Too many properties can slow down the domain picker, which then slows down the overall user experience of your customers. If you are loading the domain picker and already have a large number of domains with a lot of properties, the domain picker has to load all the domains before it gives you control in the session. This process could lead to an outage where you can't access anything on the instance until the domain picker finishes. Before you create new domains, navigate to the domain hierarchy under **Domain Admin** > **Domain Map** and make sure that you actually need to create a new domain or whether an existing domain hierarchy can work.

Using Core UI domain picker

The domain reference picker is available in Core UI. With the reference picker, you do not load all the domains at once, but rather the domain is searched as you begin to enter the name of your domain into the domain picker.

Enable the domain reference picker in Core UI by following these steps:

1. In the application navigator, enter `sys_properties.list`.
2. Set the *`glide.ui.domain_reference_picker.enabled`* property to true.
3. Refresh the browser.

Note:
Do not upload a large number of domains (over 30) via integration or import sets without doing some testing first or you might bring down your instance.

Setting up domain hierarchies

You can avoid slowdowns and performance impacts in your instance by knowing how domain hierarchies work and by setting them up properly.

Based on the domain hierarchy, users have access to the data in their home domain and any child domains. The process flows down to the child domains and the data rises up.

Make changes to the existing domain hierarchy only when needed. When you update the parent of a domain, the system re-establishes the parent domain with all its child domains that change the domain hierarchy. When the domain hierarchy updates, the system triggers a cascade update on all tables that relate to domains for the records that are created on that domain. As a result, a large number of supporting tables have to be updated too.

For the same reasons, even if you must change the domain hierarchy, never do a mass update. Imagine the number of queries that the system has to run to change the domain hierarchy. Always do an update in small batches. Before you start the next batch of updates, make sure that Domain Work Request (DWR) records are processed. DWRs are reports that display whether there are errors after you've changed the domain hierarchy.

Tracking DWR records

In the syslog_domain table, look for an information entry in the Message column for **DWR execution completed.** to confirm that DWR is completed.

Checking domain logs for errors and warnings

Check the domain logs to find errors or warnings in your domain path processes and hierarchy configurations.

You can find the domain logs in the Domain Log [syslog_domain] table. When the domain hierarchy updates, the system triggers a scheduled job to recalculate the domain paths. The domain logs table captures the results.

Look for any errors and warnings in this table. After reviewing this table, you need to resolve these errors and run the domain path validator again.

In this example of a log, the system has detected ten orphan records in the sys_ui_list table. The errors in these records must be fixed before the domain path can run successfully.

To learn more about domain-separation errors, see Troubleshoot domain separation errors.

Importance of the Default domain

Organizing your domains is a crucial part of the domain separation process. If you don't set a default domain, new tasks and user records go to the global domain. Anyone can see the records in the global domain, which means that data can be seen when it is not supposed to.

When you set the default domain, its records are not visible to any user other than an admin.

Note:
The defaults access can be changed by granting users visibility to the default domain or the parent domain.

You should always set one default domain for the domain records on your instance. The default domain is where the system automatically assigns task and user records that are not already assigned to a domain.

When you create a default domain from the Domain Administration screen, add the name Default in the **Name** field to differentiate it from other domains. Check the **Default** check box for the record.

Maintain regularly the records that you create in the default domain and move them to the correct domains. If records show up often in the default domain, you may need to investigate why. Ideally, you should make sure that all records are created in their appropriate domains (not global or default domains).

Contains queries and domain access

Use a "contains" query only in special cases, such as when users or groups need to see data from a domain that they don't have access to, but you don't want to move those users to a domain. Creating domain "contains" and user or group access for a domain should be an exception, only when absolutely needed.

"Contains" is a domain-to-domain relationship that is many-to-many, and has no effect on the flow of process. If you create a large number of domain "contains" relationships or provide broad access, you will generate queries with too many OR conditions. OR conditions are slow and impact the performance of your instance. Instead of using too many "contains" relationships, set up your domain hierarchy as follows:

Sample query

```
SELECT ... FROM task task0 ignore index(number) WHERE task0.`sys_class_name`
= 'incident' AND (task0.`sys_domain_path` = '/' OR task0.`sys_domain_path` LI
KE '!!$/!!(/%' OR task0.`sys_domain_path` LIKE '!!$/!!$/!!&/%') ORDER BY task
0.`number` DESC limit 0,20
```

Before you move users to a domain, make sure that they really should have access to that domain. Weigh the benefits and limitations. The query above is for just one contains relationship.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

If you have a domain that contains another domain, and that domain is the parent of a number of other domains, you will have many more OR conditions. Be careful when you create a domain map so that you do not impact the performance of your instance.

Domain paths query method

You can create effective queries with domain paths.

Use domain paths instead of domain spooling (`sys_domain`) or domain numbering. Queries that use domain paths are much faster than spooling or numbering.

Domain paths is the default query method for instances that have enabled domain separation.

If you want to verify the query method on your instance, look for the following system properties in the admin dashboard:

- *`If domain path is enabled`*: In the System Properties table, you see `glide.sys.domain.provider=domain_paths` and `glide.sys.domain.paths.installed=true`.
- *`If domain path is not enabled`*: In the System Properties table, you see `glide.sys.domain.provider != domain_paths,glide.sys.domain.paths.installed=false`

Slow queries and SQL debugging

Debugging SQL and slow queries can help you resolve slowness issues in an instance.

When you debug an instance, you can either enable SQL debugging to look for slow queries or you can look for slow queries by checking the Slow Queries [sys_query_pattern] table by navigating to **System Diagnostics > Stats > Slow Queries**. This table stores all the slow queries in the instance.

When you search the table, look for queries that contain `domain_path` to determine if any slow queries are due to the domain path in your instance.

If you do find slow queries, try to analyze why they are slow.

Common reasons for slow queries

- A query has too many OR conditions (for more information, see Contains queries and domain access). In the domain hierarchy, place the user or a domain at a hierarchy level where contains or visibility is not needed.
- The query method is not the domain path query method (for more information, see Domain paths query method): If you are not using the domain path query method, contact Customer Service and Support.
- A query needs a database to be indexed so you can see what is in the database quickly. If you can identify the slow query, run the "explain plan" to see if there are options for indexing available. The "explain plan" is a function of SQL that shows the query and what is going on with it.

Before Query business rules

You can use a Before Query business rule to help support data segregation on an instance. ServiceNow applications that support domain separation may support the separation of data and data routing only, have advanced business logic separation, or support tenant (customer) level administration of the application.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

A Before Query business rule is supplementary code that you use to support data segregation within domain-separated environments.

Warning:
Do not use the Before Query business rule in place of the Domain Separation plugin. This business rule does not prevent data leakage as securely as the plugin.

Using the Before Query business rule for data segregation

You can use the Before Query business rule with data segregation in these situations:

- When domain separation is not supported by a ServiceNow application and you must grant or restrict table or row access to one or more non-internal customers outside of the service provider organization.

  Note:
  Before you begin developing, contact ServiceNow Customer Support about the application roadmap for that product; domain support improvements may be planned for upcoming releases.

- When a table is domain-separated but access to its rows must be granted or restricted based on certain conditions that apply only to a set of domains in the system.

  Note:
  For example, a customer in the X domain has multiple vendors supporting that domain and those vendors are granted access to see only the records that are assigned to them.

Points to consider before creating Before Query business rules

You can script Before Query business rules to prevent parent and child table access based on a combination of user information, group memberships, companies, roles, or record-specific field conditions. Before Query business rules are put into separate domains and created to apply globally, to a specific branch of a domain hierarchy.

- Where you can, create Before Query business rules at the lowest possible part of the domain hierarchy so that the rule runs only for users that it applies to.
- Know that there are scenarios in the system where business rules may not run or where a user-triggered interaction may not trigger a business rule to run. For example, a business rule won't run when you have transform maps with Run business rules turned off, or you have scripts with the workflow disabled.
- Always populate the condition field to specify when the rule runs. For example, you can specify if the business rule applies only to certain vendors in a domain.

  Warning:
  When designing and coding business rules (especially Query business rules), limit OR clauses and searches in non-indexed fields. Too many OR clauses and searches in non-indexed fields can slow queries or affect how your instance performs.

- Use Before Query business rules only when necessary. Too many Before Query rules can affect how your instance performs.

Before Query business rules run before access control lists (ACLs) and perform better in general. This is true especially when you limit the returned results to those users in service provider (SP) environments who have access to several domains in the system.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
Filtering the data is transparent (unlike with ACLs) to users who do not see the message `Data Security restricts...` when interacting with data.

When not to use Before Query business rules and ACLs

Be careful when you use Before Query business rules and ACLs to segregate customer data. By using both business rules and ACLs, you create customizations that you then must maintain. Customizations can potentially cause performance issues. Your development teams should create processes to make sure that they don't break the system.

Domain separation provides both scalability and governance with the current domain path query method (v3), which is a widely supported framework. The ServiceNow Platform and App teams are responsible for maintaining the framework, taking the burden off the customer.

For companies with many customers in many instances, excessive use of Before queries and ACLs may cause the database queries not to perform well.

How domain separation is enabled

You can enable domain separation with a ServiceNow plugin. A product manager, supported by a development team, manages the functionality. Enhancements and fixes for domain separation functionality are included with ServiceNow releases. Instance owners can consult Customer Service and Support resources, such as the Service Portal, at https://support.servicenow.com for assistance with domain separation.

Avoiding domain path in scripts

Domain paths can cause the values of your script to change or even break, so don't use them in scripts.

Your script should not depend on the domain path because if you ever change the domain hierarchy, the domain path recalculates and its value changes. When this happens, your scripts are useless or can throw errors or break. The best strategy is not to write your scripts based on domain paths.

Use the **sys_domain** field in your scripts rather than depending on the domain path. If you ever change the domain hierarchy, the domain path recalculates and its value changes, which can cause your scripts to be useless, throw errors, or break. Look for base system business rules, which use the **sys_domain** field, to get some ideas before creating your own scripts.

The ServiceNow platform does not capture the sys_domain_path values in an update set in order to avoid issues with differences in the domain hierarchy for each instance. Therefore, you should validate the domain hierarchy after you import an update set to ensure that the domain path values for your records are correct.

To learn more about domain path, see Request domain separation and Domain Separation Center.

Domain assignments

How you assign a domain impacts the value of the sys_domain field. The assignments contain designs and business properties that affect how the application functions in each domain.

Value of the sys_domain field

The value of the **sys_domain** field contains the domain that is assigned to the record by any of the following:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Company to which the user belongs
- Business rule that is used when creating the record
- Module that is used when creating the record
- Form template that is used when creating the record
- Domain of the parent record
- Domain that is assigned to the User record
- Domain of the user who creates it

Make sure that your domain assignment strategies and designs are well documented and tested so that you are creating records as those strategies and designs are inserted into the correct domain. That way you can see that the properties of each domain should you need to duplicate or modify them.

Domain separation and the Customer Service Management (CSM) plugin

For the best outcome, be aware of how the properties in the CSM plugin work. When the plugin is enabled, you can see the status of your records in your domains.

Instance owners should contact Customer Service and Support to enable the *csm_auto_account_domain_generation* property.

Note:
This base system property is located in the system properties table and is available after CSM plugins are enabled.

What the property does

Whenever a new account in the Customer Service application is created, a domain is created and placed under the TOP domain. If the parent field on the account form is populated, and a new record is inserted, it creates that account as a subdomain of the parent.

What happens if this property is not true and the domain is enabled

New account records in a domain-separated environment are automatically placed in the default domain.

In the header bar, you can see the status of the records with the plugin enabled.

Domain separation setup and administration

Setting up domain separation involves requesting activation of a plugin, setting options, and assigning users and records to domains.

Do the following to set up domain separation:

1. Request domain separation
2. Create a domain
3. Add a domain field to a table

You can also perform these basic administrative tasks on domains:

- Enable or disable a domain
- View domain relationships
- Expand domain scope
- Create a domain-specific choice list

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

See Advanced domain separation administration for a list of tasks to perform after you set up domain separation and perform basic administration.

Request domain separation

All domain support features are activated with a plugin called **Domain Support - Domain Extensions Installer**. Administrators can request activation of this plugin.

Before you begin

To purchase a subscription, contact your ServiceNow account manager. The account manager can arrange to have the *com.glide.domain.msp_extensions.installer* plugin activated on your organization's production and sub-production instances, generally within a few days.

If you do not have an account manager, decide to delay activation after purchase, or want to evaluate the product on a sub-production instance without charge, follow these steps.

Role required: admin

About this task

If the Domain Support (com.glide.domain) plugin is already active, content in the Domain Support - Domain Extensions Installer and Domain Support - Domain Extensions plugins will not be installed to avoid potential conflict with an existing implementation.

Domain separation replaces Company Separation. Starting with the Helsinki release, the Company Separation plugin can no longer be activated. However, if company separation is already active when you activate domain separation, both plugins are active at the same time. You can control the company separation activation status with the *glide.db.separation.field* property.

Note:
Domain paths are used for all customers on Helsinki and later. Domain numbering is no longer used. Customer Service and Support can assist in the upgrade.

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Select **Request plugin** to open the **Activate Plugin** form on Now Support.
3. On the **Activate Plugin** form, provide the following information.

Activate Plugin form

Field	Description
What is your target instance	Select the instance that you want to activate the plugin on.
Which plugin would you like to activate	Select the name of the plugin to activate.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Note: If the system doesn't list the plugin you want or if you're activating the plugin on an OEM or on-premise instance, select the **Plugin I'm looking for is not listed** check box and then enter the name of the plugin.
Select Maintenance Date and Time	Select the date and time to activate the plugin.

Example

For example, see the following form to activate the Event Management plugin on an instance named SNC Instance.

4. Select **Submit**.
   After the maintenance window, the system installs the plugin on your instance. To confirm the installation, go to the Installed tab in the Application Manager.

Result

Activating the Domain Extension Installer plugin enables these features:

- Domain separation is based on the Domain `[sys_domain]` table.
- Delegated administration lets each domain have separate policy.
- All records are part of the global domain.
- The current user's domain determines the domain to use when viewing or operating on a record in a different domain.

Related topics

Domain separation plugin

Domain separation plugin

The Domain Support - Domain Extensions Installer plugin activates several domain separation features and properties at once. This plugin is typically referred to as the Domain Separation plugin.

Recommended practice for activating the Domain Separation plugin

As part of domain separation development, administrators must request activation of this plugin. For best results, activate the Domain Separation plugin at the start of the development process, preferably before any other plugin is enabled.

Important:
Request to activate the Domain Extensions Installer plugin (com.glide.domain.msp_extensions.installer) before activating Domain Separation (plugin com.snc.pa.domain_support).

If you enable Domain Separation towards the end of ServiceNow implementation or once an instance has gone live, your application is at risk in both performance and process. On established instances, depending on how things were structured in development, the risk to the

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

platform and its usability could be high. To learn more about domain separation process, see Exploring domain separation.

For instance, when the Domain Separation plugin is enabled, the **Domain** (sys_domain) column is added to the task table and every existing record is automatically placed in **global**. To use a script to assign all of the records into the correct domains, an established parent/child hierarchy is required. These types of scripted actions risk data corruption or loss, and possible production down time as large amounts of data are moved. Much of the platform code also is placed into **global**, such as business rules, client scripts, form views, and workflows.

If a customer creates code or modifies ServiceNow code, there is risk to platform performance and usability. Instance owners could severely delay their implementation or experience lengthy down-times with this type of approach.

Features of the Domain Separation plugin

These features are enabled when you activate the plugin:

- Domain separation is based on the Domain `[sys_domain]` table.
- Delegated administration lets each domain have separate policy.
- All records are part of the global domain.
- The current user's domain determines the domain to use when viewing or operating on a record in a different domain.

Domain separation recommended practices for service providers

Domain system properties and user preferences

Administrators have access to properties and user preferences that control domain scope.

Properties

New activations of domain separation automatically restrict domain scope to the record's domain for all related data or processes. When the user views a record in a form, the record's related data (such as reference picker and related list data) and applied processes (such as business rules and client scripts) are restricted to the record's domain scope. If there are records in multiple tabs, each tab has its own domain scope based on the record opened within that tab. The following properties restrict domain scope to either the record's domain and the user's current session domain.

Domain system properties

Property	Details
glide.sys.domain.use_record_domain_for_processes	Restricts domain scope to the record's domain for all processes. This property does not apply to business rules. Business rules are always processed from the domain record. • *Type*: true | false • *Default value*: true • *Location*: System Property [sys_properties] table

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Domain system properties (continued)

Property	Details
glide.sys.domain.use_record_domain_for_data	Restricts domain scope to the record's domain for all data. • *Type*: true | false • *Default value*: true in new domain activations from Fuji onwards (upgrades from instances older than Fuji do not have this property in the table) • *Location*: System Property [sys_properties] table

When either the *glide.sys.domain.use_record_domain_for_processes* or the *glide.sys.domain.use_record_domain_for_data* property is set to **true**, the following properties are not used, regardless of their setting:

- *glide.sys.domain.use_record_domain*
- *glide.sys.domain.use_record_domain_for_client_scripts*
- *glide.sys.domain.domain_change_notify*
- *glide.sys.domain.no_change_roles*

For a full list of properties see Available system properties.

Note:

In new activations of domain separation starting with the Jakarta release, the session domain determines the business rules executed on the domain table. In previous versions, business rules executed on the domain table were set based on the newly created domain's hierarchy. This behavior is modified by the *glide.sys.domain.skip_domain_insert_businessrules* property. Setting this property to true significantly improves domain insert performance.

Domain scope properties for business rules executed on the domain table

Property	Details
glide.sys.domain.skip_domain_insert_businessrules	Specifies the domain scope for business rules executed on the domain table. In new activations of domain separation, the property default is true and business rules are determined by the session domain. In existing implementations, the property default is false and the business rules are determined by the newly created domain's hierarchy.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Domain scope properties for business rules executed on the domain table (continued)

Property	Details
	• *Type*: true | false • *Default value*: True in new domain activations starting with Jakarta. False in existing implementations.
glide.sys.domain.skip_non_global_businessrule_if_nodomain	Ensures that only bus.rules from global domain are executed when using queryNoDomain() or when table is not domain-separated, so you can skip any other business rules • *Type*: true | false • Setting the property to false restores the old behavior and doesn't align with ServiceNow® recommended practices. • Recommended: Domain-separate your tables; always try to use the record's domain rather than the session domain.

User preferences

In addition, user administrators can set the following user preference globally or on a per-user basis:

Domain scope user preferences

Preference	Category	Updated By	Details
glide.domain.session_scope	Domain	Admin Only	When true, sets the default scope to the user's session domain rather than the record's domain. When false, the default scope is the record's domain. Users with the domain_expand_scope user role can still change the domain scope as needed. • **Type**: true | false • **Default value**: false

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Domain scope user preferences (continued)

Preference	Category	Updated By	Details
glide.domain.session_scope_notification	Domain	Admin Only	When true, displays a visual cue that record values include an expanded domain scope. When false, the notification is hidden. • **Type**: true | false • **Default value**: true

Domain separation application properties

Create a domain

You can create a domain by creating a record in the [domain] table.

Before you begin

Role required: admin

About this task

When creating a new domain, keep the following in mind:

- Only one domain can be the default domain.
- Only one domain can be the primary domain.

Procedure

1. Navigate to **All** > **Domain Admin** > **Domains**.
2. Click **New**.
3. Fill in the necessary fields (see table).
4. Click **Submit**.

Domain form fields

Field	Description
Name	Enter a unique name for the domain.
Type	Select a domain type that describes the domain. By default the domain types are *Vendor*, *Customer*, and *MSP*. You can also add your own choices.
Primary	Select the check box if this domain is to be the top-level domain in the hierarchy. The top-level domain only has child domains and no parent domains.
Default	Select if this domain is to be the default domain for your hierarchy.
Parent	Select the name of the domain higher in the hierarchy that contains this domain. This field must have a value for the domain to appear in the domain map.
Active	Select the check box to make the domain available for use. You must select this option for this domain to appear in the domain map.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Description	Enter a description for the domain.

Each domain record can also have several related records:

- Companies
- Contains Domains
- Contained By

What to do next

To change the domain hierarchy, go to the Contains Domains related list and select the domain records that is the child (contained) domains of the contains relationship.

Make a domain the default

Made a domain the default domain to which the system automatically assigns task and user records that are not already assigned to a domain.

Before you begin

Role required: admin

About this task

Note:
If you do not set a default domain, then new tasks and user records are placed in the global domain.

Procedure

1. Navigate to **All** > **Domain Admin** > **Domains**.
2. Open the domain you want to be the default domain, for example, Main.
3. Configure the form layout to add the **Default** field.
4. Select the **Default** check box.
5. Click **Update**.

Manually manage the domain for particular records

By default, the system automatically assigns a domain based on the user's company record. In some cases, however, domain administrators want to manually manage which domain a particular record belongs to.

Before you begin

Role required: admin

About this task

The **Managed domain** field allows domain administrators to manually select a domain for the user, group, department, location, or CI record, rather than using the domain assigned automatically from the company record. The **Managed domain** field is available on these record types.

- User records
- Group records
- Department records

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Location records
- CI records

Procedure

1. Navigate to the record you want to manually manage.
2. Select the **Managed** domain check box.
3. From the **Domain** field, select the domain for the record.
4. Click **Update**.

   Clearing the **Managed domain** check box hides **Domain** field and the record uses the domain value from the record's company.

Domain separation recommended practices for service providers

Domain Separated Tables

You can see at a glance which tables are domain-separated in your instance with the Domain Separated Tables feature.

Overview

Use the Domain Separated Tables feature to see which tables are domain-separated. Start typing "domain" in the **All** filter to access **Domain Separated Tables** in the left navigation pane.

You can filter this view to display or remove column names to look for certain properties or attributes that are included in your tables. There are two table types that display on the list:

- Tables that have an explicit *sys_domain* column present, where the **Column** name displays *sys_domain* value in the list.
- Tables that are using the *domain_master* attribute to derive domain separation from a referenced record, where the **Attributes** column includes the *domain_master=ref-field-value* value.

When you use the Show Matching or Filter Out selections on the Column name menu, you can view these two types of tables.

Domain Override Viewer

With the Domain Override Viewer, you can see and manage all your process overrides at once across the entire instance.

Overview

Rather than creating an elaborate search for overrides in your scripts, you can use the Domain Override Viewer to find them quickly. Start typing "domain" in the **All** filter to access **Domain Override Viewer** in the left navigation pane.

The table selector in the Domain Override Viewer displays a list of only the tables that contain record overrides, along with a count of overrides in that table. After you select a table, a list of all parent records with overrides is returned. You can quickly view all **parent records**, the **domain** of the parent record, and a **count** of overrides for each record.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Selecting **View Overrides** loads a new tab where all overrides, including the parent record, display in the standard list view. Select a table from the drop-down list to display all records and overrides. Select **View Overrides** on a record to view all of record specific overrides.

Note:
Only tables with overrides are listed.

To learn more, see Create domain-separated property overrides.

Enable or disable a domain

When you activate or deactivate a domain, the activation status cascades to companies within the domain.

Before you begin
Role required: admin

About this task
When you activate a company record, domain separation automatically activates the company's associated domain. For example, if you activate the ACME company, then you also activate the TOP/ACME domain.

Procedure

1. Navigate to the domain record.
2. Clear or select the **Active** check box.
3. Click **Update**.

Warning:
Do not delete domains. Deactivate domains that you no longer need instead of deleting them.

Add a domain field to a table

As an administrator, domain-separate a custom table by adding a sys_domain field to it.

Before you begin
Role required: admin

About this task
Note:

Do not add domains to base system tables.

Procedure

1. Navigate to the table's list view.
   For example, type <table name>`.list` in the navigation filter.
2. Right-click the list header and select **Configure** > **List Layout**.
3. In the **Create new field** section, enter `sys_domain` as the **Name** and `Domain ID` as the **Type**.
4. Click **Add**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

5. Click **Save**.

Note:

Any other means of creating a field adds a **u_** prefix to the column name. But with the domain field, the system automatically creates the field without the **u_** prefix. You can use the following functionality as a shortcut: Whenever you create a **sys_domain** field, name it **sys_domain** and leave the field type as is. The system automatically sets the field type to **Domain ID** and the field label to **Domain**, saving you a few clicks.

Adding domains to base system tables requires prohibitively thorough testing, updates and adding new logic. In addition in many cases, the source code is not accessible to the customer.

View domain relationships

The domain map offers domain administrators a read-only representation of the active domains on the instance and how they relate to each other.

Before you begin

Role required: admin

About this task

All domain maps must have one domain set as the primary domain. In addition, each domain in the domain map must meet these criteria:

- The **Parent** field must be filled in (the primary domain is the only exception to this).
- The **Active** check box must be selected.

The domain map does not draw domain relationships for domains that fail to meet the mapping criteria.

Procedure

1. Navigate to **All** > **Domain Admin** > **Domain Map**.
2. Click the plus (**+**) or minus (**-**) icons on the domain headers to show or hide sub domains.

Select a primary domain

The primary domain indicates the top-level domain in the domain map.

Before you begin

Role required: admin

About this task

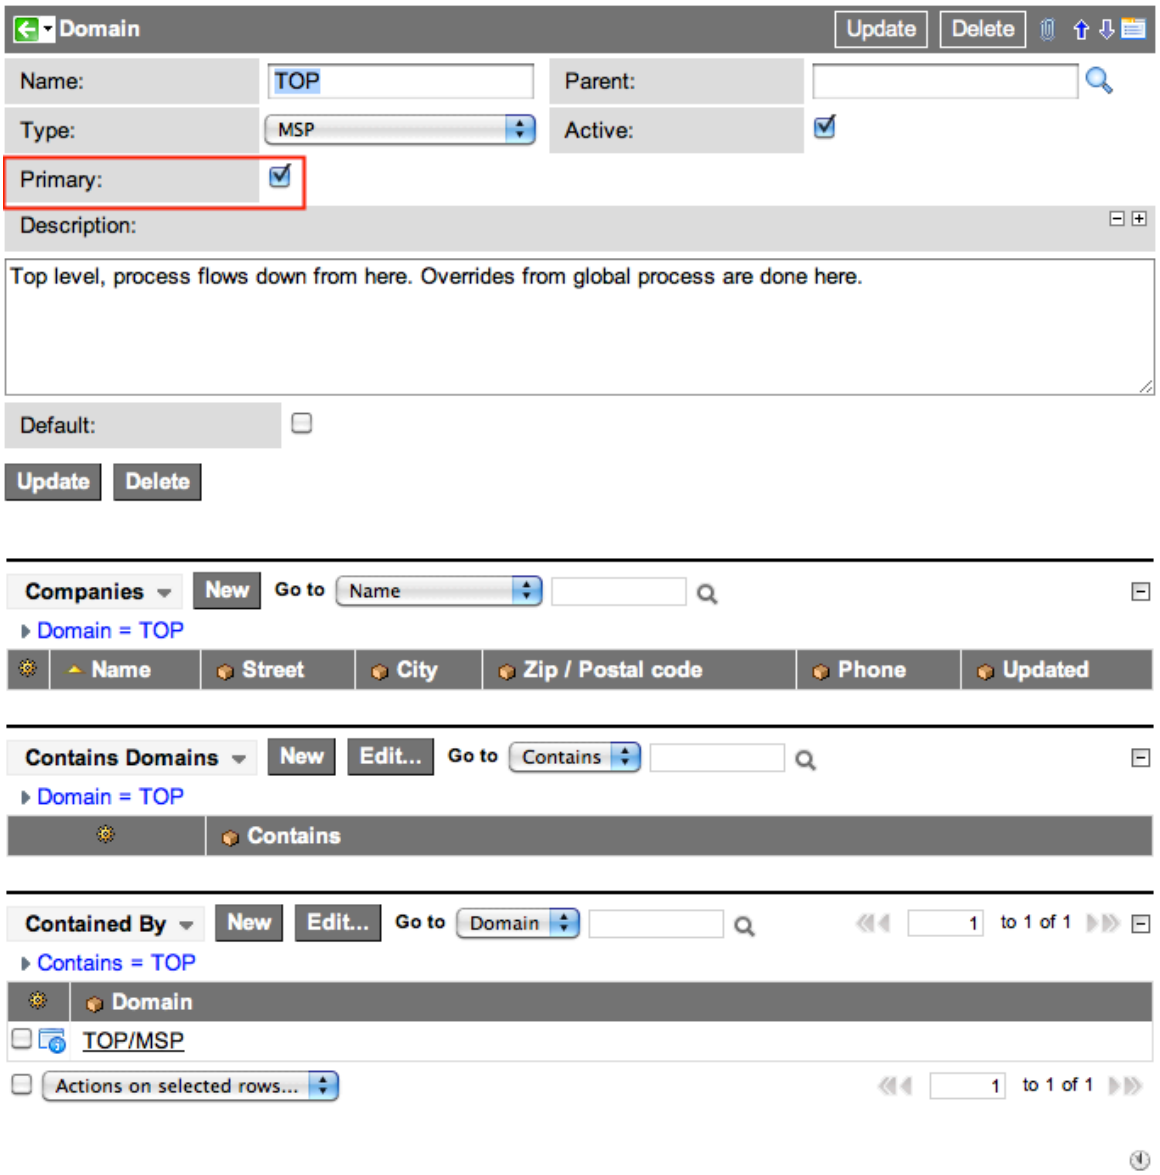
The primary domain cannot have a parent domain and must have at least one child domain. There can only be one primary domain at a time. If you select another domain as the primary domain, it overrides the previous primary domain.

Procedure

1. Navigate to **All** > **Domain Admin** > **Domains**.
2. Select the domain you want to be the primary domain, for example, TOP.
3. Select the **Primary** check box.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Click **Update**.



Create Contains relationships between domains

Create a "contains" relationship between domains to change the domain hierarchy.

Before you begin

Role required: admin

About this task

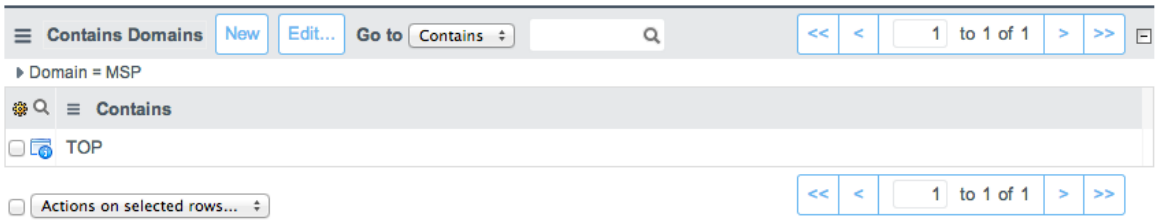
Domains in a contains relationship inherit the settings of the containing domain. The containing domain allows users to see data in the contained domain as well as any of its children. Processes are unaffected by a contains relationship.

Procedure

1. Navigate to the domain table.
2. Select the domain record that is the parent (container) domain of the new contains relationship.
3. Toggle the domain scope to switch between the session scope and record scope, if necessary.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. From the Contains Domains related list, click **Edit**.
5. Select the domain records that is the child (contained) domains of the contains relationship. Only child domains appear by default when the domain picker is set to Global. Toggle the domain scope to see all domains.
6. Click **Save**, and then click **Update**.



Related topics

Domain separation recommended practices for service providers

Expand domain scope

By default, when a user in the global domain views a table containing a **sys_overrides** column, the user sees records from only the global domain. When an admin in the global domain views a process table, that admin sees only records that are in that process table.

Before you begin
Role required: admin

Procedure

1. Change the *glide.sys.restrict_global_domain_processes* property to **true**.
2. To view records from all domains, click **Expand Domain Scope** under Related Links.
3. To return to viewing records from the global domain only, click **Collapse Domain Scope**.

Add domains to a visibility domains list

Adding a visibility domain allows a user or group to see and potentially edit records from another domain regardless of the user or group's normal domain membership.

Before you begin
Role required: admin

About this task
Assigning visibility domains to all members of a group is preferred over granting them to individual users.

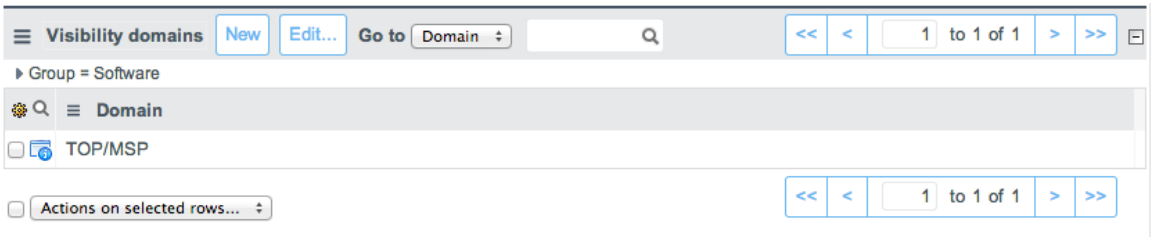
Note:
Adding a visibility domain does not change a table or record's access control rule requirements.

Procedure

1. Navigate to the group table.
2. Select the group you want to provide with visibility domains.
3. Add the **Visibility domains** related list to the form.
4. From the **Visibility domains** related list, click **Edit**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

5. Select the domain records you want the group or domain to see.
6. Click **Save**, and then click **Update**.



Grant visibility domains to an individual user

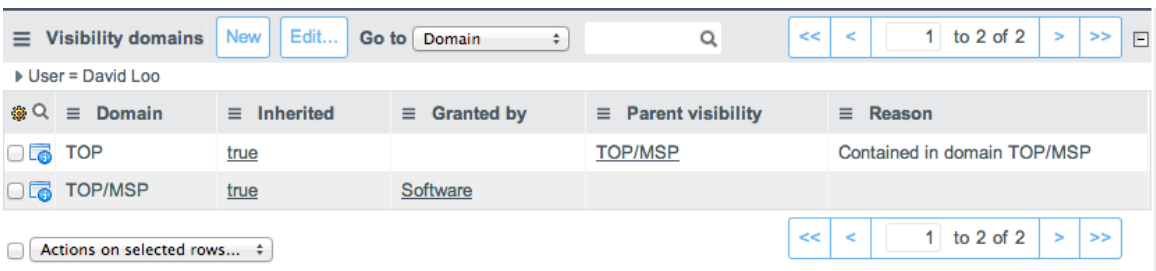
While it is possible to add visibility domains for specific users on the User form, it's best to add them only via groups. This controls permissions and access should individuals change departments or leave the company.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **User Administration** > **User**.
2. Select the user you want to provide with visibility domains.
3. Add the **Visibility domains** related list to the form.
4. From the Visibility Domains related list, click **Edit**.
5. Select the domains whose records you want the user to see.
6. Click **Save**, and then click **Update**.



The Visibility domain embedded list contains the following fields.

Field	Description
Domain	Domain that is visible to the group or user.
Inherited	Domain is inherited from domain visibility or a parent domain.
Granted By	Name of the group that granted domain visibility.
Parent visibility	Name of the parent domain and used for grouping records. If the parent record is deleted, then all records with the same parent are deleted as well.

Create a domain-specific choice list

Administrators can configure choice lists to contain entries specific to a particular domain.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin

Role required: admin

Procedure

1. Select the domain from domain picker where the choice should be added.
2. Right-click the choice field you want to customize and select **Configure Choices**.
3. Update or add choices.
4. Push changes through the normal change process such as update sets.

Note:
Administrators should ensure that choices are unique across domains to prevent administrative confusion in the global domain.

If an administrator adds a new choice from the global domain, then users from domains lower in the hierarchy see the new choice at the end of their current choice lists. If the new choice is not active at the global level, then it is available to the domain users via **Configure Choices** but does not show as an active choice.

Advanced domain separation administration

Administrators can view information about domain separation, identify potential issues, and change configuration settings.

You can perform these advanced administrative tasks on domains:

- Use domain selection menus
- View domain relationships

Use domain selection menus

The instance offers domain selection via two menu formats.

- Domain selector: provides a simple drop-down list of available domains.
- Domain reference picker: enables a reference field that offers filtering and an auto-complete, type-ahead entry feature. Use this format for longer lists.

The placement of these pickers and the procedure to show or hide them differ depending on the user interface version.

Enable domain selection menus in Core UI

Displaying the domain picker in Core UI enables the domain selector by default. After enabling the domain selector, you can add a system property to enable the domain reference picker.

Before you begin

Note:
The domain separation (plugin com.snc.pa.domain_support) is required to enable the domain reference picker.

Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

About this task

Procedure

1. Click the gear icon in the header.
2. On the General tab, click the **Show domain picker in header** switch.
   The domain selector appears in Core UI header.
3. **Optional:** Enable the domain reference picker.

   Note:
   Enabling the domain reference picker removes the global option from the list. To return to your home domain, click the return arrow next to the reference field. Admin users can click the return arrow to return to the global domain.

   a. Enter `sys_properties.list` in the application navigator.
   b. If not already present, add the `glide.ui.domain_reference_picker.enabled` property and set the value to **true**.
   c. Refresh the browser.
   The domain reference picker appears in Core UI header.

Restrict access to the domain picker

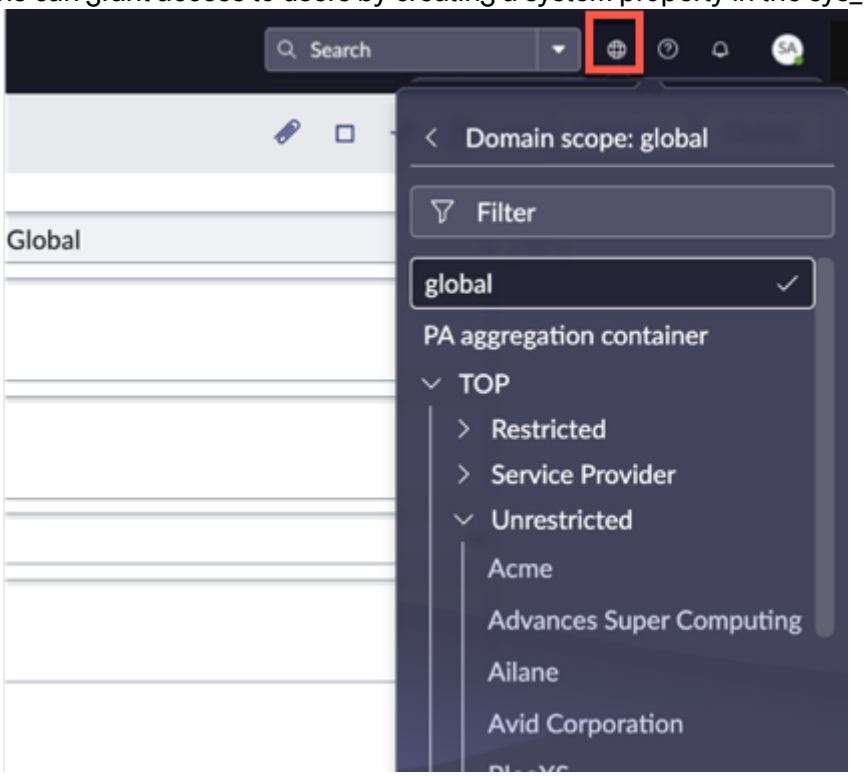
Use a system property to restrict access to the domain picker in Core UI and Next Experience.

Before you begin
Role required: admin

About this task
By default, users with the ITIL role, and roles that include the ITIL role (such as the administrator), can access the domain picker in Next Experience. You can grant other roles access by adding them to the property or restrict roles by removing them. It is recommended to restrict the role to admins only.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Admins can grant access to users by creating a system property in the sys_properties table.



Procedure

1. Open the System Properties [sys_properties] table.
2. Add this property: `glide.ui.polaris.domain_picker.role`
3. Configure the property value as a comma-separated list of roles: **admin, itil**.
   To learn more, see Configure Next Experience pickers

Domain separation application properties

The Domain Separation plugin has two new tables to give service providers more flexibility in customizing their applications that use domain separation. These tables are the System Application Property table [sys_application_property] and the System Application Property Value table [sys_application_property_value].

New tables offer more options

With service provider (SP) applications, certain actions can vary depending on the domain. However, the ServiceNow® base system System Properties [sys_properties] table is not domain-separated, so it doesn't satisfy the requirements for applications that use domain separation.

Each SP customer may want to customize their applications differently. Previously, features that could be customized were defined as only one global value. Application developers need a more flexible table. Now you can modify your application without having to create code every time you want to add or change the functionality.

How overrides work in the new tables

Developers typically use the ServiceNow System Property [sys_properties] table to create various functions in applications. If you wanted to develop an application to behave differently in different domains, you'd have to customize it yourself.

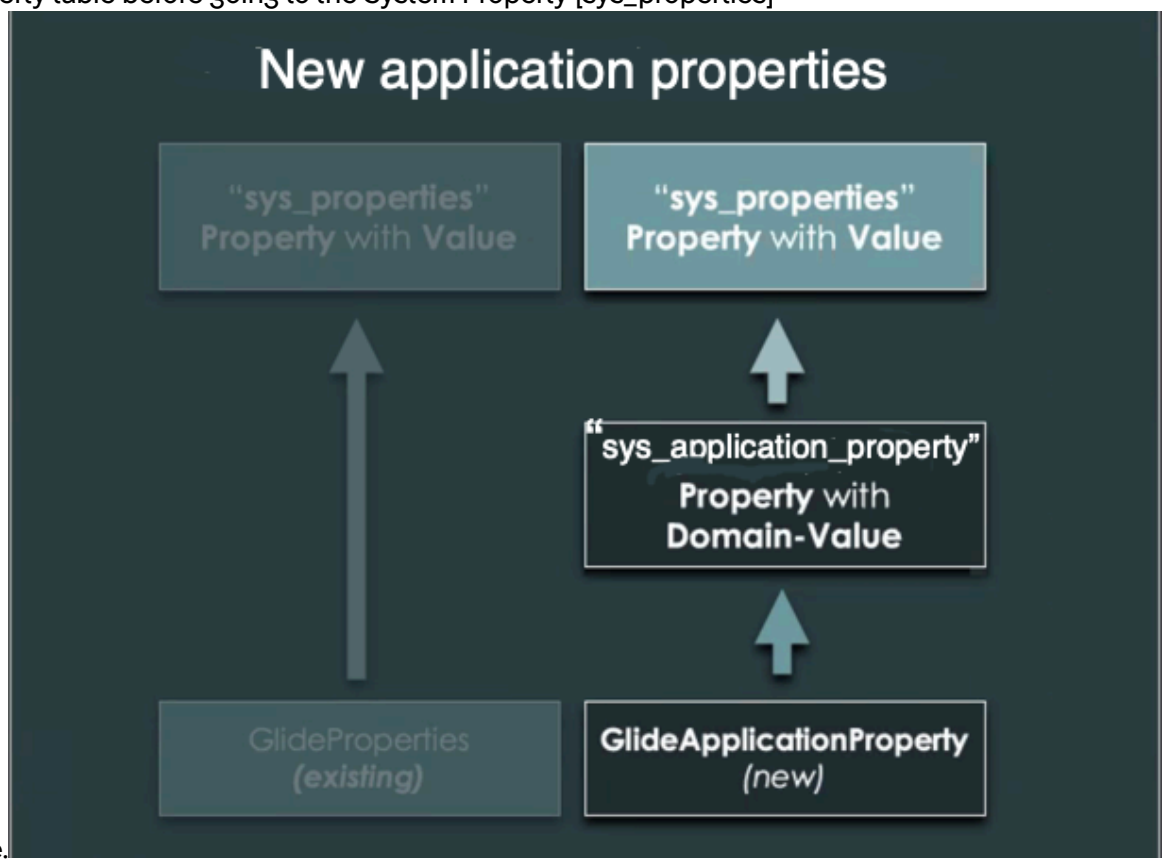
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

In the Paris release, the new Application Property [sys_application_property] table simplifies that customization. Instead of going directly to the System Property table for a value, the application property table goes to the System Application table first. This new table now stores the logic that you require to configure your application. If it finds a property in the new table, it uses that content. If there is no information in that table, it moves on to the base system properties table.

When you configure support for domain separation, you can add domain logic to this new Application Properties table. This table can contain properties that don't exist in the System Properties table. Or you can add properties to the configuration table that can override any property that you select in the System Properties table.

For example, let's say that you want to configure an application with a First day of the week feature. Sometimes, you might want the first day of the week to be Sunday. In other cases, you might want the first day of the week to be Monday. In the base system table, there might be only one Day 1 option, which is Sunday. With the new table, you can store another property, making Day 1, Sunday, and a child domain, Monday.

This figure shows how the system draws properties from the Application Property table before going to the System Property [sys_properties] table.

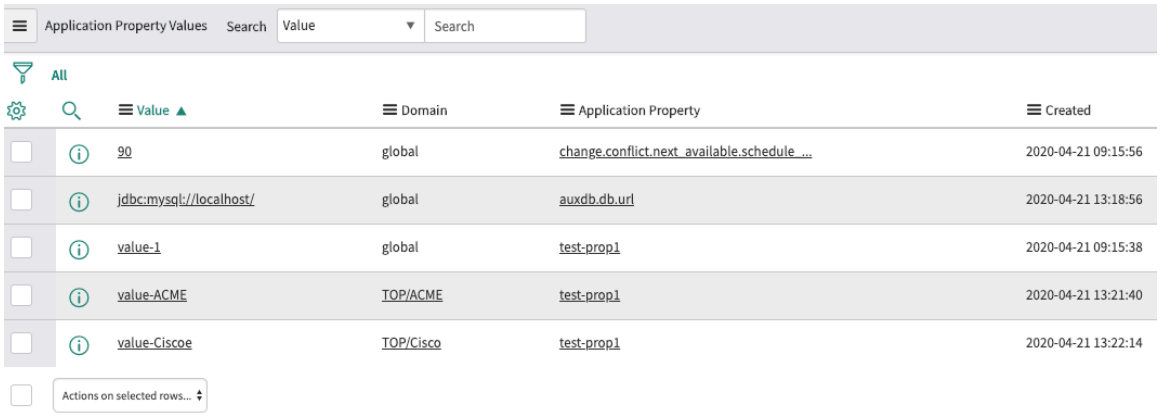


How scoped apps work in the new table

The new Application Properties table is supported from scoped applications. The application property name, similar to the system property name, is unique, which means that it is prefixed with the scope name if it is not global. The scope of an application impacts your configuration. The scope may determine which Day 1 is defined as Sunday and which as Monday. You can use the same property but customize it so that Day 1, Sunday is the parent domain and Day 1, Monday is the child domain. In the new table, there is both a domain column and a scope column, so you can set these properties for each.

You can use the Expand Domain Scope view in the sys_application_property_value table to show all overrides, as shown in the following image.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Note:

If those tables are not available, make sure that you have activated the Domain Extension Installer (com.glide.domain.msp_extensions.installer) plugin.

New application property tables

The new System Application Property [sys_application_property] table contains these fields:

- name
- description
- type (choice of string, true|false, integer, time zone, color, and so on)
- default_value
- property (reference to sys_properties)
- usage_notes
- read_roles
- write_roles
- unique key: (name)

The new System Application Property Value [sys_application_property_value] table contains these fields:

- sys_application_property (ref to sys_application_property)
- sys_domain
- sys_overrides
- value
- unique key: (sys_application_property, sys_domain)

New APIs

The new APIs are also supported in scoped apps. Domain-separated application properties have distinct APIs. The GlideApplicationProperty API has two new scriptable methods, available in both global and scoped applications. See GlideApplicationProperty - Scoped, Global to learn more about these new APIs.

Domain Migration Tool

Use the Domain Migration Tool to move a customer from a domain-separated environment to their own dedicated instance.

Domain Migration Tool plugin

The Domain Migration Tool plugin (com.glide.domain.migration_tool) simplifies the task of moving a customer from a domain-separated environment to a more flexible dedicated instance. Customers may want to migrate to a separate instance to take greater advantage of the ServiceNow AI Platform capabilities. Although the Domain Separation plugin is installed, the data and process separation properties are turned off.

Note:
You must request a cloned instance and request activation of the Domain Migration Tool plugin before you can use it.

The Domain Migration Tool runs only if both data and process separation are enabled in the domain-separated instance:

- The *glide.sys.domain.partitioning* data property must be set to **true**.
- The *glide.sys.domain.delegated_administration* process property must be set to **true**.

What the migration tool does

- Automates much of the migration process, especially cleaning up data.
- Migrates the domain-separated instance to a new dedicated instance.
- Deletes data from the dedicated instance.

  Note:
  The tool doesn't delete data that is global, in the target domain, or in additional data domains (if specified).

- Collapses process data, or if unable to collapse, deletes process data
- Keeps process records that are visible to the target domain
- Updates the sys_choice, sys_ui_list, and sys_ui_related_list special tables
- Cleans up records added by domain separation plugins:
  - Business rules
  - UI actions
  - Scheduled jobs
  - Installation exits
  - Navigation modules
- Disables domain separation and removes domains from the cloned instance:
  - Sets these properties to **false** in the cloned instance:
    - *glide.sys.domain.partitioning*
    - *glide.sys.domain.delegated_administration*
    - *glide.sys.domain.enabled*
  - Deletes all domains except the target domain and any additional specified data domains.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Updates the **Status** field in the domain_migration_tool_status table.

  Individual status of the tables

Status	Description
Pending	Default status of domain separated tables during migration. The tables are scheduled to be migrated, but have not yet started the migration.
Failure	Table level failure. If the migration process is finished with errors, this status indicates which tables have errors.
Running	The status of the table that is currently migrating. Only one table can have this status and currently migrating.
Successful	The status of the tables that have successfully migrated.
Finished successfully	The migration process is finished without errors.
Finished with errors	The migration process is finished with errors.

- Logs progress and status to syslog_domain

  The source is **MigrationTool** for all log entries associated with migration.

  - Logs each data table and how many data tables remain
  - Logs each process table and which domain's records are currently being inactivated or deleted

What the migration tool doesn't do

- Clone the instance
- Create another domain-separated instance
- Migrate records (data or process) if either data or process separation properties are disabled before you run the tool
- Alter any data on the source instance
- Delete data that is global, in the target domain, or in additional data domains (if specified)

What you must do after running the tool

The Domain Migration Tool automates the removal of data outside the desired domains (the target domain, any additional data domains, and the global domain). You must evaluate all the remaining configurations to ensure that they are appropriate and work for your dedicated instance. For example, if you had a business rule that set the domain field on records, you might want to disable this business rule, since it no longer serves a purpose.

Migrate a domain-separated instance to a dedicated instance

Move a customer from a domain-separated environment into their own dedicated instance environment.

Before you begin
Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

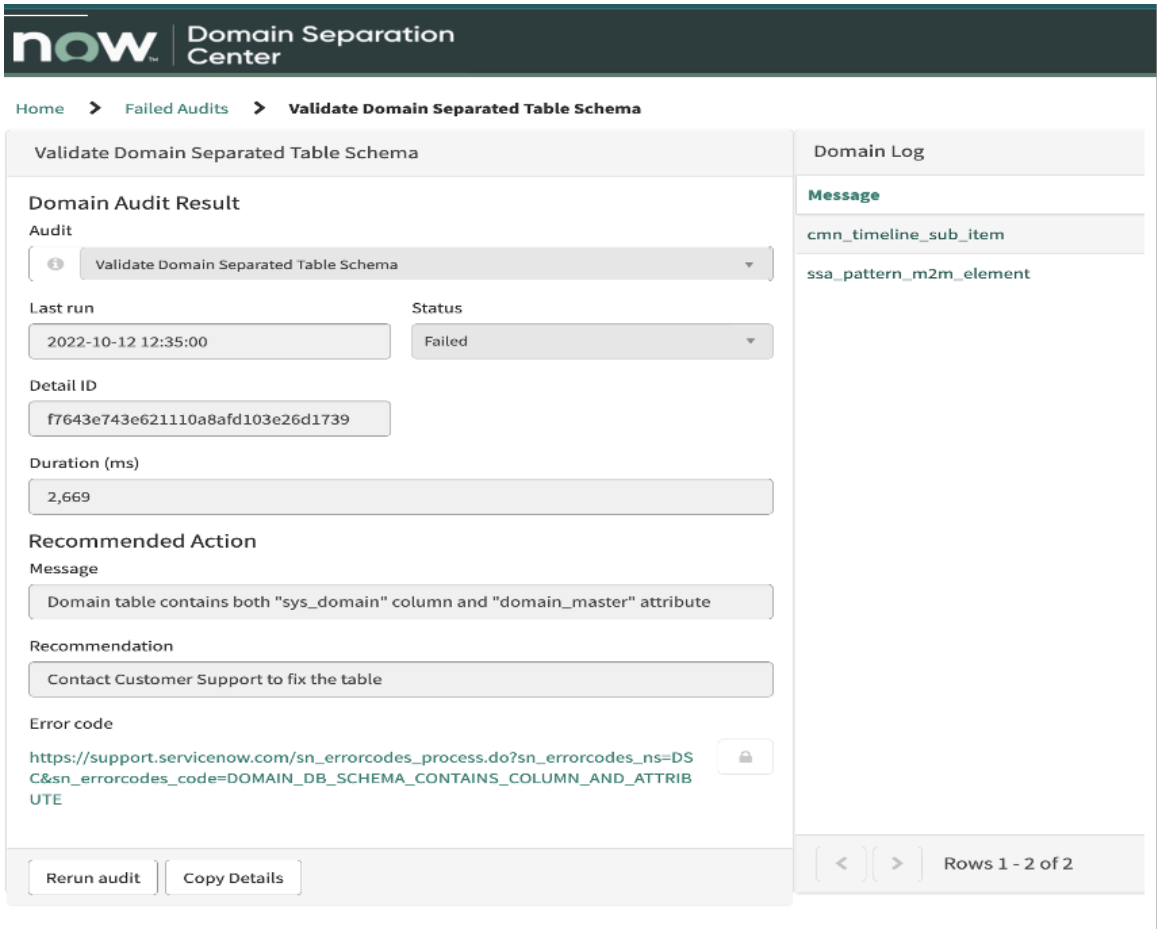
Procedure

1. Elevate to the security_admin role.
   See Elevate to a privileged role for details.
2. Navigate to **All** > **Domain Admin** > **Domain Migration Tool**.
   Also access with **domain_migration_tool_status.list**.
3. Click **New**.
4. Complete the form.

Field	Description
Target domain	Specify the domain used for both process and data that you want to migrate. Only the target domain is retained, not any of its children, unless specified in the **Additional data domains** field.
Additional data domains	Optionally, specify any additional data domains you want to migrate. If you want to migrate the target domain and all of its children, you must specify all children.

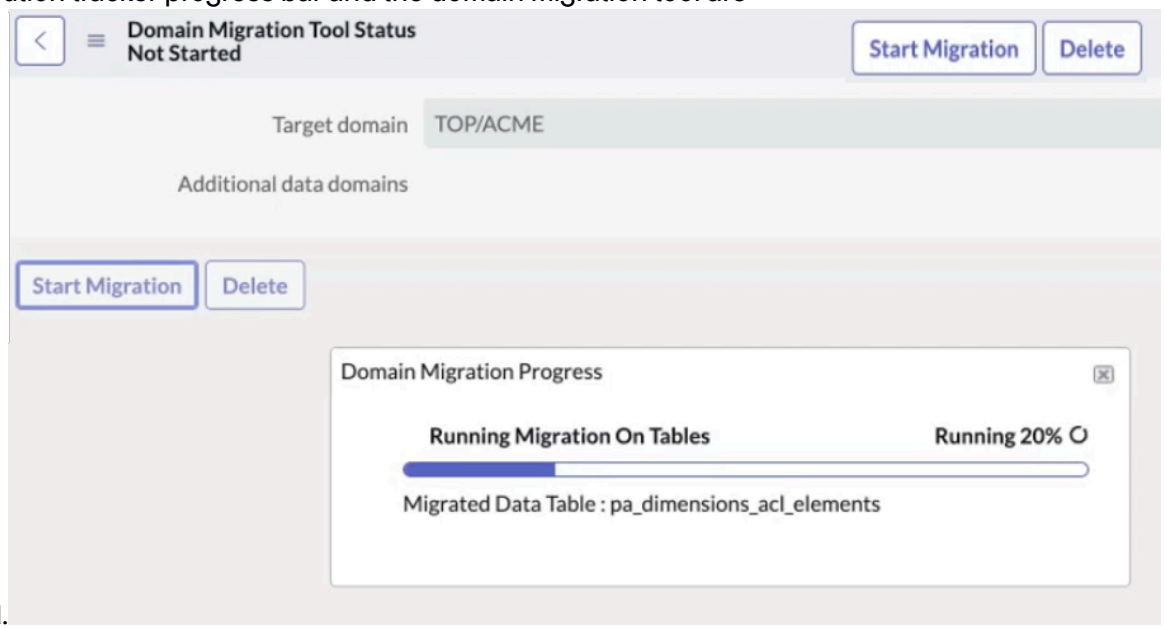
5. Select **Submit**.
6. Open the form you just submitted.
7. Navigate to **All** > **Domain Separation Center** > **Configure Audits** .
   See Domain Separation Center for additional information.
8. Set the **Validate Domain Separated Table Schema** audit to **Active** and assign a schedule.
   This is a precautionary domain audit to pre-check the schema for the health of domain separated tables. This enables you to fix errors before running the migration.
9. Run the **Audit Schedule** that includes the schema.
   See Execute audits immediately for details.
10. Address issues returned from the audit.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



11. Select **Start Migration**.

- The execution tracker progress bar and the domain migration tool are triggered.



- The current progressing migrating table is displayed along with the total percentage of successfully migrated tables.
- The table where all of the domain separated tables are recorded with the migration status, total number of records in each table, and the number of records migrated.
- The count of tables where migration failed is also recorded.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

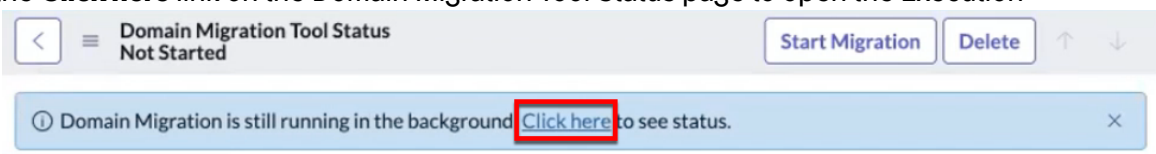
- The **Status** is updated as the tool performs its functions.
- Domain Migration is still running in the background if you close the progress bar. Access the `sys_execution_tracker` table and look for **Running Migration on Tables** to check the migration process running in the background.

The Domain Migration Tool Status displays the following fields:

Domain Migration Tool Status fields

Field	Description
Status	Displays the migration status. ○ **Migrating data tables...**: In progress status. ○ **Migration successful**: The updated status after a successful migration. ○ **Misconfiguration is observed on one of the domain separated tables**: Indicates a failure of data migration. A schema error has been found, the migration won't start. Run the audit **Validate domain separated table schema**. The audit will fail and show the tables that don't follow the schema standard. ○ **Finished with Errors in Revisit Tables**: The number of tables to address schema migration is listed. Locate the failures in the Revisit tables count and address schema issues. ○ **Domain Migration Failed for Tables...**: Non target records should be deleted manually from failed tables. ○ **Finished Successfully**: When all tables have migrated.
Target domain	The selected target domain for migration.
Additional data domains	Populates if multiple migration domains have been selected.
Revisit Tables Count	This field populates only if a table fails to migrate. If there are no failures, this count is zero. In this case, the tables will be revisited to reattempt the migration. If there are no failures, no need to revisit the tables or reattempt the migration.
Current Progressing Table	Displays the name of the table that is currently being migrated. After successful migration, this field will be empty.

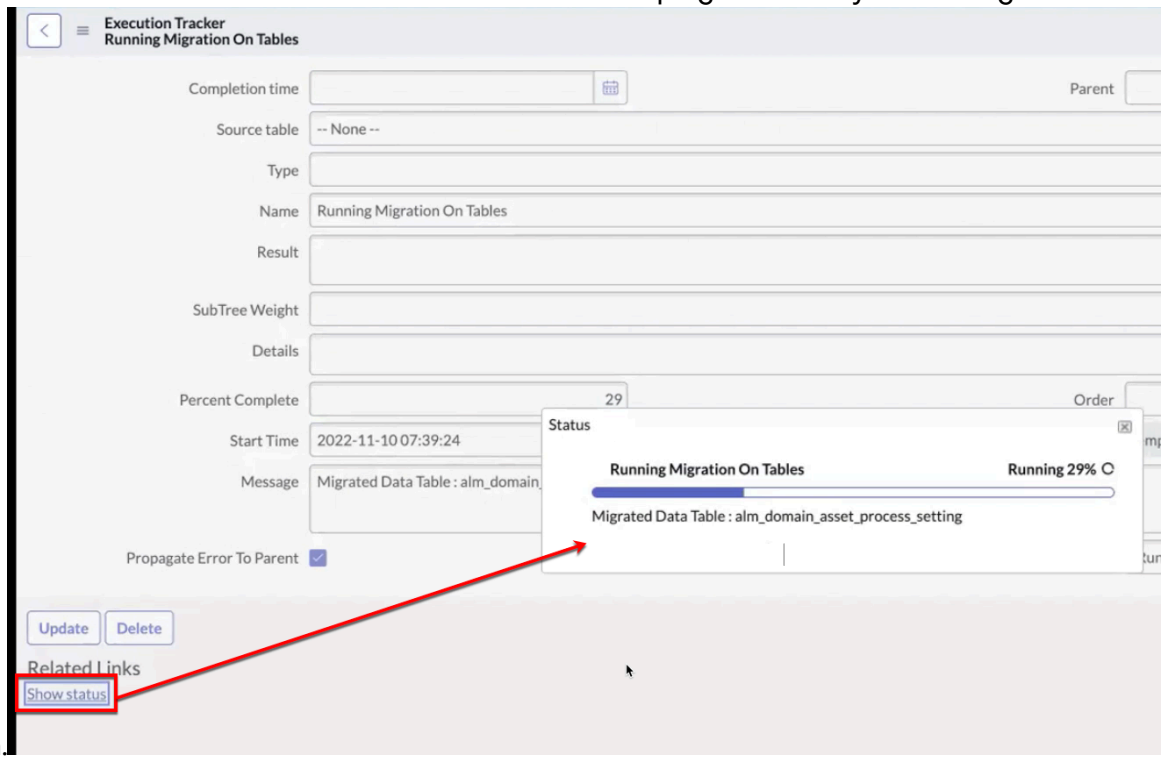
12. Select the **Click here** link on the Domain Migration Tool Status page to open the Execution Tracker.



You can also access the `sys_execution_tracker` table and look for **Running Migration on Tables** to check the migration process running in the background.

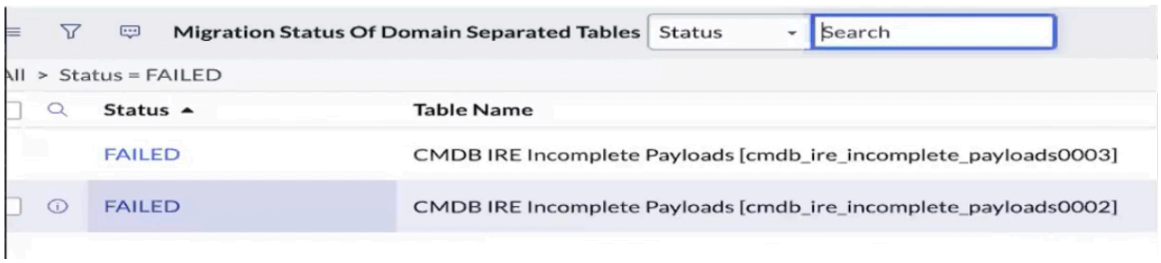
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

13. Select **Show status** in the Related Links section to access the progress bar any time during the migration.



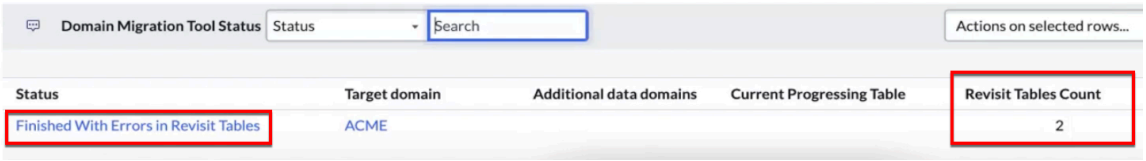
In the case that a table failed the schema check, the Migration Status of Domain Separated Tables overall status will be **Failed**.

There will be **Failed** entries for each corresponding table.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The remainder of the migration continues and a summary of all failed tables and the total number of **Revisit Tables Count** will be populated in the Domain Migration Tool Status.



The **Status** is **Finished Successfully** when the migration is complete.

Process administration

Process administration allows administrators to set domain-specific policies.

The policies set lower in the domain hierarchy override policies set higher in the domain hierarchy. While in a domain, administrators can set domain-specific versions of these global policies and settings:

- Client scripts
- System policies
- Application and module names
- Application roles
- Module filters

Warning:
All users with the admin role have special access to all system features, functions, and data because administrators can override ACL rules and pass all role checks. Grant this privilege carefully.

When users have the **admin** role, then all policies in the instance are available to them regardless of the assigned domain. They can enter a specific domain, and then only policies in that domain or higher are visible and processed during a relevant transaction. When an administrator modifies a policy that is in a higher domain or the global domain, the system automatically creates a new record for that administrator's current domain. It does not modify the original policy, application, or module record. This new record overrides the original.

To make changes to a policy in a lower-level domain, go into that domain and modify the policy. This approach creates the policy record in your domain that overrides the original, higher-level policy record.

Do not change the higher-level policy and then change the **Domain** field on that policy. This approach does not create a policy record in your lower-level domain, nor does it keep the policy record for the higher-level domain.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The **sys_overrides** field indicates that a policy, application, or module at a lower level in the hierarchy overrides a record at a higher level. The system automatically sets this field when an administrator attempts to modify a policy, application, or module that belongs to another domain higher in the hierarchy.

Rather than changing the higher-level record, the attempted update is changed into an insert, and the **sys_overrides** field is set to indicate the higher-level policy, application, or module that is being overridden. Later when the records for a relevant transaction are loaded, the overriding domain-specific policy, application, or module is used instead of the original.

Domains for process administration

By default, process administration always uses the record's domain to determine what policies to apply.

The record's domain takes precedence over the user's domain. If there are no policies in the record's domain, delegated administration checks for policies in the next highest level of the domain hierarchy. The search for domain policies continues up the domain hierarchy until reaching the global domain. If there are no domain policies lower in the domain hierarchy, processes administration uses the policies for the global domain.

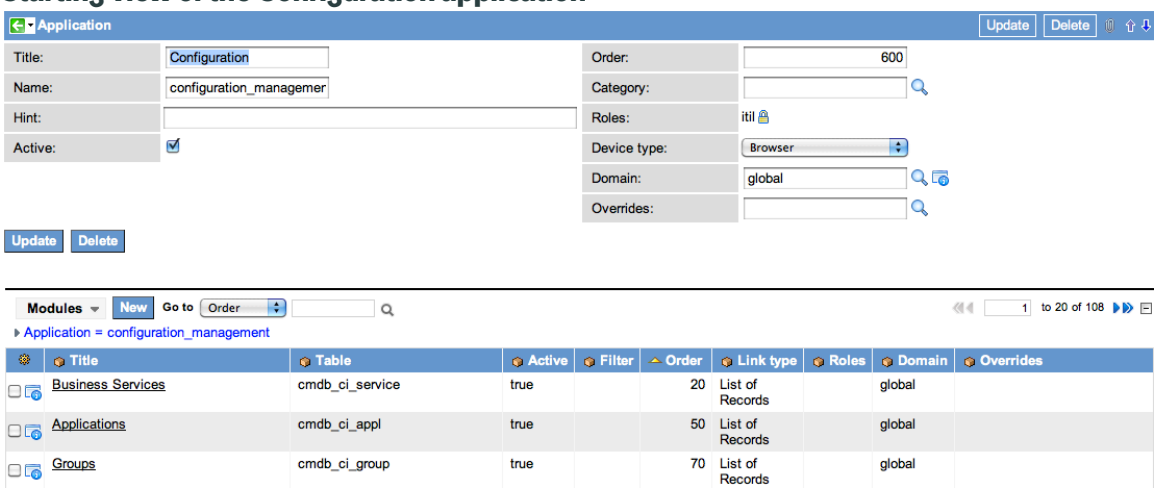
For example, Fred Luddy is a user in the Acme domain who can see records in the child domains of Acme: Atlanta, Acme: San Diego, and Acme: NY child domains. When this user opens a record in the Acme: San Diego domain, process administration first checks for policies in the Acme: San Diego domain. If there are no policies at this level of the domain hierarchy, process administration checks for policies from the Acme domain. If there are no policies in the Acme domain, process administration uses the global domain polices as there are no other domains higher in the domain hierarchy.

Sample process administration with domain specific applications

The following example illustrates process administration with domain-specific applications and modules.

As the administrator of the Oceanic domain, David Loo decides to customize the Configuration application. To start with, David reviews the modules available in the Configuration application module.

Starting view of the Configuration application



David decides to rename the Configuration application to CMDB and to allow the inventory_admin role to see the application.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Sample domain-specific changes to the Configuration application

Applications | New | Go to Title | 1 to 20 of 46

All > Active = true > Device type != Mobile

Title	Active	Order	Roles	Name	Domain	Overrides
Asset Management	true	900	asset	asset	global	
BSM Map	true		admin itil	bsm_map	global	
Change	true	400	itil	change_management	global	
CMDB	true	600	itil inventory_admin	configuration_management	Database	configuration_management
Content Management	true		content_admin	cms	global	
Contract Management	true	1,000	asset contract_manager	asset_contracts	global	
Domain Admin	true		domain_admin	domain_admin	global	
ECC	true		admin	ecc	global	
Homepage Admin	true		admin	home	global	
Incident	true	200	itil	incident_management	global	
Instance Clone	true		clone_admin	instance_clone	global	
Knowledge Base	true	800	knowledge	km	global	
Metrics	true		itil_admin metric_admin	metrics	global	
MID Server	true		admin	MID	global	
Organization Management	true	875	asset	organization_management	global	
Problem	true	300	itil	problem_management	global	
Reports	true	1,100	itil	reports	global	
SAML 2 Single Sign-on	true		admin	saml_2_single_sign_on	global	
SAML Single Sign-on	true		admin	SAML Single Sign-on	global	

Activate | Deactivate | Actions on selected rows... | 1 to 20 of 46

Next, David decides to change the Incident application by activating the **Open - in "New" State** module and adding a new filter item to show open incidents in the Oceanic category.

Sample domain-specific changes to the Open - "New" State module

Module | = Required field | Update | Delete

Title:	Open - in "New" state	Link type:	List of Records
Table:	Incident [incident]	View name:	
Order:	200	Roles:	
Application:	incident_management		
Hint:			
Active:	☑		
Image:			

Filter:

	Incident state	is	New
and	Active	is	true
and	Category	is	Database

Arguments:

```
incident_state=1^active=true
```

Update | Delete

This creates a new module entry in the application rather than overwriting the existing module in the global domain.

Enable verbose domain logging and debug messages

Domain log and debug messages allow you to troubleshoot domain configuration errors.

Before you begin

Role required: admin
Make sure you are the latest instance for best performance.

Procedure

1. In the Domain Separation Center, navigate to **Domain Admin**.
2. Click **Configure Domain Center**.
3. For **Enable verbose domain logging**, select the **Yes** check box.
4. Click **Update**.

View a real-time domain message

You can view real-time domain messages from the system logs.

Before you begin

Role required: admin

Procedure

1. Enable verbose domain logging: Navigate to **All** > **Domain Admin** > **Domain Separation Center** > **Configure Domain Center** > **Enables detail domain logging** > **Yes** (or set property `glide.sys.domain.verbose` to **True**).
2. Navigate to **System Diagnostics** > **Session Debug** > **Enable All**.
   Because this is a real time review, there is no need to let the debug session run prior to checking the log files.
3. Navigate to the session debug console to view the detailed system domain logs.
4. Search for the text Query against table.

   This query finds log messages in this format:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
08:36:43.974: [Domain Paths] Query against table
 incident restricted by domain values [Database
 Atlanta[db53580b0a0a0a6501aa37c294a2ba6b],
Database[287ee6fea9fe198100ada7950d0b1b73],
Database San Diego[db53a9290a0a0a650091abebccf833c6], global,
 NY DB[5f74727dc0a8010e01efe33a251993f9]]
```

In this example, the user viewing the Incident table only saw records that matched the Database Atlanta, Database, Database San Diego, global, and NY DB domains.

View a historical domain message

View historical domain messages in the log file to troubleshoot domain separation issues.

Before you begin

Role required: admin

Procedure

1. Enable verbose domain logging: Navigate to **All** > **Domain Admin** > **Domain Separation Center** > **Configure Domain Center** > **Enables detail domain logging** > **Yes** (or set property `glide.sys.domain.verbose` to **True**).
2. Navigate to **System Diagnostics** > **Session Debug** > **Enable All**.
3. Let the debug session run for a time period, such as a day, before checking the log files.
4. Navigate to **System Logs** > **Utilities** > **Node Log File Download**.
5. Open the record for the day you want to view.
   Log files use the naming format `localhost_log.<yyyy-mm-dd>.txt`.
6. Click the **Download** log related link.
7. Open the downloaded log file in a text editor and search for log messages with the following format:

   Query against table incident restricted by domain values `[global, Software[8a4dde73c6112278017a6a4baf547aa7]]`

   In this example, a user only saw records from the Incident table that matched the global and Software domains.

Troubleshoot domain separation errors

If you encounter domain separation issues, review this list of solutions.

Error or symptom	Solution
A domain sys_id points to a non-existent domain	This error occurs when a data record, such as a user or task record, has a `sys_domain` column value whose `sys_id` does not exist in the current domain table. The domain `sys_id` could have been accidentally deleted or it could refer to a previous domain table if you changed the domain table. To fix the error, open a list for the table containing the error, filter on the invalid `sys_domain` value. Then, either manually enter the correct `sys_domain` value or remove it.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Error or symptom	Solution
	Note: You can have invalid domain `sys_ids` in any table that references the domain table. For example, invalid domain IDs can occur in the User Visibility Domain `[sys_user_visibility]`, Group Visibility Domain `[sys_user_group_visibility]`, and Contained Domain `[domain_contains]` tables.
A domain path or domain number sys_id points to the wrong domain	This error occurs when a domain number or domain path query is out of sync with the actual domain name. This error can occur with domain numbers when adding domains requires renumbering or during the conversion from domain numbers to domain paths. To fix the error, check the results in the Domain Separation Center. If the error persists, you can manually edit the value for the `sys_domain_path` or `sys_domain_number` columns to point to the proper domain.
The domain tree structure is corrupt	This error occurs if there is a series of domain contains relationships that create an infinite loop among domains. To fix the error, open a list for the domain table and manually edit the domain contains values to not form a loop.

Post-Production Domain Separation Activation Utility

The post-production Domain Separation activation utility aids in the activation of Domain Separation in a live environment.

Post-Production Domain Separation Activation Utility plugin

The Post-Production Domain Separation Activation Utility plugin (com.glide.domain.activation_utility) simplifies the task of creating a domain-separated environment in a post production live environment. Customers may want to activate Domain Separation on post production environments to take greater advantage of the ServiceNow AI Platform capabilities. The utility provides a step-by-step guided setup for creating domains.

Note:
The process of populating domain records in domain separated tables requires downtime or restricted access to the instance.

What the Activation utility does

- Provides a step-by-step guided setup for creating domains.
- Runs a background job to handle the installation of domain separation with both Process and Data Separation properties disabled.
- Keeps process records that are visible to the target(first) domain
- Detects, identifies, and logs errors during the domain creation process
- Presents resolutions for common errors
- Logs all actions performed during the setup process for audit purposes
- Generates a detailed summary, including all actions taken, domains created, and any changes made to the syste

© 2026 ServiceNow, Inc. All rights reserved.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Domain Job Management

Queue multiple Domain Separation updates sequentially into a single background job using the Domain Job Manager.

When a Domain record is modified such as reparenting or a change in hierarchy, by default, a job executes to fix all the records in domain separated tables. You can control when this behavior occurs with the **Domain Job Manager** and monitor ongoing job progress with the **View Job Progress** button.

Use the **Domain Job Manager** to pause domain jobs, queue multiple domain table changes and trigger the queued job when ready with all the changes.

Domain Job Progress

Label	Description
Job Type	The current job type
Status	The status of the job, see **Job state** in the job manager for more information.
Progress	Ongoing job progress

Domain Job Manager

Field	Description
Job Type	Support job types: Hierarchy change
Job State	• Active • Paused **Note:** By default paused jobs will auto resume in 1 hour. Check this option to disable this and manually activate the job later

Delete by domain

Clean up inactive leaf level domains in the domain hierarchy with a controlled and automated tool.

Before you begin

Role required: domain separation admin

Procedure

1. **All** > **Domain Admin** > **Cleanup Queue**
2. Select the **Prepare For Cleanup** button.
3. Select the domains to queue for deletion.
   The list shows all the available inactive leaf level domains that can be selected for deletion.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Select **Save**.
   Selected domains will now reflect a **Ready for Staging** state in the table. Domains must be staged before they are queued for deletion.
5. Select the **Move to Staging** button.
6. Enter the number of days to retain the staged domain before deletion.

   Note:
   Once the domain moves to the **Staged and Deletion Planned** state, it cannot be removed from the clean up queue.

Before a domain is deleted, domain administrators can access the data footprint of the domain.

7. Select the **Preview Domain Data** button.
   A job will be queued to scan the inactive domains for metadata.
8. After the job has executed, select a domain record to view its metadata.

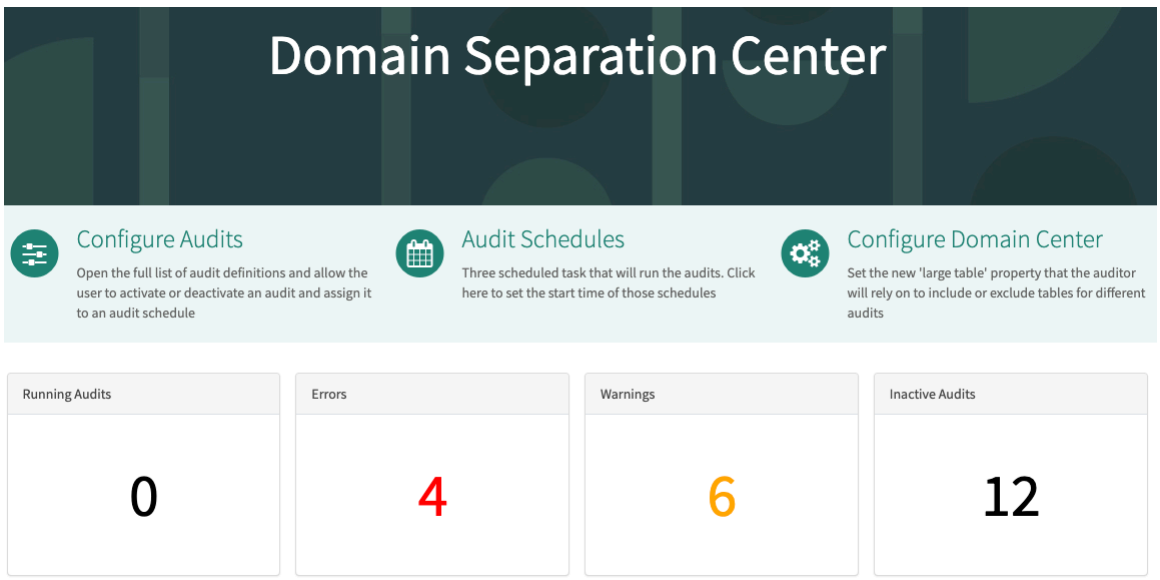
Domain Separation Center

Audit your domains regularly to reveal problems.

overview

The Domain Separation Center is a dashboard where you can schedule and configure audits for all of the domains stored in your domain_audit_definition table. The dashboard enables you to review audit results and dig deeper into domain errors and warnings. You can find the Domain Separation Center dashboard at `<ServiceNow-instance-name>/domaincenter`.

The Domain Separation Center provides many audits. You cannot create your own. You can, however, configure how often they run. Audits run on all of the domains stored in the domain_audit_definition table.



Configure audits

You can configure whether an audit is active and how frequently it runs.

1. In the Domain Separation Center, select **Configure Audits**.

   The **Configure Audits** page displays.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

2. Configure each audit you want to be active. Audits are inactive by default.
   a. Select an audit.
   b. Select the **Active** box to activate the audit.
   c. Specify how often the audit runs in the **Frequency** field.

      The Domain Separation Center runs all audits marked with the same frequency at the same time. Do not select **Daily** for audits run on large tables.

   d. Repeat these steps for each audit you want to activate.
3. Select **Save**.

Audit schedules

Configure one or more audits to run daily, weekly, or monthly. The scheduler specifies what days and times to run those audits. All audits with the same scheduling frequency run sequentially staring at the time you configure.

1. In the Domain Separation Center, select **Audit Schedules**.

   The **Audit Schedule** page displays.

2. Configure the audit schedules.
   a. Select a schedule name.
   b. Specify the time of day to run the audit.

      Time units are measured with the 24 hour clock, that is, 14 equals 2 PM.

   c. For weekly schedules, select the day of the week to run the audit, where 1 is Sunday.
   d. For monthly schedules, select the day of the month to run the audit.
   e. Repeat the procedure for the other schedules.
3. Select **Save** to save the configuration changes.
4. Select **Execute Now** to run all of the audits scheduled to run at the frequency shown at the top of the right pane, for example, if the pane title is, **Domain Audit Schedule - Daily**, all of the audits that run daily are run.

To see the status of a running audit, in the Domain Separation Center, select the number in the **Running Audits** box.

Execute audits immediately

Audits typically run as scheduled. You can, however run all audits on command.

1. In the Domain Separation Center, select **Audit Schedules**.

   The **Audit Schedule** page displays.

2. Select the name of the audit schedule you want to run, for example, daily, weekly, or monthly.
3. Select **Execute Now**.

To see the status of a running audit, in the Domain Separation Center, select the number in the **Running Audits** box.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Configure the Domain Separation Center

1. In the Domain Separation Center, select **Configure Domain Center**.
2. On the **Configure Domain Center** page, for **Enables detail domain logging**, select **Yes** to store detailed logs that help diagnose domain-related issues. Detailed logging might cause performance issues.

   These logs refer to server-side logs in the syslog_domain table. For information about viewing the logs, see View audits with warnings and failures.
3. In the slushbucket, select and move all of your large tables into the **Selected** column.

   Daily audits should not run on large tables. Grayed-out table names in the **Selected** column are large and cannot be moved to the **Available** column.
4. Select **Update**.

View audits with warnings and failures

On the dashboard, **Errors** and **Warnings** provide detailed information about audits that encountered problems. Logs related to domain separation reside on your server in the syslog_domain table.

1. In the Domain Separation Center, select the number in the **Errors** or **Warnings** box.

   The **Errors** or **Warnings** page displays, respectively.
2. Select one of the audits in the list.

   The page displays detailed information about problems with the audit you selected. The messages in **Audit Result Details** refer to values in the syslog_domain table for table audits that revealed errors or warnings.
3. To see the logs on the server that provide information about warning or error audits:
   a. Copy the **Detail ID** value in the left panel of a warning or error.
   b. In the Filter Navigator of HI, enter *`syslog_domain.do`*.

      The Domain Log page displays.
   c. In the **Source** search field, enter `=<Detail-ID>` (no space after the equals sign), for example, =f6a00fd29a85b300a9503a81b9169678.

      The Domain Log page displays only the logs related to the audit with the Detail ID you specified. Each row in the table specifies a different record the audit found problems in. Notice that the **Message** field on this page matches the values displayed in the Domain Service Center's **Message** column. The format of the message matches the audit type.
4. Select:
   - **Rerun Audit**—Rerun an audit to see if it still encounters a warning or error.
   - **Deactivate Audit**—Inactivate an audit.
   - **Copy Details**—Copy audit details to the clipboard.

View running and pending audits

Active audits periodically run or are queued to run, as scheduled. You can view their status as they run.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

1. Select the number in the **Running Audits** box to view audits that are currently running or pending running.

   The **Running Audits** page displays.

2. Select an audit for more information about it.

View inactive audits

1. Select the number in the **Inactive Audits** box.

   The **Inactive Audits** page displays all of the audits that are currently deactivated.

2. Select one of the audits to display more information about it.
3. To activate an audit, select the **Active** box and use the **Frequency** field to specify how often the audit runs.
4. Select **Update**.

Configure the Domain Separation Center

Specify which tables in domains are large and whether you want detailed logging.

Before you begin

Role required: admin

About this task

You can schedule audits to run on a daily, weekly, or monthly basis. Audits run on large tables can take a significant amount of time. For that reason, avoid running audits daily on large tables. Starting a new audit on one that is taking more than a day to run can have negative consequences.

Detailed logging can provide greater insights into problems found during audits, however might cause performance issues.

Procedure

1. In the Domain Separation Center, select **Configure Domain Center**.
   The Configure Domain Center page appears.
2. Select **Yes** for **Enables detail domain logging**, to store detailed logs that help diagnose domain-related issues.
   These logs refer to server-side logs in the Domain Log [syslog_domain] table. For information about viewing the logs, see the View audits with warnings and failures section.
3. In the list, move all of your large tables into the **Selected** column.
   Daily audits should not run on large tables. Grayed-out table names in the **Selected** column are large and cannot be moved to the **Available** column.
4. Select **Update**.
5. If you have large tables that should never be audited, set the *`com.glide.domain.audit.big_tables.additional`* system property to a comma-separated list of those table names.

Configure audits

Configure whether an audit is active and how frequently it runs.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin
Role required: admin

Procedure

1. In the Domain Separation Center, click **Configure Audits**.
   T appears.
2. On the Configure Audits page, configure each audit you want to be active.
   Audits are inactive by default.
   a. Click an audit.
   b. Click the **Active** check box to activate the audit.
   c. Specify how often the audit runs in the **Frequency** field.
      The Domain Separation Center runs all audits marked with the same frequency at the same time. Do not select **Daily** for audits run on large tables.
   d. Repeat steps a-c for each audit you want to activate.
3. Click **Save**.

Schedule audits

Specify the time and day that audits are run.

Before you begin
Role required: admin

About this task
You configured one or more audits to run daily, weekly, or monthly. The scheduler specifies what days and times to run those audits. All audits with the same scheduling frequency run sequentially starting at the time you configure.

Procedure

1. In the Domain Separation Center, click **Audit Schedules**.
   The Audit Schedule page appears.
2. Configure the audit schedules.
   a. Click a schedule name.
   b. Specify the time of day to run the audit.
      Time units use the 24-hour clock (that is, 14 equals 2 PM).
   c. For weekly schedules, select the day of the week to run the audit, where 1 is Sunday.
   d. For monthly schedules, select the day of the month to run the audit.
   e. Repeat the procedure for the other schedules.
3. Click **Save** to save the configuration changes.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. **Optional:** Click **Execute Now** to run all the audits scheduled to run at the frequency shown at the top of the right pane.
   For example, if the pane title is **Domain Audit Schedule - Daily**, **Execute Now** immediately runs all the audits that are scheduled to run daily.

What to do next
To see the status of a running audit, in the Domain Separation Center, click the number in the **Running Audits** box.

Execute audits immediately

Audits typically run as scheduled. You can, however, run all audits on command.

Before you begin
Role required: admin

About this task
You cannot run individual audits manually. You can, however, run all audits that are configured with the same scheduling frequency. For example, you can run all audits that are configured to run daily.

Procedure

1. In the Domain Separation Center, click **Audit Schedules**.
2. Click the name of the audit schedule you want to run (for example, daily, weekly, or monthly).
3. Click **Execute Now**.

What to do next
To see the status of a running audit, in the Domain Separation Center, click the number in the **Running Audits** box.

View audits with warnings and errors

The Domain Separation Center provides details about audit errors and warnings.

Before you begin
Role required: admin

About this task
On the Domain Separation Center dashboard, **Errors** and **Warnings** provide detailed information about audits that encountered problems. Logs related to domain separation reside on your server in the syslog_domain table. Errors are issues that require immediate attention. Warnings do not lead to failures but present best practices, for example, not making the domain name too long.

Procedure

1. In the Domain Separation Center, click the number in the **Errors** or **Warnings** box.
   The **Errors** or **Warnings** page appears.
2. Click one of the audits in the list.
   The page displays detailed information about problems with the audit you selected. The messages in **Audit Result Details** refer to values in the syslog_domain table on the server for table audits that revealed errors or warnings.
3. To see the logs on the server that provide information about warning or error audits:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

a. Copy the **Detail ID** value in the left panel of a warning or error.

b. On the instance running the Domain Separation Center, in the **Filter navigator**, enter *syslog_domain.list*.
The Domain Log page appears.

c. In the search field of the **Source** column, enter `=<Detail-ID>` (no space after the equals sign), for example, `=f6a00fd29a85b300a9503a81b9169678`.
The Domain Log page displays only the logs related to the audit with the Detail ID you specified. Each row in the table specifies a different record the audit found problems in. Notice that the **Message** field on this page matches the values displayed in the **Message** column of the Domain Service Center. The information included in the message matches the audit type.

4. **Optional:** Select one of the following:
   - **Rerun Audit** — Rerun an audit to see if it still encounters a warning or error.
   - **Deactivate Audit** — Inactivate an audit.
   - **Copy Details** — Copy audit details to the clipboard.

View running and pending results

You can view running and pending audits to see their status.

Before you begin
Role required: admin

About this task
Active audits periodically run or are queued to run, as scheduled. You can view their status as they run.

Procedure

1. Click the number in the **Running Audits** box to view audits that are currently running or pending running.
   The Running Audits page appears.
2. Click a running or pending audit to see information about it.

View inactive audits

You can view all inactive audits in one place and optionally activate them.

Before you begin
Role required: admin

Procedure

1. Click the number in the **Inactive Audits** box.
   The Inactive Audits page displays all the audits that are currently deactivated.
2. Click one of the audits to display more information about it.
3. **Optional:** Activate an audit by clicking the **Active** box and specifying how often the audit runs in the **Frequency** field.
4. Click **Update**.

servicenow

Authentication

ServiceNow's authentication validates the identity of a user who accesses an instance, and then authorizes the user to features that match the user's role or job function.

Get started

Authentication factors

Secure your voice agent access by choosing from flexible authentication options such as app-based codes, push prompts, SMS, SoftPIN or knowledge-based checks.

Multi-Provider single sign-on (SSO)

Username and password configured in identity providers, which have a matching user account in the database.

OAuth inbound and outbound

OAuth based authentication validates the identity of the client that attempts to establish a trust on the system by using an authentication protocol.

API access policy

API access policy defines the permissions and access to an API that can be controlled through a policy.

Multi-factor authentication (MFA)

MFA enables you to provide second level of authentication that includes using passcode from an authentication app, hardware key, biometric authenticator, SMS, or Email.

Time limited authentication

Certificate based authentication

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Configure link based authentication on the ServiceNow instance. The configured link can be shared with the user through Email or SMS and user can use those links to login to instance.

Unique PEM encoded certificates mapped to users instead of user name and password for certificate based authentication.

LDAP

Integrate with a Lightweight Directory Access Protocol (LDAP) directory to streamline the user login process

Digest token authentication

Username and the secret in the table, perform an hash operation that is user-specific such as SHA1, SHA 256, or MD5. This value has to be appended as part of the URL suffix, which works on the query param.

Self-registration

Use external user self-registration to on-board a large volume of external users to your instance.

You can use several different methods to authenticate users. User credentials are matched to different saved credentials for each method.

Note:

- The Okta SSO plugin is deprecated.
- To learn more about the security properties that affect authorization processing, see Access control in Instance Security Hardening Settings.
- You can use SAML and Digest Authentication through the Multiple Provider SSO application.

Adaptive authentication

Use the Adaptive authentication policy framework to enforce contextual authentication controls to the right users at the right time. Adaptive authentication uses authentication policies to evaluate authentication requests and then either deny or allow access to your instance based on the specified policy conditions.

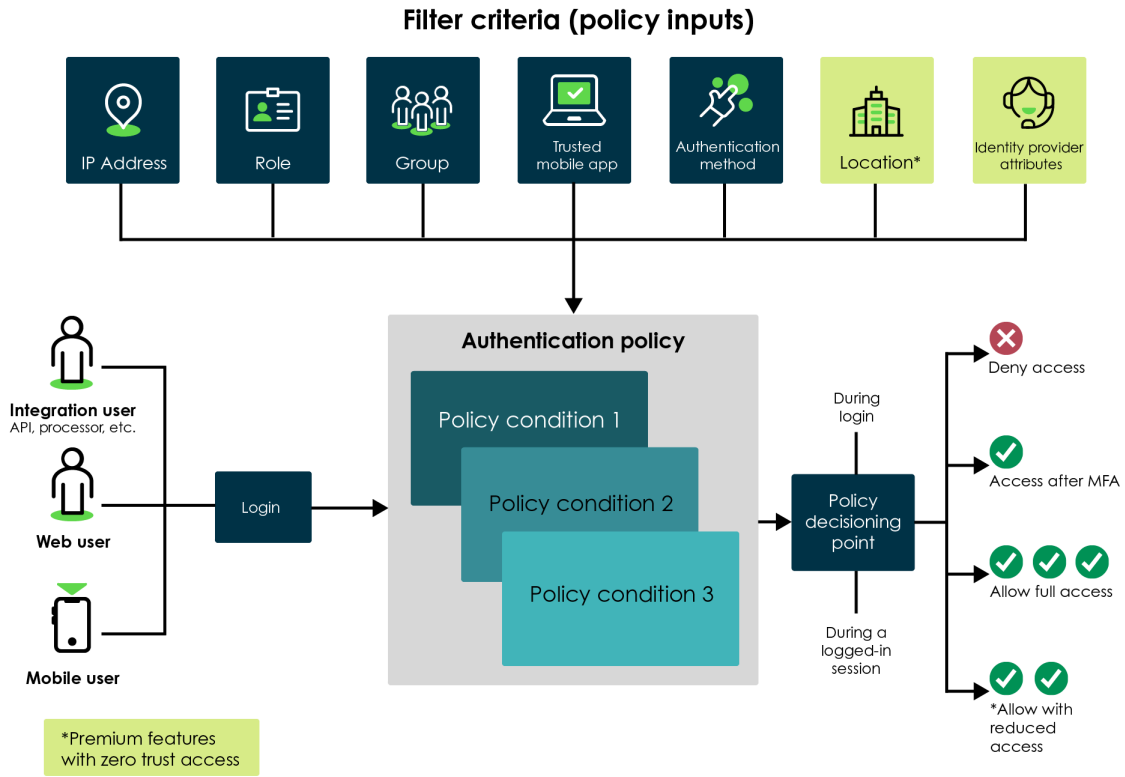
Use adaptive authentication policies and contexts to restrict the access to your instance for users and APIs based on criteria like IP address, user role, and user group. You can configure the built-in authentication policies according to your security requirements.

For example, an administrator can configure the *`Allow Access Policy`* to allow logins from users only within a trusted range of IP addresses and who are members of a specific role. When

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

assigned to the *Post-authentication context*, the access policy denies access from untrusted IP addresses.

To set a custom message in the language of your instance you need to add key, value pair in `sys_ui_message.list` and update the `sys_ui_message` record. When you login with an incorrect password, the custom message in the preferred language is displayed.



Adaptive authentication components

Authentication policies

Authentication policies evaluate authentication requests based on the specified policy conditions and either allow or deny access depending on the output of policy conditions evaluation. For example, access is allowed only if all the policy conditions specified in **Allow Access Policy** evaluate to true.

Authentication policies use information provided by filter criteria to compare against the policy's conditions to determine whether to grant access to the instance. For example, a filter criteria provides a user's IP address, and a policy condition determines whether this address is within the specific range before granting access. Learn more about authentication policies in Authentication policies.

Authentication policy contexts

Authentication policy contexts define how and when policies are enforced during the login process. The pre-authentication context executes before the user is shown a login screen. The post-authentication context executes after the user enters their credentials. To use a policy, it must be assigned to a policy context. For details on these contexts, see Authentication policy contexts.

Filter Criteria

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Filter criteria (also called policy inputs) are used as inputs for policy conditions. Policy conditions use these inputs to verify and meet the requirements of authentication requests. These inputs provide information like user role, IP range, and identity provider. For more detail on filter criteria, see Filter criteria.

Authentication properties

Use authentication properties to control whether adaptive authentication is active on your instance. You can also use properties to enabled debugging, and define the messaging users see when access is blocked. For details on these properties, see Configure adaptive authentication properties.

REST API access policies

You can use the filter criteria of adaptive authentication framework to restrict access to inbound ServiceNow REST APIs. For more information, see REST API access policies.

Domain separation and adaptive authentication

Adaptive authentication is supported on domain separated instances on the authentication policy condition level. Policy conditions affect the domain in the records **Domain** [sys_domain] field. Policy conditions in the global domain affect all domains.

Adaptive Authentication Events

You can use the adaptive authentication events table to know about the events that have occurred specific to the adaptive authentication feature. For more information, see Adaptive Authentication Events.

Activate adaptive authentication

You can activate the Adaptive Authentication plugin (com.snc.adaptive_authentication) for Adaptive Authentication if you have the admin role.

Before you begin

Role required: admin.

About this task

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the **Adaptive Authentication** (com.snc.adaptive_authentication) plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.

3. Select **Install** to start the installation process.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

What to do next

Configure your authentication policies to enforce contextual authentication controls on your instance.

Once your policies are configured. Enable adaptive authentication using the **Enable Authentication Policy** policy. For details on adaptive authentication properties, see Configure adaptive authentication properties.

Filter criteria

Filter criteria (also called policy inputs) are used as inputs for policy conditions to verify and meet the requirements of an authentication request.

Use filter criteria to supply information authentication policies such as a user's IP address, roles, or groups. Add these criteria in the **Policy conditions** section of your policies.

There are seven types of filter criteria used in adaptive authentication. Your authentication policies can use one or more of these criteria to evaluate authentication requests.

Note:
Location filter and Identity Provider filter are available with Zero Trust Access feature. For more information, see Zero Trust Access (ZTA).

Filter criteria types

Type	Description
IP filter criteria	Use IP filter criteria to filter users based on the user's IP addresses. Both IPv4 and IPv6 are supported.
Role filter criteria	Use role filter criteria to filter users based on their roles.
Group filter criteria	Use group filter criteria to filter users based on the user group to which the user belongs.
Location filter criteria	Use location filter criteria to filter users based on the user location.
Identity Provider Attribute filter criterias	Use the Identity Provider attributes that are received from SAML response from the IdP as a filter criteria for authentication.

Generic Criteria

In addition to the previously listed types, there are four generic filter criteria. These criteria do not appear in your filter navigator, but you can select them while adding policy inputs to your authentication policies.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Generic filter criteria types

Type	Description
Authentication Scheme	Use to filter based on user's authentication scheme. This criteria is a choice type with two options: • User name and Password, which denotes a local login • SSO, which denotes a Multi-SSO(SAML, OIDC, or Digest) based login. **Note:** This Filter Criteria is available only when the **Integration - Multiple Provider Single Sign-On Installer**[com.snc.integration.sso.multi.installer] plugin is installed.
Identity Provider	Use to filter based on the user's identity provider. Use along with the authentication scheme criteria to have granular control over login process. This criteria is a reference to the **Identity Providers** [sso_properties] table. **Note:** This Filter Criteria is available only when the **Integration - Multiple Provider Single Sign-On Installer**[com.snc.integration.sso.multi.installer] plugin is installed.
Role-based MFA	Use to filter based on the role-based MFA feature. This criteria is a boolean type filter criteria which denotes whether role-based MFA is enabled for the user.
User-based MFA	Use to filter based on the user-based MFA feature. This criteria is a boolean type filter criteria which denotes whether user-based MFA is enabled for the user.
Trusted mobile app	Trusted mobile app filter for enabling instance access from mobile app.

IP Filter

Use IP filter criteria to filter the users based on the user's IP addresses. Both IPv4 and IPv6 are supported.

IP filter criteria allows you to filter users based on the user's IP addresses. You can configure an authentication policy to allow or deny access to a specific address or range of addresses.

Create IP filter criteria

IP filter criteria allows you to filter users based on the user's IP addresses. You can configure an authentication policy to allow or deny access to a specific address or range of addresses.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **Adaptive Authentication** > **Filter Criteria** > **IP Filter Criteria**.
2. Click **New**.

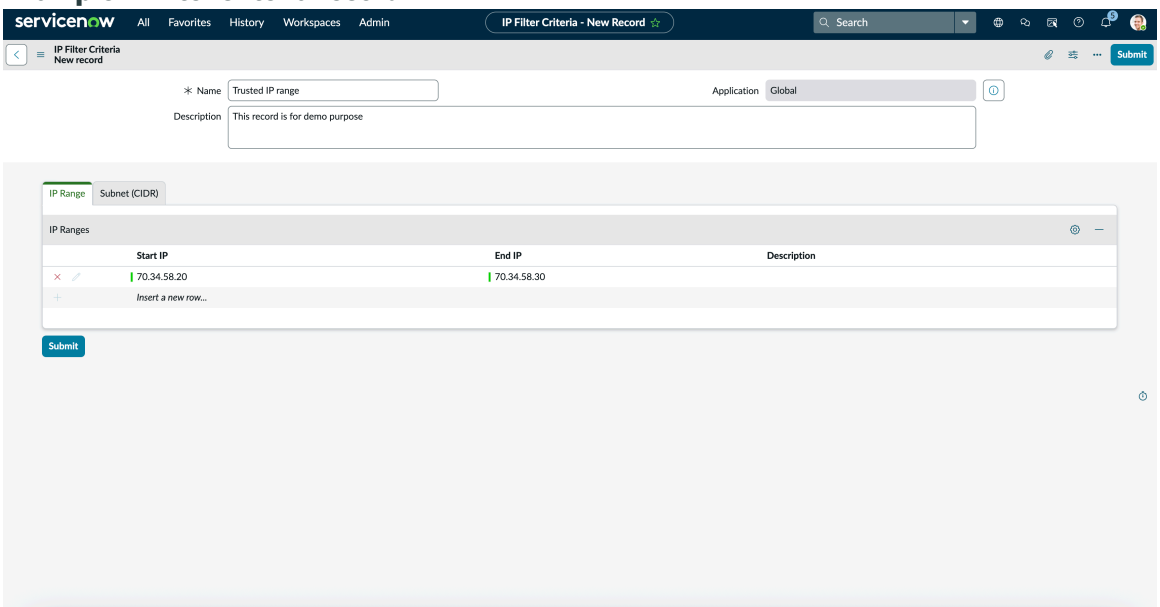
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. On the form, fill in these fields.

IP Filter Criteria form

Field	Description
Name	Name to identify the IP network.
Description	Short description of the IP network.
Application	Scope of the application.

Example IP filter criteria record



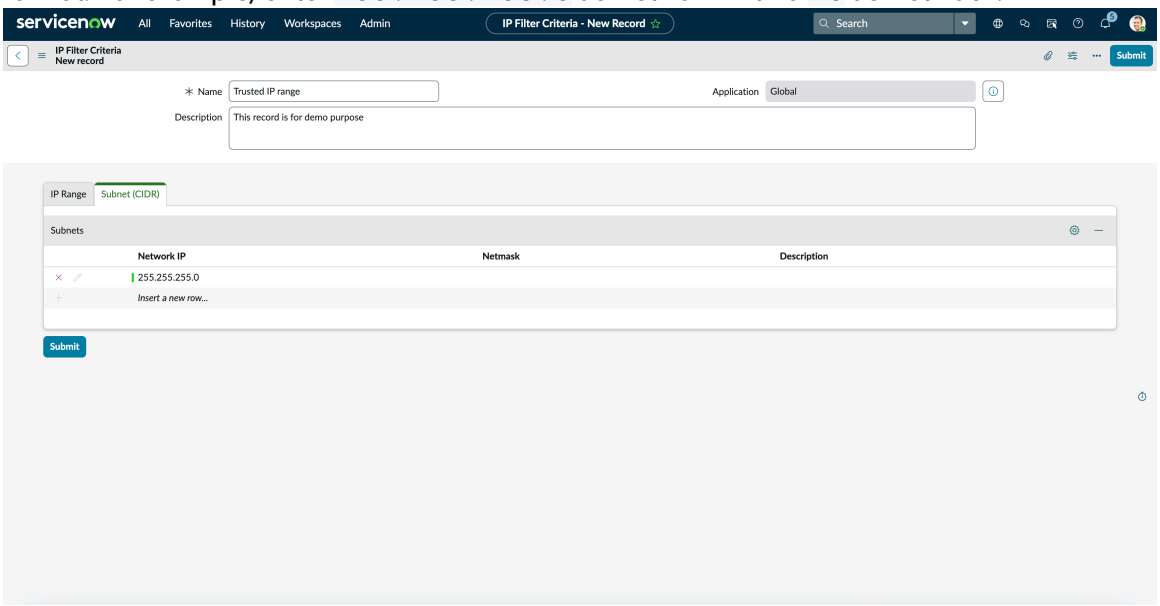
4. Right-click the form header and click **Save**.
5. From the **IP Range** tab, double-click **Insert a new row**.
   You can enter a single IP address or multiple ranges of IP addresses. For example, for a range of IP addresses enter `192 . 0 . 2 . 0` in the **Start IP** column and `192 . 0 . 2 . 255` in the **End IP** column.

   Note:
   For a single IP addresses, make sure that you enter the same IP address in the **Start IP** address and **End IP** columns. When you enter an IP address in the **Start IP** column, leave the **End IP** column blank and then save the record. The **End IP** column is auto-populated with the same **Start IP** address.

6. From the **Subnet (CIDR)** tab, double-click **Insert a new row**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Enter the Network IP address and Netmask in the Classless Inter-Domain Routing (CIDR) format. For example, enter 255 . 255 . 255 . 0 as Network IP and 25 as Netmask.



Role Filter

Use role filter criteria to filter users based on their roles.

Role filter criteria allows you to filter users based on the roles. You can configure an authentication policy to allow or deny access to a list of user roles.

Create role filter criteria

Role filter criteria allows you to filter users based on the roles. You can configure an authentication policy to allow or deny access to a list of user roles.

Before you begin

Role required: admin

Procedure

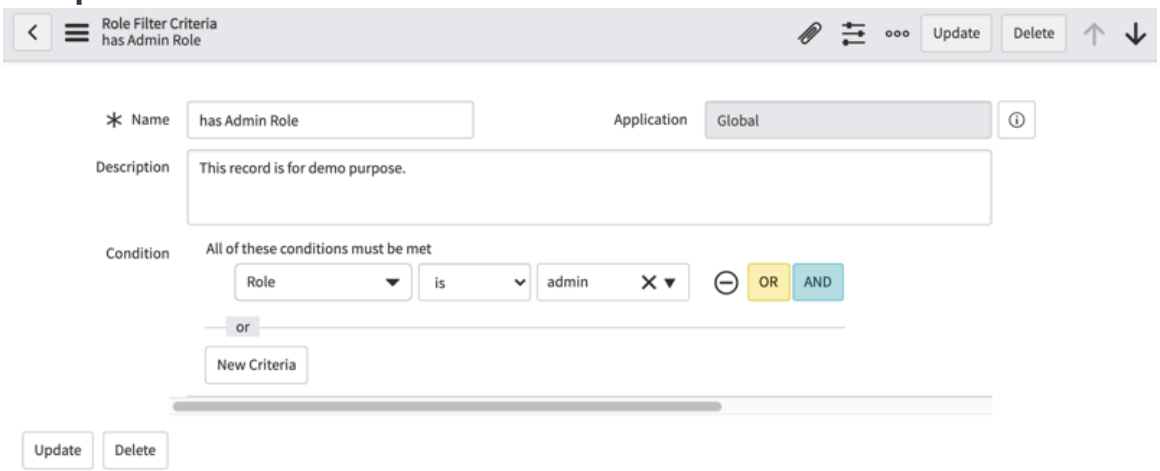
1. Navigate to **All** > **Adaptive Authentication** > **Filter Criteria** > **Role Filter Criteria**.
2. Click **New**.
3. On the form, fill in these fields.

Role Filter Criteria form

Field	Description
Name	Name to identify the role.
Application	Scope of the application.
Description	Short description of the role.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Example role filter criteria record

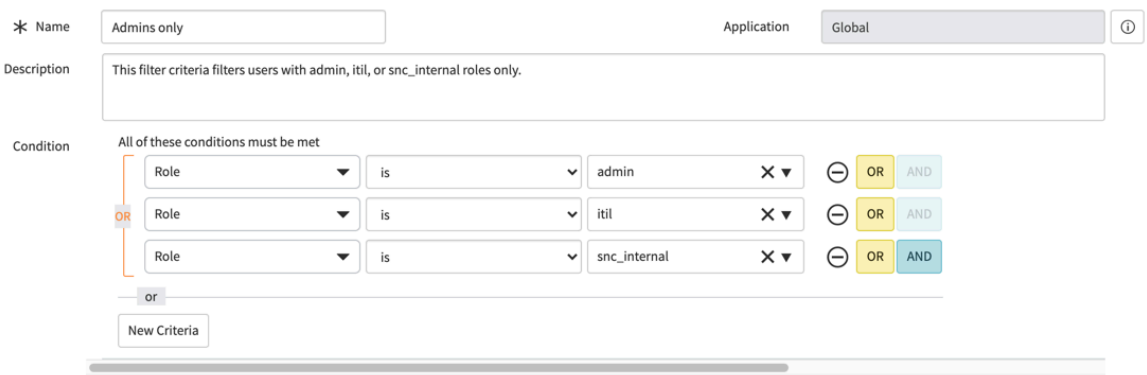


4. From the **Roles for criteria**, double-click **Insert a new row**.
5. Create a condition for a specific role using the Condition Builder.

   For example, you can create a condition that allows only users with admin, itil, or snc_internal roles. For more information about Condition Builder, see Create a condition statement using the condition builder.

   Note:

   - Currently, Dot-walking is not supported in role filter criteria.
   - Following operators are not supported for role filter criteria:
     - Is not
     - Does not contain
     - Is different from
     - Is empty
     - Is same as
     - Is not empty
     - Is empty string



Group Filter

Use group filter criteria to filter users based on the user group to which the user belongs.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Group filter criteria allows or denies user access based on the user group to which the user belongs.

Create group filter criteria

Group filter criteria allows or denies user access based on the user group to which the user belongs.

Before you begin

Role required: admin

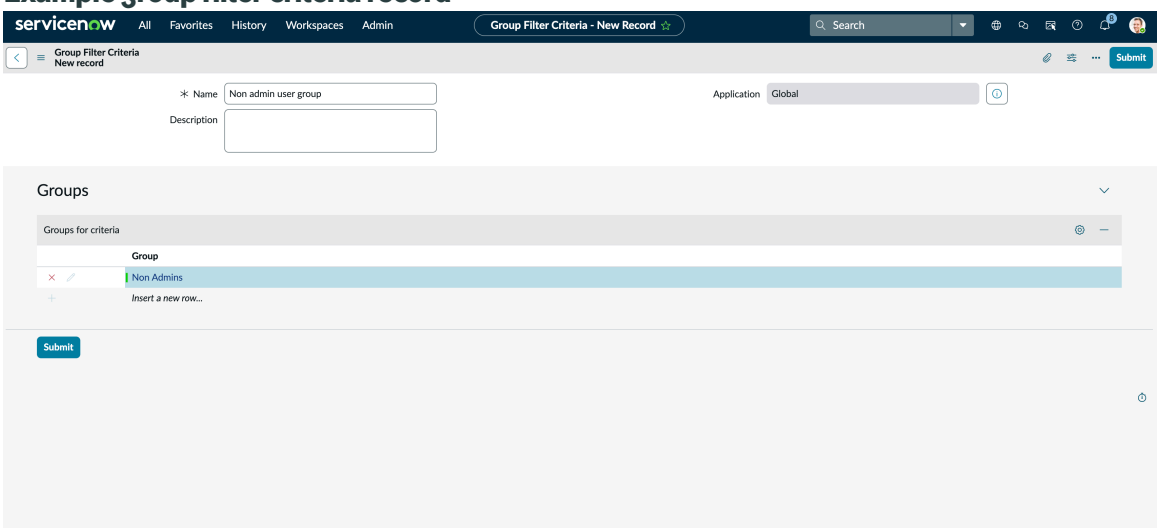
Procedure

1. Navigate to **All** > **Adaptive Authentication** > **Filter Criteria** > **Group Filter Criteria**.
2. Click **New**.
3. On the form, fill in these fields.

Group Filter Criteria

Field	Description
Name	Name to identify the group.
Description	Short description of the group.
Application	Scope of the application.

Example group filter criteria record



4. From the **Groups for criteria** tab, double-click **Insert a new row**.
5. Click the search icon , look up, and select a user group.
6. Click the save icon.

Location Filter

Location filter criteria can be used as filter input for users based on the user location.

Location filter is a filter criteria that the admins can use while crafting the authentication policies based on the physical location of the device.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:

- Location filter is available with Zero Trust Access feature. For more information, see Zero Trust Access (ZTA).
- The instance should be on ADCv2. If the instance isn't on ADCv2, then user location information won't be available.

The location filter criteria enable you to perform the following:

- Act as policy input act for policy conditions to verify and meet the requirements for authentication.
- Provide an ability to create adaptive authentication policies based on the **country**.
- Allow or not allow instance access to a given geography.
- Use the geo location-based pre-authentication or post authentication policy to:
  - Prevent access from sanctioned countries, outside of a tight privacy-controlled region, company discretion.
  - Allow access to areas only within applicable privacy region and company discretion.
  - Configure country-based allow list for authentication.

Use cases

Following are some of the use case for using location filter criteria for Adaptive Authentication:

- Block access to the instance from a country.
- Allow access to the instance only from a particular country.
- Enforce step-up authentication or MFA to log in based on country.
- Reduce or limit roles for the user based on the country.
- Location Filter criteria can be used for MFA, Zero Trust Access (ZTA), Pre-authenication context, and Post authentication context.

Location Identification

The location services for identifying the location of the user are provided by a third-party service - MaxMind.

The location of the user is identified through the VPN, from the x-forwarded-for header. In case if there's no header populated by the service, then only the VPN IP (location) is displayed as the user location.

Note:
If there are incorrect locations displayed after the location filter configuration, see the KB article to troubleshoot.

Activate Location Based Access

Activate the **Zero Trust - Location Based Access** (`com.snc.zero_trust_location_access`) to allow admins to configure adaptive authentication policies based on the location of the user.

Before you begin
Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Dependant plugin: Adaptive authentication
- Plugin type: Paid and requires license.
- The instance should be on ADCv2. If the instance is not on ADCv2, then user location information will not be available.

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the **Zero Trust - Location Based Access** (`com.snc.zero_trust_location_access`) plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

   Note:
   When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

   You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Create location filter criteria

Use location filter criteria to filter input for users authentication based on the user location.

Before you begin

Role required: admin

Plugin required: **Zero Trust - Location Based Access** (`com.snc.zero_trust_location_access`).

Property: Enable the Adaptive authentication property.

Note:
Administrators can only create the policy based on location filters if the location is available for the current user session.

Procedure

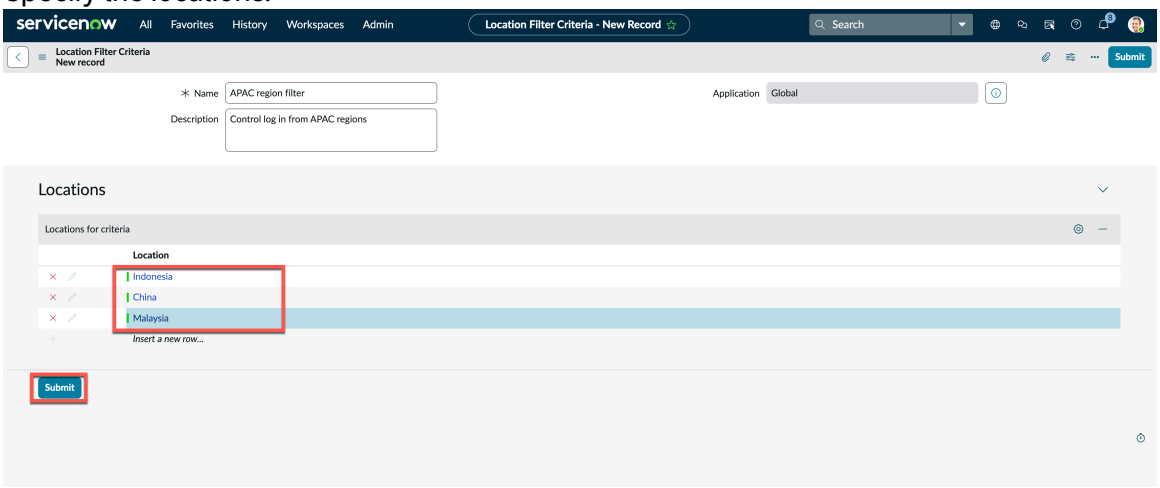
1. Navigate to **All** > **Adaptive Authentication** > **Filter Criteria** > **Location Filter Criteria**.
2. Select **New**.
3. On the form, fill in these fields.

Location Filter Criteria form

Field	Description
Name	Name to identify the criteria.
Description	Short description of the criteria.
Application	Scope of the application.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. In the **Locations** sections, under the Locations for criteria tab, double-click to **Insert a new row**.
5. Specify the locations.



6. Select **Submit**.

Tutorial: Use Location Filter criteria

Describes steps to use location filter criteria in the authentication policy and restrict access to the users based on the location.

Before you begin

Role required: admin

Plugin required: **Zero Trust - Location Based Access** (`com.snc.zero_trust_location_access`).

Property: Enable the Adaptive authentication property.

> **Note:**
> Administrators can only create the policy based on location filters if the location is available for the current user session.

The following procedure describes how to create and use the location filter criteria in an authentication policy.

Procedure

1. Navigate to **All** > **Adaptive Authentication** > **Filter Criteria** > **Location Filter**.
2. Select **New**.
3. On the form, fill in these fields.

Location Filter Criteria form

Field	Description
Name	Name to identify the criteria.
Description	Short description of the criteria.
Application	Scope of the application.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. In the **Locations** sections, under the Locations for criteria tab, double-click to **Insert a new row**.
5. Specify the locations.

   For example, use some of the APAC regions to control the logins of the users coming from APAC.

   Based on the criteria set in the example, you can control logins from `Indonesia`, `China`, and `Malaysia` for your instance.

6. Select **Submit**.
7. Use the filter criteria created in any of the authentication context (Pre, Post, MFA) and Session Access.

   To know more about the configuration based on authentication context and session access, see:

   - Location Filter in Pre Authentication Context
   - Location Filter in Post Authentication Context
   - Location Filter in MFA Context
   - Location Filter for Session Access

   You can use the Property ID - Error message to be displayed to the user when login fails due to authentication policy failure (`glide.auth.policy.ui.error.message`) to customize the error message.

Use Location Filter in Pre Authentication Context

Use the location filter criteria created in the Pre Authentication Context.

Before you begin
Role required: admin

Plugin required: **Zero Trust - Location Based Access** (`com.snc.zero_trust_location_access`).

Create a Location Filter with the countries that you want restrict access to the users based on the location. For more information, see Create location filter criteria.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

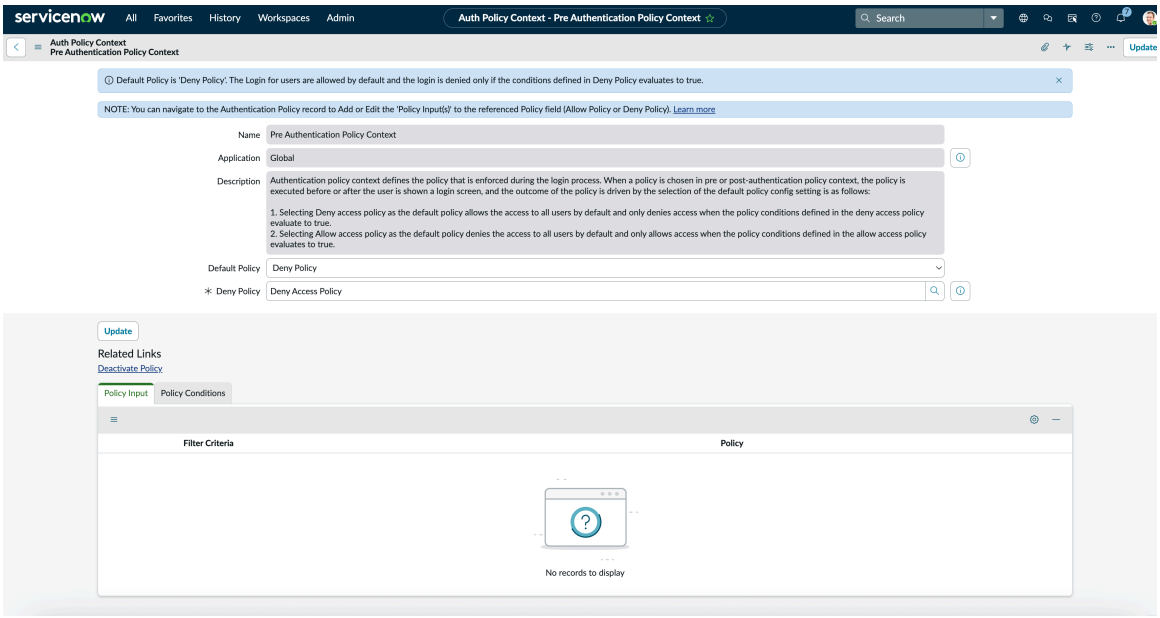
Procedure

1. Navigate to **All** > **Adaptive Authentication** > **Auth Policy Context** > **Pre Authentication Context**.

   When a policy is chosen in the pre authentication policy context:

   - Selecting the Deny access policy as the default policy allows the access to all users by default and only denies access when the policy conditions defined in the deny access policy evaluate to true.
   - Selecting the Allow access policy as the default policy denies the access to all users by default and only allows access when the policy conditions defined in the allow access policy evaluates to true.

   The example shows how you can restrict the logins from the specified locations. You can choose the Deny Access and the associated policy (Deny Access) as the Pre Authentication policy and specify the policy inputs and conditions.

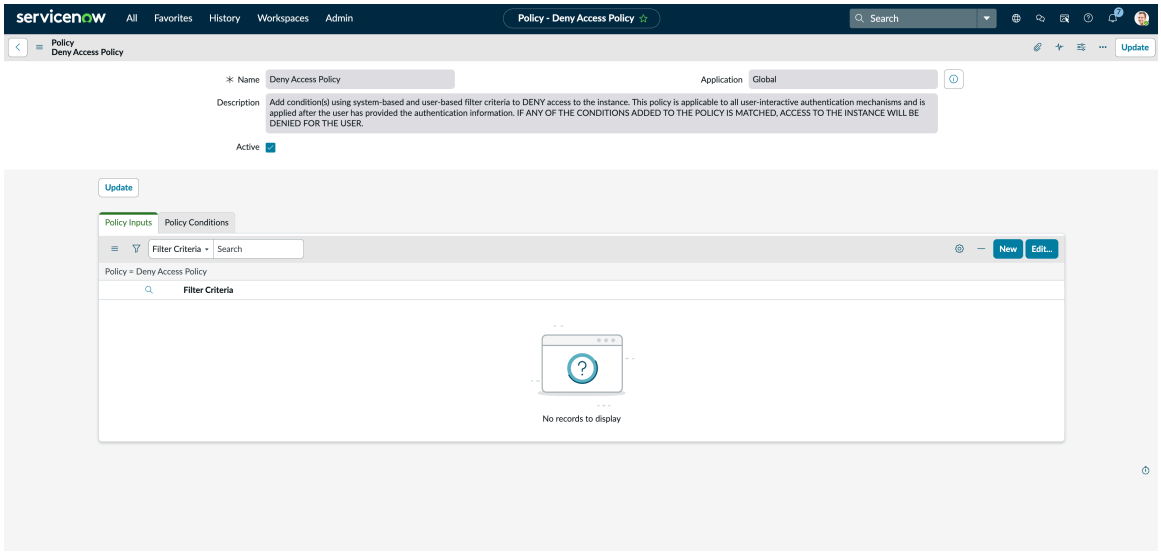


2. Select the information icon and then select **Open Record** to open the **Deny Policy** record.

   Note:
   The example described in this task is **Deny Policy**. You can also use **Allow Policy** and set the conditions accordingly to control the logins.

3. In the Deny Access Policy, under the Policy Inputs section, select **New**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

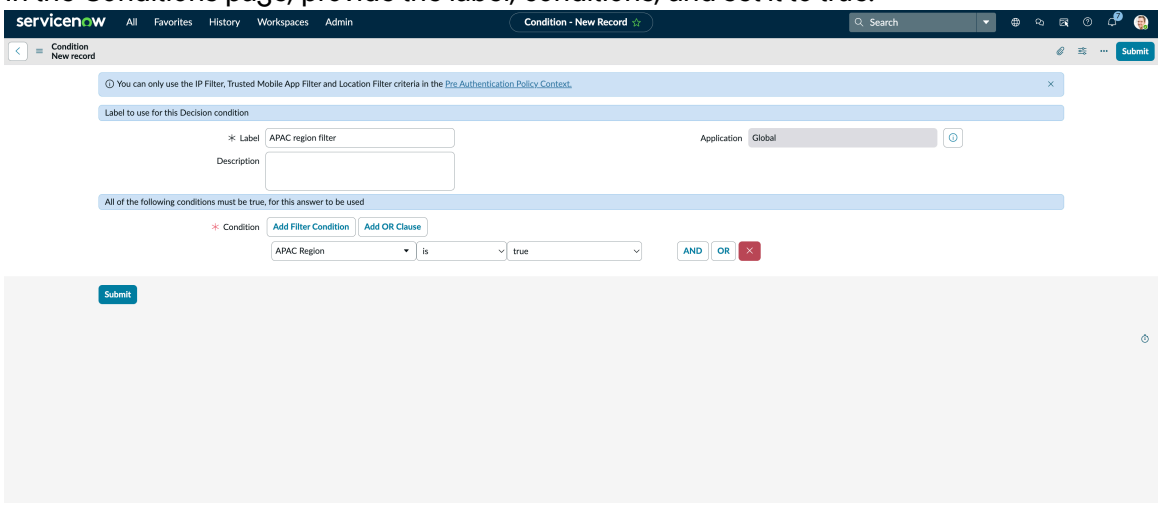


4. Add the Location Filter input and **Save**.

   For example, APAC Region.

   The filter is added as **Policy Inputs**.

5. Select the Policy Conditions tab and select **New**.
6. In the Conditions page, provide the label, conditions, and set it to true.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:

- In this example, the selection of true as a condition implies that the user logging from the configured regions won't be able to log in to the instance.
- If the condition is set to false, then only users from configured regions are able to log in to the instance and the other users won't be able to log in to the instance.

7. Select **Submit**.
   The users selecting the instance link and logging from the configured countries will be displayed an error message about the access denial (error message configured by their administrators on the policy properties page).

Use Location Filter Post Authentication Context

Use the location filter criteria created in the Post Authentication Context.

Before you begin

Role required: admin

Plugin required: **Zero Trust - Location Based Access** (`com.snc.zero_trust_location_access`).

Create a Location Filter with the countries that you want restrict access to the users based on the location. For more information, see Create location filter criteria.

Procedure

1. Navigate to **All** > **Adaptive Authentication** > **Auth Policy Context** > **Post Authentication Context**.

   When a policy is chosen in the post authentication policy context:

   - Selecting the Deny access policy as the default policy allows the access to all users by default and only denies access when the policy conditions defined in the deny access policy evaluate to true.
   - Selecting the Allow access policy as the default policy denies the access to all users by default and only allows access when the policy conditions defined in the allow access policy evaluates to true.

   The example shows on how you can configure a `itil` users with a condition to only access the instance from the specified location (US). And the `itil` users can't log in from other countries.

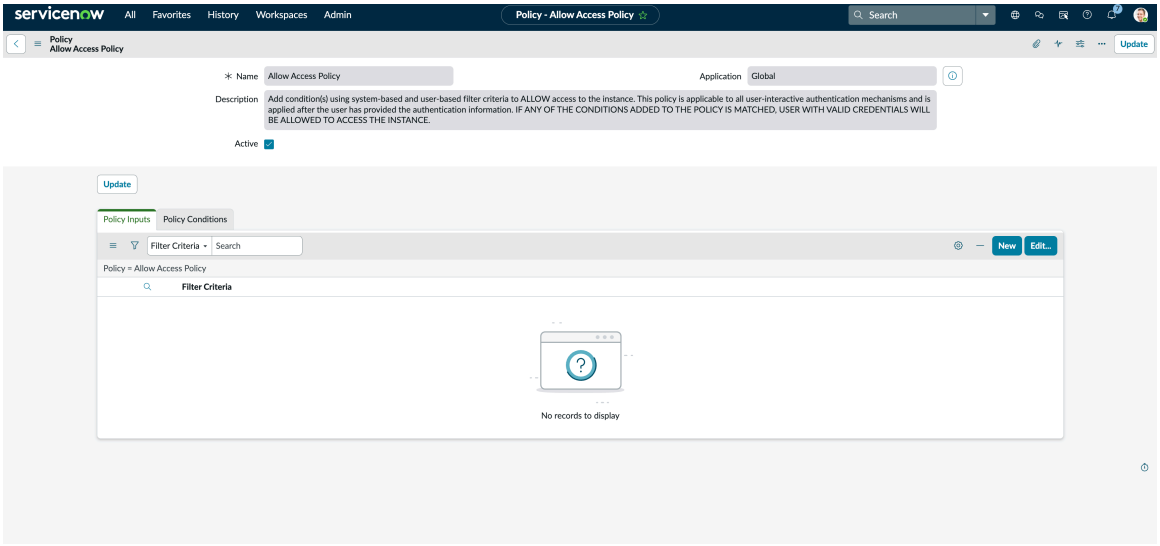
   After users providing their credentials on the login page. You can choose the Allow Access and the associated policy (Allow Access) as the Post Authentication policy and specify the policy inputs and conditions.

2. Select the information icon and then select **Open Record** to open the **Allow Policy** record.

   Note:
   The example described in this task is **Allow Policy**. You can also use **Deny Policy** and set the conditions accordingly to control the log in.

3. In the Allow Access Policy, under the Policy Inputs section, select **New**.

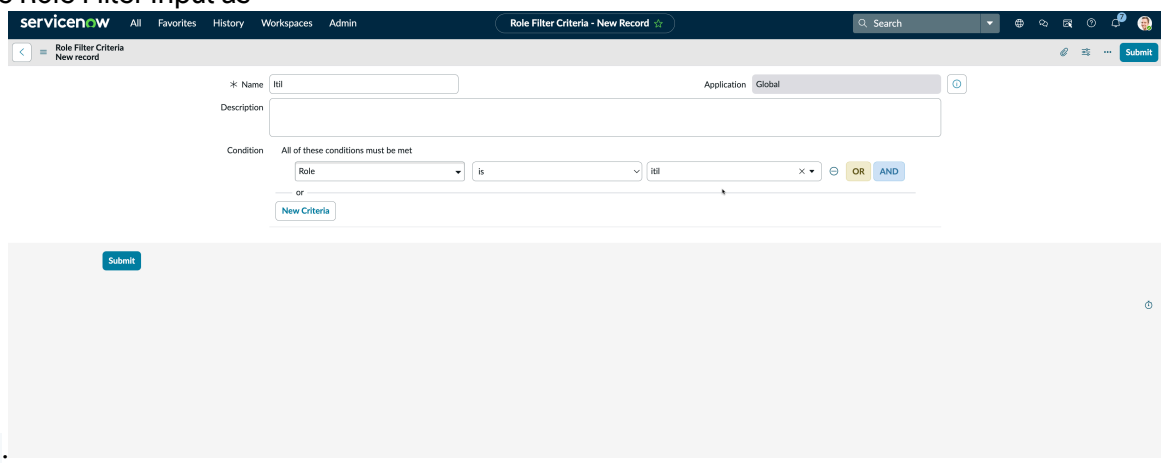
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



4. Add the Role Filter criteria and Location Filter criteria.

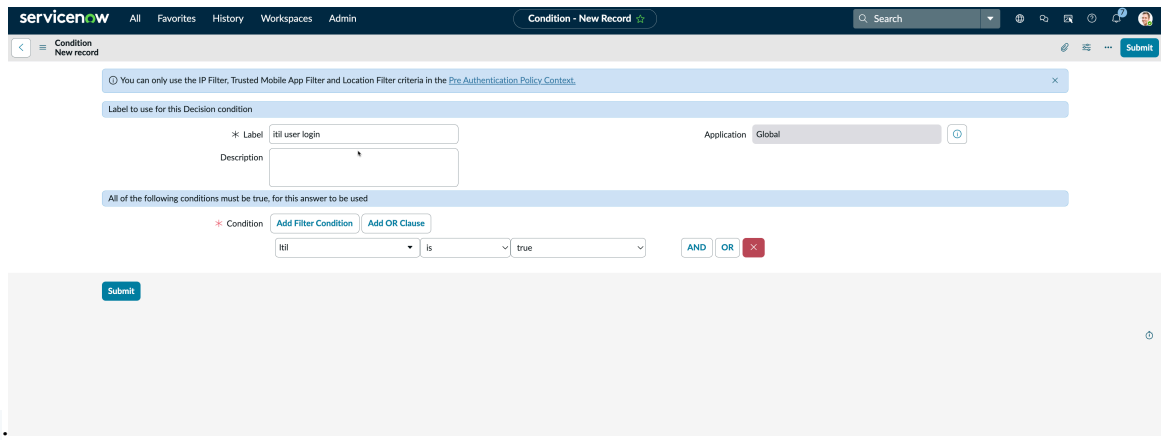
a. Adding Role Filter criteria:

- Create Role Filter Input as



`itil`.

- Create Role Filter Condition and set it to



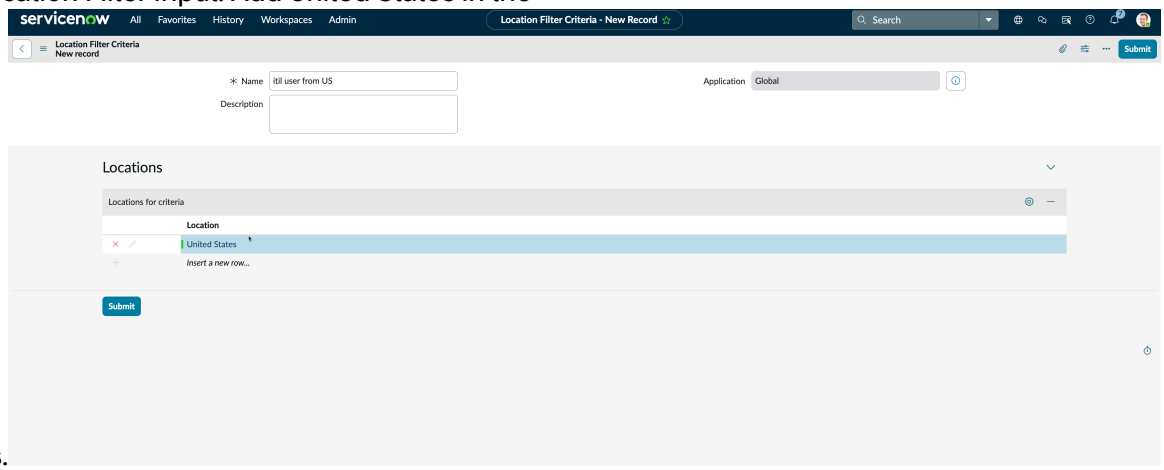
`true`.

For more information on how to create role filter criteria, see Create role filter criteria.

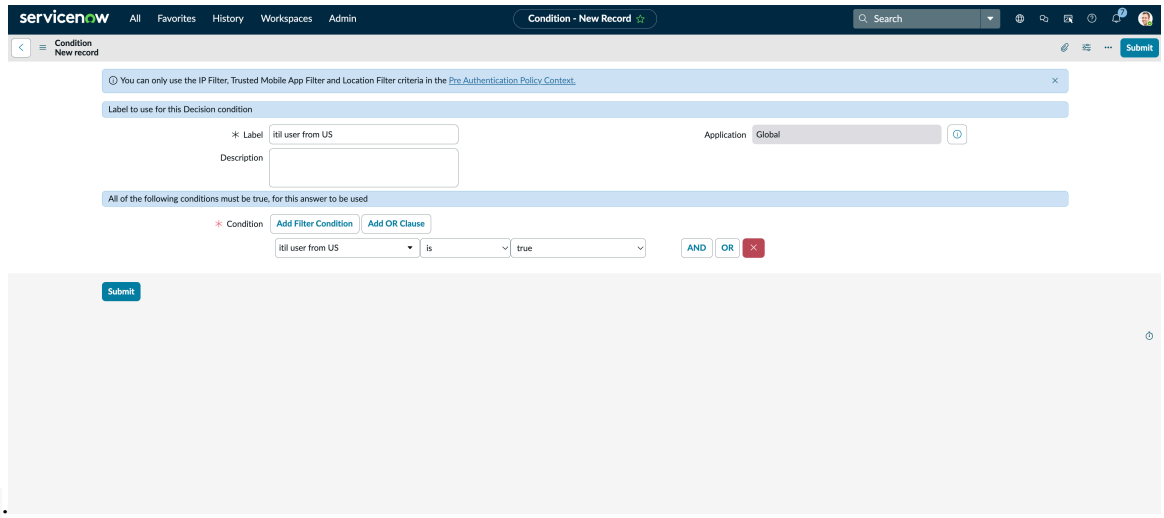
b. Adding Location Filter criteria:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Create Location Filter Input. Add United States in the Locations.



- Create Location Filter Condition and set it to `true`.

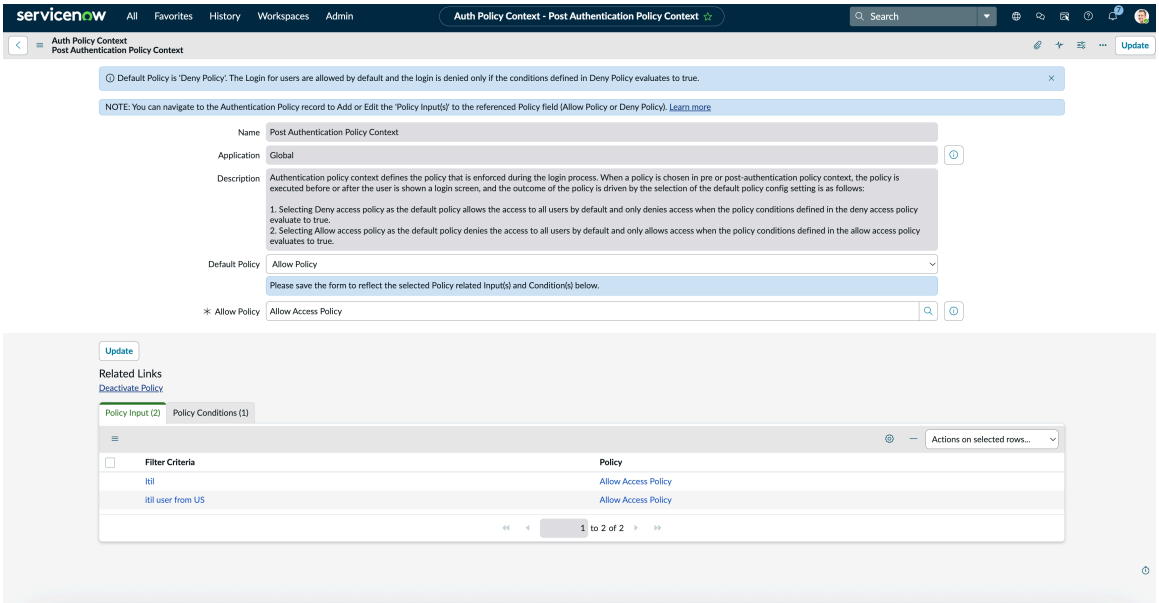


For more information on how to create role filter criteria, see Create location filter criteria.

The Allow Access Policy shows the Policy Inputs and Conditions that are created in the previous steps:

- Policy Inputs: itil, itil user from US
- Policy Conditions: itil user login, itil user from US condition.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Note:

- In this example, the selection of true as a condition implies that the `itil` users logging from the configured country (US) are able to log in to the instance.
- If the condition is set to false, then the `itil` users from the configured country (US) won't be able to log in to the instance and the other users won't be able to log in to the instance.

5. Select **Submit** or **Update** to update the Post Authentication Context.
   The `itil` users selecting the instance link, specifying their credential and then logging outside the configured country (US) is displayed an error message about the access denial (error message configured by their administrators on the policy properties page).

Use Location Filter in MFA Context

Use the location filter criteria created in MFA Context.

Before you begin

Role required: admin

Plugin required: **Zero Trust - Location Based Access** (`com.snc.zero_trust_location_access`).

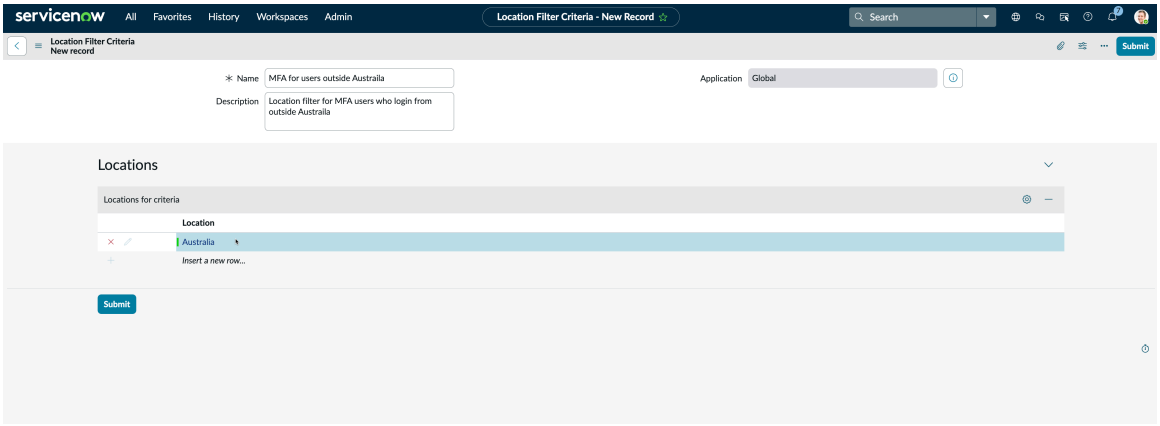
The following procedure describes on how to create a Location Filter with the countries that you want to configure MFA as a second factor for authentication to the users based on the location.

Procedure

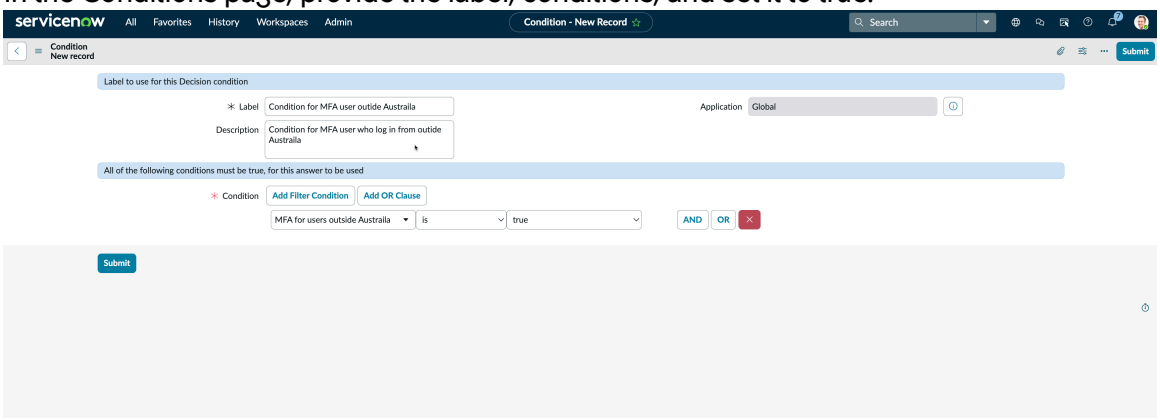
1. Navigate to **All** > **Adaptive Authentication** > **Auth Policy Context** > **MFA Context**.
2. Select the **Step-Up MFA Policy** information icon and then select **Open Record** to open the **MFA Context**.
3. On the Step-Up MFA Policy page, under the Policy Inputs tab, select **New**.
4. Add the Location Filter input and **Submit**.

   For example, you want to display MFA for users logging in to the instance outside Australia.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



5. On the Step-Up MFA Policy page, select the Policy Conditions tab and select **New**.
6. In the Conditions page, provide the label, conditions, and set it to true.



7. Select **Submit**.
8. On the Step-Up MFA Policy page, activate the MFA Policy if it's **Deactivated**.
9. Select **Update** to update the configuration.

   The users outside the configured country (Australia) selecting the instance link, specifying their credential; will be shown with the MFA screen to provide the second factor credentials to log in to the instance.

Use Location Filter for Session Access

Use the location filter criteria created in Session Access to reduce roles based on the location of the user.

Before you begin

Role required: admin

Plugin required: **Zero Trust - Location Based Access** (`com.snc.zero_trust_location_access`).

The following procedure describes on how to create a Location Filter with the countries that you want to remove or limit roles to the users based on the location.

Procedure

1. Navigate to **All** > **Zero Trust Access** > **Session Access Role Configurations**.
2. To create a session access role configuration, select **New**.
3. On the form, fill the fields:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Session Access Role Configuration

Field	Description
Name	Name of the configuration
Description	Short description of the configuration.
Policy	Choose the access policy. Use the look-up icon to view the list of policy. **Note:** You must add the location filter input and conditions by opening the policy record.
Action	**Remove Roles** or **Limit to Roles**. ○ **Remove Roles**: When the configured user logged in, the list of roles provided in the Role or Group List are removed for the logged-in session. ○ **Limit To Roles**: When the configured user logged in only the selected roles is provided to the user and all the other roles are removed for the logged-in session.
Role List	Choose the role from the Role List.
Group List	Choose the role from the Group List.

4. Select, **Submit**.

   The login for users based on the configured countries is as follows:

   - If **Remove Roles**, the users from the configured countries in the location filter will be removed with the roles configured for the session.
   - If **Limit To Roles**, the users from the configured countries in the location filter has only the roles that are configured for the session.

   To know more about how to remove or limit roles for a session, see Tutorial: Use Zero Trust Access.

Identity Provider Attributes Filter

Use the Identity Provider attributes that are received from the Security Assertion Markup Language (SAML) response and OpenID Connect (OIDC) from the Identity Provider (IdP) as a filter criteria for authentication.

To fetch all the attributes from an IdP through the SAML and OIDC response, you should perform a test connection with the IdP. After a successful test connection, the attributes are added in a new tab in the Identity Provider configuration page.

For more information see the following topics:

- Identity Provider attributes for Security Assertion Markup Language
- Identity Provider attributes for OpenID Connect

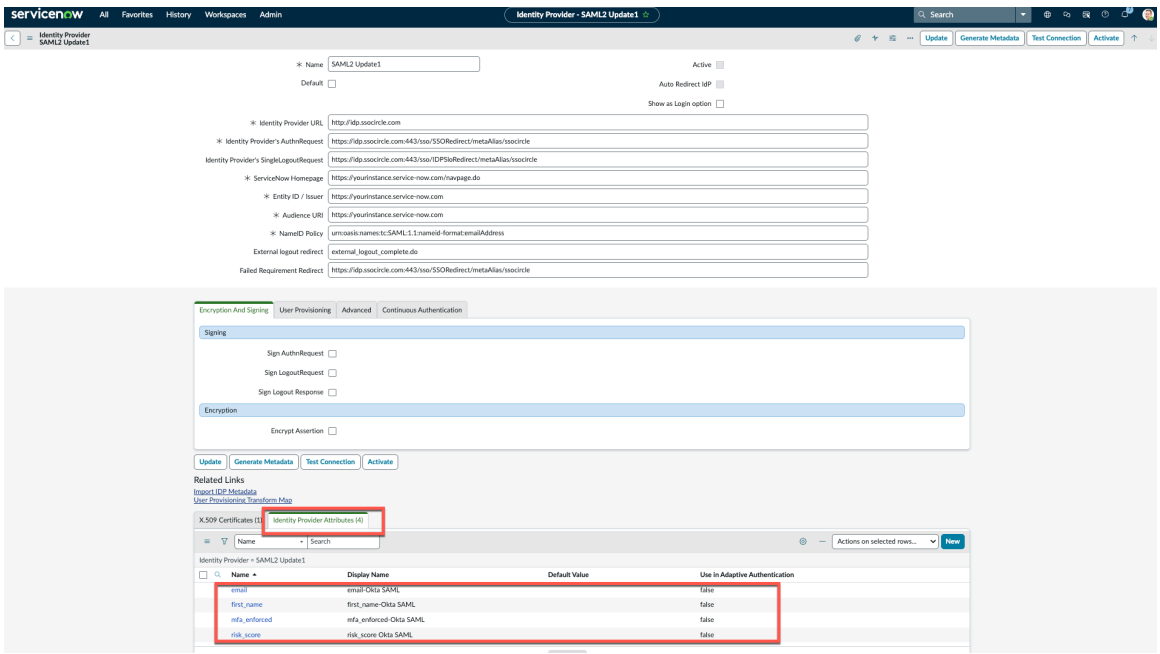
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Identity Provider attributes for Security Assertion Markup Language

Use the Identity Provider attributes that are received from the Security Assertion Markup Language (SAML) response and OpenID Connect (OIDC) from the Identity Provider (IdP) as a filter criteria for authentication.

To fetch all the attributes from an IdP through the SAML response, you should perform a test connection with the IdP. After a successful test connection, the attributes are added in a new tab in the Identity Provider configuration page.

- Identity Provider filter is available with Zero Trust Access feature. For more information, see Zero Trust Access (ZTA).
- IdP attribute filter criteria can be used in Post-authentication context, Zero Trust Access (ZTA) session relegation, and Multi-factor Authentication context.



You can also add attributes by selecting **New** from the Identity Provider Attributes section and use those attributes for Adaptive Authentication by setting it to `true`.

The **Identity Provider Attributes** are displayed with the following details:

Location Filter Criteria form

Field	Description
Name	Attribute name that is provided by the Identity Provider.
Display Name	Display Name is the detailed name that is used for the filter criteria. **Note:** You can provide a readable name as a Display Name, in some cases the Display Name provided by the Identity Providers are lengthy and not readable.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Location Filter Criteria form (continued)

Field	Description
Default Value	Default value is used for filter criteria evaluation in case the attribute is missing in the SAML response.
Use in Adaptive Authentication	Option to use the Attribute in the Adaptive Authentication.

Note:
Attributes that are populated from Azure IdP have name and display name limited to characters, due to the name length of the attribute.

You can also add new attributes by selecting **New** in the **Identity Providers Attributes** section.

If the Use in Adaptive Authentication is set to true, then the selected attribute is added as filter criteria in the Generic Filter Criteria. For example, **risk_score** set to `true`. The Generic Filter Criteria page has a new filter created.

Use Identity Provider Attribute as Filter Criteria for SAML

Use the Identity Provider (IDP) attribute from the Security Assertion Markup Language (SAML) response as a filter criteria for authentication policy.

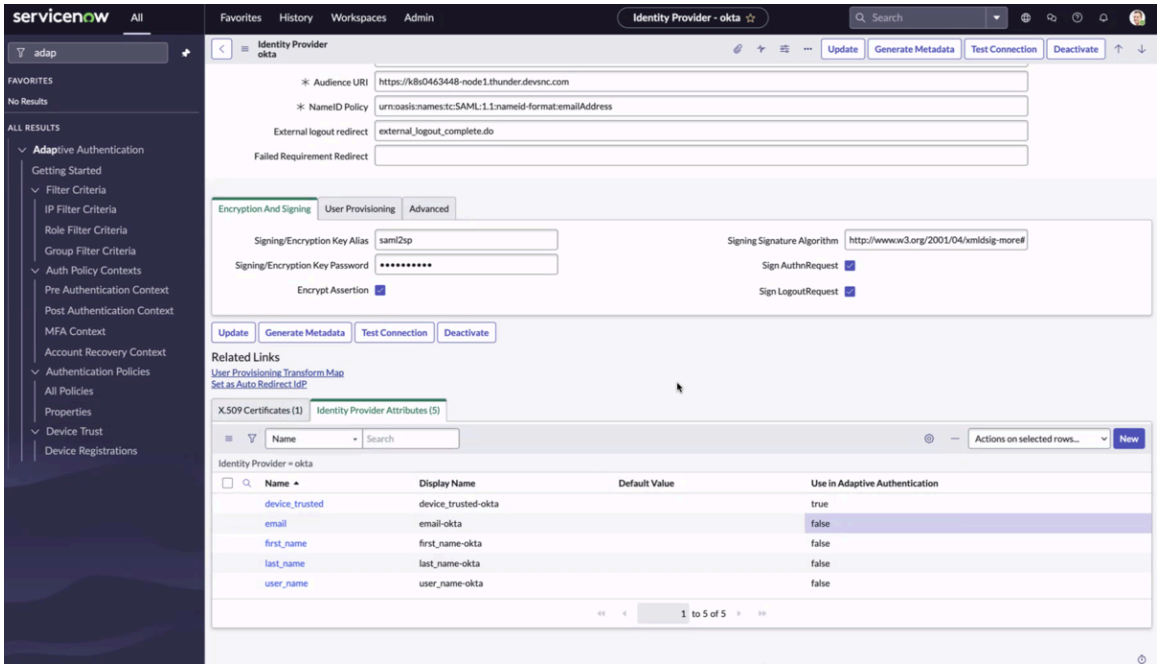
Before you begin
Role required: admin

You can create session access policy using policy context (Pre-Authentication, Post Authentication, multi-factor authentication) and filter criteria (Role, Group, IP, Location) with policy inputs and conditions.

The following procedure shows steps to configure the IdP attribute from the SAML response as a policy input to control authentication in the **Post Authentication Context**, **Multi-factor authentication (MFA) Context**, and **Zero Trust - Policy based session access**.

The Okta IDP attributes are as displayed in the following screenshot. You should set the Use in Adaptive Authentication as true to use it in the **Post Authentication Context**, **Multi-factor authentication (MFA) Context**, and **Zero Trust - Policy based session access** policies.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Note:
Policies in the post-authorization, MFA, Zero Trust - Policy based session access execute after the users enter the credentials or SSO response.

Procedure

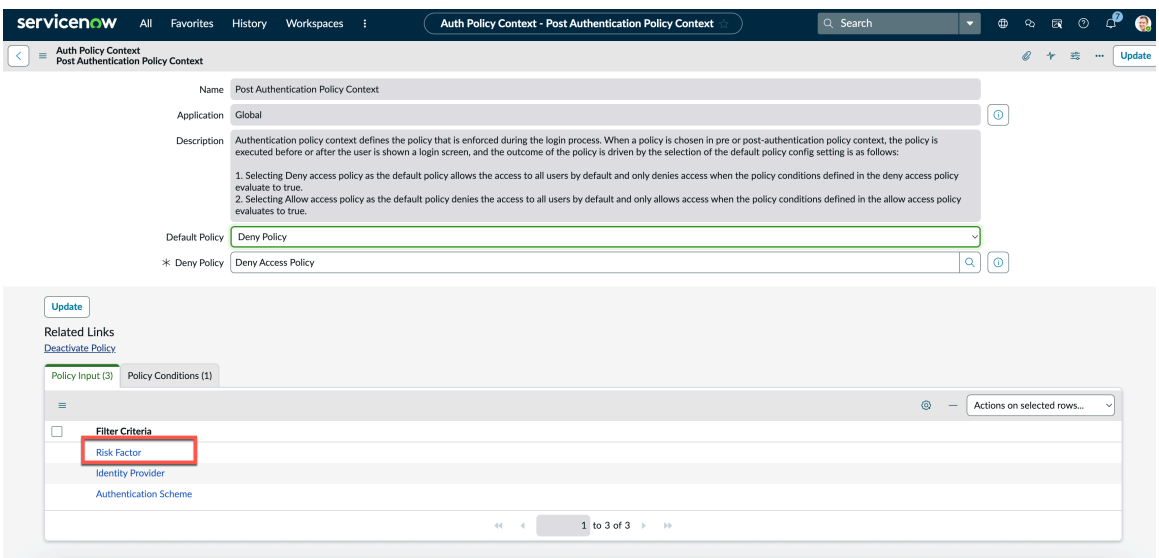
1. Use of IDP attribute in Post Authentication Policy Context.
   Example: Configuring to enable logins from the Okta IDP attributes if the device is trusted.

   a. Navigate to **All** > **Adaptive Authentication** > **Auth Policy Contexts** > **Post Authentication Policy Context.**.

   b. Select **Allow Policy** and open the policy record.

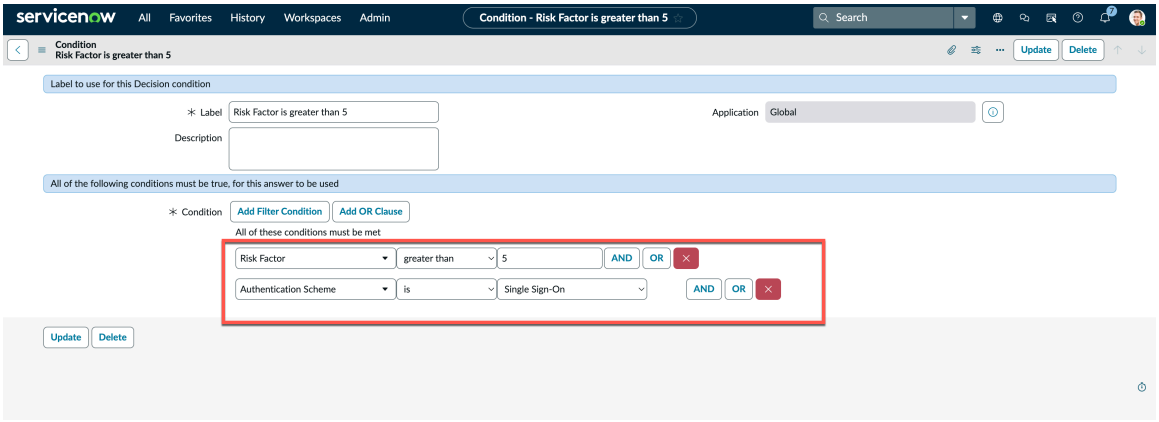
   c. In the Policy Input, create the Policy Input and Policy Condition.

   - **Policy Input**: Add **device_trusted-okta**.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **Policy Conditions**: **device_trusted-okta** is `trusted` and **Identity Provider** is `okta`.



Based on this configuration, when the device is trusted from the Okta (IdP), then the user is authenticated to the instance.

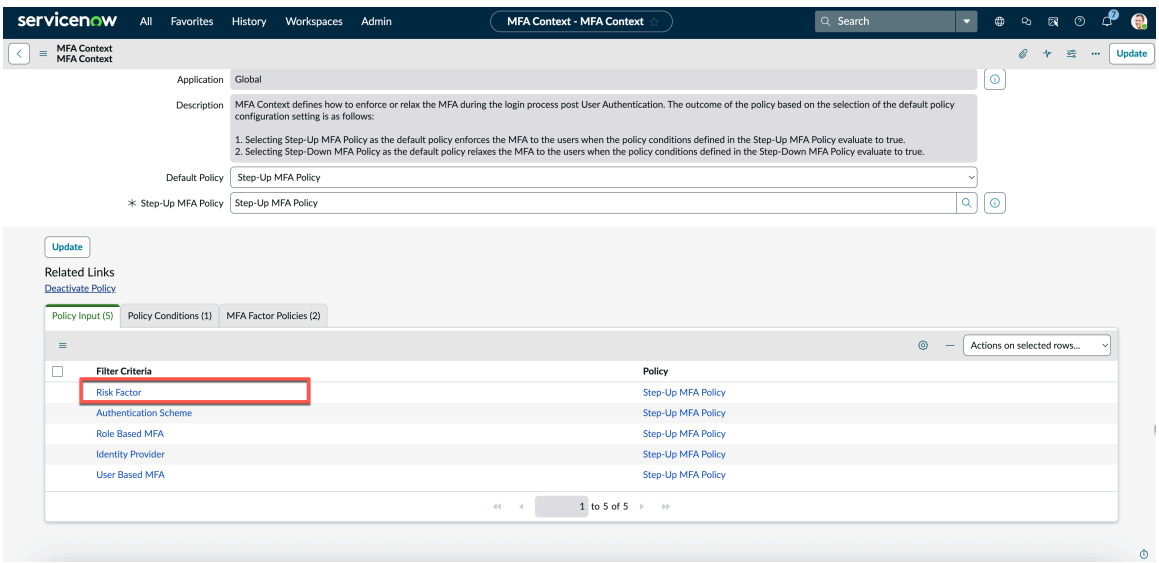
For more information on how to create Post Authentication Context with Policy and Condition, see Post-authentication context.

2. Use of IDP attribute in MFA Policy Context.
   Example: Configuring to enable MFA from the Okta IDP attributes if the device isn't trusted.

   a. Navigate to **All** > **Adaptive Authentication** > **Auth Policy Contexts** > **MFA Authentication Policy Context.**.

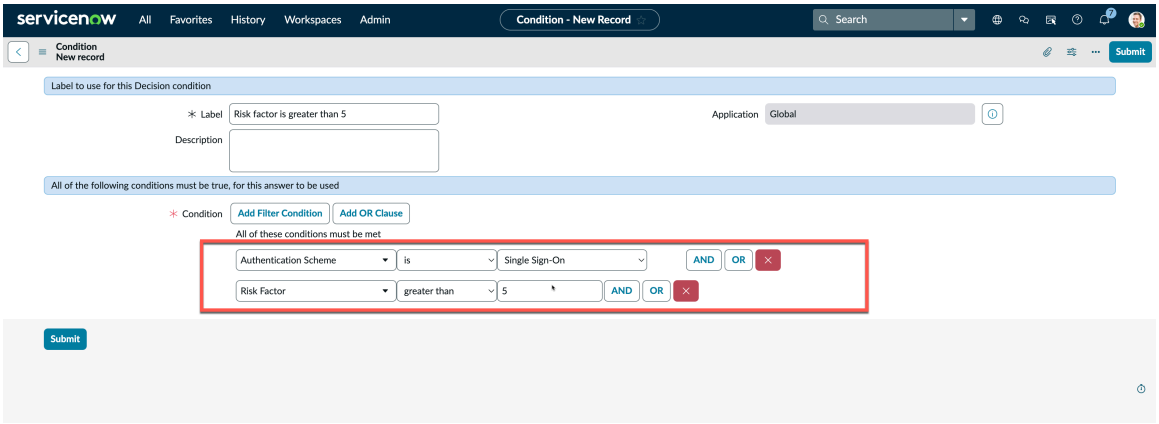
   b. In the Policy Input, create the Policy Input and Policy Condition.

   - **Policy Input**: Add **device_trusted-okta**.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **Policy Conditions**: **device_trusted-okta** is `not_trusted` and **Identity Provider** is `okta`.



Based on this configuration, when the device is not-trusted from the Okta (IdP), then the user shown a second factor authentication to log in to the instance.

For more information on how to create MFA Context with Policy and Condition, see Multi-factor Authentication context.

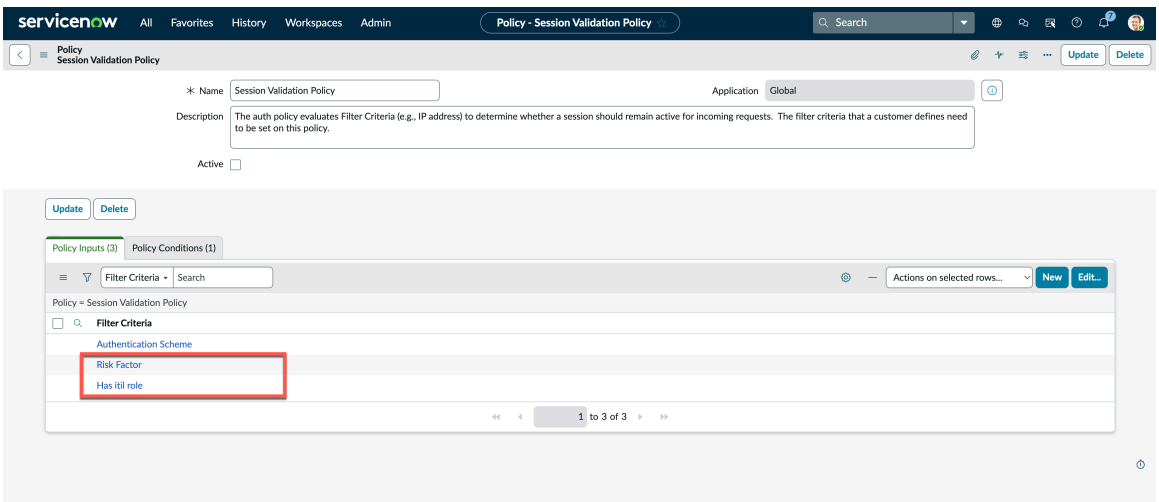
3. Use of IDP attribute in Zero Trust - Policy based session access.
   Example: Configuring to reduce the privilege of `Itil` role from Okta IDP attributes if the device isn't trusted.

   a. Navigate to **All** > **Zero Trust Access** > **Session Access Role Configurations**.

   b. Create a Session Access role configuration.

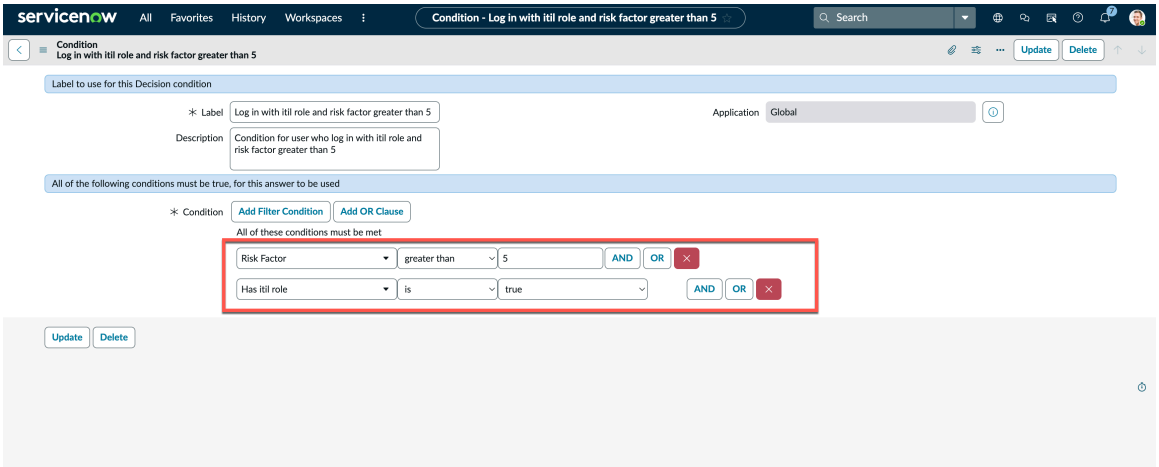
   c. In the Policy Input, create the Policy Input and Policy Condition.

   - **Policy Input**: Add **device_trusted-okta** and **has itil role**.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **Policy Conditions**: **device_trusted-okta** is `not_trusted`, **Identity Provider** is `okta`, and **has itil role** is `true`.



Based on this configuration, when the `itil` user using a device that is not-trusted from the Okta (IdP), then the user's privileges are reduced for the logged in session.

For more information on how to create Zero Trust - Policy based session access with Policy and Condition, see Zero Trust Access (ZTA).

Identity Provider attributes for OpenID Connect

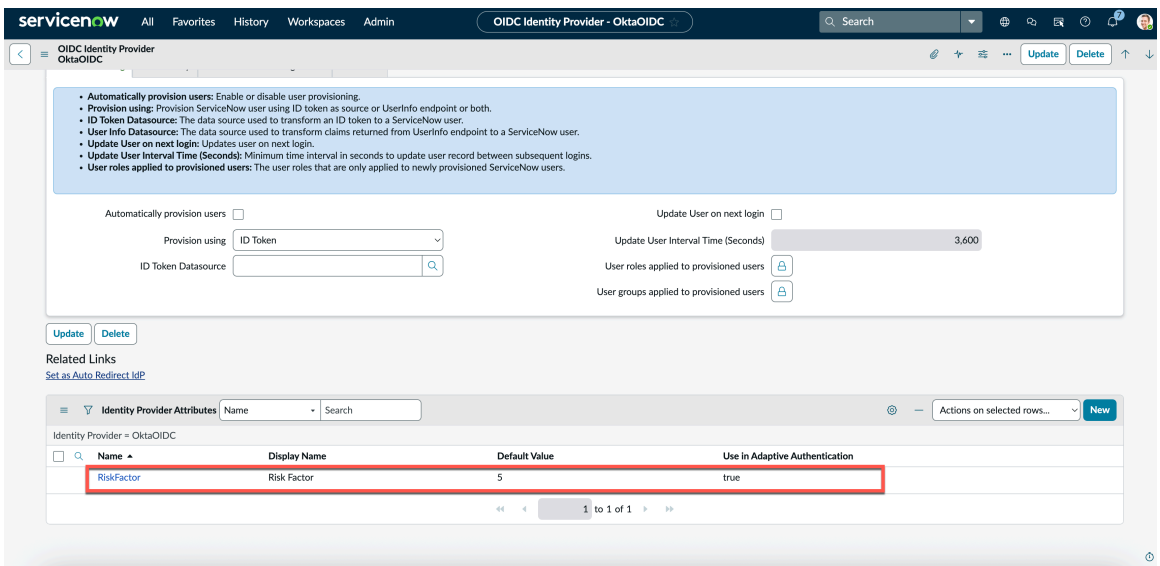
Use the Identity Provider attributes that are received from the OpenID Connect (OIDC) from the Identity Provider (IdP) as a filter criteria for authentication.

You can manually create the IdP attributes based on the claims received as part of the ID token.

Note:

- Identity Provider filter is available with Zero Trust Access feature. For more information, see Zero Trust Access (ZTA).
- IdP attribute filter criteria can be used in Post-authentication context, Zero Trust Access (ZTA) session relegation, and Multi-factor Authentication context.

Start the configuration by adding the IdP attributes by selecting **New** from the Identity Provider Attributes section and use those attributes for Adaptive Authentication by setting it to `true`.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The **RiskFactor** defined in the OIDC configuration in the Identity Provider Attributes is from the ID token claims. This value can be an existing claim or custom claim as configured in the IdP side. Use this claim in various authentication context to customize and control the log in behavior of the user.

The **Identity Provider Attributes** are displayed with the following details:

Location Filter Criteria form

Field	Description
Name	Attribute name that is provided by the Identity Provider.
Display Name	Display Name is the detailed name that is used for the filter criteria. **Note:** You can provide a readable name as a Display Name, in some cases the Display Name provided by the Identity Providers are lengthy and not readable.
Default Value	Default value is used for filter criteria evaluation in case the attribute is missing in the SAML response.
Use in Adaptive Authentication	Option to use the Attribute in the Adaptive Authentication.

Note:
Attributes that are populated from Azure IdP have name and display name limited to characters, due to the name length of the attribute.

You can also add new attributes by selecting **New** in the **Identity Providers Attributes** section.

If the Use in Adaptive Authentication is set to true, then the selected attribute is added as filter criteria in the Generic Filter Criteria. For example, **risk_score** set to `true`. The Generic Filter Criteria page has a new filter created.

Use Identity Provider Attribute as Filter Criteria for OIDC

Use the Identity Provider (IDP) attribute from the OpenID Connect (OIDC) response as a filter criteria for authentication policy.

Before you begin
Role required: admin

You can create session access policy using policy context (Pre-Authentication, Post Authentication, multi-factor authentication) and filter criteria (Role, Group, IP, Location) with policy inputs and conditions.

The following procedure shows steps to configure the IdP attribute from the SAML response as a policy input to control authentication in the **Post Authentication Context**, **Multi-factor authentication (MFA) Context**, and **Zero Trust - Policy based session access**.

The Okta IDP attributes are as displayed in the following screen shot. You should set the Use in Adaptive Authentication as true to use it in the **Post Authentication Context**, **Multi-factor authentication (MFA) Context**, and **Zero Trust - Policy based session access** policies.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
Policies in the post-authorization, MFA, Zero Trust - Policy based session access execute after the users enter the credentials or SSO response.

Procedure

1. Use of IDP attribute in Post Authentication Policy Context.
   Example: Configuring to enable log in from the Okta IDP attributes if the device is trusted.

   a. Navigate to **All** > **Adaptive Authentication** > **Auth Policy Contexts** > **Post Authentication Policy Context.**.

   b. Select **Allow Policy** and open the policy record.

   c. In the Policy Input, create the Policy Input and Policy Condition.

   - **Policy Input**: Add **Risk Factor**.

   - **Policy Conditions**: **Risk Factor** greater than `5` and **Authentication Scheme** is `Single Sing-On`.

   Based on this configuration, when the device is trusted from the Okta (IdP), then the user is authenticated to the instance.

   For more information on how to create Post Authentication Context with Policy and Condition, see Post-authentication context.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

2. Use of IDP attribute in MFA Policy Context.
   Example: Configuring to enable MFA from the Okta IDP attributes if the device isn't trusted.

   a. Navigate to **All** > **Adaptive Authentication** > **Auth Policy Contexts** > **MFA Authentication Policy Context.**.

   b. In the Policy Input, create the Policy Input and Policy Condition.

   - **Policy Input**: Add **Risk Factor**.

   - **Policy Conditions**: **Risk Factor** greater than `5` and **Authentication Scheme** is `Single Sing-On`.

   Based on this configuration, when the device is not-trusted from the Okta (IdP), then the user shown a second factor authentication to log in to the instance.

   For more information on how to create MFA Context with Policy and Condition, see Multi-factor Authentication context.

3. Use of IDP attribute in Zero Trust - Policy based session access.
   Example: Configuring to reduce the privilege of `Itil` role from Okta IDP attributes if the device isn't trusted.

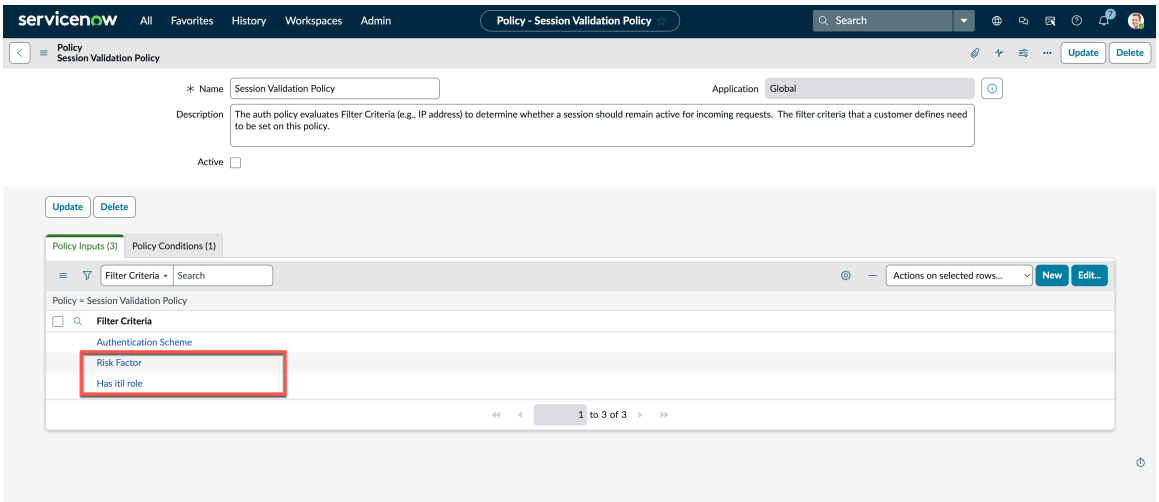
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

a. Navigate to **All** > **Zero Trust Access** > **Session Access Role Configurations**.

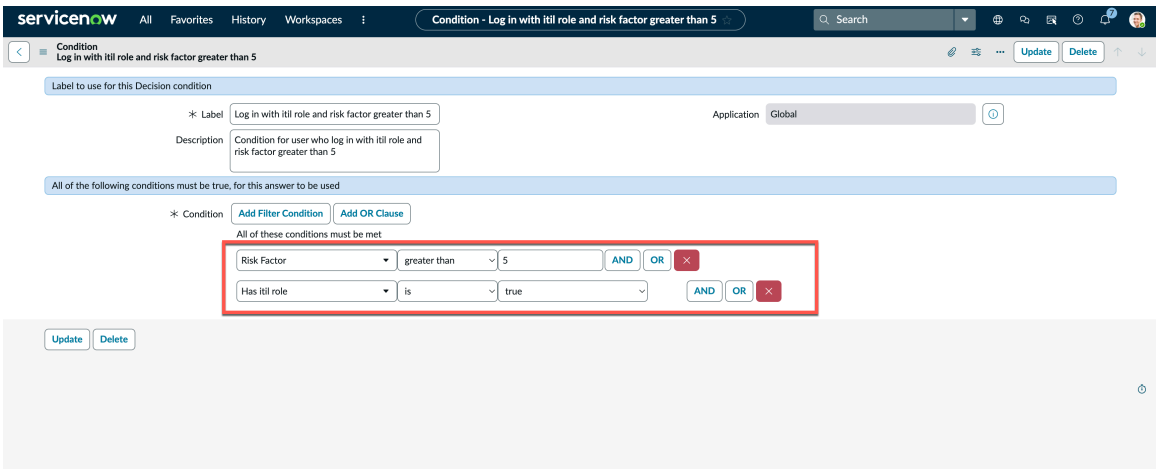
b. Create a Session Access role configuration.

c. In the Policy Input, create the Policy Input and Policy Condition.

- **Policy Input**: Add **Risk Factor** and **Has itil role**.



- **Policy Conditions**: **Risk Factor** greater than `5` and **Authentication Scheme** is `Single Sing-On`.



Based on this configuration, when the `itil` user using a device that is not-trusted from the Okta (IdP), then the user's privileges are reduced for the logged in session.

For more information on how to create Zero Trust - Policy based session access with Policy and Condition, see Zero Trust Access (ZTA).

Authentication policy contexts

Use authentication policy contexts to determine how and when your instance enforces authentication policies.

Authentication contexts define how and when a policy is enforced during the login process. Assign a policy to a policy context to define inputs and conditions regarding how your instance handles authentication.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Pre-authentication context

Policies in the pre-authorization context execute when a user first accesses the instance, before the they see a login screen. You can use the pre-authorization context to allow or deny access before your users are prompted for login credentials based on your selected policy. Because these policies evaluate before a user enters any information, those policies cannot take criteria such as a user's roles or groups into account.

For more detail on this context, see Pre authentication context.

Post-authentication context

Policies in the post-authorization context execute after your users enter their credentials or SSO response. Your instance allows or denies access based on your selected policy. Because your users have identified themselves via their login credentials, the policy can use user information to determine whether to grant access.

For more detail on this context, see Post-authentication context.

MFA (Multi-Factor Authentication) context

Policies assigned to the MFA context define whether to enforce MFA during the login process. Whether your instance enforces MFA is determined by the configuration of policies in this context. For more detail on this context, see Multi-factor Authentication context.

Account recovery context

Administrators can configure account recovery (ACR) to perform recovery activities such as addressing SSO misconfiguration or expired certificates. To use account recovery, you must register at least one admin account as an account recovery user. Single sign-on can’t be activated on your instance until there is at least one account configured. For more information about the context that can be set, see Account recovery context.

Session Validation context

The Session Validation context can be used with the Adaptive authentication policy framework. The framework uses authentication policies to evaluate authentication requests (session) and then either deny or allow access based on policy conditions. For more information, see Session validation context.

Default policy

Within the policy context, you can define a default policy in the **Default Policy** field. This default defines how your instance responds to the result of your policy. The available default policy options are determined by which context you are using. Detail on these options can be found in the docs describing these individual contexts.

Pre authentication context

The pre authentication policy context defines how and when a policy is enforced during the login process. The policy used in this context executes before your users see a login screen.

Pre authentication context record

Policies in the pre authentication context execute when a user first accesses the instance, before they see a login screen.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

You can use the pre authentication context to allow or deny access before your users are prompted for login credentials based on your selected policy. Because these policies evaluate before a user enters any information, those policies can't take criteria such as a user's roles or groups into account.

Use the fields in the **Pre Authentication policy context** record to define how your instance uses your policy.

Pre Authentication context form

Field	Description
Name	Name of the policy context. This field is static and can't be changed.
Description	Description of the context
Default Policy	Defines the default behavior of this context when evaluating the policy. Select from the following options. **Allow Policy** Denies access to all users by default, and only allows access when the conditions the policy selected in the **Allow Policy** field evaluate to true. **Deny Policy** Allows access to all users by default, and only denies access when the conditions the policy selected in the **Deny Policy** field evaluate to true.
Allow Policy	The policy used for this context uses. This field appears only when the **Default Policy** field is set to **Allow Policy**.
Deny Policy	The policy used for this context uses. This field appears only when the **Default Policy** field is set to **Deny Policy**.

Note:

You can only use the IP Filter, Trusted Mobile App Filter, and Location Filter criteria in the Pre Authentication Policy Context.

Policy inputs and conditions

The **Policy Input** and **Policy Conditions** tabs display the inputs and conditions of the policy selected in the **Allow Policy** or **Deny Policy** field. These tabs serve as a reference, but can't be used to change the policy inputs or conditions. To modify your policy, navigate to the policy using the reference icon ( ) next to the **Allow Policy** or **Deny Policy** field.

This example shows a pre authentication policy context record configured to deny access by default. The context uses a policy called **Deny access policy**. That policy has a set of inputs and conditions that are displayed in the **Policy Input** and **Policy Condition** tabs.

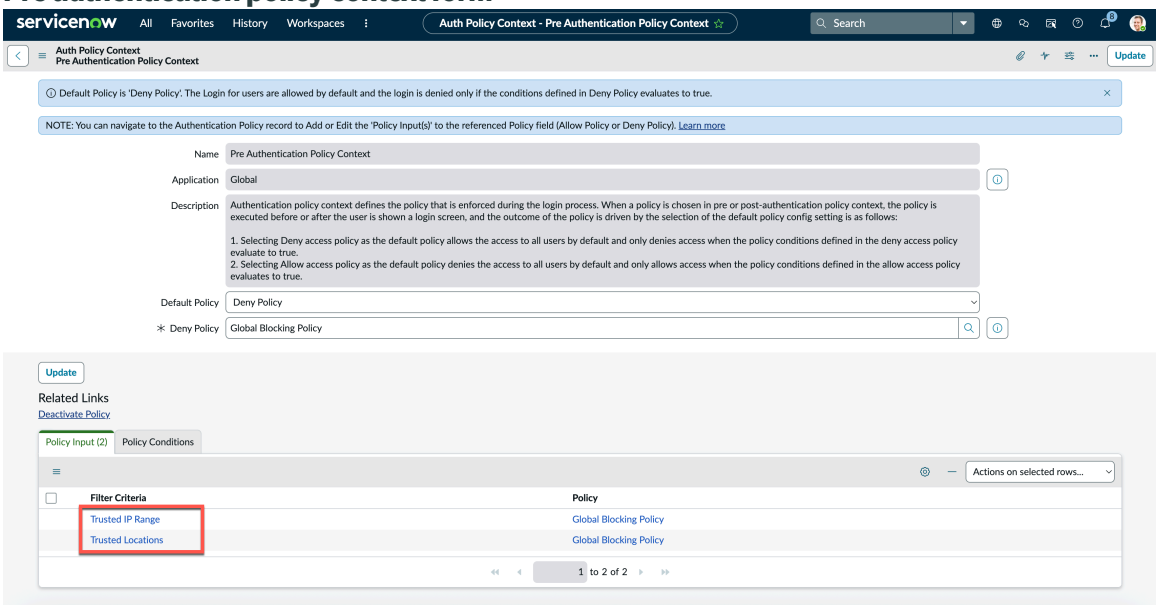
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:

- Only IP-Based filters, Location based filters, or Trusted Mobile App filter can be used in the pre authentication policy context.
- Whenever there's a pre authentication set with non absolute conditions or filter criteria, you're displayed with an error message stating that the policy or context can't be configured. It's recommended to validate all the inputs for the pre authentication context before executing it to the instance.

  For example: If the administrator is outside the trusted network and configures pre authentication context with IP ranges, if the IP ranges are mismatched with the current session of the admin, the admin is blocked.

Pre authentication policy context form



Post-authentication context

The Post Authentication policy context defines how and when a policy is enforced during the login process. The policy used in this context executes after your users see a login screen.

Post-authentication context record

Policies in the post-authorization context execute after your users enter their credentials or SSO response. Your instance allows or denies access based on your selected policy. Because your users have identified themselves via their login credentials, the policy can use user information such as role or group to determine whether to grant access.

Use the fields in the Post-authentication policy context record to define how your instance uses your policy.

Post-authentication context form

Field	Description
Name	Name of the policy context. This field is static and cannot be changed.
Description	Description of the context
Default Policy	Defines the default behavior of this context when evaluating the policy. Select from the following options.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Post-authentication context form (continued)

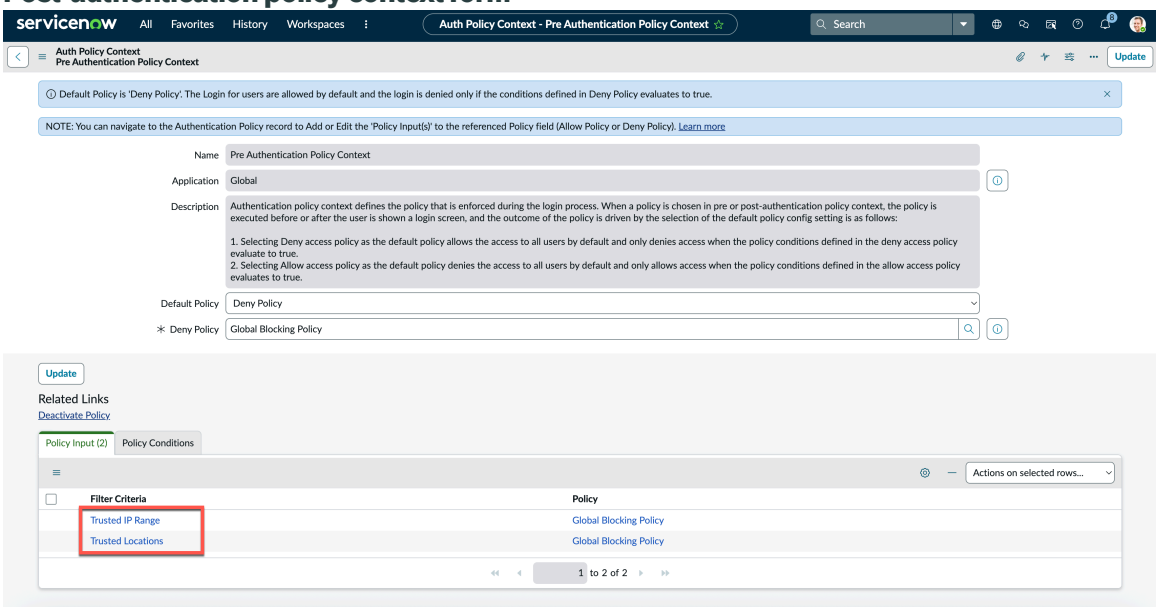
Field	Description
	Allow Policy Denies access to all users by default, and only allows access when the conditions the policy selected in the **Allow Policy** field evaluate to true. **Deny Policy** Allows access to all users by default, and only denies access when the conditions the policy selected in the **Deny Policy** field evaluate to true.
Allow Policy	The policy used for this context uses. This field appears only when the **Default Policy** field is set to **Allow Policy**.
Deny Policy	The policy used for this context uses. This field appears only when the **Default Policy** field is set to **Deny Policy**.

Policy inputs and conditions

The **Policy Input** and **Policy Conditions** tabs display the inputs and conditions of the policy selected in the **Allow Policy** or **Deny Policy** field. These tabs serve as a reference, but cannot be used to change the policy inputs or conditions. To modify your policy settings, navigate to the policy using the reference icon (ⓘ) next to the **Allow Policy** or **Deny Policy** field.

This example shows a post-authentication policy context record configured to deny access by default. The context uses a policy called **Deny access policy**. That policy has a set of inputs and conditions that are displayed in the **Policy Input** and **Policy Condition** tabs.

Post-authentication policy context form



Multi-factor Authentication context

The Multi-factor Authentication (MFA) policy context uses a policy to define how and when MFA is enforced during the login process.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

MFA context record

The MFA policy context defines whether your users must provide a second form of authentication when logging in. This context does not deny access to your instance as the post-authentication and pre-authentication policies. The policy you select in this context takes precedence over user or role-based configurations for multi-factor authentication.

To access the MFA context, navigate to **All** > **Multi-factor Authentication** > **MFA Context**.

Use the fields in the Post-authentication policy context record to define how your instance uses your policy.

Note:

- If the default policy is **Step-Up MFA Policy**, users will be shown with Multi-factor Authentication if policy configured in **Step-Up MFA Policy** evaluates to true. Policy takes precedence over the user or role based configuration.
- MFA with SSO login will only be available if `glide.authenticate.mfa.with.multisso.enabled` Property is set to true.
- You can navigate to the Authentication Policy record to Add or Edit the 'Policy Input(s)' to the referenced Policy field (**Step-Up MFA Policy** or **Step-Down MFA Policy**).
- MFA context policy applies only for user log ins. It does not apply for API authentication, basic auth, and OAuth resource owner password credential grant.

MFA context form

Field	Description
Name	Name of the policy context. This field is static and cannot be changed.
Description	Description of the context
Default Policy	Defines the default behavior of this context when evaluating the policy. Select from the following options. **Step-Up MFA Policy** Enforces MFA to users when the policy conditions defined in the **Step-Up MFA Policy** field evaluate to true. **Step-Down MFA Policy** Enforces MFA by default. MFA is not enforced only when the policy conditions defined in the **Step-Down MFA Policy** field evaluate to true.
Step-Up MFA Policy	The policy used for this context uses. This field appears only when the **Default Policy** field is set to **Step-Up MFA Policy**.
Step-Down MFA Policy	The policy used for this context uses. This field appears only when the **Default Policy** field is set to **Step-Down MFA Policy**.

Policy inputs and conditions

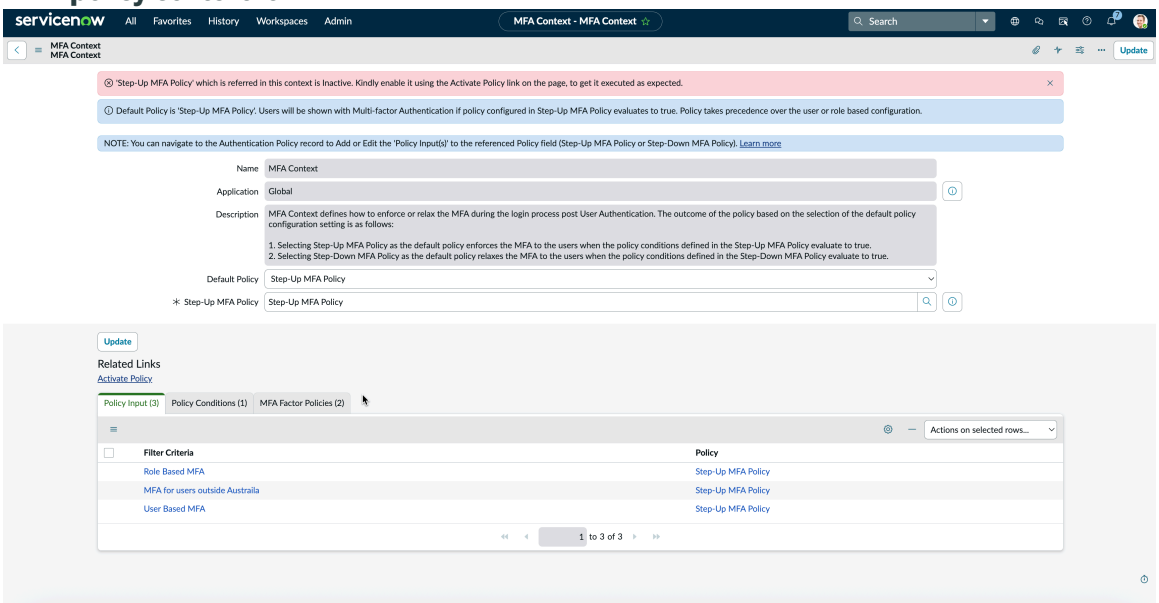
The **Policy Input** and **Policy Conditions** tabs display the inputs and conditions of the policy selected in the **Step-Up MFA Policy** or **Step-Down MFA Policy** field. These tabs serve as a reference, but cannot be used to change the policy inputs or conditions. To modify your policy settings, navigate to the policy using the reference icon (ⓘ) next to the **Step-Up MFA Policy** or **Step-Down MFA Policy** field.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
Policy conditions can be created from here, but as a good practise it is recommended to add new policy conditions from policy page.

This example shows an MFA context record configured using a step-up MFA policy. This default policy means that MFA is enforced only when the conditions defined in the policy evaluate to true. The context uses a policy called **Step-Up MFA policy**. That policy has a set of inputs and conditions that are displayed in the **Policy Input** and **Policy Condition** tabs.

MFA policy context form



MFA factor policies

MFA factor policies are a critical component of an organization's security posture, enabling you to enforce additional verification steps beyond passwords. These policies define the authentication methods that users must employ to access providing a flexible and customizable approach to authentication. For more information, see Multi-Factor Authentication factor policies.

Account recovery context

The account recovery context uses a policy to define how and when the account recovery can be established.

Administrators can view and modify this context and its associated policy by navigating to **Multi-Provider SSO** > **Account Recovery** > **Account Recovery Context**.

Note:
By default the policy is **Allow Policy**. The Login for users are restricted by default and the login is allowed only if the conditions defined in **Allow Policy** evaluates to true.

Use the fields in the account recovery context record to define how your instance uses the policy.

Account recovery context form

Field	Description
Name	Name of the policy context. This field is static and cannot be changed.
Description	Description of the context

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

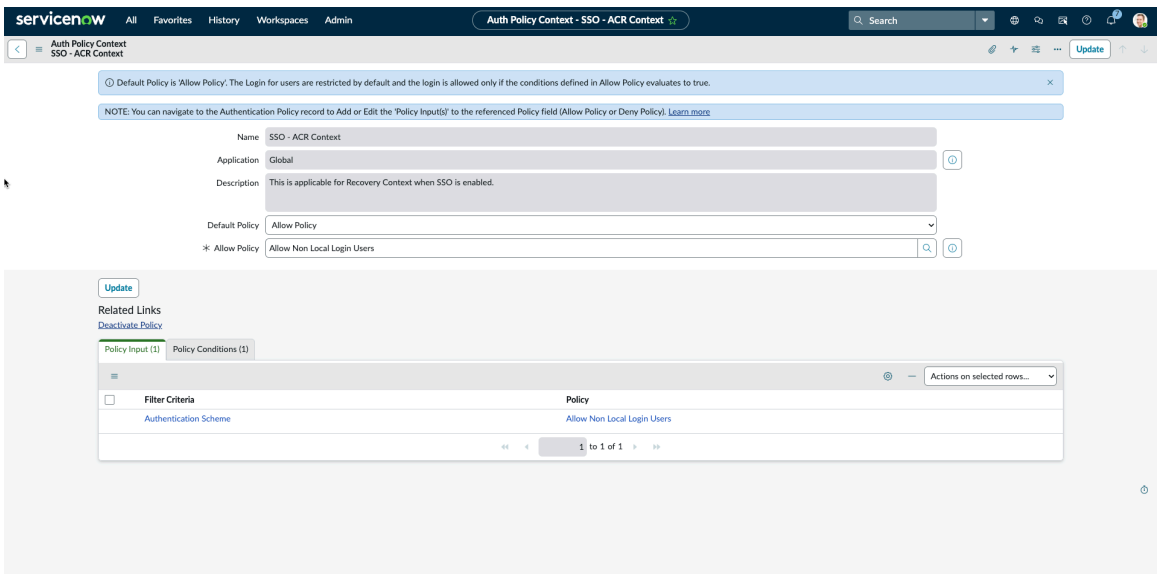
Account recovery context form (continued)

Field	Description
Default Policy	Defines the default behavior of this context when evaluating the policy. Select from the following options: • Allow Policy • Deny Policy
Allow Policy	This field appears only when the **Default Policy** field is set to **Allow Policy**.
Deny Policy	This field appears only when the **Default Policy** field is set to **Deny Policy**.

Policy inputs and conditions

The **Policy Input** and **Policy Conditions** tabs display the inputs and conditions of the policy selected in the **Allow Policy** or **Deny Policy** field. These tabs serve as a reference, but cannot be used to change the policy inputs or conditions. To modify your policy settings, navigate to the policy using the information icon next to the **Allow Policy** or **Deny Policy** field.

Note:
Policy conditions can be created from here, but as a good practice it is recommended to add new policy conditions from policy page.



Session validation context

Use the Session Validation Context as an additional layer of protection against session or cookie hijacking.

You can use the Session Validation Context with the Adaptive authentication policy framework. The framework uses authentication policies to evaluate authentication requests and then either denies or allows access based on policy inputs and conditions.

The Session Validation Context policy can be used in conjunction with post auth policy, where an admin can enforce IP restrictions to certain or all users during the logged in session.

The Session Validation Context feature evaluates the IP-addresses based on the conditions you set and allows access to the instance within a session. The Session Validation Context outcome

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

is set based on selecting **Allow Policy** as this policy terminates the user session immediately unless one of the policy conditions defined in the allow access policy evaluates to true.

Note:
The Session Validation Context for an authentication policy can only be with **Allow Policy**.

The Session Validation Context works based on the following mechanism:

- Captures the user's IP address on session creation from user request and stores it in the session and database.
- Rejects a request when its IP address differs from that in the session or outside of the customer defined valid IP ranges you defined.

Note:
The Session Validation Context is:

- Available only for authenticated users.
- Not applicable for guest user sessions or native mobile apps.
- Optional and based on the requirement that it can be configured.
- Executed only for the post-login requests.

Benefits of Session Validation

The Session Validation Context has the following benefits:

- Restricts access to ServiceNow® when hijackers copy a user's session cookies from one device to another to impersonate the session.
- Restricts the user's session access if they're using an insecure network.
- Configures the various rules and IP ranges by user group or role for user logins.

Session Validation context record

Policies in the session validation context execute post-login requests.

Use the fields in the session validation policy context record to define how your instance uses your policy.

Session Validation context form

Field	Description
Name	Name of the policy context. This field is static and can’t be changed.
Description	Description of the context.
Default Policy	Defines the default behavior of this context when evaluating the policy. Select from the following options. **Allow Policy** Denies access to all users by default, and only allows access when the conditions in the **Allow Policy** field evaluate to true. **Deny Policy** Allows access to all users by default, and only denies access when the conditions in the **Deny Policy** field evaluate to true.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Session Validation context form (continued)

Field	Description
Allow Policy	The policy used for this context. This field appears only when the **Default Policy** field is set to **Allow Policy**.
Deny Policy	The policy used for this context. This field appears only when the **Default Policy** field is set to **Deny Policy**.

You can choose the **Session Validation Policy** as Allow Policy or Deny Policy based on the policy input and policy conditions.

Note:

You can only use the IP, Role, and Group filter criteria for Session Validation policy.

Policy inputs and conditions

The **Policy Input** and **Policy Conditions** tabs display the inputs and conditions of the policy selected in the **Allow Policy** or **Deny Policy** field. These tabs serve as a reference; but they can't be used to change the policy inputs or conditions. To modify your policy, navigate to the policy using the reference icon next to the **Allow Policy** or **Deny Policy** field.

Activate Session Validation Context

Use Session Validation Context to restrict access to ServiceNow® when hijackers copy a user's session cookies from one device to another to impersonate the session or restricts the user's session access if they're using an insecure network.

Before you begin

Role required: admin

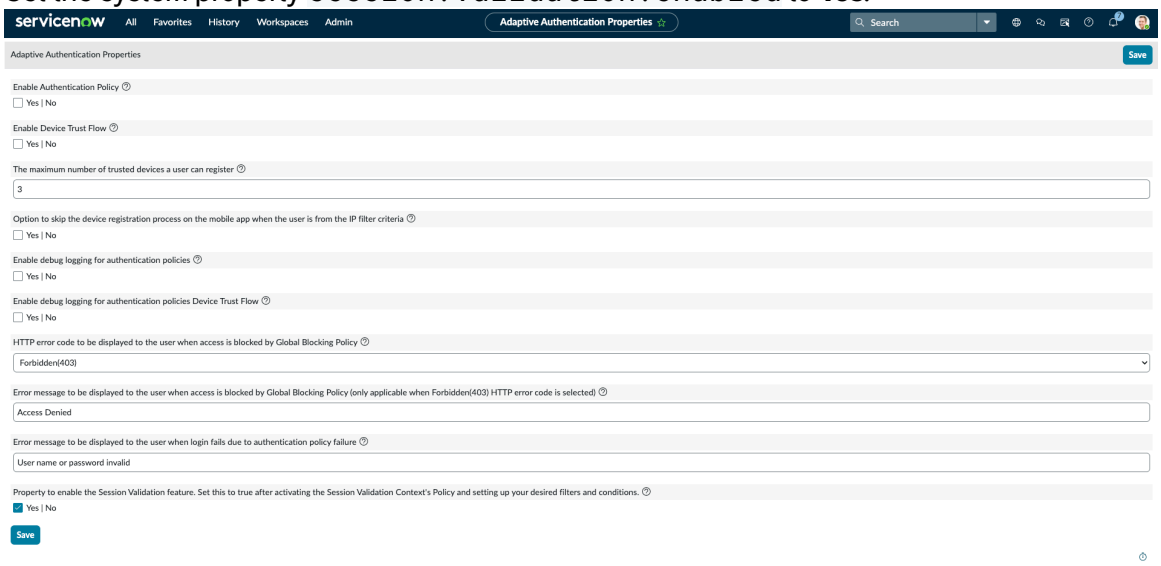
To use the session validation, you must perform the following steps:

Procedure

1. Navigate to **All** > **Adaptive Authentication** > **Authentication Policies** > **All Policies**.
2. Select the **Session Validation Policy** in the Policies (`sys_authentication_policy_list.do`) page.
3. Specify the **Policy Inputs** and **Policy Conditions**.
4. Set the conditions to **true** or **false** for the filters that you've added.
5. Select the **Active** check box to activate the policy after you set up the Session Validation Policy is set up with policy inputs and conditions.
6. Select a **Force AuthnRequest** check box for the default identity provider in the sso_properties table if the instance has SSO configured.
7. Navigate to **All** > **Adaptive Authentication** > **Authentication Policies** > **Properties**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

8. Set the system property `session.validation.enabled` to **Yes**.



Result

The Session Validation feature is activated. You can configure the policy inputs and conditions for the policy to use the feature. To learn more, see Tutorial: Configuring session validation.

Tutorial: Configuring session validation

Configure session validation within the Adaptive Authentication framework to provide as an additional layer of protection for session or cookie hijacking.

Before you begin

Role required: admin

Plugin required: **Adaptive Authentication** (com.snc.adaptive_authentication)

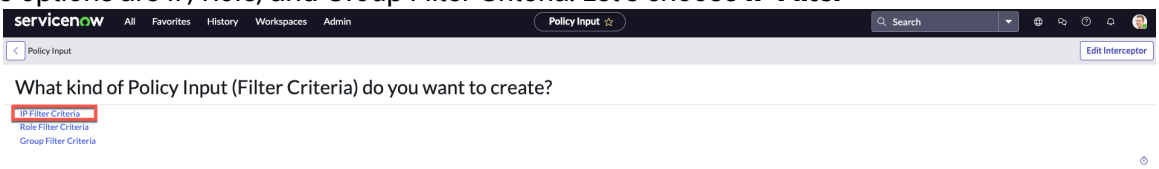
To configure Session Validation, you must perform the following steps:

Procedure

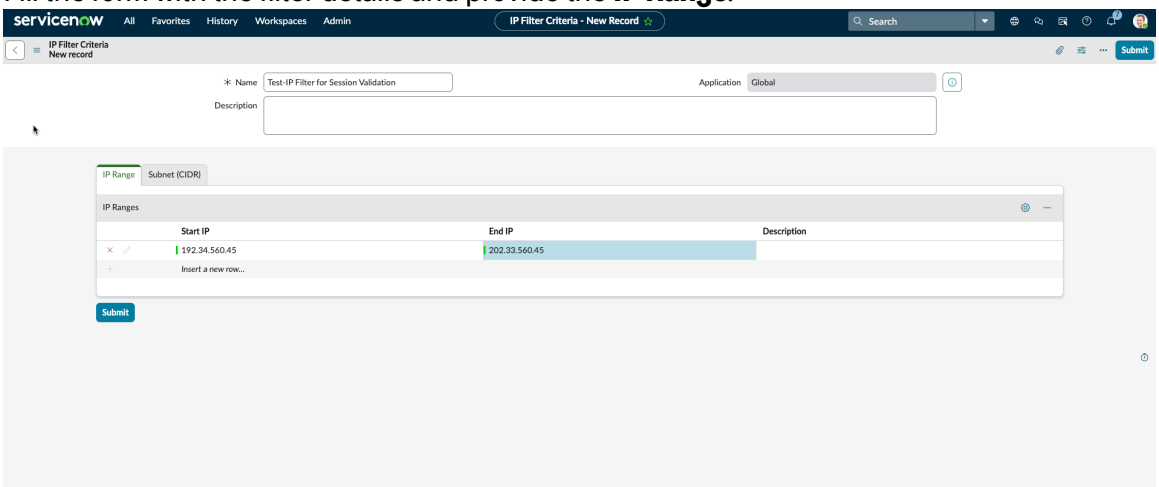
1. Navigate to **All** > **Adaptive Authentication** > **Authentication Policies** > **All Policies**.
2. Select the **Session Validation Policy** in the Policies (`sys_authentication_policy_list.do`) page.
3. Select **Policy Inputs**.
   a. Select **New** or **Edit**.
   b. Choose the kind of Policy Input (Filter Criteria) that you want to create.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Available options are IP, Role, and Group Filter Criteria. Let's choose **IP Filter Criteria**.



c. Fill the form with the filter details and provide the **IP Range**.



To learn more about how to create an IP Filter, see Create IP filter criteria.

d. Select **Submit**.

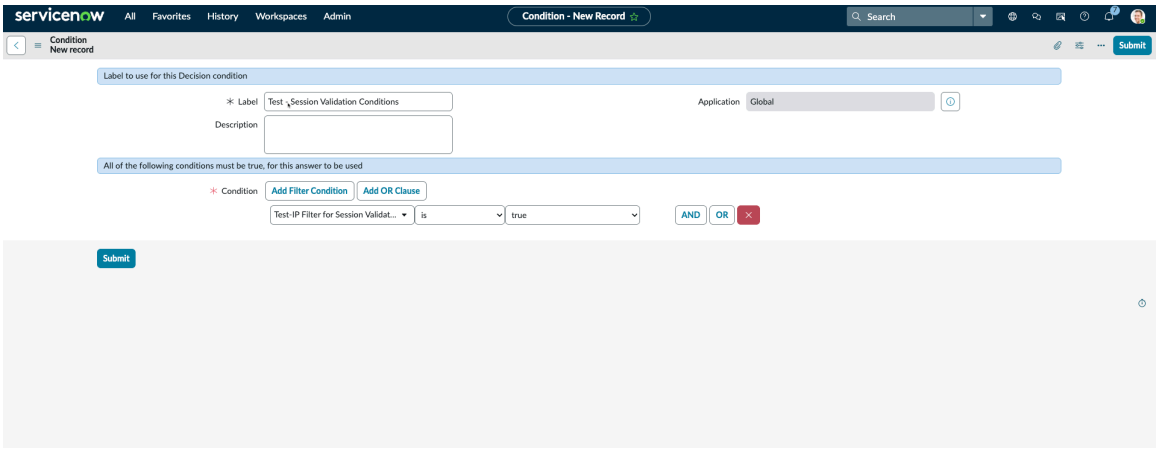
4. Select **Policy Conditions** on the Session Validation Policy page.

a. Select **New**.

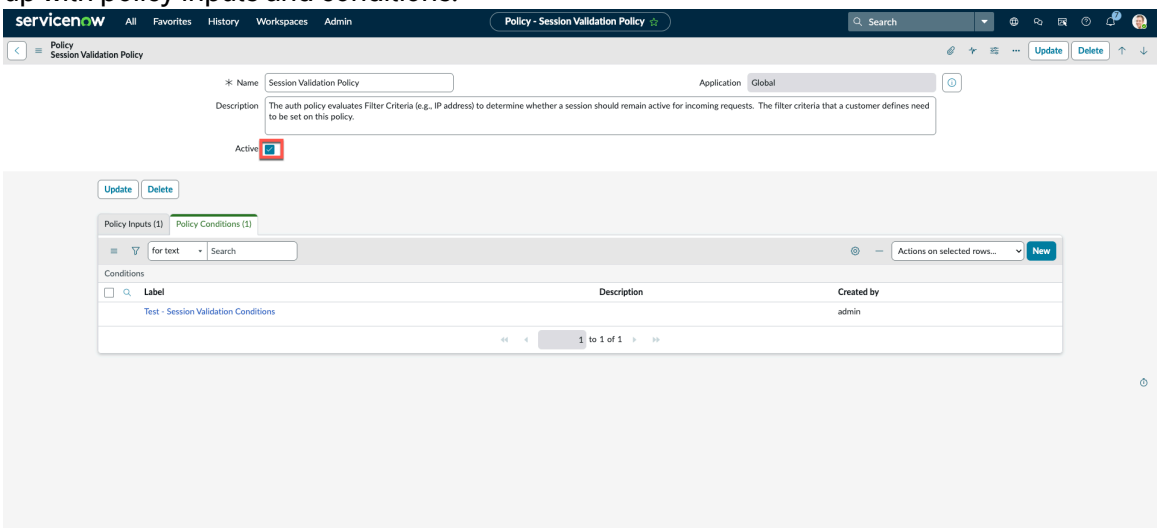
b. Fill the form and set the Condition for the Policy Input.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
You can set the conditions to `true` or `false` based on the configuration of the policy input. In this example, it is set to `true`. Setting the condition to true in this case allows only the user with the configured IP address to log in.

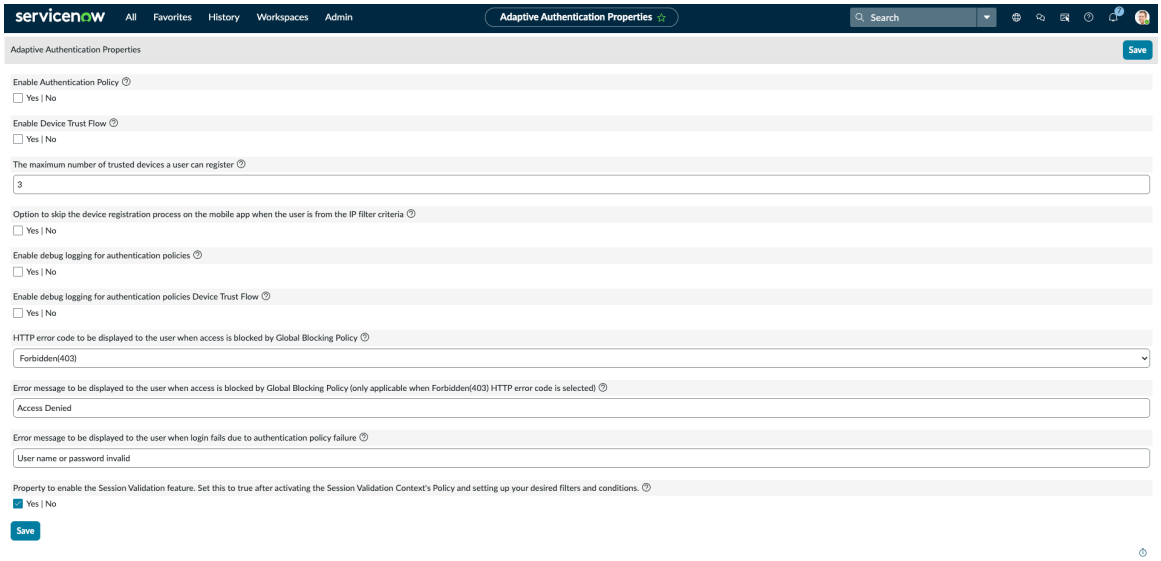


5. Select the `Active` check box to activate the policy after the Session Validation Policy is set up with policy inputs and conditions.



6. Navigate to **All** > **Adaptive Authentication** > **Authentication Policies** > **Properties** and enable the Session Validation property.

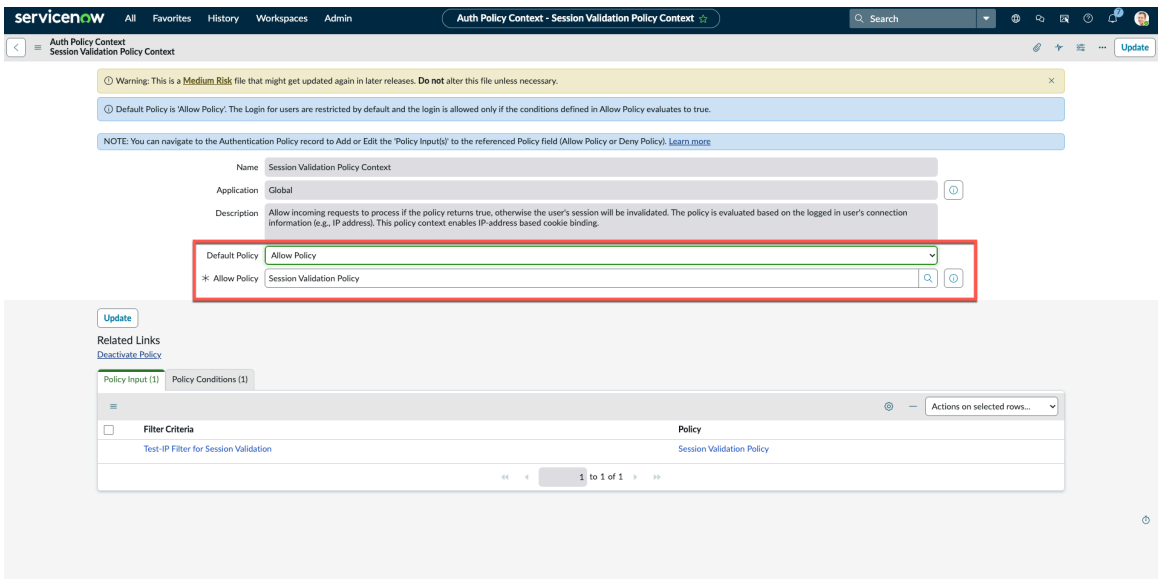
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



7. Navigate to **All** > **Adaptive Authentication** > **Auth Policy Contexts** > **Session Validation Context**.
8. Set the Default Policy to **Allow Policy** or **Deny Policy** to set the session validation context according to the policy input and policy conditions.

Note:
By default:

- The Session Validation context is set to **Allow Policy**.
- Allow Policy is selected as **Session Validation Policy**.
- The Session Validation Context for an authentication policy can only be with **Allow Policy**.



Result

The configuration evaluates the login session based on the following:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Restricts access to the ServiceNow® instance when hijackers copy a user's session cookies from one device to another to impersonate a session.
- Restricts the user's session access if they're using an insecure network.

Authentication policies

Authentication policies evaluate authentication requests based on the specified policy conditions and either allow or deny access depending on the output of policy conditions evaluation. For example, access is allowed only if all the policy conditions specified in **Allow Access Policy** evaluate to true.

Use the built-in authentication policies or create an authentication policy according to your security requirements. You can find the policies on your instance by navigating to **Adaptive Authentication** > **Authentication Policies** > **All Policies**.

Note:
At any point of time, either Allow Access Policy or Deny Access Policy can be executed but not both.

Policy	Description
Allow access policy	Denies all the authentication requests by default. Allows only the authentication requests that match the specified policy conditions.
Allow access pre-auth policy	Allow access pre-auth policy.
Allow non local login users	Choose this policy to allow non-local login users. Used in the context of SSO recovery flows.
Deny access policy	Allows the authentication requests by default. Denies only the authentication requests that match the specified policy conditions.
Global blocking policy	Denies the access requests of users and APIs before authentication. This policy can be used as an alternative to the IP Address Access Control.
Session Validation Policy	The authentication policy evaluates Filter Criteria (For example, IP address) to determine whether a session should remain active for incoming requests. You must set the filter criteria on this policy.
Local login deny policy	Choose this policy to block all local logins. Used in the context of SSO recovery flows.
Step-down MFA policy	Choose **Step-Down MFA Policy** as the default policy in situations where users do not require MFA authentication. When the policy conditions defined in the Step-Up MFA Policy evaluate to true, users are not required to login using MFA.
Step-up MFA policy	Choose **Step-Up MFA Policy** as the default policy to require MFA authentication when the

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Policy	Description
	policy conditions defined in the Step-Up MFA Policy evaluate to true.

Configure an authentication policy

Configure an authentication policy to define inputs and conditions to used to grant access to an instance or enforce multi-factor authentication.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **Adaptive Authentication** > **Authentication Policies** > **All Policies**.

   Note:
   To see examples of completed policies, you can review these policies on your instance:
   - DEMO POLICY - Allow Local Login for Admins from the Trusted IP Range only
   - DEMO POLICY - Allow Local Login for Admins only
   - DEMO POLICY - Restrict Username and Password based Authentication for specific users

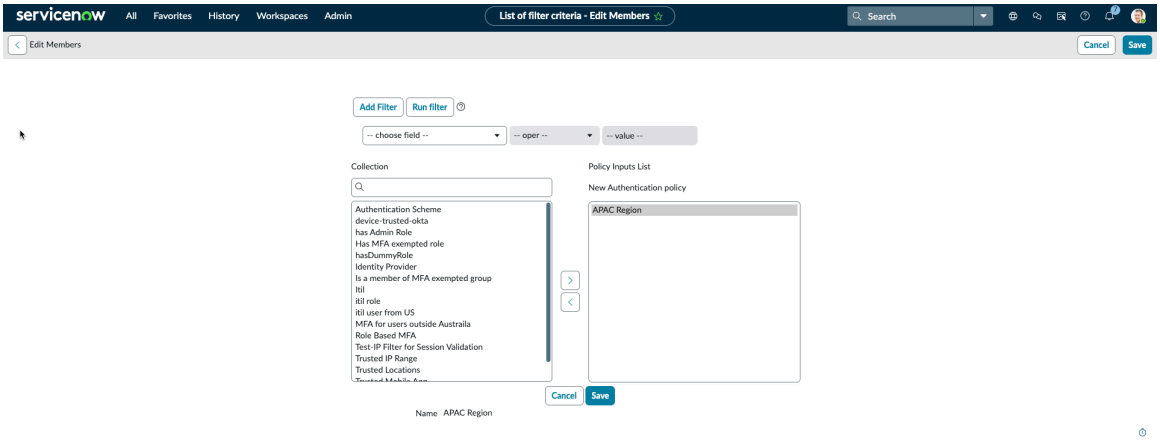
2. Click the **New** button to create a new policy record.
3. In the **Policy** form, fill in the fields.

   Policy form

Field	Description
Name	Name of your policy.
Application	The scoped application for the policy. This field is filled automatically with the current application.
Description	Description of the policy
Active	Whether the policy is active.

4. From the **Policy Inputs** tab, click **Edit**.
5. Select one or more filter criteria from the **Collection** list and move them to **Policy Inputs List** of **Allow Access Policy** list.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Note:
For information on creating your own filter criteria to use in this section, see Filter criteria.

6. From the **Policy Conditions** tab, click **New**.
7. On the form, fill in the fields:

Condition form

Field	Description
Label	Name to identify the condition.
Description	Description of the condition.
Condition	Logical combination of multiple policy inputs (filter criteria) that is used to evaluate authentication requests. For example, you can create conditions that allow only contractors from a list of trusted IP addresses.

8. **Optional:** Repeat step 7 to create additional policy conditions.

Note:
If you create multiple policy conditions, the final output of the access policy depends on the logical OR output of the all policy conditions. This means the policy will evaluate to true if any one of your policy conditions is met.

9. Click **Save**.

Add an authentication policy to an authentication policy context

Add an authentication policy to one of the authentication policy contexts. The authentication context uses the policy inputs and conditions to determine whether uses are granted access to the instance, or whether MFA is enforced for your users.

Before you begin
Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Adaptive Authentication** > **Auth Policy Contexts**, and select one of the entries depending on your needs.

   Pre Authentication Context

   Use the pre-authorization context to evaluate your policy before the user sees the login screen. Users are granted or denied access based on this evaluation.

   Post Authentication Context

   Use the post-authorization context to evaluate your policy after the user enters their login credentials. Users are granted or denied access based on this evaluation. Because this evaluation takes place after the instance identifies the user, policies in this context can make their evaluation based on user data, such as their role or group.

   MFA Context

   Use the MFA context to determine whether a user must use multi-factor authentication when logging in.

   Session Validation Context

   Use the session validation context to evaluate the IP-Address that are set based on the conditions defined as a filter and allows access to the instance within a session.

2. In the **Default Policy** field, select a value.
   The value in this field determines how the context uses the outcome of your policy's conditions.

   The available options in this field depend on the selected context. For details on these contexts, see Authentication policy contexts.

3. Assign a policy to the context.
   The name of the field depends on which context you have selected.

   Pre-authentication and Post-authentication context

   These contexts have a **Deny Policy** or **Allow Policy** field, depending on the selection in the **Default Policy** field.

   MFA context

   This context has a **Step-Up MFA Policy** or **Step-Down MFA Policy** field, depending on the selection in the **Default Policy** field.

   Session validation context

   This context has a **Allow Policy** or **Deny Policy** field, depending on the selection in the **Default Policy** field.

4. Click **Update**.
   After updating the record, you can see your policy's inputs and conditions in the **Policy Input** and **Policy Conditions** tabs.

Adaptive Authentication Events

You can use the adaptive authentication events table to know about the events.

Following are some of the logs that can be tracked in the adaptive authentication events table:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- `glide.adaptive.auth.log.success.event`: To know the `success` events for Post Auth, API logins.
- `glide.adaptive.auth.log.mfa.relax.event`: To know the `mfa_relaxation` events for MFA Context.

Note:

- For Pre-Auth Context, Rest API Access policies of type "`pre_auth`": By default `Failure` events are logged. `Success` events `can't` be logged.
- For Post Auth Context, Rest API Access policies of type other than "`pre_auth`": By default `Failure` events or logged. For `Success` events to log, you need to enable the `glide.adaptive.auth.log.success.event` property.
- For MFA: By default `MFA Enforcement` events are logged.
- For MFA Relaxation events to log, you need to enable the `glide.adaptive.auth.log.mfa.relax.event` property. `MFA Relaxation` would log the same event as `MFA Enforcement`, but with the `Result` Field populated with `False`.

Configure adaptive authentication properties

After activating Adaptive Authentication, configure adaptive authentication properties according to your security requirements.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **Adaptive Authentication** > **Authentication Policies** > **Properties**.
2. Configure these properties:

Adaptive Authentication Properties

Property	Description	Value
Enable Authentication Policy (glide.authenticate.auth.policy.enabled)	Option to enable the authentication policy.	Yes | No
Enable debug logging for authentication policies (glide.authenticate.policy.debug)	Option to enable debug logging for the authentication policies.	Yes | No
HTTP error code to be displayed to the user when access is blocked by Global Blocking Policy (glide.authenticate.global.blocking_policy.login_code)	HTTP error code that displays during login when the Global Blocking Policy blocks a user	Select from: ○ Forbidden(403) ○ Not Found(404)
Error message to be displayed to the user when access is blocked by Global Blocking Policy (only applicable when Forbidden(403) HTTP error code is selected) (glide.authenticate.global.blocking_policy.error_message)	Error message that displays when the Global Blocking Policy blocks access.	Text field
Enable Device Trust Flow (glide.authenticate.preauth.allow.trusted.device)	Option to enable the trusted device flow.	Yes | No

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property	Description	Value
Maximum number of trusted device a user can register (glide.trusted.device.max.count)	It is the maximum number of trusted device a user can register.	Text field
Skip the device registration for device trust flow if the user is from the trusted network (glide.authenticate.preauth.skip.user.registration)	Option to skip registration if the user is trying to register from the trusted network	Yes | No
Property to enable the Session Validation feature. Set this to true after activating the Session Validation Context's Policy and setting up your desired filters and conditions (session.validation.enabled)	Option to enable the Session Validation feature. Set this to true after activating the Session Validation Context's Policy and setting up your desired filters and conditions.	Yes | No

Tutorial: Configure adaptive authentication

Use these example steps to configure adaptive authentication on an instance.

To use this tutorial, you must have an instance with Adaptive Authentication activated. For details on this process, see Activate adaptive authentication.

The example guides you through creating a new policy and applying it to an instance. In this tutorial you will:

Create a filter criteria record

Create a group filter criteria record to use as an input for your policy. This record allows your policy to determine access based on a user's group. In these steps you define the group or groups the policy uses to determine access.

Create a policy

Create a policy that determines whether a user can access the instance. This policy uses the group filter criteria record you create as an input. In these steps you also define policy conditions that define how the policy uses the policy input to determine user access.

Configure a policy context

Configure the **Post Authentication Policy Context** to use your new policy. When configured, your instance denies access to users within the group defined in the filter criteria record.

Create a filter criteria record

Learn how to create a criteria record to use as a policy input for your adaptive authentication policy.

Before you begin

Role required: admin

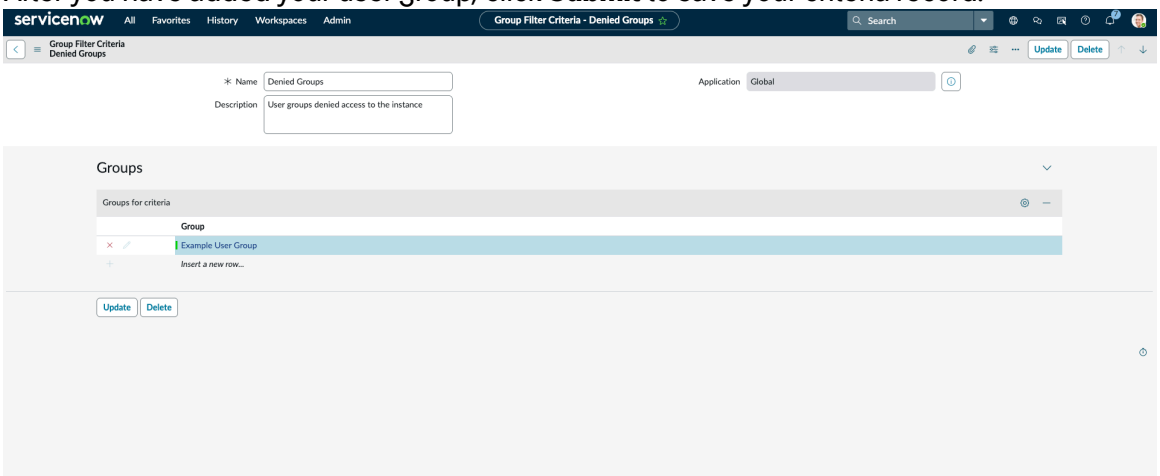
To deny access to your instance based on user groups, you must create a group filter criteria record. This record defines a user group or a set of user groups that your policy can grant or deny access. In this example, you will create a group filter criteria record for a single user group.

For details on user groups and how they are used in your instance, see Exploring user administration.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Adaptive Authentication** > **Filter Criteria** > **Group Criteria**.
2. Click **New** to create a new record.
3. In the **Name** field, enter a name for your record.
   For example, `Denied Groups`.
4. In the **Description** field, enter a brief description.
   For example, `User groups denied access to the instance`.
5. In the **Groups for criteria** list, double-click **Insert a new row...**.
6. Enter the name of a user group, or click the reference icon ( ) to select a group from a list.
   If you want to create a new user group for your filter criteria, click the reference icon ( ), and then click the **New** button. For more details on creating user groups, see Create a user group.
7. After you have added your user group, click **Submit** to save your criteria record.



Create a policy

Learn how to create a policy to deny access to user groups defined in your group filter criteria.

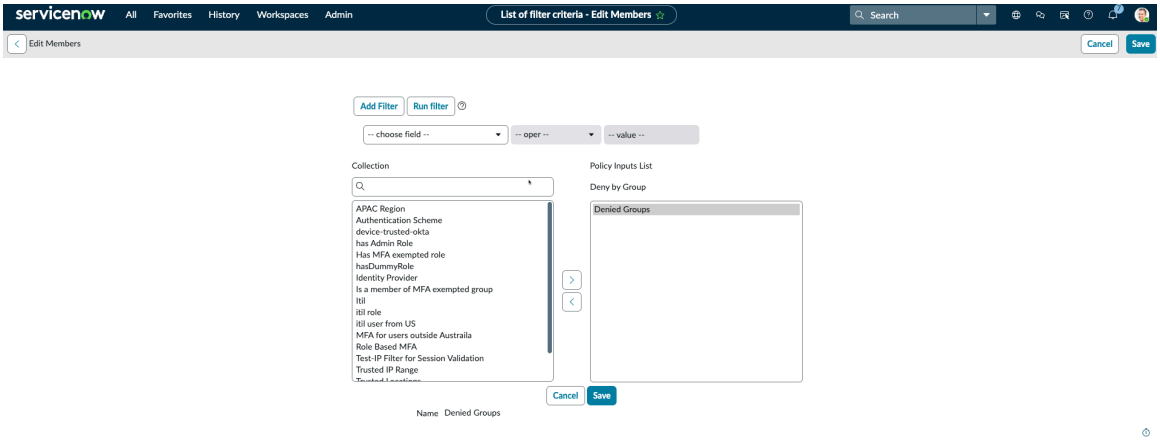
Before you begin

Role required: admin

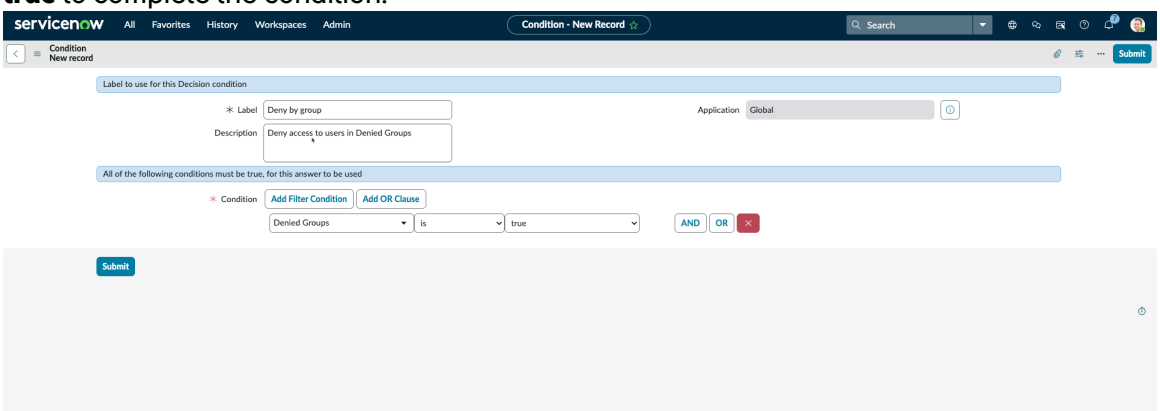
Procedure

1. Navigate to **All** > **Adaptive Authentication** > **Authentication Policies** > **All Policies**.
2. In the **Policies** list, click **New**.
3. In the **Name** field, enter a name for your record.
   For example, `Deny by Group`.
4. In the **Description** field, enter a brief description.
   For example, `User groups denied access to the instance`.
5. Right-click the form header and click **Save**.
   After saving, the **Policy Inputs** and **Policy Conditions** lists display on the form.
6. In the **Policy Inputs** list, click **Edit**.
7. In the list collector, add the filter criteria created in the previous steps to your policy.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



8. Click **Save**.
   The instance saves the policy input and displays the policy record displays again.
9. In the **Policy Conditions** list, click **New**.
10. In the **Label** field, create a label for this condition, for example `Deny by group`.
11. In the **Description** field, enter a brief description.
    For example, `Deny access to users in Denied Groups`.
12. In the **Condition** field, select the filter criteria you created in previous steps, then select **is**, and **true** to complete the condition.



13. Click **Save**.

Configure a policy context

Configure the Post Authentication Policy Context to use your new policy. When configured, your instance denies access to users within the group defined in the filter criteria record.

Before you begin

Role required: admin

Procedure

1. **Adaptive Authentication** > **Auth Policy Contexts** > **Post Authentication Context**.
   You must use the **Post Authentication Context** because the policy used in this tutorial must evaluate what group a user is in. This information is only available after enters their credentials.
2. In the **Default Policy** field, select `Deny Policy`.
   This selection grants access to users by default, and only denies access when the policy conditions evaluate to true.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. In the **Deny Policy** field, select the policy you created the previous steps.
4. Click **Update** to save the policy context record.

Adaptive Authentication for Trusted Mobile Apps

Access your ServiceNow from untrusted networks by using the Now Mobile app.

Adaptive Authentication for Trusted Mobile Apps

Adaptive Authentication for Trusted Mobile Apps enables users to access the ServiceNow instance using the Now Mobile app. The instance is protected behind a trusted IP network boundary.

The following are some of the scenarios where you need access to the instance while you are outside your network.

As an employee, you require access the Now Mobile app and Employee Service Center (portal) from outside the network. The Trusted mobile app filter enables you to identify the incoming request originating from a trusted Now Mobile app that is linked to a user account.

As an admin, you can configure the policy. The policy enables users to register their mobile devices and access the instance on a trusted network.

As a user, you can register your mobile device by scanning the QR displayed on the instance. After the registration, you can log in to your instance from the Now Mobile app, using your credentials.

Note:
To register the mobile device, you must be on a trusted network. After the registration, you can log in to the instance from other networks as well.

Features

As an admin, you can use the following features:

- Configure policies by using trusted app filter criteria.
- Create policy conditions with a new filter criteria for trusted mobile apps.
- Support all login methods on the trusted mobile app for the users (Local login, SAML, OIDC, and MFA).
- Revoke a trusted device.
- Add security events for all device registration or revocation actions. The events can be used to notify the user.
- Support security events for signature failures, cookie validation failures, invalid tokens, invalid headers, or query parameters.
- Control the maximum number of registered devices.
- Prevent a new device registration, unless the user removes an existing-paired device.
- Capture the last time that a device was used.

Activate Trusted Mobile App

Activate Adaptive Authentication with Trusted Mobile app by using the authentication policy and filter conditions.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

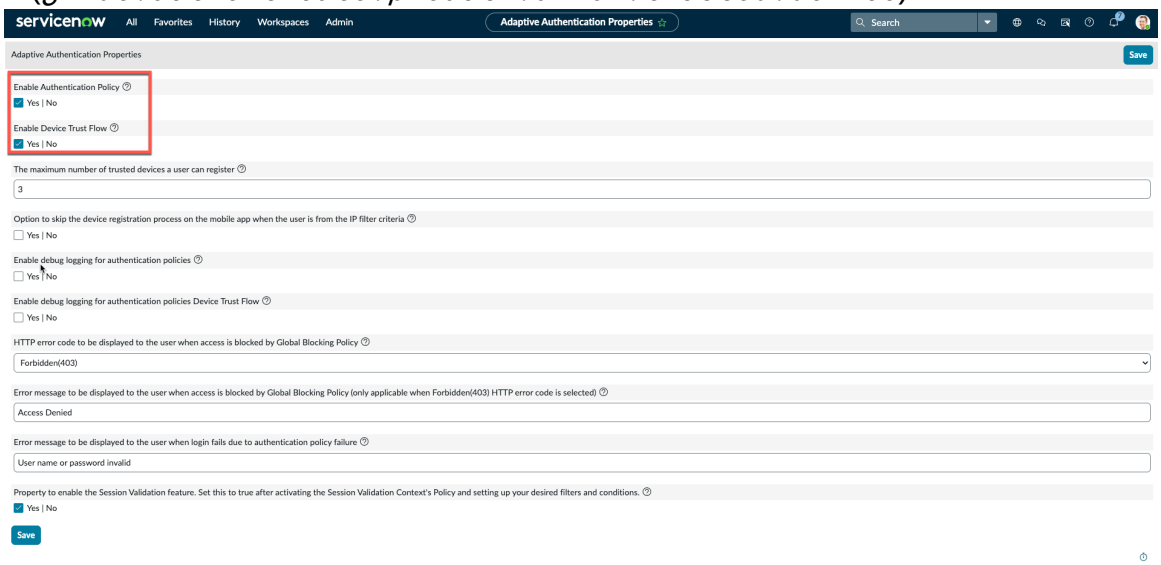
Before you begin

Make sure the Adaptive Authentication (*com.snc.adaptive_authentication*) plugin is installed.

Role required: admin

Procedure

1. Navigate to **All** > **Adaptive Authentication** > **Authentication Policies** > **Properties**.
2. On the Adaptive Authentication Properties page, enable the following properties:
   - Enable the Authentication Policy (*glide.authenticate.auth.policy.enabled*)
   - Enable Device Trust Flow (*glide.authenticate.preauth.allow.trusted.device*)



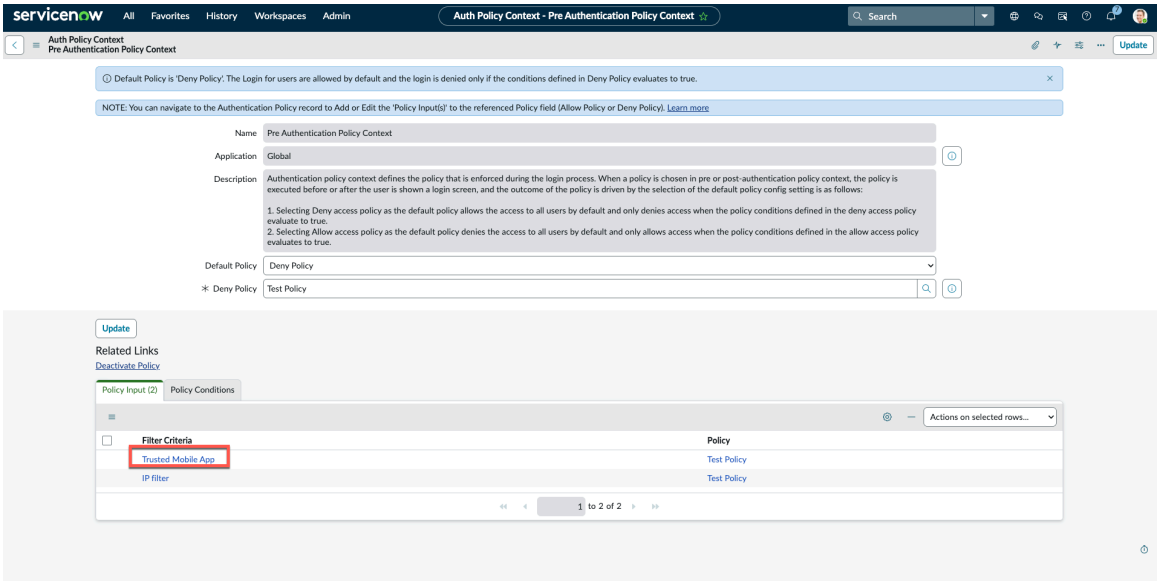
> **Note:**
> To disable the device trust flow property, you must remove the conditions with trusted mobile filter. Otherwise, an error message is displayed to remove the conditions.

3. Navigate to **All** > **Adaptive Authentication** > **Auth Policy Contexts** > **Pre Authentication Context**.
4. Define the conditions in the Pre Authentication context.
   For more information, Pre authentication context.

> **Note:**
> By default, the policy condition is **Deny Policy**. You can change to **Allow Policy**. These policies are direct opposites.
>
> - With the **Allow Policy**, all users are denied access by default, and it only allows access when the allow access policy conditions are true.
> - With the **Deny Policy**, all users are allowed access by default, and it only denies access when the deny access policy conditions are true.

In the Policy Input, the policy input **Trusted Mobile App** is a policy input for the trusted mobile app.

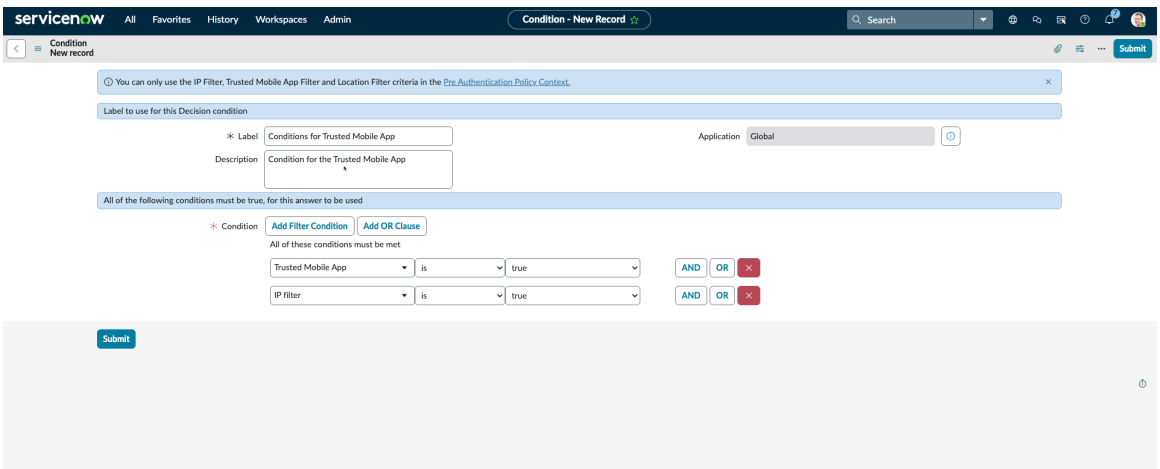
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



5. In the Policy Conditions, create the condition by clicking **New**.
6. On the form, fill the fields.

Filter Condition form

Field	Description
Label	Name of the condition
Description	Description of the condition
Application	Application scope for this record.
Condition	Conditions based on AND and OR. Because the Auth Policy is **Allow Policy**, the condition for Trusted Mobile App is set true in the example shown on the image.



7. Click **Submit**.

Result

The policy input and filter conditions are created for the Trusted Device feature. Users can proceed with using the Trusted Device feature to access the ServiceNow instance from untrusted networks by using the Now Mobile app. For more information, see Register a trusted device.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Register a trusted device

Register a trusted device to access the ServiceNow instance outside the network.

Before you begin

You must be in the trusted network to perform the trusted device registration.

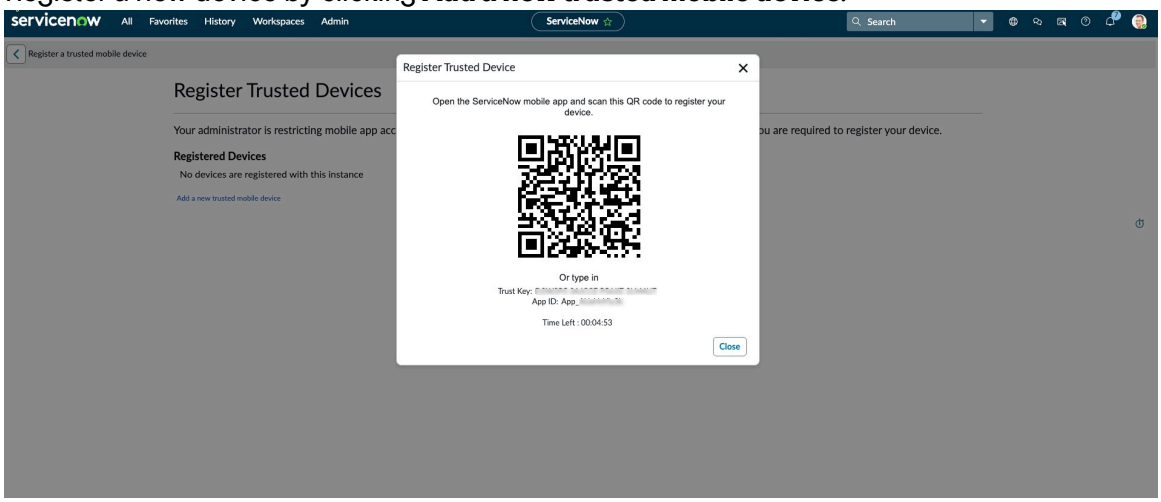
Role required: none

Procedure

1. Navigate to one of the following menu options:
   - On the ServiceNow AI Platform, navigate to **All** > **Self-Service** > **My Profile**.

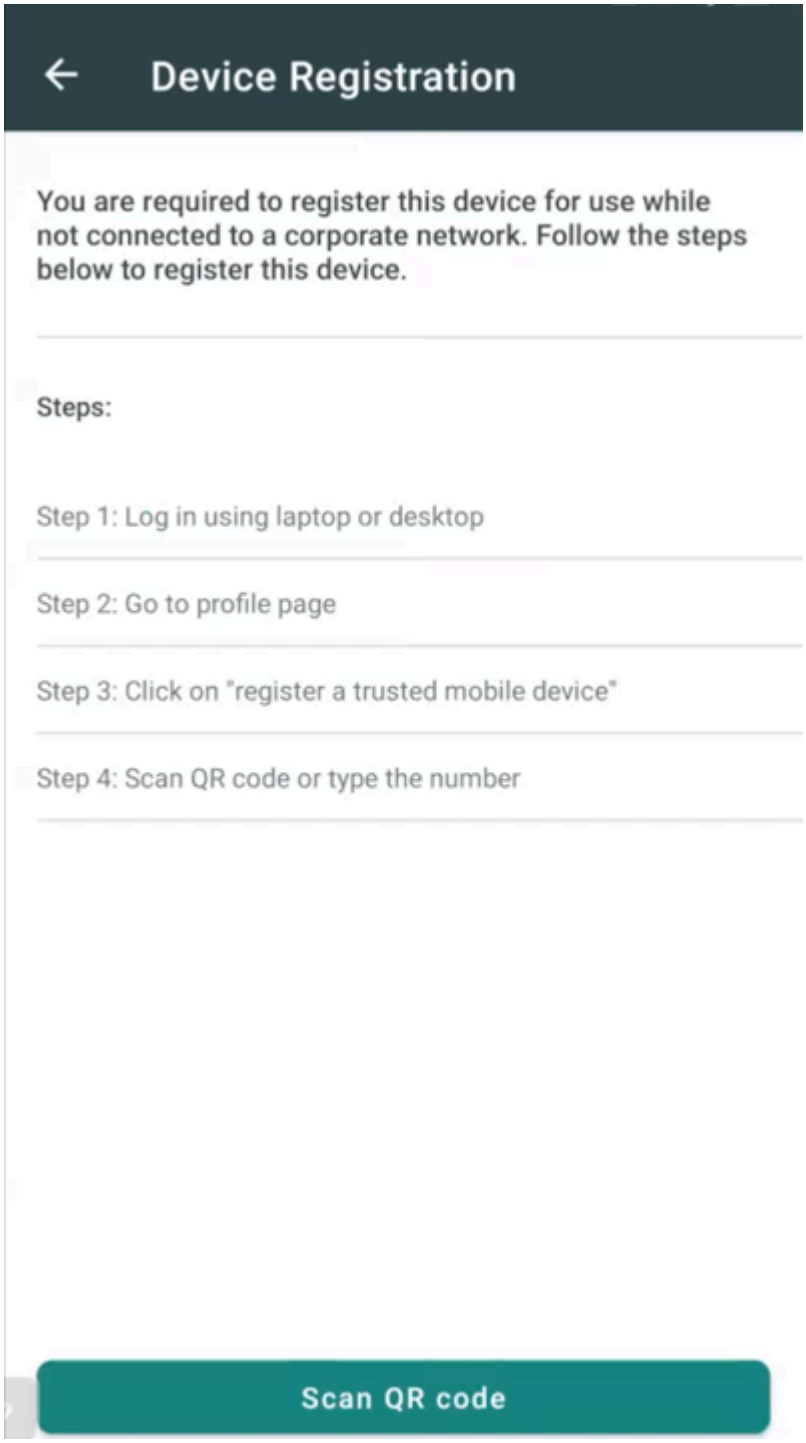
     Note:
     You can also access your profile by clicking your user name in the instance header.

   - On the Now Support, click the profile and select **Trusted Device**.
2. In your user profile, click **Register a trusted mobile device** in the Related Links section.
   The Register Trusted Devices page is displayed.
3. Register a new device by clicking **Add a new trusted mobile device**.



4. In the Device Registration screen on your ServiceNow mobile app, tap the **Scan QR code** button and scan the QR code that is displayed on your laptop or desktop.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

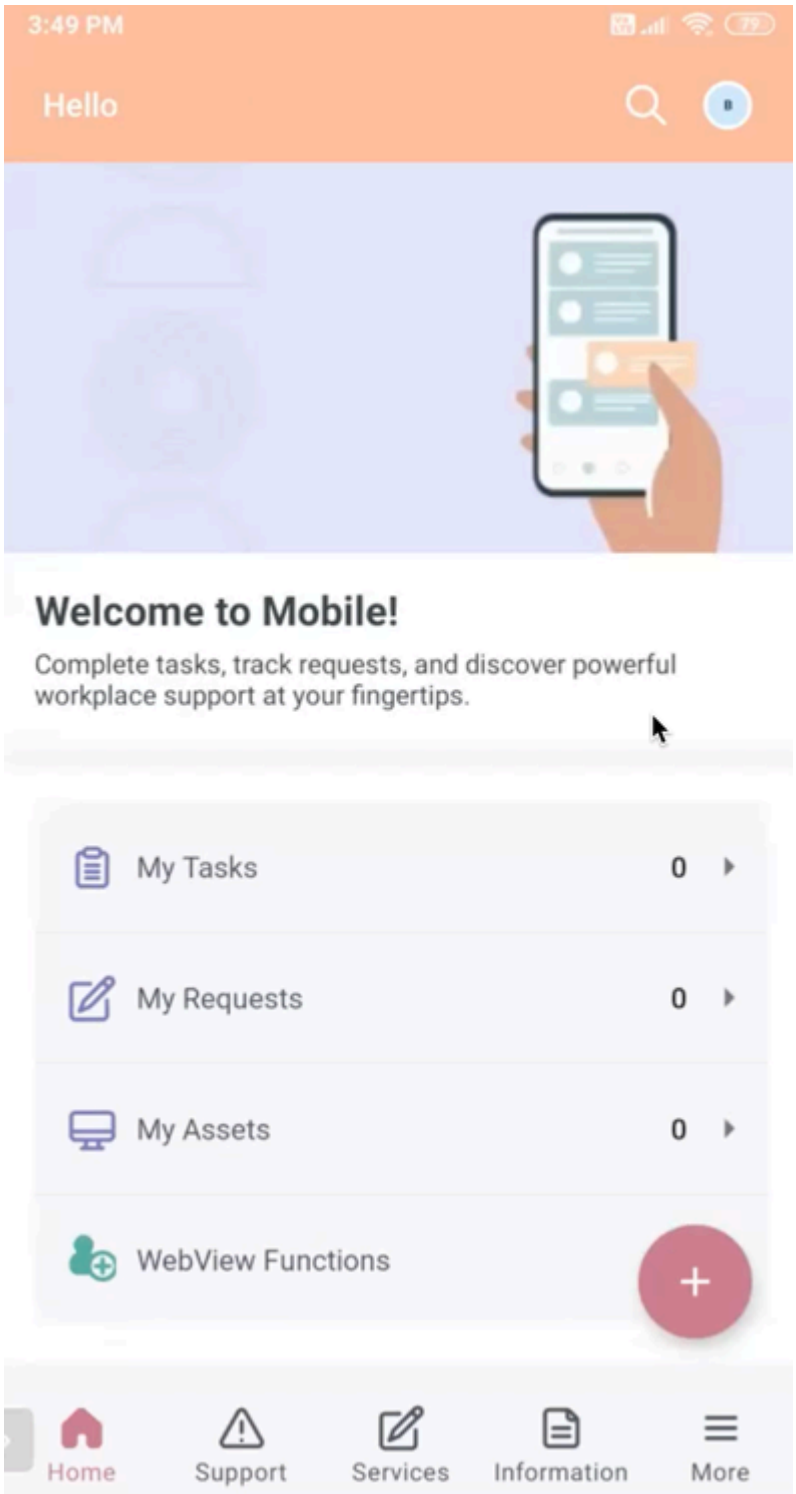


The Registration process will complete and you will be prompted to your login page to complete your authentication.

5. Specify your credentials and log in to the Now Mobile app.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The mobile home screen is displayed.



Result

In the Register Trusted Devices page on your laptop or desktop, the registered device is displayed. You can use the icon if you want to remove the registered device from the page.

What to do next

Navigate to **All** > **Adaptive Authentication** > **Device Trust** > **Device Registration** to view all the details of the registered device.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Manage your trusted device

Manage your trusted device from the Trusted Device registration page.

Before you begin

Role required: none

Procedure

1. Navigate to one of the following menu options:
   - On the ServiceNow AI Platform, navigate to **All** > **Self-Service** > **My Profile**.

     Note:
     You can also access your profile by clicking your user name in the instance header.

   - On the Now Support, click the profile and select **Trusted Device**.
2. In your user profile, click **Register Trusted Device** in the Related Links section.
   The Register Trusted Devices page is displayed.
3. On the Register Trusted Devices page, remove the device by clicking the icon.

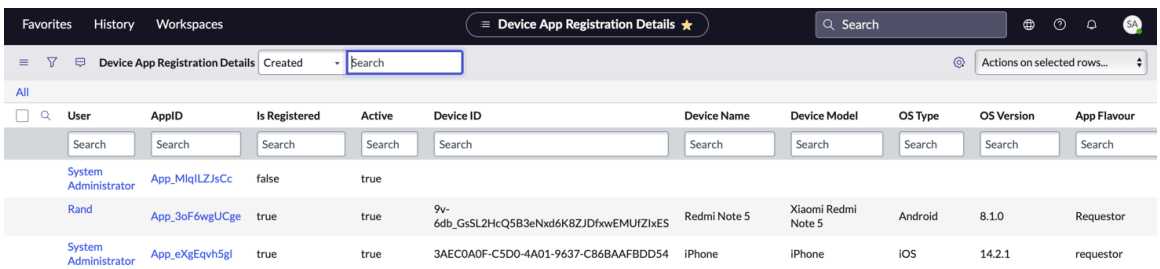
Note:
The deleted mobile device must be registered again to access the instance.

Registration details of registered devices

View the details of devices that are registered with your ServiceNow instance.

To view all the details of the registered device with the instance, navigate to **All** > **Adaptive Authentication** > **Device Trust** > **Device Registration**.

Use the filter to identify the device. Click the **AppID** field to know more about the registered device.

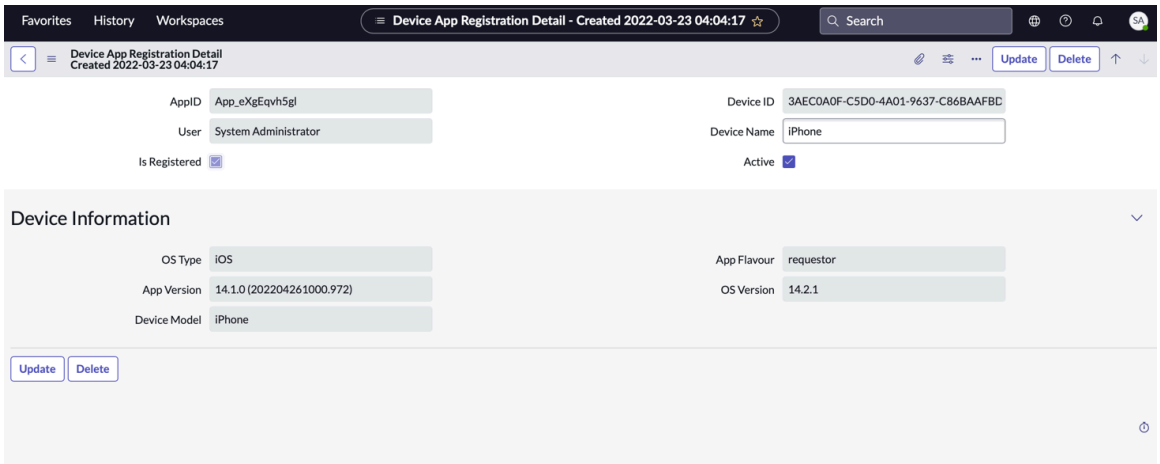


The following details are displayed for the device:

- AppID
- Device ID
- User
- Device Name
- Device Information such as:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- OS Type
- App Flavour
- App Version
- OS Version
- Device Model



Trusted Mobile App troubleshooting

Review these troubleshooting scenarios to resolve issues with Trusted Mobile App.

The following sections describe some troubleshooting scenarios and ways to troubleshoot.

Time difference between instance and mobile (clock-skew)

If there is a clock-skew, you can adjust or reset the clock on your mobile device for using the Trusted device.

QR code expiry within five minutes

The QR code for Trusted device feature expires within five minutes. In such a case, you can click for a new QR code.

Note:
The QR code expiry can be extended. To extend the code expiry, contact your admin.

System property has changed

If the system property has changed, verify the registration based on the system property for the valid credential that can be used for login.

Maximum device registered

If the maximum number of device registrations is reached, remove the existing device or contact your admin to change the maximum device count.

API authentication

Authentication configurations for API.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

API based Authentication in ServiceNow®'s validates the identity of a user who accesses an instance, and then authorizes the user to features that match the user's role or job function while making an API call to the ServiceNow® instance.

Following are the types of API Authentication in ServiceNow®:

- Certificate based authentication
- OAuth
- Token-based authentication

Certificate based authentication

Certificate-based authentication lets you mutually authenticate inbound API requests using certificates from a trusted Certificate Authority (CA).

Certificate-based authentication for Inbound web services

Authenticate inbound requests to ServiceNow SOAP and REST APIs. To set up mutual authentication for inbound web services, see Set up Certificate-based authentication.

OAuth

OAuth based authentication validates the identity of the client that attempts to establish a trust on the system by using an authentication protocol.

OAuth 2.0 - Open Authorization is the industry-standard protocol for authorization, that ocuses on client developer simplicity while providing specific authorization flows for web applications, desktop applications, and mobile devices.

Inbound

Create an endpoint for external clients that want to access your instance. This creates an OAuth client application record and generates a client ID and client secret that the client needs to access the restricted resources on the instance. For more information see, OAuth inbound.

Token-based authentication

Token-based authentication for inbound REST APIs configuration using API Key or HMAC.

Support API tokens for REST API end points so that the ServiceNow® for the user authentication.

Token-based authentication for inbound REST APIs configuration can be performed on the ServiceNow® instance with the API Key or HMAC token.

API Key and HMAC Authentication for inbound REST APIs

Support API tokens for REST API endpoints so that the ServiceNow® user name and password isn't visible in the webhook URL.

Enable API key-based authentication to securely authenticate inbound webhook URL.

To use the API Key and HMAC Authentication, you must install the (Plugin: `com.glide.tokenbased_auth`) in the ServiceNow® instance.

Warning:
Use **POST** request when submitting any sensitive information to the server.

Installing API Key and HMAC Authentication has dependencies on the following plugins:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- REST API Auth Scope Plugin (`com.glide.rest.auth.scope`)
- REST API Access Policy Plugin (`com.glide.rest.policy`)
- Authentication scope (`com.glide.auth.scope`)

Benefits

API Key and HMAC Authentication for inbound REST APIs enables:

- Ability to specify API key or HMAC token for REST API authentication.
- Ability to associate a user account with the API key or HMAC token.
- Ability to specify a token as query parameter or header within the REST API call.
- Ability to associate authentication scope with API key or HMAC token configurations so that API keys can only be used to invoke APIs associated with a particular scopes.
- Ability to associate an API key or HMAC token configuration with an authentication profile that can be used in API access policies.

Activate API Key and HMAC Authentication

You can activate the plugin API Key and HMAC Authentication (`com.glide.tokenbased_auth`) in your ServiceNow® instance.

Before you begin

Role required: admin.

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the API Key and HMAC Authentication plugin (`com.glide.tokenbased_auth`) using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

   Note:
   When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

   You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Configure API key - Token-based authentication

Configure an API key to support authentication for REST API endpoints.

Before you begin

Role required: admin

Plugin required: API Key and HMAC Authentication (`com.glide.tokenbased_auth`)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Create an inbound authentication profile.

   a. Navigate to **All** > **System Web Services** > **API Access Policies** > **Inbound Authentication Profiles**.

   b. Select **New**.
   The system displays the message `What kind of authentication profile?`

   c. Select **Create API Key authentication profiles**.

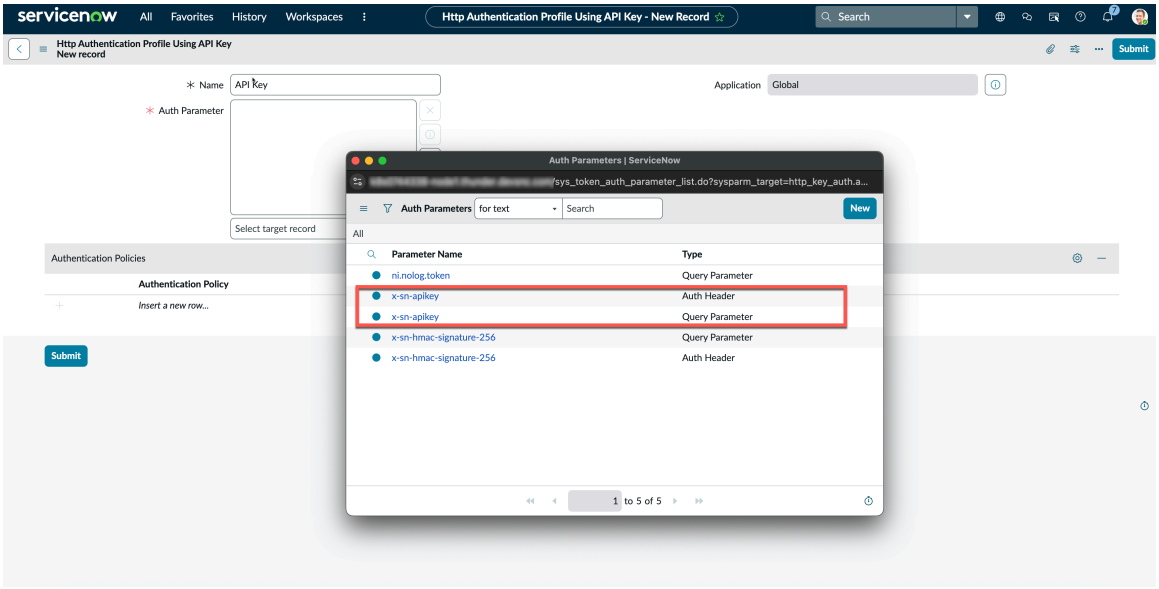
   d. On the form, fill in the fields.

API Key authentication profiles

Field	Description
Name	Name to identify the authentication policy.
Application	Scope of the authentication policy.
Auth Parameter	Select the auth parameter for the authentication request. You can select the default options or create a new auth parameter: ▪ x-sn-apikey: Auth Header ▪ x-sn-apikey: Query Parameter header

Note:
The selected option has to be defined in the REST call in the Auth Header or Query Parameter.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Note:
If you wish to add a prefix for the API-Key, Open the Auth Parameter file that you have selected and specify the **Prefix** field.

e. Submit the form.

2. Create a REST API key.

a. Navigate to **All** > **System Web Services** > **API Access Policies** > **REST API Key**.

b. Select **New**.

c. On the form, fill the fields:

API Key

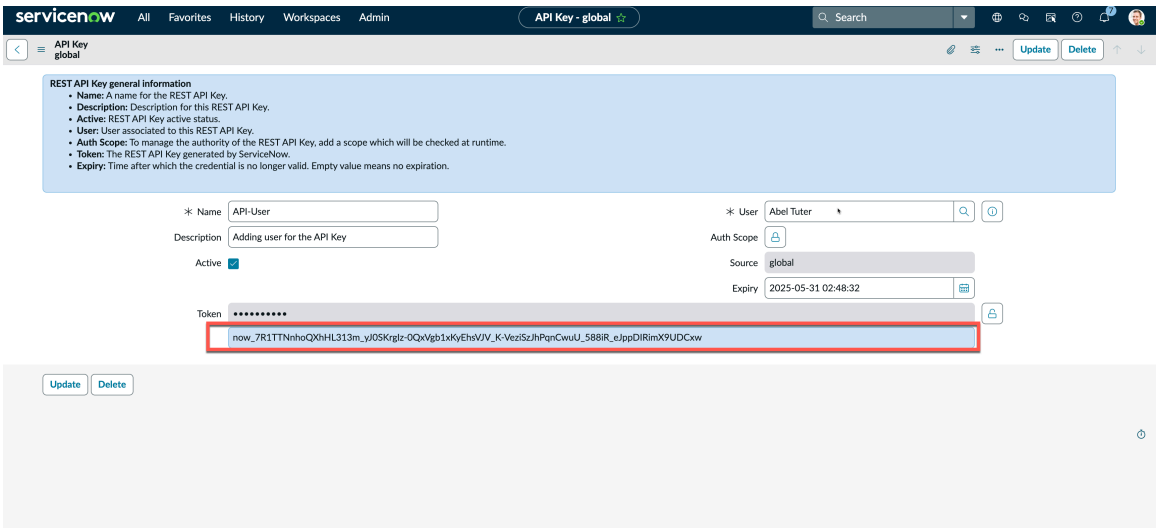
Field	Description
Name	Name to identify the REST API Key
Description	Description for the REST API Key.
Active	Status of the REST API Key.
User	User associated to the REST API Key. Use the look-up icon to select the user.
Auth Scope	Option to add auth scope to manage the authority of the REST API Key.
Token	The REST API key generated by the ServiceNow AI Platform. Copy the key to use as part of the REST API call within the Header or Query parameter.
Expiry	Time after which the credential is no longer valid. Empty value means no expiration.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Note: For more information, about expiry of token, see Cleaning up token Expiry .

d. Submit the form.

e. Open the record that was created to view the token generated by the ServiceNow AI Platform for the user.



3. Create a REST API Access policy.

a. Navigate to **All** > **System Web Services** > **REST API Access Policies**.

b. Select **New**.

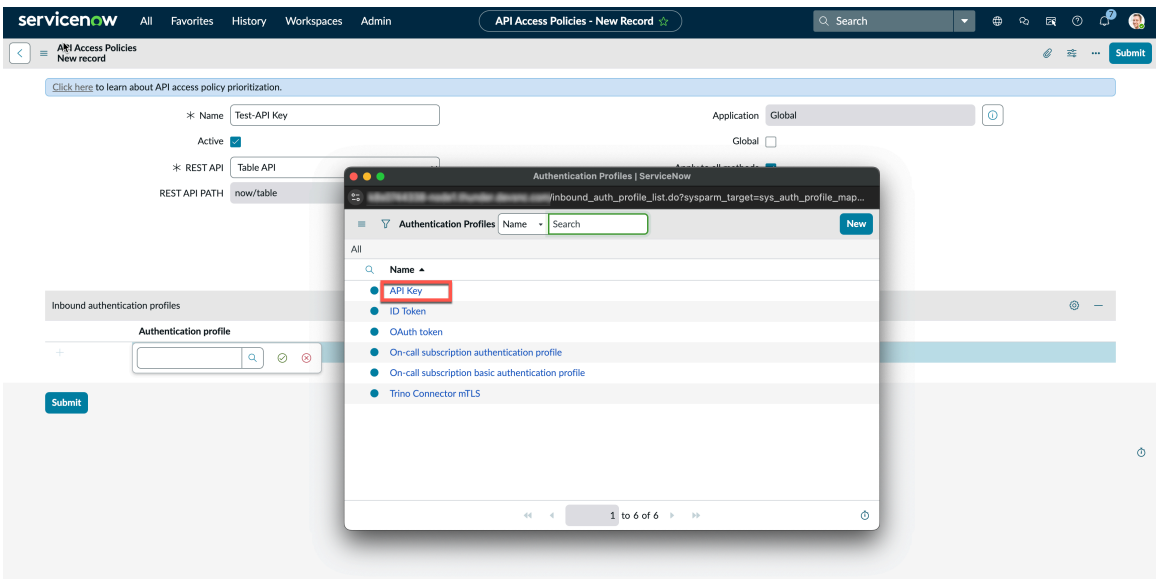
c. On the form, fill in the fields.

API Access Policies

Field	Description
Name	Unique name of the API access policy.
Active	Option to make the API access policy active.
REST API	The REST API to which the access policy is applied. For example, **Attachment API**.
REST API PATH	API path of the REST API. This field is auto-populated based on the selected REST API. For example, **now/attachment**.
HTTP Method	Method used for interacting with the API. This field is auto-populated based on the selected REST API.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Version	Version of the API. For example, **v1**. This field is auto-populated based on the selected REST API. **Note:** If you want to create an authentication policy for all versions of a REST API, you must create individual policies for each version.
Resource	Child resource of the REST API. This field is auto-populated based on the selected REST API. For example, **/now/attachment**
Application	Scope of the application.
Global	Enable this field to apply auth policy to all methods, versions, and resources for the API. **Note:** Token Based Auth isn't allowed in the Global REST API Policy.
Apply to all methods	Enable this field to apply the auth policy for the API to all the methods, versions, and resources for the API.
Apply to all resources	Enable this field to apply the auth policy for the API to all the versions.
Apply to all versions	Enable this field to apply the auth policy for the API to all the resources.



d. Add the API Authentication profile that was created.

e. Submit the form.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

You can send the REST API call with the x-sn-apikey (token) that was generated by the ServiceNow AI Platform during the API Key creation within the Header or Query parameter based on the configuration for authentication.

Warning:
Use **POST** request when submitting any sensitive information to the server.

Configure HMAC - Token-based authentication

Configure HMAC to support authentication for REST API endpoints.

Before you begin
Role required: admin

Plugin required: API Key and HMAC Authentication (`com.glide.tokenbased_auth`)

Note:
While configuring the HMAC, ensure the name of the script that starts with HMAC to populated in the script list view.

Procedure

1. Create an HMAC configuration.

   a. Navigate to **All** > **System Web Services** > **API Access Policies** > **HMAC Configuration**.

   b. Select **New**.

   Note:
   You can also use the **Default HMAC SHA256 Base64 Encoding** which is created when installing the plugin.

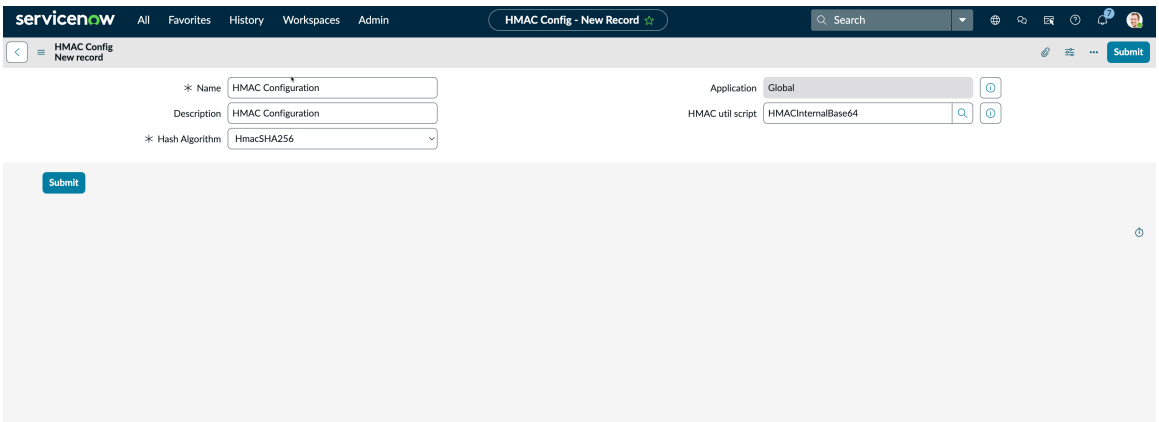
   c. On the form, fill the fields:

HMAC Configuration

Field	Description
Name	Name for the HMAC configuration.
Application	Scope of the configuration.
Description	Detailed description about the configuration.
Hash Algorithm	Choose the Hash Algorithm. Options available: ▪ HmacSHA256 ▪ HmacSHA384 ▪ HmacSHA512
HMAC util script	Utility script for HMAC.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Note: If you validate HMAC authentication using Request body, Time stamp and Secret with no Key Id, then do the following: ▪ Create a customized script include as HMAC util script ▪ Use that script include util to interpret the passed in timestamp, and request body. For every shared secret created in the ServiceNow® instance, there is a key ID. You need to configure the key ID into Default key id in HMAC auth profile.



d. Submit the record.

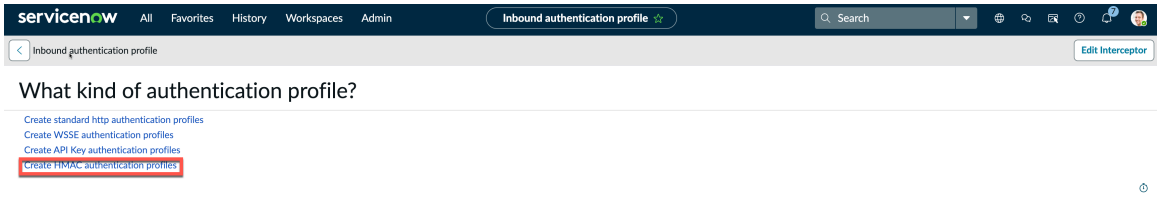
2. Create an inbound authentication profile.

a. Navigate to **All** > **System Web Services** > **API Access Policies** > **Inbound Authentication Profiles**.

b. Select **New**.
The system displays the message `What kind of authentication profile?`

c. Select **Create HMAC authentication profiles**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



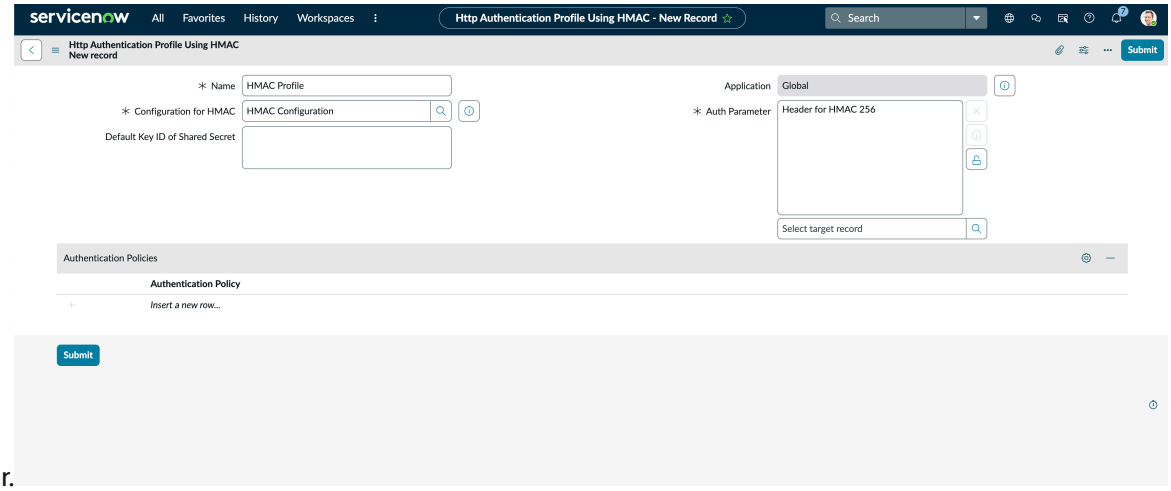
d. On the form, fill in the fields.

HMAC authentication profiles

Field	Description
Name	Name to identify the authentication policy.
Application	Scope of the authentication policy.
Configuration for HMAC	Select the HMAC configuration that was created.
Auth Parameter	Select the auth parameter for the authentication request. You can select the default options or create a new auth parameter: ▪ x-sn-hmac-signature-256: Auth Header ▪ x-sn-hmac-signature-256: Query Parameter
Default Key ID of Shared Secret	The token information that can be updated in this field for using HMAC.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
The selected option has to be defined in the REST call as part of the Auth Header or Query Parameter.



e. Submit the form.

3. Create an HMAC secret.

a. Navigate to **All** > **System Web Services** > **API Access Policies** > **REST API HMAC Secret**.

b. Select **New**.

c. On the form, fill the fields:

REST API HMAC Secret

Field	Description
Name	Name to identify the REST API HMAC secret.
Description	Description for the REST API HMAC secret.
Active	Status of the REST API HMAC secret.
User	User associated to the REST API HMAC secret. Use the look-up icon to select the user.
Key ID	Key ID that must be sent as part of the REST call. Key ID is generated after submitting the form.
Shared Secret	Shared secrets of the user. For example, the password.
Source	Source of the record.
Expiry	Time after which the credential is no longer valid. Empty value means no expiration.

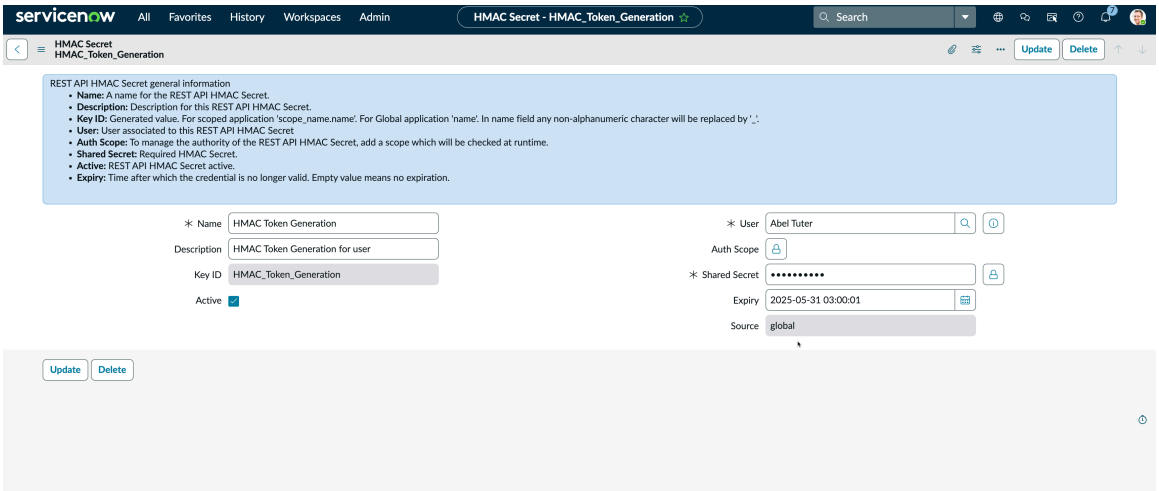
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Note: For more information, about expiry of token, see Cleaning up token Expiry .

d. Submit the form.

e. Open the record that was created.

Find the Key ID generated by the ServiceNow AI Platform for the user.



Note: You can add the Key ID that was generated during the Key ID in the Authentication Profile that was created for HMAC if you don't want to specify the Auth or Query parameter for the API call.

4. Create a REST API access policy.

a. Navigate to **All** > **System Web Services** > **REST API Access Policies**.

b. Select **New**.

c. On the form, fill in the fields.

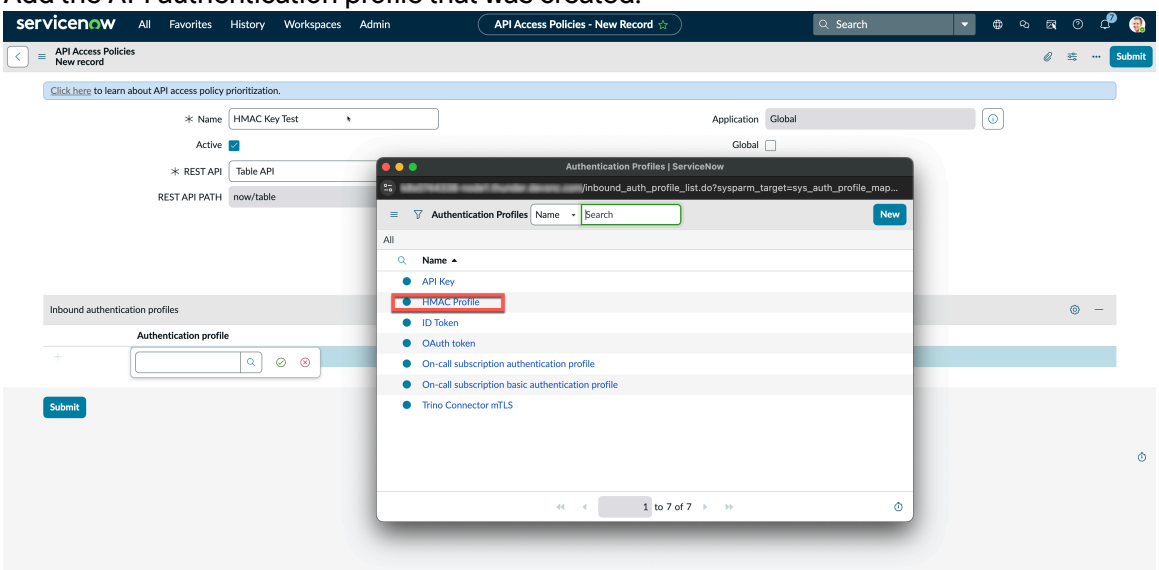
API Access Policies

Field	Description
Name	Unique name of the API access policy.
Active	Option to make the API access policy active.
REST API	The REST API to which the access policy is applied. For example, **Attachment API**.
REST API PATH	API path of the REST API. This field is auto-populated based on the selected REST API. For example, **now/attachment**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
HTTP Method	Method used for interacting with the API. This field is auto-populated based on the selected REST API.
Version	Version of the API. For example, **v1**. This field is auto-populated based on the selected REST API. **Note:** If you want to create an authentication policy for all versions of a REST API, you must create individual policies for each version.
Resource	Child resource of the REST API. This field is auto-populated based on the selected REST API. For example, **/now/attachment**
Application	Scope of the application.
Global	Enable this field to apply auth policy to all methods, versions, and resources for the API. **Note:** Token Based Auth isn't allowed in the Global REST API Policy.
Apply to all methods	Enable this field to apply the auth policy for the API to all the methods, versions, and resources for the API.
Apply to all resources	Enable this field to apply the auth policy for the API to all the versions.
Apply to all versions	Enable this field to apply the auth policy for the API to all the resources.

d. Add the API authentication profile that was created.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

e. Submit the form.
You can send the REST API call:

- With the x-sn-hmac-signature-256 that was generated by ServiceNow® during the API Key creation within the Header or Query parameter based on the configuration for authentication.
- With pre-request Script with Shared Secret specified as part of the request.

Warning:
Use **POST** request when submitting any sensitive information to the server.

Cleaning up token Expiry

Details about how to clean up token expiry by using different system properties.

Once the API Key or HMAC secret expires, the details is retained for 7 days. A scheduled job `Clean expired Token Auth Credentials` deletes the expired API Keys or HMAC Secrets after that. You can configure this behavior and control the deletion using the following properties:

- **com.snc.platform.security.token.auth.cleanup**: Use this property if you want to delete expired API Keys and HMAC tokens. By default `true`.
- **com.snc.platfrom.security.token.auth.days.expired.api_key.is.kept**: Set the value based on your requirement to determine the number of days you want the keep the expired `API` token in the system. By default 7.
- **com.snc.platfrom.security.token.auth.days.expired.hmac_key.is.kept**: Set the value based on your requirement to determine the number of days you want the keep the expired `HMAC` token in the system. By default 7.

To navigate to the token expiry property, enter `sys_properties.list` in the navigation bar and then search for the following properties. Change the expiry based on your requirement.

API access policy

API access policy defines the permissions and duration of access to an API.

API access policy enables you to restrict access to inbound ServiceNow® APIs based on the authentication type and the specified filter criteria of the access policy.

Following are the three level auth policy support for the non-interactive sessions:

- **REST API**: Admin can define a global API auth policy or API specific auth policy.
- **SOAP API**: Admin can define a global API auth policy or API specific auth policy.
- **System/Export Processor**: Admin can define five base system auth profiles, which can be used to apply auth profile to processors API auth policy or processor specific auth policy.

Note:
If you add a global auth policy, then the policy applies for all the REST APIs, SOAP APIs, or System/Export Processors.

Following are the plugins auto-installed for API policies and authentication scope:

- com.glide.rest.policy
- com.glide.soap.policy

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- com.glide.processor.policy
- com.glide.rest.auth.scope

You can configure the default Global Blocking Policy or create a custom API access policy according to your security requirements. And apply filter criteria that contain filter conditions or queries that are used as policy inputs for an authentication policy.

The following API access policies are supported in ServiceNow®:

- REST API access policies
- SOAP API access policies

For information about policies related to export processors, see Access policy for System or Export Processors.

REST API access policies

REST API access policies allow you to restrict access to inbound REST APIs based on the authentication type and the specified filter criteria of the access policy.

A REST API, also known as RESTful API is a type of application programming interface (API) that adheres to the guidelines of REST architectural style. REST APIs provide a high degree of flexibility making it prevalent across the web.

Filter criteria contains filter conditions or queries that are used as policy inputs for an authentication policy.

You can configure the default Global Blocking Policy or create a custom API access policy according to your security requirements. For example, you can create a custom API access policy that allows only OAuth 2.0 authentication type from a specified range of IP addresses. Authentication requests of other authentication types and access requests from IP addresses other than the specified IP addresses are denied.

Activate REST API access policy

You can activate the REST API Access Policy plugin (com.glide.rest.policy) if you have the admin role. The application includes demo data and installs related ServiceNow® Store applications and plugins if they are not already installed.

Before you begin

Role required: admin.

About this task

The following items are installed with REST API Access Policy:

- Plugins: com.gilde.auth.profile, com.snc.adaptive_authentication, com.snc.platform.security.oauth
- Tables: sys_api_access_policy, sys_auth_profile_mapping, auth_policy_mapping, inbound_auth_profile, std_http_auth.

For more information, see Adaptive authentication.

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the REST API Access Policy plugin (com.glide.rest.policy) using the filter criteria and search bar.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.

3. Select **Install** to start the installation process.

Note:
When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Create an authentication profile

Create an authentication profile and add one or more authentication policies to the profile. You can also configure the **ID Token** and **OAuth Token** authentication profiles that are available by default.

Before you begin

Role required: admin

Note:
You can apply authentication policies, IP range, role-based, user-based, and so on with mutual authentication and customized authentication.

Procedure

1. Navigate to **All** > **System Web Services** > **API Access Policies** > **Inbound Authentication Profiles**.
2. Select **New**.
   The system displays the message. `What kind of authentication profile?`
3. Select **Create standard http authentication profiles**.
4. On the form, fill in the fields.

Standard Authentication Profile form

Field	Description
Name	Name to identify the authentication policy.
Description	Description of the authentication policy.
Active	Option to make the authentication policy active.
Application	Scope of the authentication policy.
Type	Type of the authentication available. You can select **Basic Auth**, **ID Token**, **Certificate based Auth**, or **OAuth**.
OAuth Entity	OAuth Entity profile. This field appears only when **ID Token** or **OAuth** is selected from **Type**.

5. Double-click **Insert a new row**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

6. Select an authentication policy from the list and select the save icon .

Note:
Don't select Allow Access Policy or Deny Access Policy. These policies are meant only for user logins.

You can add one or more authentication policies for an authentication profile.

Note:

Authenticate Header [WWW-Authenticate].

When REST API Access Policy is active we will return the most recently mapped authentication profile in the authenticate header. In the case you want the server to return all the authentication schemes, use the `glide.security.response.authenticate.header.auth_profile.first_scheme_on` property and set it to **false**. The response is returned with multiple header. For example:

```
< WWW-Authenticate: BEARER realm="Service-now"
< WWW-Authenticate: BASIC realm="Service-now"
```

Create REST API access policy

Create an API access policy and map an authentication profile to restrict the authentication type for a REST API. For example, you can create an API access policy that allows only ID token authentication for a REST API.

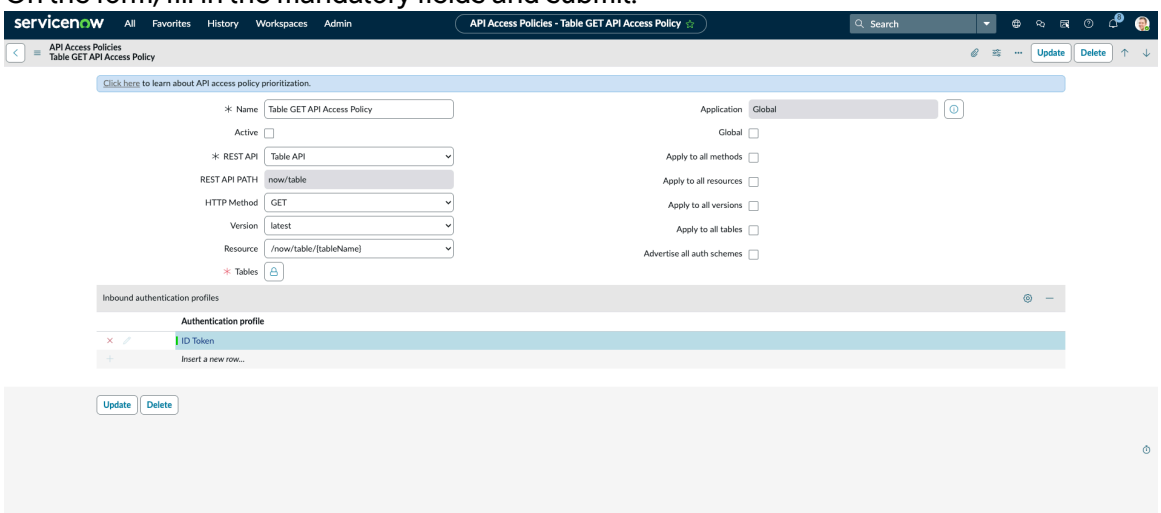
Before you begin

Make sure that an authentication profile is created. For more information, see Create an authentication profile.

Role required: admin

Procedure

1. Navigate to **All** > **System Web Services** > **REST API Access Policies**.
2. Select **New**.
3. On the form, fill in the mandatory fields and submit.



Note:
You must reopen the submitted form to populate additional fields.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

API Access Policies

Field	Description
Name	Unique name of the API access policy.
Active	Option to make the API access policy active.
REST API	The REST API to which the access policy is applied. For example, **Attachment API**.
REST API PATH	API path of the REST API. This field is auto-populated based on the selected REST API. For example, **now/attachment**.
HTTP Method	Method used for interacting with the API. This field is auto-populated based on the selected REST API.
Version	Version of the API. For example, **v1**. This field is auto-populated based on the selected REST API. **Note:** If you want to create an authentication policy for all versions of a REST API, you must create individual policies for each version.
Resource	Child resource of the REST API. This field is auto-populated based on the selected REST API. For example, **/now/attachment**
Table	The tables to which the API access policy applies. This option only applies to policies for the *Table* API.
Application	Scope of the application.
Global	Option to apply the policy to all methods, versions, and resources for the API.
Apply to all methods	Option to apply the policy to all the methods, versions, and resources for the API.
Apply to all resources	Option to apply the policy to all or the API resources.
Apply to all versions	Option to apply the policy to all or the API versions.
Apply to all tables	Option to apply the policy to all tables. This option only applies to policies for the *Table* API.
Advertise all auth schemes	Determines whether the `WWW-Authenticate` header includes all configured authentication schemes. When set to `false` (default), the header includes only the most recently configured authentication profile in the policy. When

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	set to `true`, the header lists all configured authentication schemes.

Note:
To understand more about the API access policy prioritization, see API access policy prioritization.

4. Double-click **Insert a new row**.
5. Select an inbound authentication profile from the list and select the save icon.
   For example, you can add **Basic Auth**, **ID Token**, **Certificate based Auth**, **OAuth** or **WSSE Auth**.
   a. To add one or more inbound authentication profiles, select **New** to create a new profile.
   b. Choose **What Kind of authentication profiles?**.
      - **Create standard http authentication profiles**
      - **Create WSSE authentication profiles**
      - **Create API Key authentication profiles**
      - **Create HMAC authentication profiles**

   c. After creating the authentication profile, save the record.
6. Select **Submit** to submit the REST API access policy.

API access policy prioritization

Learn about the policy prioritization logic if there are multiple API access policy configured for your ServiceNow® instance.

API access policies are prioritized based on the type of REST API policy set on your ServiceNow® instance.

The approach is defining different weights for each part of the API such as,method, resource, and version.

The API policy is prioritized for non-global first, then global. In other words, a non-global access policy will always override a global API access policy.

Prioritization logic are as follows:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Prioritization

Fields	Priority	Prioritization Logic
Method, resource, and version	1	If the 3 fields matches with the policy then that policy takes the 1st priority.
Method+ resource	2	If the 2 fields matches with the policy then that policy takes the 1st priority.
Resource + version	3	If the 2 fields along with the field **Apply to all methods** matches with the policy then that policy takes the 3rd priority.
Resource	4	If the field along with the field **Apply to all methods** matches with the policy then that policy takes the 4th priority.
Method + version	5	If the 2 fields along with the field **Apply to all resources** matches with the policy then that policy takes the 5th priority.
Method	6	If the field along with the field **Apply to all resources** matches with the policy then that policy takes the 5th priority.
Version	7	If the field along with the fields **Apply to all methods** and **Apply to all versions** matches with the policy then that policy takes the 7th priority.
Global and Apply to all methods	8	If the fields **Global** is `true` and **Apply to all methods** is `false` then that policy takes the 8th priority.
Global and Apply to all methods	9	If the fields **Global** is `true` and **Apply to all methods** is `true` then that policy takes the 9th priority.

REST API Auth Scope

Use the REST API Auth Scope to provide access to a specific REST API

Earlier, the client without any scope have access to all APIs unless the API is protected by REST API Auth Scope or the client has `useraccount` scope.

After creating REST API Auth Scope record, to access this REST API you must associate the same Auth Scope to the OAuth Entity which should have access to this REST API. For a new OAuth Entity, the default Auth Scope is empty.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
Unless you have REST API Auth Scope record, the REST API can be accessed by any valid OAuth Entities.

You must manually link the Auth scope within the OAuth Entity. The `useraccount` is a special scope, if it's associated with an OAuth Entity it can access any API even if you have created a REST API Auth Scope record with a different auth scope.

To learn more about how to use the API Auth Scope in the new Inbound integration experience, see Inbound integrations.

Note:

- After the REST API Auth scope is enabled and added to the auth scope for the REST API, then all the existing OAuth token won't able to access this API anymore unless admin adds this auth scope to the corresponded OAuth entity
- The admin is responsible to making sure the oauth_entity has the right auth scope after to link the auth scope with the REST API.
- OAuth access tokens issued by ServiceNow supports the auth scope.
- OIDC token that is not issued by ServiceNow is validated by ServiceNow.
- OIDC token has its scope from IDP when you require an ID token. Here the auth scope is for ServiceNow instead of third party (IdP).

Configurations for REST API Scope

To configure the REST API Scope, perform the following tasks:

- Create an auth scope
- Link auth scope with the REST API
- Link auth scope with OAuth entity
- Perform OAuth flow to get OAuth access token
- Use the OAuth access token to make the API call

Activate REST API Auth Scope

You can activate the REST API Auth Scope plugin (com.glide.rest.auth.scope) to link the OAuth entity with authentication scopes.

Before you begin
Install the following plugins:

- OAuth 2.0
- REST API Provider
- Authentication scope
- REST API Scope

Note:
The *REST API Scope* plugin is added as part of the Tokyo release.

Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the REST API auth Scope (*com.glide.rest.auth.scope*) plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

   Note:
   When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

   You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

REST API Auth Scope properties and tables

The REST API Auth Scope plugin (com.glide.rest.auth.scope) includes the following system properties, tables, and scripts.

REST API Auth Scope Properties

REST API Auth Scope adds the following system properties.

Properties

Name	Description
com.glide.rest.api.auth.scope.check	This property is used to turn-off the platform level auth scope check. If set to false, during the runtime the auth scope check is skipped whether it is linked or not linked with the REST API. By default this property is set to true. This properties is used when you want to revert to previous release behavior.
glide.oauth.token.scope.useraccount	This property is only used when *useraccount* auth scope is deleted and is added back manually by end user. In this case, the sys ID for the *useraccount* is changed. It is required to update this property to the new sys_id. During the runtime, auth scope sys ID is used instead of auth scope name.

REST API Auth Scope Tables

REST API Auth Scope the following tables.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Tables

Name	Description
Authentication Scope (sys_auth_scope)	This table defines the auth scope that can be linked with the REST API and OAuth entity. The auth scope name must be unique and it is global.
REST API Auth Scope (sys_api_access_scope)	This table links REST API with auth scope.

Configure REST API Auth scope

Link the OAuth entity with an auth scope to manage the token to access the REST APIs that are linked with the auth scope.

Before you begin

Install the following plugins:

- OAuth 2.0
- REST API Provider
- Authentication scope
- REST API Auth Scope

Note:
The *REST API Auth Scope* plugin is added as part of the Tokyo release.

Role required: admin

Procedure

1. Navigate to **All** > **API Auth Scopes** > **REST API Auth Scope**.
   The REST API Auth Scopes page is displayed.
2. To configure a new REST API Auth Scope, click **New**.
3. On the form, fill in the fields.

REST API Auth Scope

Name	A unique name that identifies the REST API Auth Scope.
Active	Select the check box to make the configuration active.
Application	Read-only application scope.
REST API	The REST API to which the auth scope is applied. For example, the Table API.
Auth Scope	Select the auth scope from the lookup icon.
REST API PATH	API path of the REST API. This field is auto-populated based on the selected REST API. For example, now/table.

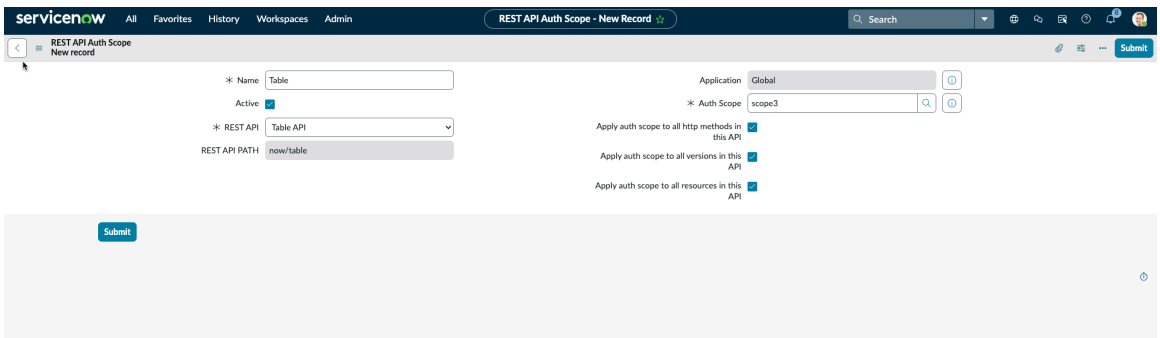
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

HTTP Method	Method used for interacting with the API. Select the method from drop-down list. You can disable the **Apply auth scope to all http methods in this API** field on the form manually to select the method.
REST API Version	Version of the API. For example, v1. This field is auto-populated based on the selected REST API. You can disable the **Apply auth scope to all versions in this API** field on the form manually to select the version.
Resource	Child resource of the REST API. This field is auto-populated based on the selected REST API. For example, /now/table. You can disable the **Apply auth scope to all resources in this API** field on the form manually to select the resources.
Apply auth scope to all http methods in this API	When enabled, applies the auth scope to all the http methods in the API.
Apply auth scope to all versions in this API	hen enabled, applies the auth scope to all versions in the API.
Apply auth scope to all resources in this API	When enabled, applies the auth scope to all resources in the API

4. Click **Submit**.
   Based on the selected REST API and Auth Scope, the APIs retrieves information that is particular to the scope.

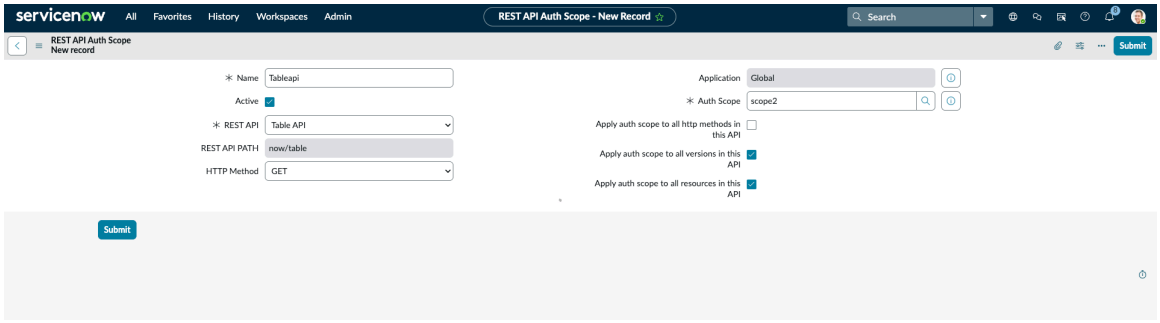
Example: Consider creating three REST API Auth Scope for Table API

The first auth scope is mapped to the **Table API** with all the http methods, versions, and resources enabled.

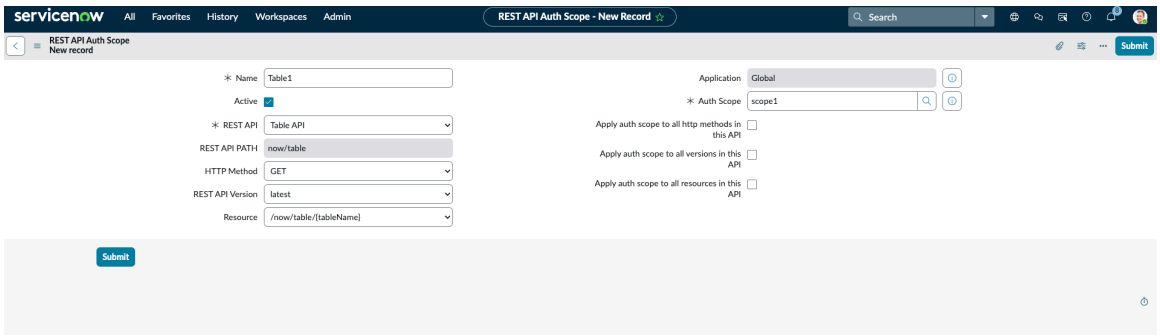


The second auth scope is mapped to the **Table API** with all the versions and resources enabled. But, you choose the HTTP Method, in this example, the **GET** method.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



The third auth scope is mapped to the **Table API** without the http methods, versions, and resources enabled. But, you choose the HTTP Method, Version, and Resource manually. In this example, HTTP Method is **GET**, REST API Version is **latest**, and Resource is `/now/table/{tableName}`.



If all these auth scopes are created, you can use **GET** method with all the three scopes, but for **POST**, **PUT**, **DELETE**, or **PATCH** methods only **scope3** can be used.

REST API scope troubleshooting

Troubleshooting actions can help resolve common issues when setting up or running the REST API scope.

Troubleshooting

Issue	Action
REST API is linked with auth scope, however in runtime there is no auth scope check even using Bearer token authentication.	• Make sure the sys_api_access_policy record is active. Runtime ignores inactive records. • Check if property *com.glide.rest.api.auth.scope.check.enable* is set to false. • Check if the OAuth token has `useraccount` auth scope.
REST API is linked with *auth_scope1*, however the access token which has *auth_scope2* is also able to access it.	• Check if this record is active. • Check for this REST, check if any other records, which have the same APIs but different apply methods, versions, or resource.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Troubleshooting (continued)

Issue	Action
REST API is linked with auth scope, however in runtime there is no auth scope check for *basicAuth* and *mutualAuth*.	It is expected since the REST API auth scope only applies to the OAuth access token or OIDC token. It doesn't apply BasicAuth, Session Cookie and Certificate based authentication.
REST API call return 403 when using the OAuth access token.	Check for the error message "Missing required api access scope". If found then the auth scope check fails for this REST API
Pre-defined `useraccount` is deleted and not sure to restore.	Export `useraccount` as `xml` from the other instance and import it or create an `useraccount` and modify system property *glide.oauth.token.scope.useraccount* to the newly created sys_id record.

Frequently asked questions

Following are some of the frequently asked question when using the REST API Auth scope:

Can one OAuth token be linked with several auth scopes?

Yes, one `oauth_entity` can be linked with multiple auth scopes, every OAuth token issued by this `oauth_entity` has the same auth scopes.

Can different OAuth tokens with different auth scopes access the same REST API?

Yes, for the same REST API, it may be accessed by different auth scopes. As long as one auth scope is matched, the auth scope returns the results.

Can OAuth access token with `useraccount` auth scope access any REST APIs?

Yes, the `useraccount` has full access to auth scope.

Can OAuth access token OAuth scope be changed dynamically?

Yes, the auth scoped is not hard-coded with the access token in the `oauth_credential` table. Instead auth scope is getting from linked `oauth_entity` during runtime.

Can OAuth token keep same auth scopes after refresh?

Yes, auth scope will not change after token refresh, unless `oauth_admin` modify auth scope linked with `oauth_entity`.

Pre-defined `useraccount` auth scope record is deleted, can a new auth scope with name `useraccount` be created?

Creating a new auth scope with the same `useraccount` doesn't work. In the runtime, it uses the `sys_id` instead of name to do the auth scope check, modify the system property *glide.oauth.token.scope.useraccount* to the newly created `sys_id` record.

If admin modify auth scoped linked with `oauth_entity`, are all the existing OAuth access token issued by this OAuth entity changed also?

Yes, the auth scope is not directly linked with the OAuth access token, it is getting from `oauth_entity` during runtime.

Can different OAuth access tokens issued by the same `oauth_entity` have different auth scopes?

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

No, all access to the token is issued by the same `oauth_entity` and always have the same auth scopes.

Can a user define different auth scopes for a particular endpoint?

No, there is a unique constrain check for a particular REST API endpoint. However for the same REST API endpoint, it may have more than one matched auth scopes.

Is the auth scope check used for BasicAuth also?

No, auth scope check is only OAuth access token and OIDC token, it is not applied for *`basicAuth`* and *`mutualAuth`*

SOAP API access policies

SOAP API access policies allow you to restrict access to inbound SOAP APIs based on the authentication type and the specified filter criteria of the access policy.

The SOAP API access policies enables you to have the ability to apply the inbound authentication profile and API access policies to inbound SOAP and scripted SOAP APIs.

You can leverage ServiceNow API access policies like IP range and role based restrictions to allow or disallow inbound SOAP API calls based on the authentication.

As an admin, you can perform the following actions to apply the policies.

- Activate SOAP API Access Policy and Authentication Profile plugins. For more information, see Activate SOAP API access policy.
- Create SOAP API Access Policies and associate those policies with an authentication profile. For more information, see Create SOAP API access policy and Create an authentication profile.

  Note:
  The policies are applicable to SOAP table API or scripted SOAP API. Besides the standard `http` and `WSSE` authentication profile.

- Create authentication policies such as IP range, role-based restrictions and associate this policy to the authentication profile. For more information, see Create an API authentication policy.

Activate SOAP API access policy

For SOAP API access policy, install the SOAP API Access Policy (`com.glide.soap.policy`) plugin.

Before you begin
Role required: admin

About this task
The following item is installed with SOAP API Access Policy Plugin: Processor Access Policy (`com.glide.processor.policy`)

Dependent Plugin: Authentication Profile (`com.glide.auth.profile`)

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the SOAP API Access Policy plugin (`com.glide.soap.policy`) using the filter criteria and search bar.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.

3. Select **Install** to start the installation process.

> **Note:**
> When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Create an authentication profile

Create an authentication profile and add one or more authentication policies to the profile. You can also configure the **ID Token** and **OAuth Token** authentication profiles that are available by default.

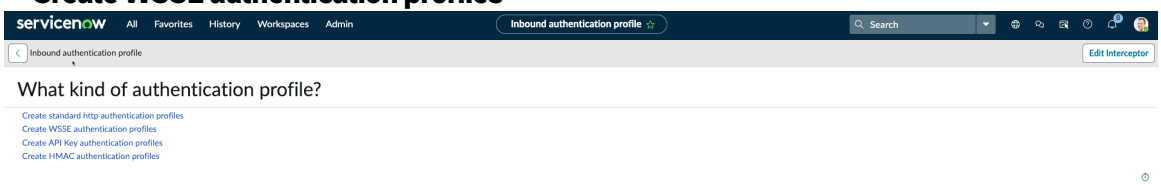
Before you begin

Role required: admin

> **Note:**
> You can apply authentication policies, IP range, role-based, user-based, and so on with mutual authentication and customized authentication.

Procedure

1. Navigate to **All** > **System Web Services** > **API Access Policies** > **Inbound Authentication Profiles**.
2. Select **New**.
   The system displays the message. `What kind of authentication profile?`
3. Choose **What Kind of authentication profiles?**.
   - **Create standard http authentication profiles**
   - **Create WSSE authentication profiles**



4. On the form, fill in the fields.

Standard Authentication Profile form

Field	Description
Name	Name to identify the authentication policy.
Description	Description of the authentication policy.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Active	Option to make the authentication policy active.
Application	Scope of the authentication policy.
Type	Type of the authentication available. You can select **Basic Auth**, **ID Token**, **Certificate based Auth**, **OAuth**, or **WSSE** (In case of WSSE Authentication profile).
OAuth Entity	OAuth Entity profile. This field appears only when **ID Token** or **OAuth** is selected from **Type**.

5. Double-click **Insert a new row**.
6. Select an authentication policy from the list and select the save icon .

Note:
Don't select **Allow Access Policy** or **Deny Access Policy**. These policies are meant only for user logins.

You can add one or more authentication policies for an authentication profile.

When there's a change in the authentication profile, the Authorization header returns a value specific to the changes made at that time. To have the ability to get all the authentication schemes returned in the `WWW-Authenticate` header, you must activate `glide.security.response.authenticate.header.auth_profile.first_scheme_only` to **false**. The response is returned with multiple headers. For example:

```
< WWW-Authenticate: BEARER realm="Service-now"
< WWW-Authenticate: BASIC realm="Service-now"
```

Create SOAP API access policy

Create an API access policy and map an authentication profile to restrict the authentication type for a SOAP API. For example, you can create an API access policy that allows only ID token authentication for a SOAP API.

Before you begin

- Make sure that an authentication profile is created. For more information, see Create an authentication profile.
- Role required: admin

Procedure

1. Navigate to **All** > **System Web Services** > **API Access Policies** > **SOAP API Access Policies**.
2. Click **New**.
3. On the form, fill in the fields.

API Access Policies form

Field	Description
Name	Unique name of the API access policy.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
SOAP API	SOAP API to which the access policy is applied. For example, **GetProperty API**.
Application	Scope of the application.
Active	Option to make the API access policy active.

4. In the Inbound Authentication section, double-click **Insert a new row**.
5. Select an inbound authentication profile from the list and click the save icon .
   For example, you can add **Basic Auth**, **ID Token**, **Certificate based Auth**, **OAuth** or **WSSE Auth**.

   a. To add one or more inbound authentication profiles, click **New** to create a new profile.

   b. Choose **What Kind of authentication profiles?**.

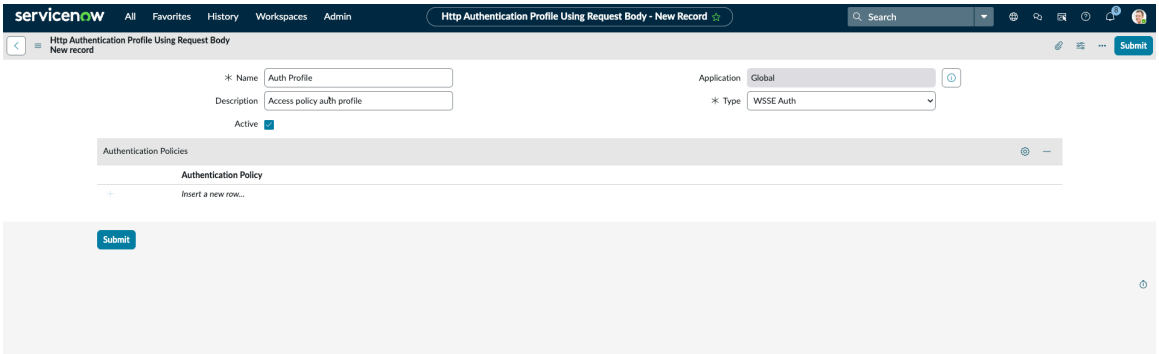
   - **Create standard http authentication profiles**
   - **Create WSSE authentication profiles**

   c. To create a WSSE authentication profile, on the form, fill in the fields.

WSSE Authentication Profile

Field	Description
Name	Unique name of the API access policy.
Description	Description of the authentication profile.
Application	Scope of the application.
Active	Option to make the API access policy active.
Type	WSSE Auth as authentication profile WSSE (Web Security).

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



d. After creating the authentication profile, save the record.

6. Click **Submit** to submit the SOAP API access policy.

Create a global API access policy to protect SOAP APIs

Create a single global API access policy to protect all the SOAP APIs.

Before you begin

- Role required: admin
- Install the **Processor Access policy** (`com.glide.processor.policy`) plugin
- Make sure that an authentication profile is created. For more information, see Create an authentication profile.

The following steps describes how to create a single global access policy to protect all the SOAP APIs.

> **Note:**
> The policies defined at the individual SOAP API levels overrides the **SOAPProcessor** level global access policy.

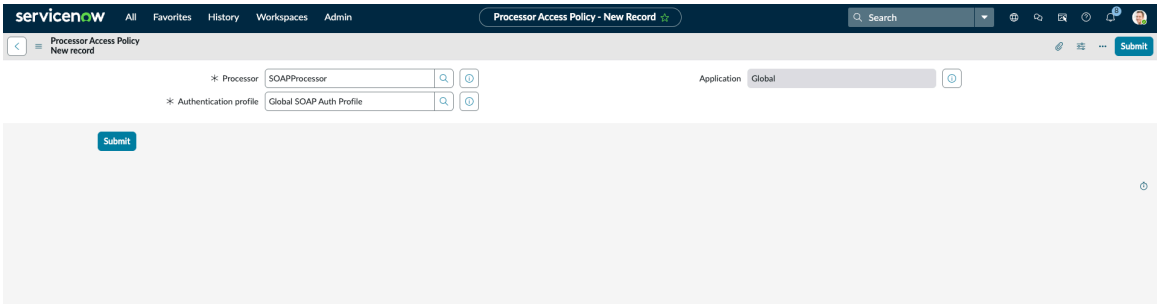
Procedure

1. Navigate to **All** > **System Security** > **Process Access Policies**.
2. On the form, fill in the fields.

Process Access Policy form

Field	Description
Processor	Name to identify the authentication policy. For example select, **SOAPProcessor** (Authentication profile).
Application	Scope of the authentication policy. Default: Global
Authentication Profile	Type of the authentications profile. Select, **Global SOAP Auth Profile**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



3. Select **Submit**.

Filter criteria for APIs

Filter criteria contains filter conditions or queries that are used as policy inputs for an authentication policy. Policy inputs are used to group one or more filter criteria and define the policy conditions of an authentication policy. For example, an IP Filter Criteria define an IP address in the Classless Inter-Domain Routing (CIDR) format or a range of IP addresses.

You can create filter criteria based on the user's IP address, role, and the user group to which they belong.

Note:
You also use the filter criteria created from the **Adaptive Authentication** module. For more information, see Adaptive authentication.

You can create filter criteria for APIs using the same process as filter criteria for adaptive authentication. For details see Filter criteria.

Related topics

- Create IP filter criteria
- Create role filter criteria
- Create group filter criteria

API Authentication Policies

Authentication policies evaluate authentication requests based on the specified policy conditions and either allows or denies access depending on the matching criteria.

You can use the built-in Global Blocking Policy or create an authentication policy according to your security requirements. Global Blocking Policy denies the authentication requests of users and APIs based on the specified filter criteria.

Note:
Do not use or modify Allow Access Policy and Deny Access Policy. These policies are meant only for user logins.

Create an API authentication policy

Authentication policies allow you to enforce access restrictions on the APIs based on the specified filter criteria.

Before you begin
Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

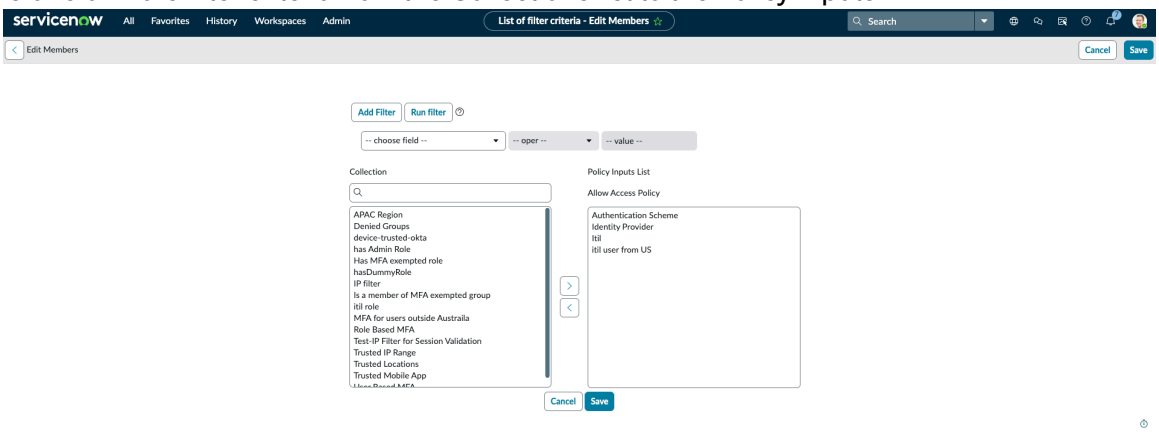
Procedure

1. Navigate to **All** > **System Web Services** > **API Authentication Policy**.
2. Click **New**.
3. On the form, fill in these fields.

Policy form

Field	Description
Name	Name to identify the policy.
Description	Short description of the policy.
Application	Scope of the application.

4. Right-click the form header and select **Save**.
5. From the Policy Inputs tab, select **Edit** to add the existing Filter Criteria.
   You can also create a new Policy Input. For more information, see Create policy inputs.
6. Move one or more filter criteria from the Collections list to the Policy Inputs



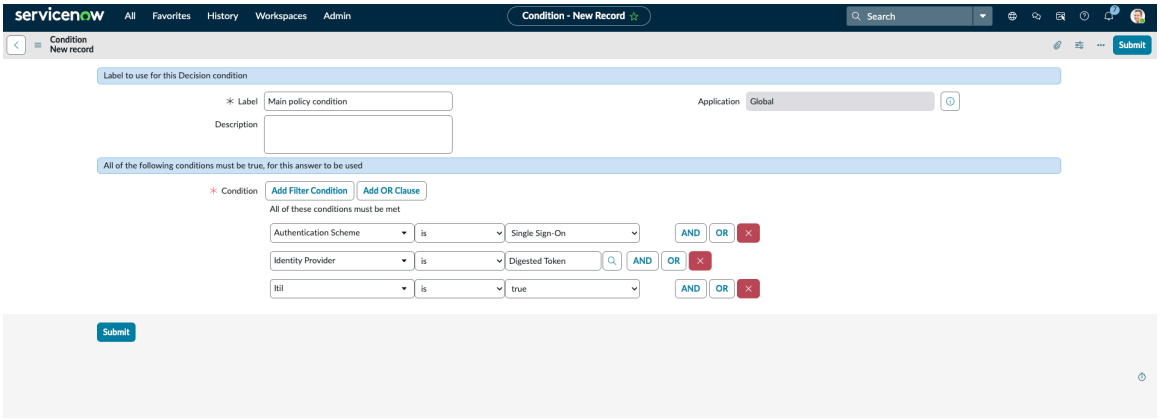
List.

7. Select **Save**.
8. From the Policy Conditions tab, select **New**.
9. On the form, fill in these fields.

Condition form

Field	Description
Label	Name of the policy condition.
Description	Short description of the policy condition.
Application	Scope of the application.
Condition	One or more conditions that are combined with **OR** filter.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



10. Select **Submit**.

Configure global blocking policy for APIs

Global blocking policy denies the authentication requests of users and APIs based on the specified policy conditions. This policy can be used as an alternative to the IP Address Access Control.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Web Services** > **API Access Policies** > **Global Blocking Policy**.
2. From the **Policy Inputs** tab, click **Edit**.
3. Select one or more filter criteria from the **Collection** list and move them to **Global Blocking Policy** list.
   You can also add additional filters.
4. From the **Policy Conditions** tab, click **New**.
5. On the form, fill these fields:

Condition Form

Field	Description
Label	Name to identify the condition.
Description	Description of the condition.
Condition	Logical combination of multiple policy inputs (filter criteria) that is used to evaluate authentication requests. For example, you can create conditions that allow only contractors from a list of trusted IP addresses.

Access policy for System or Export Processors

Ability for System or Export Processors to leverage processor access policy to secure all the export endpoints.

Ability to secure all the export endpoints and apply the inbound authentication profile and processor access policies at a global or instance level.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:

- Non-public processors, including the export processors like CSV, PDF, etc are supported for access policies.
- Script processors are also supported for access policies.

Sample use cases

- Admin can block the RSS processor if not intending to use it, by leveraging the API access policy.
- Admin can create an authentication profile with basic authentication and associate an authentication policy that always evaluates to false.

  Example, Create IP criteria with a range from `0.0.0.0` to `255.255.255.255` (add Ipv6 address space as well) and then add policy condition with the false operator. By this way, policy conditions will always evaluate as false, and the API access policy will block the access irrespective of where the request is originating.

- Allowing access to the processor only from a trusted network.

Activate Processor access policy

For Processor, install the Processor Access policy (`com.glide.processor.policy`) plugin.

Before you begin
Role required: admin

About this task
The following items are installed with Processor Access Policy:

- System Property: com.glide.auth.profile.supported.processor.list
- Module in the navigation: Processor Access Policies

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the Processor Access Policy (`com.glide.processor.policy`) plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.

3. Select **Install** to start the installation process.

   Note:
   When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

   You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

What to do next
.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Configure authentication profile for the processors, for more information see, Configure Authentication profile for Processor.

Configure Authentication profile for Processor

Apply authentication profile for the export processors.

Before you begin
Role required: admin

Plugin required: Processor Access Policy (`com.glide.processor.policy`)

Procedure

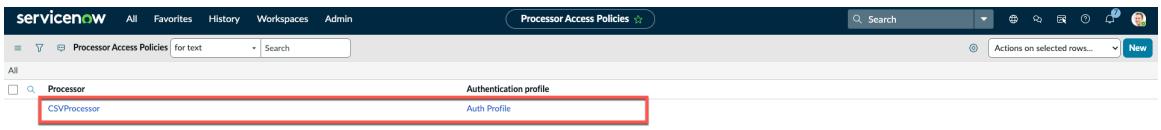
1. Navigate to **All** > **System Security** > **Processor Access Policies**.
2. To add authentication profile to the processor, click **New**.
3. On the form, fill in the fields.

Process Access Policy form

Field	Description
Processor	Name to identify the authentication policy. **Note:** Public processors are not supported. If a non-supported processor is selected, then an error is displayed during submission of the processor.
Application	Scope of the authentication policy. Default: Global
Authentication Profile	Type of the authentications profile. You can select **ID Token** or **OAuth Token**.

4. Click **Submit**.
   The authentication profile is applied to the processor.

   For example, OAuth authentication profile is configured for the CSV Processor. In this case, you have to use OAuth access token for the exporting using CSV as an export option.



Authentication factors

Authentication factors help identify and verify callers, allowing only authorized users to access AI voice agents on the ServiceNow AI Platform.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Explore	Configure
Learn the features and business value of authentication factors for voice agents.	Understand how to configure authentication factors for voice agents.

Explore authentication factors for AI voice agents

Authentication factors are the elements used for caller identification and authentication. In secure voice agent environments, the process begins with identifying the caller, followed by authenticating their identity before granting access. A robust security strategy combines multiple factors to confirm that only authorized users interact with AI voice agents.

When configuring an AI voice service to support natural, conversational exchanges, it's crucial to select authentication factors that reliably verify a user's identity. Caller access to specific voice agents is determined by the authentication types and methods configured by the administrator.

In this context, two categories of authentication mechanisms are supported:

Single-factor authentication

Single-factor authentication requires the user to confirm the identity through a single verification method. Within the ServiceNow AI Platform voice agent configuration, you can select from three supported authentication factors:

- Knowledge-based authentication (KBA)
- Soft PIN
- Time-based one-time Password (TOTP)

Each method offers a distinct approach to user verification, enabling for secure access tailored to the needs of the service.

Multi-factor authentication

Multi-factor authentication (MFA) requires users to verify their identity with two methods, such as a PIN and an authenticator app code. This approach enhances security and user confidence by making accounts and voice services harder for attackers to compromise.

- Primary factor: Initial verification method (such as Soft PIN, TOTP).
- Secondary factor: An additional verification method that strengthens security (such as sending push notifications through **Okta Verify**).

> **Note:**
> Multi-factor authentication is selected as the primary factor by default, you can change the default behavior by setting the **glide.voice.authenticate.mfa_mandatory** property to `false`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Overview of the supported authentication factors

Time-based one-time password (TOTP) authentication

- TOTP is a temporary numeric code generated by apps like **Okta Verify** on the user's registered device.
- TOTP is recommended for users needing stronger protection, as codes are generated locally and are resistant to interception.

Push notification - Okta Verify

- Users approve authentication requests via a push notification on their registered mobile device.
- The factor is fast, convenient, and offers high security as a second factor, but requires an internet connection and secure device management.

SoftPIN authentication

- Soft PIN is a 6-digit personal numeric the user is enrolled.
- The factor is suitable for verifying returning users in low-risk, self-service scenarios. It's quick to use and device-independent but can be vulnerable to observation or reuse.

SMS One-time passcode (OTP) authentication

- SMS OTP is a temporary numeric code sent to the user's registered mobile phone.
- SMS OTP is easy to deploy and familiar. However, it's susceptible to SIM-swapping and delivery issues and shouldn't be the only factor for critical operations.

Knowledge-based authentication (Security Questions)

- Knowledge-based authentication (KBA) are pre-set security questions configured by the admin, such as "`What are the last four digits of your SSN?`"
- Mostly used for low-risk operations, KBA requires no additional device but isn't secure and shouldn't standalone for sensitive actions.

To learn more about voice service and how to create them, see Create an AI voice assistant.

Configure authentication factors for AI voice agents

To secure voice agent environments, configure authentication factors that first identify the caller, then authenticate them before granting access.

Configuration involves:

- User identification
- User authentication

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

User identification

User identification forms the foundational layer of security for AI voice agents. You can configure knowledge-based authentication (KBA) to establish the caller identity before any authentication steps.

User authentication

After identification, authentication confirms the caller's identity before enabling access to sensitive resources or actions. ServiceNow AI Platform supports both single-factor and multi-factor authentication (MFA), enabling administrators to tailor security configurations according to assurance levels and user roles. Supported factors include numeric PINs, authenticator app codes, one-time passwords over SMS, push notifications, and knowledge-based questions.

Recommendations

- You're encouraged to leverage multi-factor authentication as the default approach for optimal security.
- You should regularly review and update authentication factor configurations to address evolving threats and maintain conformance.

The following matrix shows the authentication factor combinations based on assurance level and authentication strategy:

Authentication factor combinations

Factor	Security Assurance	Recommended as Single Factor	Recommended as First Factor (MFA)	Recommended as Second Factor (MFA)	Learn more about configuration
Time-based one-time password (TOTP) authentication	High	Y	Y	Y	Authenticator Applications
Push notification - Okta Verify	High	Y	Y	Y	Configure push notification (Okta Verify)
SoftPIN authentication	Medium	Sometimes	Y	Y	Configure Soft PIN
SMS One-time passcode (OTP) authentication	Medium	N	N	Y	Multi-factor authentication Providers
Knowledge-based authentication (Security Questions)	Low	N	Y	N	Configure knowledge-based authentication

Important:
Y = Recommended | Sometimes = Use with Caution | N = Not Recommended

© 2026 ServiceNow, Inc. All rights reserved.

Time-based one-time password (TOTP) authentication

A time based one-time password (TOTP) is a secure authentication factor that verifies user identity by generating a unique, time-sensitive code.

TOTP authenticator apps like **Okta Verify** generate temporary numeric codes on a registered device, usually a mobile phone. These codes are only valid for a short time and can't be used more than once. This approach offers enhanced security compared to static passwords.

Use case

TOTP authenticator apps are suitable for users who require stronger protection than standard multi-factor authentication (MFA) methods.

Key strengths

The TOTP authenticator apps method offers the following advantages:

- Local generation: One-time passwords are generated directly on the user's device and don't require an internet or mobile network connection.
- Security: TOTP is resistant to interception and SIM-swapping attacks, providing robust protection for the authentication process.

Important considerations

While TOTP authenticator apps are a secure and convenient authentication method, there are few considerations to keep in mind:

- Initial setup: Users must set up the authenticator app on a registered device.
- Device management: Users must re-enroll when devices are replaced or reset.
- Phishing risk: One-time codes can be compromised if entered on untrusted or malicious sites.

TOTP authenticator apps are an effective method to strengthen your organization's security posture. For detailed configuration instructions, see Authenticator Applications.

Push notification - Okta Verify

The **Okta Verify** app push notification enables users to securely approve authentication requests directly on their enrolled mobile devices.

During authentication, users receive a push notification via the **Okta Verify** app, enabling them to review request details and approve access without manually entering a verification code.

Use case

Okta Verify push notification is recommended as a robust and convenient second factor for ServiceNow AI Platform authentication flows, providing enhanced security and a seamless user experience.

Key strengths

The **Okta Verify** push notification method offers the following advantages:

- A streamlined process enables quick and easy authentication.
- Resilient against various attack vectors, reinforcing the authentication process.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Important considerations

While **Okta Verify** push notification is a secure and convenient authentication method, there are few considerations to keep in mind:

- Connectivity: Requires a reliable internet connection and a compatible mobile device.
- User Vigilance: Users should carefully review each authentication prompt to help prevent unintended approvals.
- Device Security: Registered devices must be protected with screen locks or biometric safeguards to help prevent unauthorized access.
- Device Re-enrollment: If a device is replaced or reset, users must re-enroll to maintain uninterrupted authentication.

Okta Verify push notification enhances organizational security while providing a convenient authentication experience. For detailed configuration instructions, see Configure push notification (Okta Verify).

Configure push notification (Okta Verify)

Configure **Okta Verify** to receive push notifications for secure and convenient identity verification.

Before you begin

Role required: auth_factors_admin

The push notification authentication factor on **Okta** must be enabled. To learn more, see Okta Support Center.

Note:

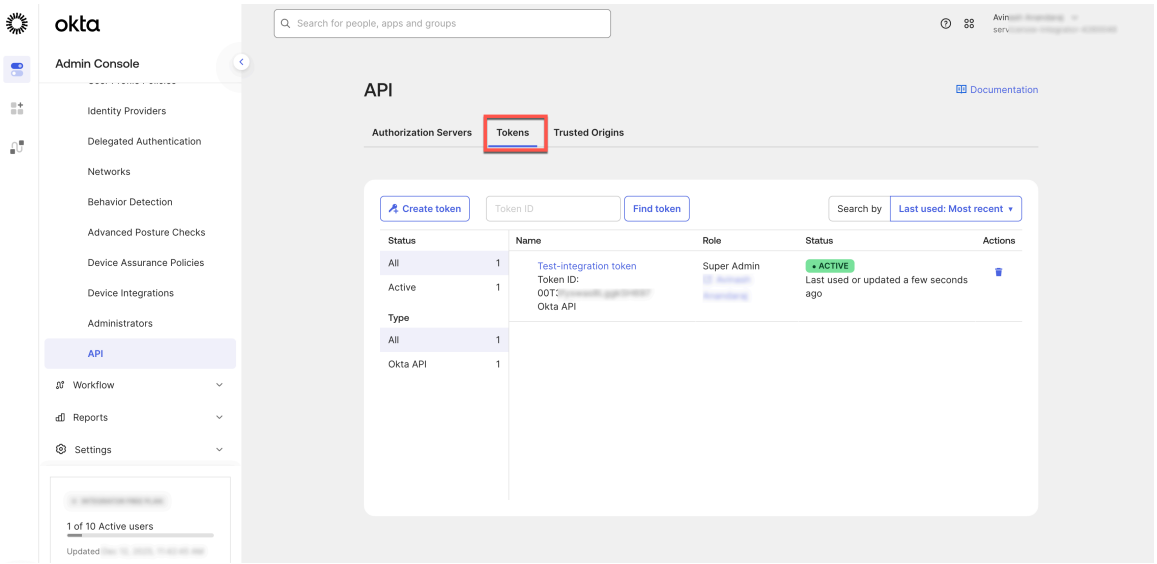
- Currently, only **Okta Verify** is supported for push notifications with ServiceNow AI voice agents.
- The users must have the **Okta Verify** app installed and configured on their phones.

Procedure

1. Log in to your Okta admin account.
2. Navigate to **Security** > **API**.
3. Select **Tokens**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Okta Admin Console



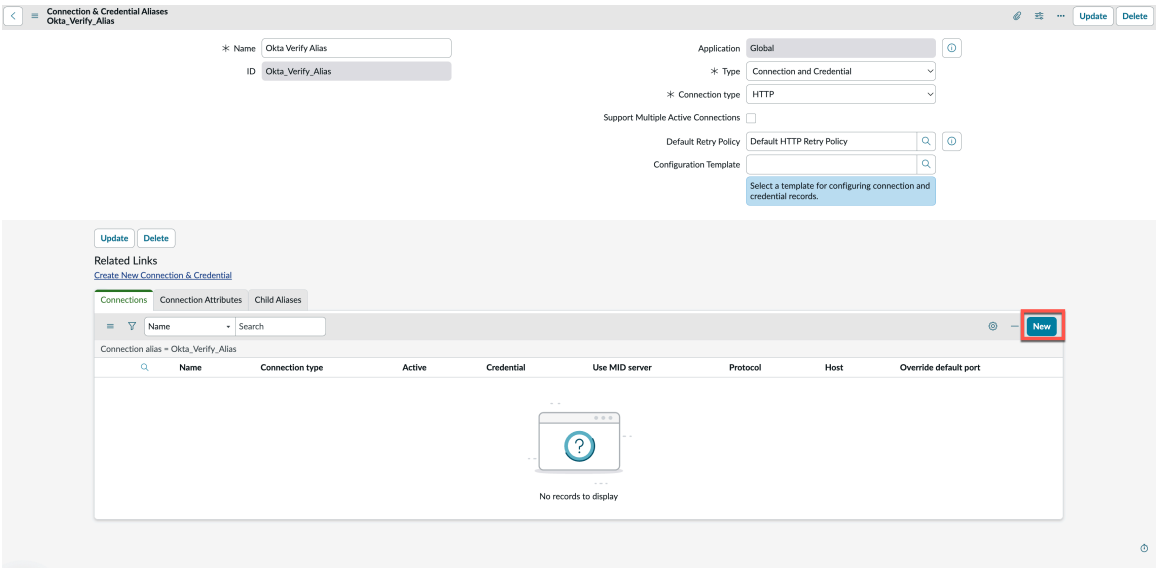
4. Select **Create** token to create token and copy its value.

   For example, `00EYJEm|b34aYVi0Yaav3KnqxsItV_mPI9_p2N46Cc`.

5. On the instance, open the **Connection & Credential Alias** record.

   For example, `<instance_url>/sys_alias.do?sys_id=692e16a0ffb72210d487ffffffffff1b`.

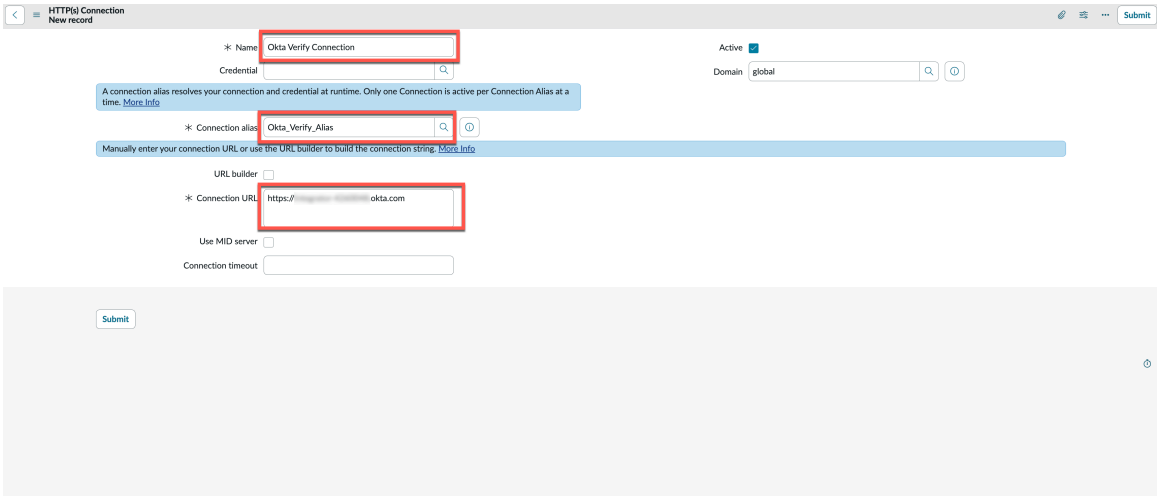
Connection & Credential Alias new record



6. Select **New** under the Connections tab.
7. Specify the following field on the **HTTP(s) Connections** form.
   - Name
   - Connection alias
   - Connection URL

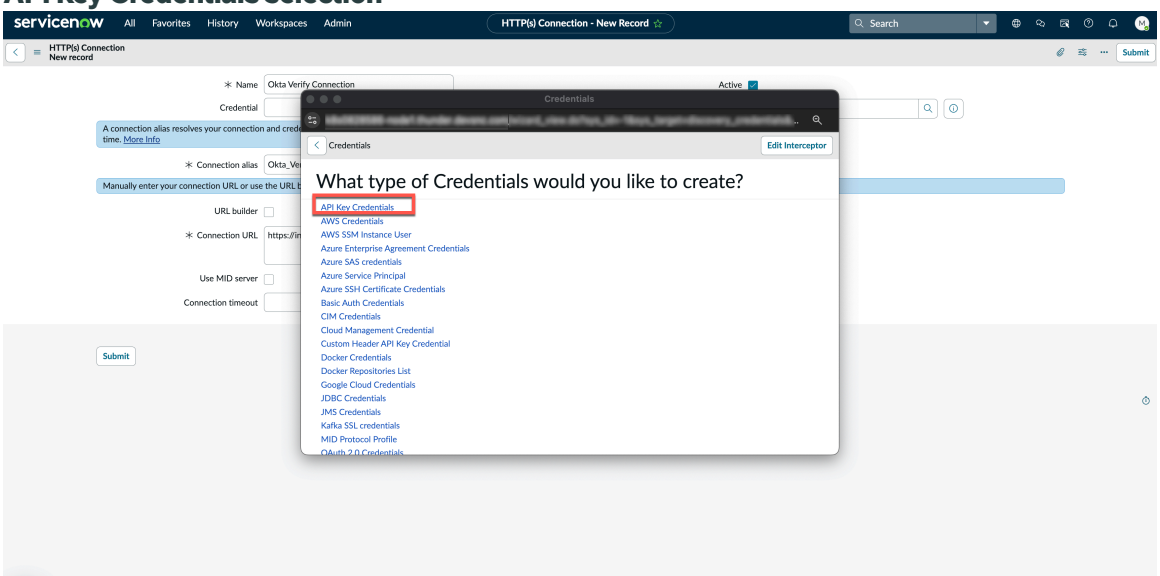
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

HTTP(s) Connections details



8. Select the **Search** icon next to Credentials to add new **API Key Credentials**.

API Key Credentials selection

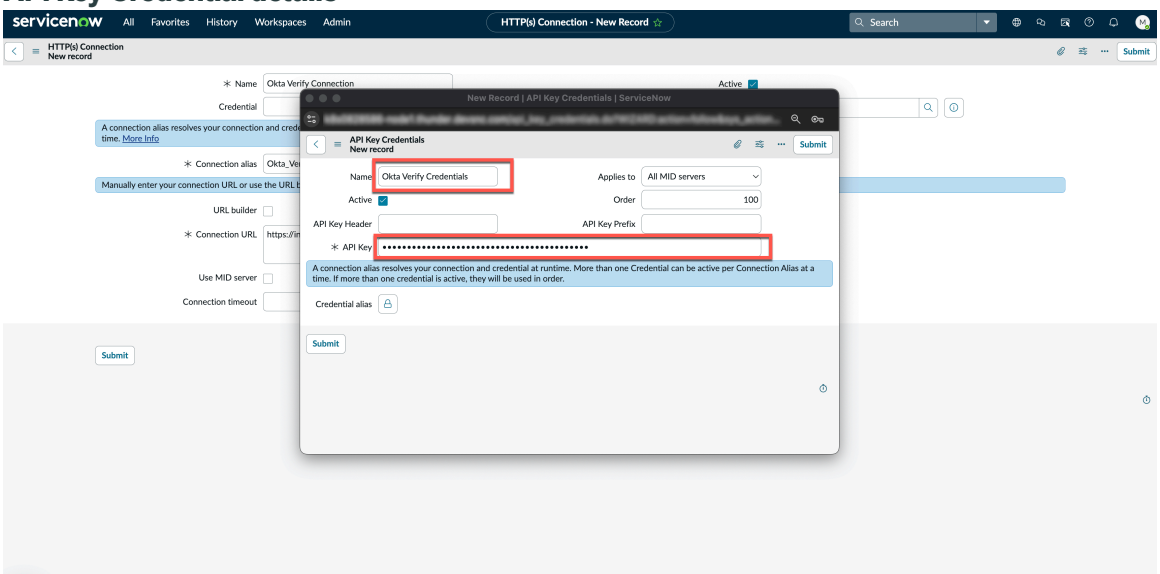


9. Specify the **Name** and **API Key** on the API Key Credentials form.

> **Note:**
> The API key should be prefixed with 'SSWS'. If the copied token value is `00iJ88ydm9ZLnDNE8AeGsmjcUC-ZFyCt3pts2pNTwZ` you must provide the value as `SSWS 00iJ88ydm9ZLnDNE8AeGsmjcUC-ZFyCt3pts2pNTwZ`.

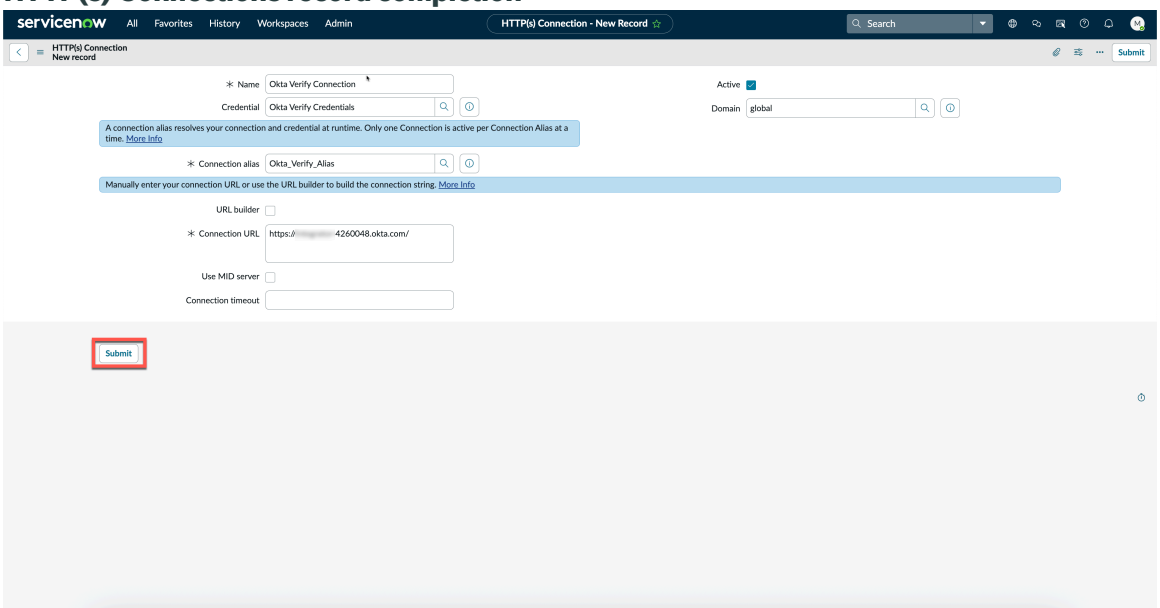
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

API Key Credential details



10. Select **Submit** to submit the API Key Credentials.
11. Select **Submit** on the Connection record.

HTTP(s) Connections record completion



SoftPIN authentication

Soft PIN is an authentication method that verifies a user's identity through a personal numeric PIN set up in advance, specifically designed to support AI Voice Agent authentication.

Use case

Soft PIN is ideal for low-risk scenarios, such as verifying returning users accessing self-service features. It isn't recommended for high-risk or privileged actions.

Key strengths

The SoftPIN method offers the following advantages:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Fast and straightforward user experience.
- Functions without internet or device-specific requirements.

Important considerations

While SoftPIN is a secure and convenient authentication method, there are several considerations to keep in mind:

- Susceptible to reuse, observation, and social engineering.
- Not suitable as the sole authentication method for sensitive or privileged operations.

Soft PIN can be used for your specific use case. For detailed configuration instructions, see Configure Soft PIN.

Configure Soft PIN

Users are required to configure Soft PIN before it can be used for authentication with ServiceNow AI Platform.

Before you begin
Role required: none

> **Note:**
> Soft PIN enrollment is available to all users and is used exclusively for AI Voice Agent authentication.

Procedure

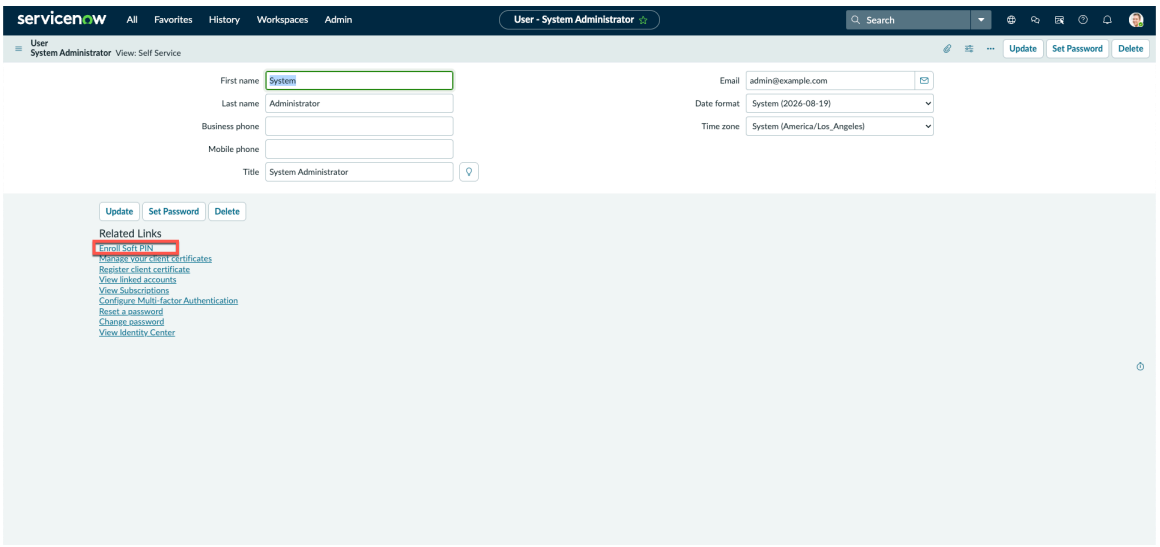
1. Navigate to the Soft PIN enrollment page using any of the following:
   - **Service Portal**: Go to your **User Profile** and select **Enroll Soft PIN**.

Soft PIN on Service Portal

   - **Platform UI**: Go to your **User Profile** and select **Enroll Soft PIN** under Related Links.

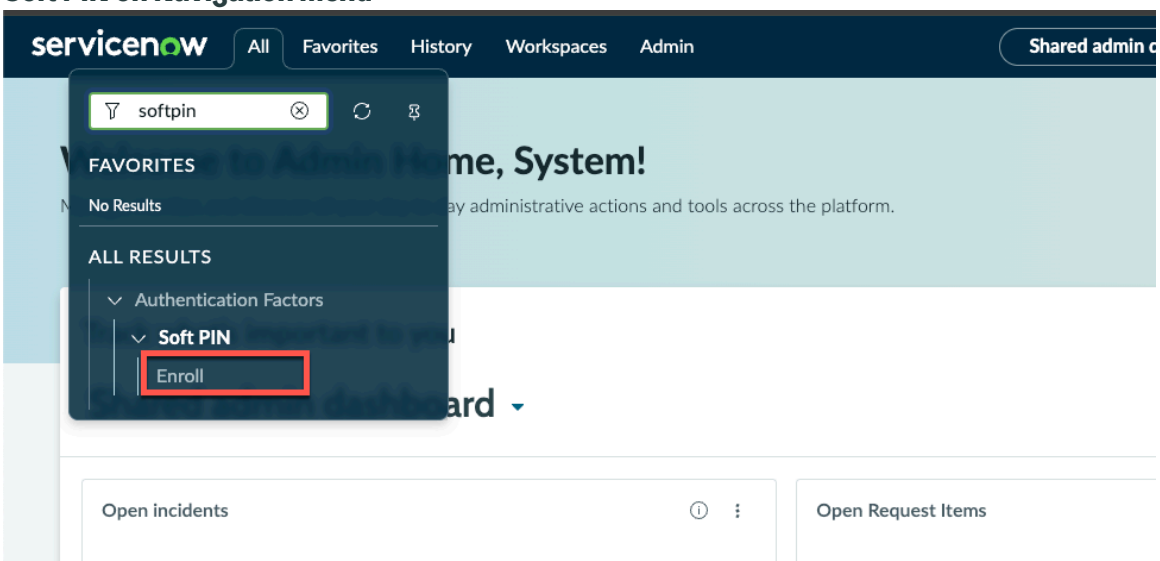
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Soft PIN on Platform UI



- **Navigation menu**: Select **All** > **Authentication Factors** > **Soft PIN** > **Enroll**.

Soft PIN on Navigation menu

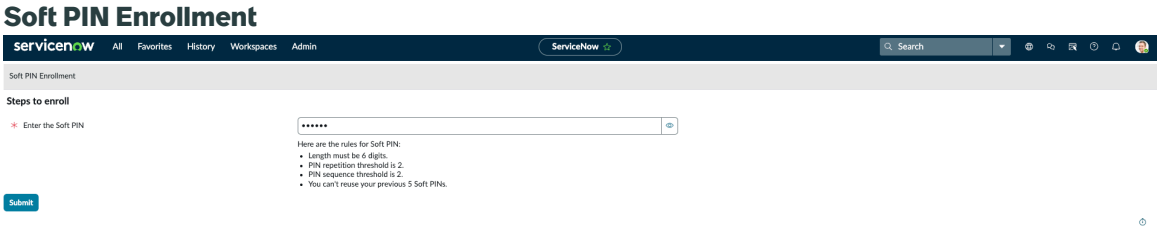


2. Create a PIN that meets these requirements:

Rules for Soft PIN:

- The PIN must be exactly six digits in length
- No single digit must be repeated more than twice consecutively
- Don’t use ascending or descending numeric sequences longer than two digits
- Can’t reuse any of your previous five PINs

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



3. Select **Submit**.

Result
You can use the submitted Soft PIN to authenticate various ServiceNow system or service. For example, AI voice service.

Note:
Users are eligible for Soft PIN enrollment only if their user ID is present in **sys_user** table. If its missing, an enrollment failure message is displayed.

SMS One-time passcode (OTP) authentication

SMS one-time password (OTP) authentication is a method used to verify user identity by sending a temporary, numeric code to the user's registered mobile number. The user enters this code to complete authentication.

Use case

- Serves as a secondary authentication factor, particularly for users without authenticator apps.
- Recommended for medium-risk scenarios, such as verifying changes to profile information and approving login attempts.

Key strengths

The SMS OTP method offers the following advantages:

- Familiar and easy for users to adopt
- No additional app installation required
- Simple to deploy and integrate

Important considerations

While SMS method is a convenient authentication method, there are several considerations to keep in mind:

- Vulnerable to SIM-swapping, interception, and delivery delays.
- Reliant on mobile network availability.
- Not recommended as the sole authentication factor for high-risk or sensitive operations.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

SMS OTP can enhance overall security when used appropriately. For detailed configuration instructions, see Multi-factor authentication Providers.

Knowledge-based authentication (Security Questions)

Knowledge-based authentication (KBA) is an identification and authentication method that verifies callers by prompting them to answer preconfigured questions across conversational AI channels, such as AI voice agents. KBA also supports validation against external systems through custom scripts, enabling identification of callers whose data resides outside ServiceNow AI Platform.

These questions leverage personal information that only the authorized user should know, such as the last four digits of their SSN. KBA relies on information known only to the caller, adding an extra layer of security for applications and services. However, due to the nature of this information, KBA is best suited for low-risk scenarios.

Use Case

Low-risk authentication (for example, general IT support, public documentation access, and so on).

Key Strengths

The KBA method offers the following advantages:

- No additional device or internet connectivity required
- Familiar to most users

Important Considerations

While the KBA method is a convenient authentication method, there are several considerations to keep in mind:

- Low security as answers can be guessed, obtained from public records, or exposed via social engineering.
- Not recommended as the sole verification method for sensitive operations.

KBA can enhance overall security when used appropriately. For detailed configuration instructions, see:

- Create KBA questions
- Create KBA answers
- Map KBA questions to answers
- Assign KBA questions to your AI voice agent service

Configure knowledge-based authentication

Configure knowledge-based authentication (KBA) to identify and authenticate callers by prompting them to answer preconfigured questions across conversational AI channels, such as AI voice agents.

Before you begin
Role required: auth_factors_admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Authentication Factors** > **Knowledge Based Factor**.
2. Perform the following:
   - Create KBA questions
   - Create KBA answers
   - Map KBA questions to answers
   - Assign KBA questions to your AI voice agent service

   After creating the KBA configurations, you can use it as an identification and authentication method.

Create KBA questions

Create knowledge-based questions that can be preconfigured as security questions to confirm the user's identity.

Before you begin

Role required: auth_factors_admin

Procedure

1. Navigate to **All** > **Authentication Factors** > **Knowledge Based Factor** > **Questions**.
2. Select **New** on the Knowledge Based Questions page.
3. Specify the following fields on the form:

Common fields (required for all input types)

Field	Description
Question	Define a security question to be used for user identity verification. Example: `What is your business phone number?`
Application	Global application scope is selected by default.
Keyword	Enter the primary keyword that best describes the question. Example: `business_phone`.
Category	Select the category. Options: - Others - Phone Number **Note:** Selecting **Phone Number** enables partial matching against the stored phone number, for example, matching even if the area code is not included.
Input Type	Select how the user provides their answer. Options:

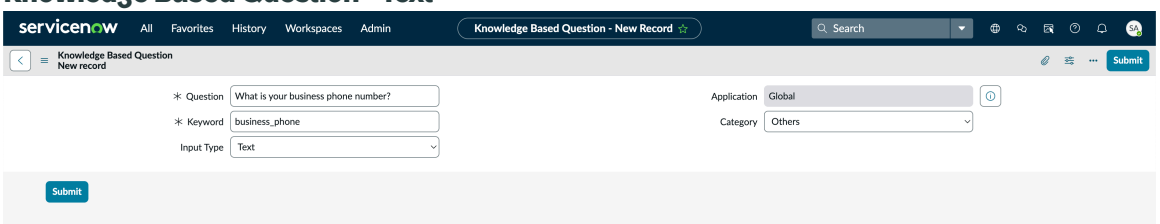
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	○ **Text** (user enters a numeric response via phone keypad) ○ **Voice** (user speaks their response).

4. Select the Input Type:

   a. Option A: Input Type as **Text**.

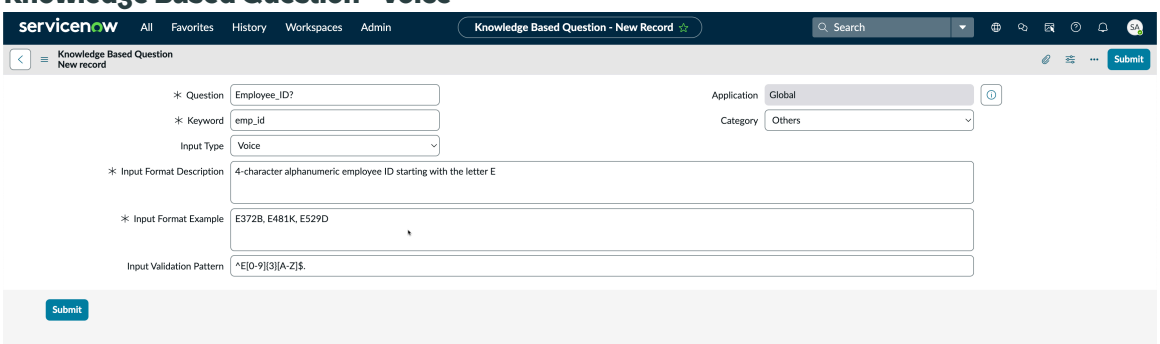
Knowledge Based Question - Text



> **Note:**
> If Input Type is set to **Text**, no additional fields are required.

   b. Input Type as **Voice**.

Knowledge Based Question - Voice



> **Note:**
> The following fields available as a mandatory field when Input Type is set to **Voice**.

Voice input fields

Field	Description
Input Format Description	Describe the expected format and structure of the spoken response. For example: 5-character alphanumeric employee ID starting with the letter E.
Input Format Example	Specify comma-separated examples of valid spoken responses. For example: E372B, E481K, E529D.
Input Validation Pattern	Specify a regular expression pattern to validate the spoken response against the

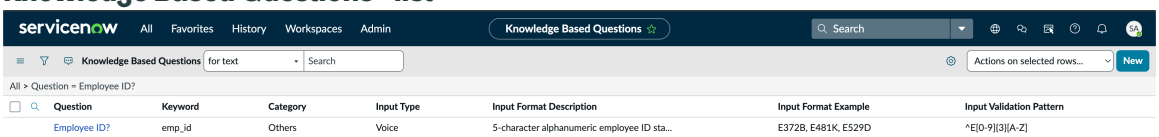
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	expected format. For example: ^E[0-9]{3}[A-Z]$.

5. Select **Submit**.

Result
You're redirected to the Knowledge Based Questions list view. Verify if your question is successfully added.

Knowledge Based Questions - list



Create KBA answers

Create knowledge-based answers for the preconfigured security questions to confirm the user's identity.

Before you begin
Role required: auth_factors_admin

KBA validates answers against records in ServiceNow AI Platform tables by default. To validate against an external source such as a CRM or order management platform, select **Identification** in the Script Configuration field. External data is never imported or stored in ServiceNow AI Platform; the script handles all interaction with the external system. For the caller to be eligible for authentication, the script output must return `sys_user` table.

The User Column field determines whether an identified caller can proceed to authentication. When populated with a field that links to a system user account, the caller is eligible for authentication. When left empty or mapped incorrectly, the caller is treated as a guest — the caller can access personalized, non-sensitive information but cannot be authenticated.

Procedure
1. Navigate to **All** > **Authentication Factors** > **Knowledge Based Factor** > **Answers**.
2. Select **New** on the Knowledge Based Answers page.
3. Specify the following fields on the form:

Common fields

Field	Description
Script Configuration	Select the type of script-based validation. Options: ○ **None** (validate against a ServiceNow table) ○ **Identification** (validate a caller's identity via a custom script against an external system).

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Note: When the Script Configuration set to **Identification**, the Answer Table, Answer Column, and User Column fields are replaced by a Script editor.
Description	Define a description for the answer. For example: Business Phone Number.
Application	Global application scope is selected by default.

4. Specify the following fields for configuring internal source:

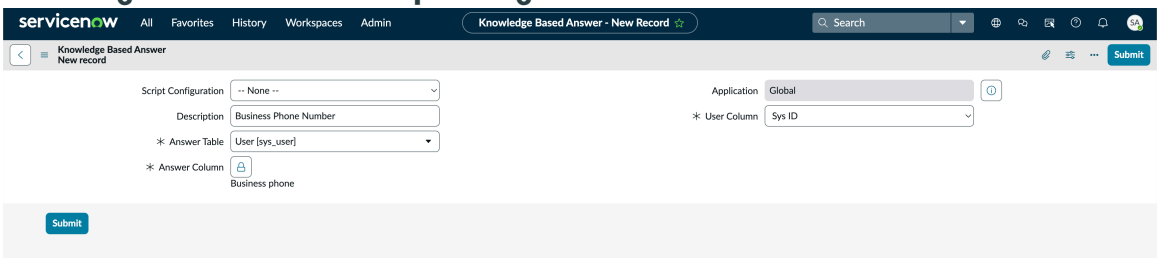
Note: The following fields are available when Script Configuration is set to **None**.

Internal source fields

Field	Description
Answer Table	Select the answer table. **Note:** The selected table should have a field referenced to the `sys_user` table.
Answer Column	Select the answer column from the **Available** list. Example: `Business phone`.
User Column	Select the field that links records in the Answer Table to a system user account. For example: sys_user. **Note:** ○ All fields from the Answer Table are displayed, but only fields that reference a system user account can be selected. If the Answer Table is `sys_user`, the `sys_id` field can also be selected. ○ When populated with a valid `sys_user` reference, the answer supports identification and authentication. When left empty, the answer supports guest identification only. ○ Whether this field is required is controlled by the `glide.auth_factors.kba.enable_user_col` property. To know more about the properties, see System Properties.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Knowledge Based Answer - Script Configuration: None



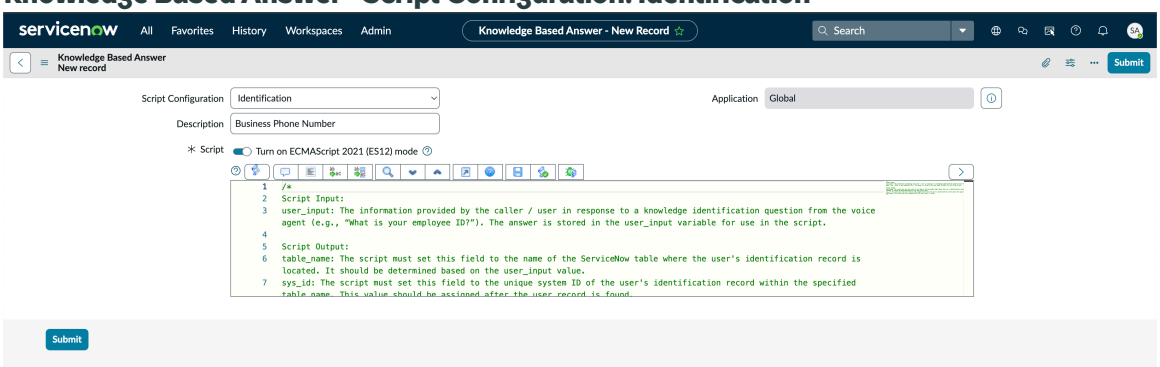
5. Specify the following fields for configuring external source:

> **Note:**
> The following field is available when Script Configuration is set to **Identification**.

External source fields

Field	Description
Script	Define the custom script to validate the answer against an external system. Script requirements are as follows: ○ The script must be scoped. ○ The system receives the caller's answer as `user_input` and must return the **table_name** and matched record's `sys_id` as the output. ○ For records in tables other than `sys_user`, the **table_name** must also be returned. ○ Script execution is limited to 15 seconds by default. This is to avoid long wait times for the caller. To adjust, configure the `glide.auth_factors.kba.script_execution_t` To learn more see, System Properties.

Knowledge Based Answer - Script Configuration: Identification



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
One question can have many answers. All answers for that question must follow the same rule:

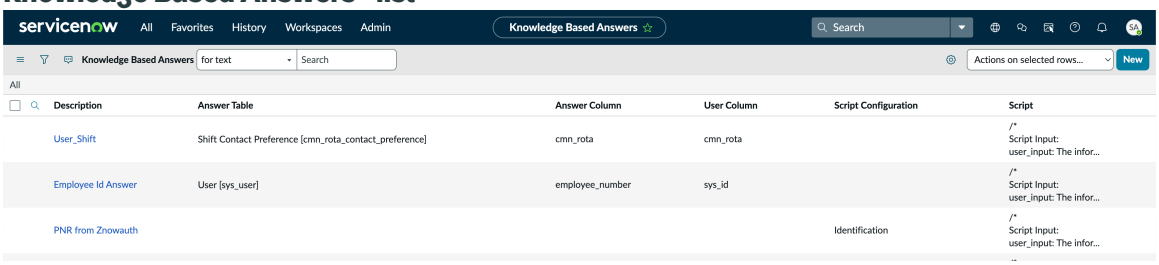
- Either all answers support identification only
- Or all answers support identification and authentication

You cannot have some answers that authenticate users and others that don't for the same question.

6. Select **Submit**.

Result
You're redirected to the Knowledge Based Answers list view. Verify if your answer is successfully added.

Knowledge Based Answers - list



The following properties control the behavior of knowledge-based authentication (KBA), including security question validation, answer matching, and user identification settings.

System properties

System properties	Description	Value
`glide.auth_factors.kba.enable_user_column`	Controls whether the User Column field is mandatory when creating or updating an answer. **Note:** All answers mapped to the same question must follow the same pattern — either all supporting identification and authentication, or all supporting identification only. Mixing is not supported.	`false`
`glide.auth_factors.kba.script_execution_timeout`	Controls the script execution time limit in seconds for external source validation. Minimum: 1 second, Maximum: 30 seconds.	`15`

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Map KBA questions to answers

Create knowledge-based questions and answer mapping to confirm the user's identity.

Before you begin

Role required: auth_factors_admin

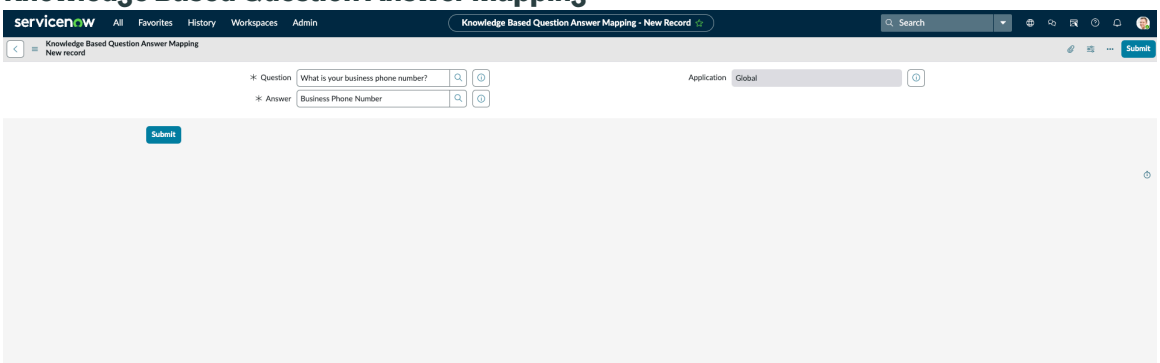
Procedure

1. Navigate to **All** > **Authentication Factors** > **Knowledge Based Factor** > **Question Answer Mappings**.
2. Select **New** on the Knowledge Based Question Answer Mappings page.
3. Specify the following fields on the form:

Knowledge Based Question Answer Mappings

Field	Description
Question	Select the question that you would like to map with the answer. Example: `What is your business phone number?`
Application	Global application scope is selected by default.
Answer	Select the answer for mapping to the question. Example: `Business Phone Number`.

Knowledge Based Question Answer Mapping



4. Select **Submit**.

Result

You're redirected to the Knowledge Based Question Answer Mappings list view. Verify if your mapping is successfully added.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Knowledge Based Question Answer Mappings - list

Assign KBA questions to your AI voice agent service

Specify the questions that should be used for user identification and authentication with a specific voice agent.

Before you begin

Role required: auth_factors_admin

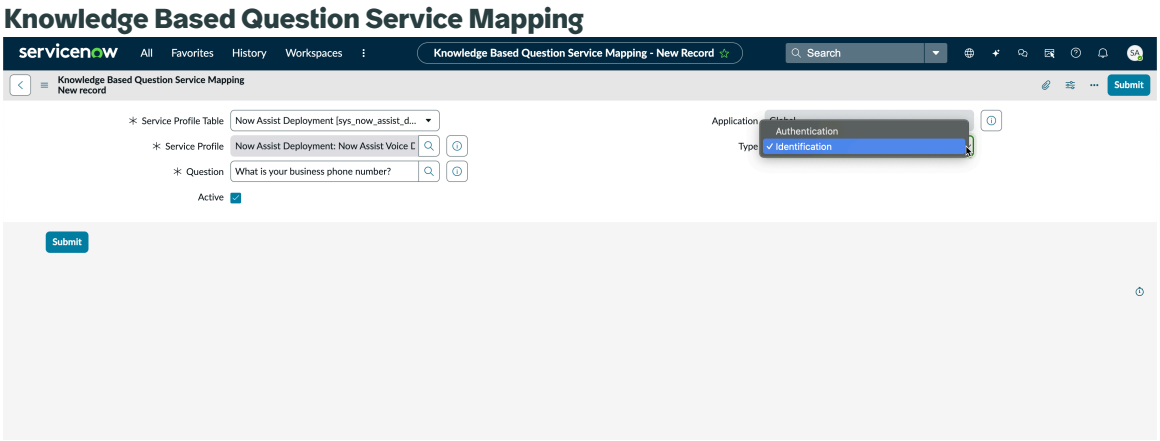
Procedure

1. Navigate to **All** > **Authentication Factors** > **Knowledge Based Factor** > **Question Service Mappings**.
2. Select **New** on the Knowledge Based Question Service Mappings page.
3. Specify the following fields on the form:

Knowledge Based Question Service Mappings

Field	Description
Service Profile Table	Select the table for your service.
Application	Global application scope is selected by default.
Service Profile	Select the service profile. Example: Choosing a voice agent: **Now Assist Voice Deployment - 22**.
Type	Select the type for which you would use the service mapping. Options: ○ Authentication ○ Identification **Note:** The **Type** field is the only differentiating factor between **Identification** and **Authentication** configuration using KBA.
Answer Column	Select the question that you want to use for the service verification.
Active	Select to set the configuration active.

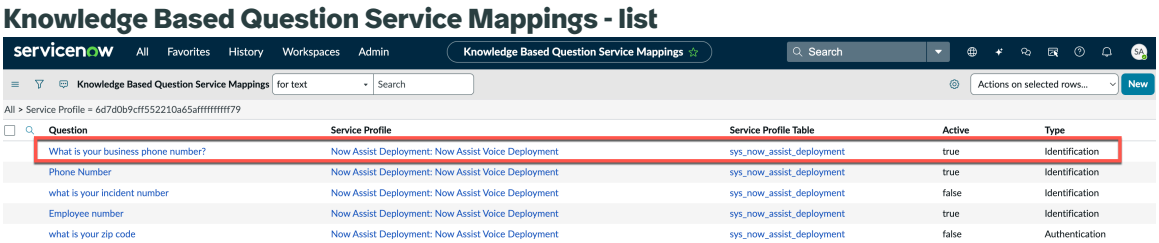
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



4. Select **Submit**.

Result

You're redirected to the Knowledge Based Question Service Mappings list view. Verify if your mapping is successfully added.



Certificate-based authentication

Certificate-based authentication lets you mutually authenticate user logins or inbound API requests using certificates from a trusted Certificate Authority (CA).

Note:
Certificate Based Authentication is not supported on the On-Prem and edge encryption enabled instance.

Certificate-based authentication for user interface logins

Enable end users to use PIV (Personal Identity Verification) or CAC (Common Access Card) cards to log in to the ServiceNow AI Platform or Service Portal instead of using a user name and password. To set up mutual authentication for user interface logins, see Set up Certificate-based authentication.

After Certificate-based authentication is set up, end users can finalize their set up and log in. See Log in using Certificate-based authentication.

Certificate-based authentication for Inbound web services

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Authenticate inbound requests to ServiceNow SOAP and REST APIs. To set up mutual authentication for inbound web services, see Set up Certificate-based authentication.

Set up Certificate-based authentication

Set up mutual authentication for either user interface-based logins or inbound web services.

Before you begin

Role required: admin

Check that your instance is using an ADCv2 load balancer. For more information, see theADCv2 Migration knowledge article. If your instance is not using the ADCv2 load balancer, contact Now Support.

Procedure

Set up Certificate-based authentication in order to:

- Allow end users to securely log in to the ServiceNow AI Platform or Service Portal using PIV or CAC cards. After certificate-based authentication is enabled, you can self-register the PEM certificate or an administrator can map the certificate for you. See Log in using Certificate-based authentication.
- Enable mutual authentication for inbound web services. Once Certificate-based authentication is set up, the system uses the provided certificates to mutually authenticate requests to access ServiceNow REST and SOAP APIs.

Activate Certificate-based authentication

You can activate the Certificate-based authentication plugin (com.glide.auth.mutual) for ServiceNow AI Platform if you have the admin role.

Before you begin

Role required: admin.

About this task

The following Tables are installed with Certificate-based authentication:

- sys_user_certificate
- sys_ca_certificate
- sys_ca_certificate_api_track

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the Certificate-based authentication plugin (com.glide.auth.mutual) using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Register CA certificate

Register root certificates or intermediate certificates to make them available for authentication.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **Certificate Based Authentication** > **CA Certificate Chain**.
2. Click **New**.
3. On the form, fill in the fields:

Mutual Auth CA Certificate form

Field	Description
Name	Name to identify the certificate.
Expiration notification	Option to warn users when a certificate is about to expire.
Notify on expiration	List of users to be notified when the certificate expires.
Warn in days to expire	Number of days when a notification is sent to users before a certificate expires.
Active	Option to make the client certificate active.
Format	PEM
Type	Type of certificate. Options include: ○ **CA Cert**: The root CA certificate. Can also include intermediate certificates in the chain. CA certificates are automatically synced with the load balancer. Use this option when possible to avoid missing a required certificate in the chain. ○ **Intermediate Cert**: An intermediate certificate in the certificate chain. This certificate remains on the instance only and is not synced with the load balancer. Only use this option if you need to add an intermediate certificate to an existing chain.
Short description	Short description of the user client certificate.

Note:
During the certificate upload, the read-only fields, **Valid from**, **Expires**, **Expires in days**, **Issuer**, and **Subject**, **Certificate Chain**, and **PEM Certificate** are extracted and auto-populated.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Click **Submit**.
5. **Optional:** Click **Validate Stores/Certificates** to validate the certificate.

Map PEM certificate to user

Map PEM certificates to users to enable them to log in using PIV or CAC cards or to authenticate inbound requests. You can map multiple PEM certificates to a user.

Before you begin

- Role required: admin
- Make sure that you have the Privacy Enhanced Mail (PEM) certificate of the user.

Note:
After the Map PEM certificate to User configuration, the "verify certificate" will fail. This is because the PEM certificate is not stored.

Procedure

1. Navigate to **All** > **Certificate Based Authentication** > **User to Certificate Mapping** and click **New**.
2. On the form, fill in these fields:

User Client Certificate form

Field	Description
Name	Name of the user client certificate.
Expiration notification	Option to warn users when a certificate is about to expire.
Warn in days to expire	Number of days when a notification is sent to users before a certificate expires.
Notify on expiration	List of users to be notified when the certificate expires.
Active	Option to make the client certificate active.
User	User who is mapped to the client certificate. The system receives the client certificate from either the inbound request or certificate registration, and then uses the user designated in this field to initiate a session to execute the request.
Short description	Short description of the user client certificate.
Format	Privacy Enhanced Mail (PEM) format is a base-64 encoded Distinguished Encoding Rules (DER) certificate.
Type	Client cert. This field is read only.

Note:
During the certificate upload, the read-only fields, **Valid from**, **Expires**, **Expires in days**, **Issuer**, and **Subject** are extracted and auto-populated.

3. Click the attachments icon and upload the certificate.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Click **Submit**.
   The certificate is validated and mapped to the specified user if the certificate is from a trusted Certificate Authority (CA).

Configure Certificate-based authentication properties

Use system properties to enable or disable certificate-based authentication features.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **Certificate Based Authentication** > **Properties**.
2. On the form, fill in the fields:

Certificate Based Authentication Properties form

Property	Description
Enable certificate based authentication	Option to enable to Certificate-based authentication for both user interface logins and inbound web services. Default: true
Show 'Log in with PIV/CAC' option in login screen	Displays the **Log in with PIV/CAC card** option on the login screen. Allows users to log in using Certificate-based authentication using the user interface. Default: false
Enable auto-redirect for certificate based login	Determines whether to require that the user click **Log in with PIV/CAC card** after selecting a registered certificate and entering their PIN. Activate to automatically log in the user after they select a registered client certificate and enter their PIN. Deactivate to require that the user click **Log in with PIV/CAC card** after they select a registered client certificate and enter their PIN. Default: false

Log in using Certificate-based authentication

After your administrator sets up Certificate-based authentication, you can register the client certificate and log in using your PIV (Personal Identity Verification) or CAC (Common Access Card) card.

Register client certificate for your PIV or CAC card

Before you log in to ServiceNow AI Platform using your PIV or CAC card, you must register the client certificate of your PIV or CAC card. If you are not able to register the client certificate, contact your administrator. Your administrator can also register the client certificate of your PIV or CAC card.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin

- Make sure that Certificate-based authentication is enabled.
- Make sure that a card reader is connected to your computer and your PIV or CAC card is inserted.
- Role required: none

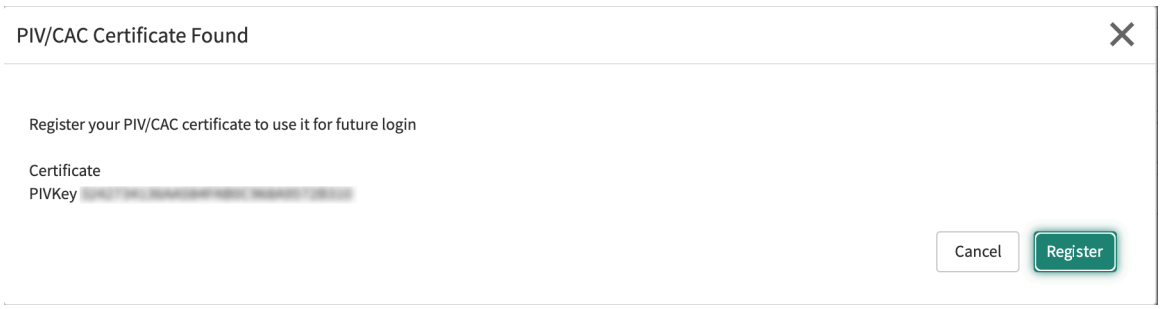
About this task

If you need an admin to register your client certificate, see Map PEM certificate to user.

Procedure

1. Log in to ServiceNow AI Platform using your user name and password.
2. Click your name from the **User Menu** and select **Profile**.
3. From the **Related Links**, click **Register client certificate**.

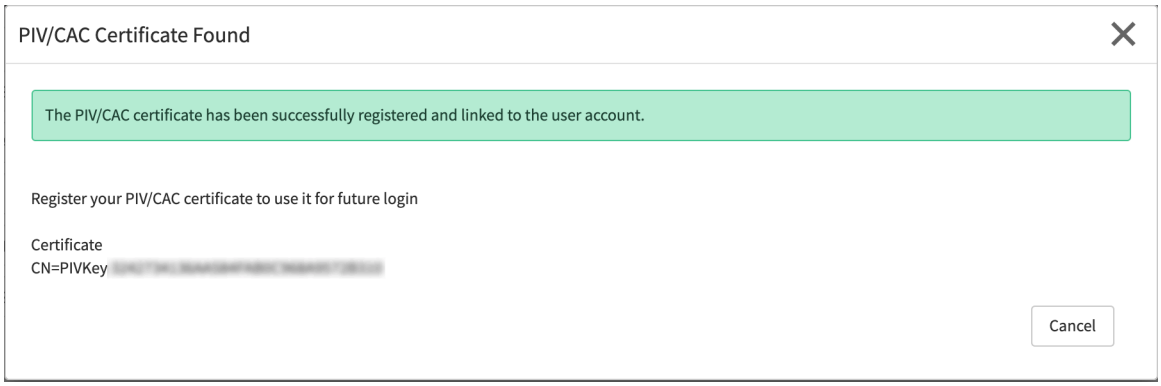
   If a valid is certificate is available, the following message displays:



4. Click **Register**.

   After the registration is successful, the following message displays:

   ```
   The PIV/CAC certificate has been successfully registered and
   linked to the user account.
   ```



The next time you log in to your ServiceNow AI Platform, you can log in using your PIV or CAC card. For more information, see Log in to ServiceNow AI Platform using PIV or CAC card.

Log in to ServiceNow AI Platform using PIV or CAC card

You can log in with your PIV or CAC card instead of user name and password when Certificate-based authentication is enabled on ServiceNow AI Platform.

Before you begin

- Role required: none
- Make sure that Certificate-based authentication is enabled.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

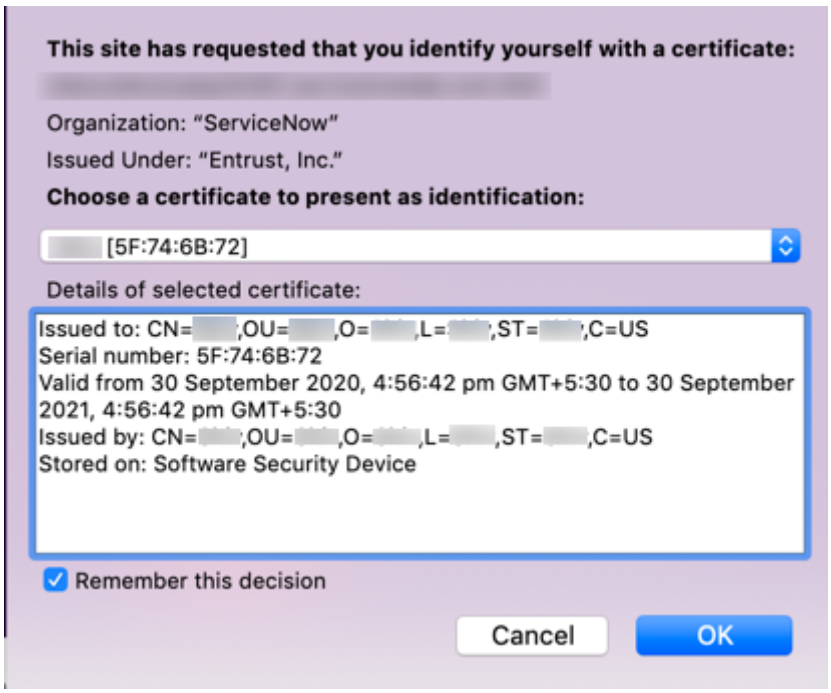
- Make sure that a PIV or CAC card reader is connected to your computer.
- Make sure that a client certificate of your PIV or CAC card is mapped to you. For more information, see Register CA certificate.

Procedure

1. Insert your PIV or CAC card into the card reader.
2. Navigate to your instance in a browser.
   Browser prompts for a PIN for your PIV or CAC card.
3. Enter the PIN of your PIV or CAC card in the browser prompt.

   Note:
   If you forget your PIN, contact your administrator.

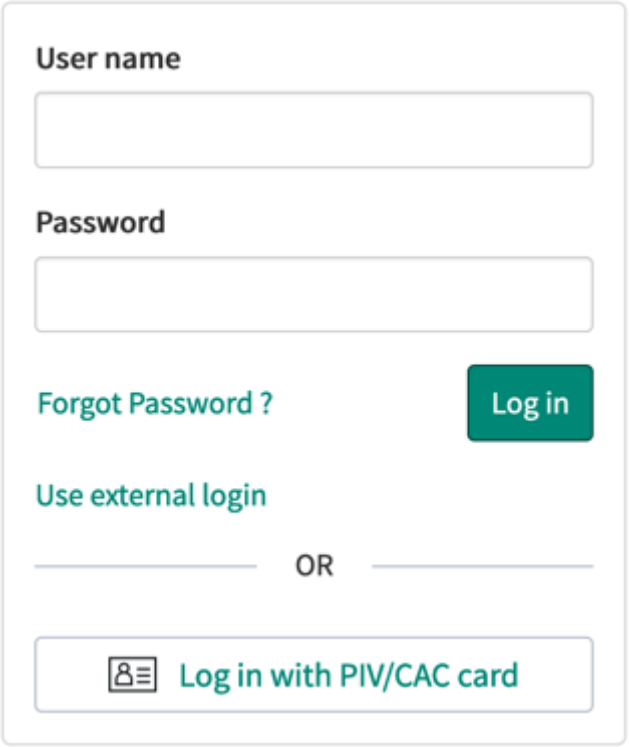
4. If you enter a correct PIN, the browser displays a prompt to select a certificate.



5. Select a certificate from the browser prompt.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

If the certificate is valid and mapped to you, you are redirected to the login page.



6. Click **Log in with PIV/CAC card** button.

   To log out of the ServiceNow AI Platform, you must remove the PIV or CAC from the card reader and then close the browser.

Manage your client certificates

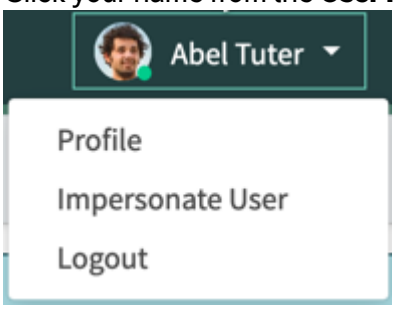
View and delete client certificates associated with your account.

Before you begin

- Make sure that Certificate-based authentication is enabled.
- Role required: none

Procedure

1. Log in to ServiceNow AI Platform using your user name and password.
2. Click your name from the **User Menu** and select **Profile**.



3. From the **Related Links**, click **Manage your client certificates**.
   The User Client Certificates [sys_user_certificate] table opens and displays certificates that are associated with your account.
4. View or delete certificates associated with your account.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Custom instance URLs

You can enable your ServiceNow instance to be accessible from a company-branded or custom URL.

Custom URL overview

You can use custom URL to enable ServiceNow instance to be accessible from one or more company-branded or custom URLs.

Custom URLs can be associated with specific portal. For example, admin can define `http://support.acme.com` for CSM portal and `http://hr.acme.com` for HR portal. In such situation there is a need to redirect users to different IdPs for authentication on the basis of the custom URL that users are accessing.

Important:

- Do not create a custom URL with more than 100 domains per instance.
- You must delete custom URL record from ServiceNow instance first and then delete any Domain Name Server (DNS) entries from the DNS server.
- Any deletion of DNS entry from DNS server prior to deletion of custom URL record from ServiceNow instance would result in blocking the deletion of other corresponding custom URL records from ServiceNow.

From Tokyo, you can allow users to auto-redirect to specified IdPs defined at the custom URL record.

Note:
Custom URLs are not available for on-premise customers or developer instances. Also, the URL must be public-facing.

Only the owner of the top-level domain (TLD) or any subdomain can configure the custom URL to a DNS subdomain. For example, your instance might have the following designated URL and additional custom URLs:

Custom URL example

Example URLs	Usage
`https://acme.service-now.com`	The initial domain name for Acme that came with the ServiceNow instance.
`https://support.acme.com`	A custom URL that associates to your ServiceNow instance. This URL is referred to as an alias (CNAME) of the initial domain name.
`https://US-support.acme.com`	A secondary custom URL that associates to a service portal on your instance. Your instance can support multiple custom URLs to the same service portal.

Custom URL considerations outside of your instance

Before you can associate a custom URL, you must own (or purchase) a URL through a domain provider. There are also specific configurations necessary before you can create and associate a custom URL on your instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Custom URL configurations

Configuration items	Description
Set the CNAME with the provider	The CNAME record must be set as the ServiceNow instance URL.
Determine your dedicated VIP status	The status of VIP.

Note:
When deleting or updating CNAME records which point to your instance, you must follow this sequence to avoid dangling records in the instance. First, delete the CNAME records from your instance and then remove or update the CNAME setting at your DNS provider.

Activate custom URLs

Enable custom URLs to be set up on your ServiceNow instance. You can activate the Custom URL plugin (com.snc.customurl) if you have the admin role.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Definition** > **Plugins**.
2. Find and click the **Custom URL** plugin.

   Note:
   Do not select the **Custom URL - Internal** plugin, which is an internal component for scripted custom URL APIs.

3. On the Custom URL record, click the **Activate/Repair** related link.
4. In the Plugin Activation window, click **Activate**.
   When the Plugin Activation window reopens with a message that the plugin is activated, click **Close & Reload Form** to stay on this form.
5. In the Plugin Files related list, find the following property, and change the setting value:

Option	Description
glide.customurl.enabled	To enable custom URLs, set the value to **True**. By default, this property is set to **False**, which means that you cannot associate a custom URL. **Note:** To disable this feature, set this property back to **False**.

6. Click **Update**.

Set a custom URL as the instance URL

Add a custom URL to your instance configuration to use instead of your ServiceNow URL.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin

Role required: admin

You must activate the custom URL plugin and have purchased or registered a URL before adding the custom URL to your instance.

Procedure

1. Navigate to **All** > **Custom URL** > **Custom URLs**.
2. You should either:
   - Click **New** to associate a new domain name that is new to your instance.
   - Select a custom URL already set up to set as your instance URL.
3. Fill in the appropriate fields:

Custom URL fields

Field	Description
Domain Name	Fully qualified domain name (FQDN) of the custom URL. The FQDN is a CNAME redirect created in the name server record for the custom domain. **Note:** For example, in the name server for acme.com, you might create an entry: `support.acme.com 300 IN CNAME acme.servicenow.com`
Is Instance URL	Check box to enable this custom URL for all outbound URLs. Only one active custom URL can be the instance URL. To enable this setting for a custom URL, click **Set as Instance URL** on the URL record. Any previous custom URLs are then removed.
Status	Status of the custom URL record. If the status is **Active**, the custom URL is provisioned and ready to use.
Service Portal	Service portal that you want to use when you redirect users to your instance using the custom URL.
Identity Provider	Identity Provider for the custom URL enables you to allow users to auto-redirect to specified IdPs defined at the custom URL record.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

A custom URL should activate within six hours on your instance.

Note:

- You must delete custom URL record from ServiceNow instance first and then delete any Domain Name Server (DNS) entries from the DNS server.
- Any deletion of DNS entry from DNS server prior to deletion of custom URL record from ServiceNow instance would result in blocking the deletion of other corresponding custom URL records from ServiceNow.

Custom URL with Identity Provider

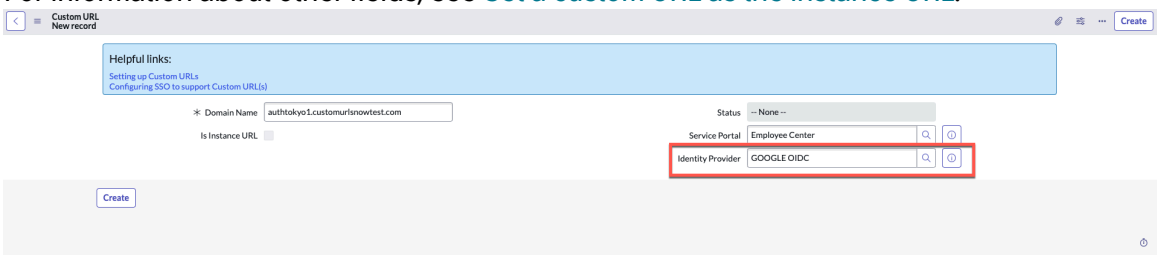
Set your custom URL with the Identity Provider to enable the user to login with their IdP's.

Before you begin

Role required: admin

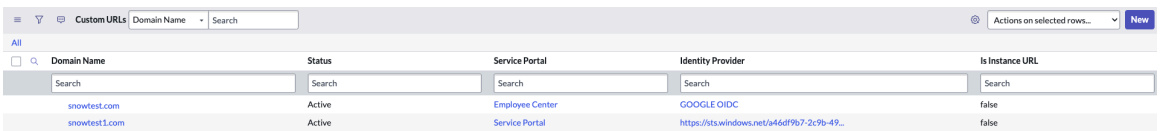
Procedure

1. Navigate to **All** > **Custom URL** > **Custom URLs**.
2. Click **New**.
3. Provide the details of the IdP in the **Identity Provider** field.
   For information about other fields, see Set a custom URL as the instance URL.



4. Click **Create**.

   The record is created and displayed on the Custom URL page.



When the custom URL is accessed, the user is redirected to the Identity Provider that is configured. In this case, accessing the `snowtest.com`, the user is navigated to the **Employee Center**, and then redirected to the Google Identity Provider.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:

- If the Service Portal field is empty and the Identity Provider field is defined, when the user accesses the custom URL, the user is directly navigated to the configured Identity Provider.
- If both the Service Portal and Identity Provider field is defined, when the user accesses the custom URL with the Service Portal that is defined, the user is navigated to the configured Identity Provider.
- If both the Service Portal and Identity Provider field is defined, when the user accesses the custom URL with the different portal that is not defined, the user is navigated to the auto-redirect Identity Provider if configured on the instance.

5. Use the credentials to login to the application.

Custom URL datacenter job information

Every custom URL that is associated to your instance has a corresponding ServiceNow datacenter job which runs and shows URL information that is pertinent to your instance as described in the table.

Job field	Description
Job ID	Unique ID of the job that checks the domain of the custom URL.
Last Run At	Date and time when the job last ran.
Payload	List of domains or custom URLs that were sent to the datacenter for CERT provisioning.
Poll Count	Number of times that the results have polled for this job.
Result	Verifies and validates each domain or custom URL sent in a payload.
Status	Status of the datacenter job.

Generate SP metadata for SAML/SSO custom URL installations

A SAML or SSO installation needs the SP metadata generated for the IdP before the custom URL instance generates.

Before you begin

Role required: admin
The IdP needs SP metadata for the instance to authenticate and forward requests.

Note:
Adding the Assertion Consumer Service URL (SP login URL) might be different for each IdP (Azure, ADFS, or Okta).

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Choose your installed SSO plugin:

Option	Description
Multi-Provider SSO	Navigate to **Multi-Provider SSO** > **Identity Providers**. Choose an IdP and click the **Generate Metadata** button. The integration automatically generates the instance's SP metadata from the system property settings.
SAML 2 SSO	Navigate to **SAML 2 Single Sign-on** > **Metadata**. The integration automatically generates the instance's SP metadata from the system property settings.

2. Copy the SP metadata in the text box.

   For example:

```
<EntityDescriptor xmlns="urn:oasis:names:tc:SAML:2.0:metadata"
 entityID="https://yourinstance.service-now.com">
  <SPSSODescriptor AuthnRequestsSigned="false"
 WantAssertionsSigned="true"
 protocolSupportEnumeration="urn:oasis:names:tc:SAML:2.0:protoc
ol">
  <SingleLogoutService
 Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-Redirect"
 Location="https://yourinstance.service-now.com/navpage.do" />

 <NameIDFormat>urn:oasis:names:tc:SAML:1.1:nameid-format:emailA
ddress</NameIDFormat>
  <AssertionConsumerService isDefault="true" index="0"
 Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"
 Location="https://yourinstance.service-now.com/navpage.do" />
  <AssertionConsumerService index="1"
 Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"
 Location="https://yourinstance.service-now.com/consumer.do"/>
 </SPSSODescriptor>
</EntityDescriptor>
```

3. Provide the instance SP metadata to the IdP.
   For example, SSOCircle allows a user to provide the SP metadata online.
4. **Optional:** To set up custom URLs in Azure:
   a. Go to **App Registrations**.
   b. Select **All apps** from the menu.
   c. Select the **ServiceNow App**.
   d. Click settings to configure the URL.
5. **Optional:** To set-up custom URLs in Okta:
   a. Create two ServiceNow UD Okta Applications.
   b. One Okta Application for the "service-now.com" instance URL.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

c. One Okta Application for the custom URL.

Note:

- Disable the **Disable Force Authentication** within the Okta configuration for the **Test Connection** to run successfully.
- If you're testing the Identity Provider record associated with the base URL, ensure you've to login to the instance with the base URL.
- If you're testing the Identity Provider associated with the Custom URL, ensure you've to login to the instance with the Custom URL.

6. **Optional:** To use OAuth authentication, set up the redirect URL as all the registered custom URLs in the OAuth application endpoint configuration for the external client applications. The redirect URL is synonymous with the callback URL that the authorization server redirects to.
7. **Optional:** To use Google reCAPTCHA service, set up an API key pair.

Custom URL errors and fixes

A list of common errors and associated fixes for a custom URL setup and configuration.

Errors during setup

Error message	Fix
Unable to create a Custom URL. Try again later.	There might be an issue outside of your control interfering with the custom URL creation. Run at a different time before contacting support. **Note:** It usually takes 30 minutes to create a custom URL. If it is taking longer, contact https://support.servicenow.com/now?draw=case.
Unable to submit your new Custom URL request because another Custom URL request for your instance is still in progress.	Check the status on your Custom URL Jobs before you submit a new request.
You must clear the following properties before the instance URL can be set: Glide Proxy, Glide Servlet.	
The provisioning of <custom_domain> is still in progress. This process can take up to X hours. Your instance administrator will receive a notification when this process completes.	After the provisioning on an instance starts for a custom URL, you must wait for the process to complete before the status changes.
<custom_domain> is now set as the new instance URL. <base.service-now.com> is still in service, but all new URLs, such as in notifications, will use <custom_domain>.	Only one URL can be designated as the instance URL. The other URLs that are associated with your instance can be active, but only the instance URL can use notifications.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Error message	Fix
The Custom URL <custom_domain> is set to be immediately removed from the instance configuration and revert back to <base.service-now.com>. <custom_domain> continues an association to this instance as long as the CNAME record in your DNS is set.	This message confirms that you intend to change your custom URL. By accepting this confirmation, you initiate the change of the URL to your instance. Any URL that is on your Domain Name list, as a custom URL, can be active unless you remove it from the CNAME record on your provider.
You cannot modify glide.servlet.uri. This property is set by Custom URL.	
You cannot modify glide.proxy.host. This property is set by Custom URL.	
The CNAME record for <custom_domain> does not point to <base.service-now.com>.	The configuration on the URL provider side is not correct. Check your configuration on the CNAME record.
Missing CNAME record for <custom_domain>.	The CNAME record must be configured from your URL provider before the custom URL can be set for your instance.

Installation exits

Installation exits are customizations that exit from Java to call a script before returning back to Java.

Note:
Functionality described here requires the **Admin** role.

Available installation exits

Navigate to **System Definition** > **Installation Exits**. Some installation exit names (Login, Logout, ValidatePassword, ExternalAuthentication) are reserved and cannot be changed. Other installation exits can override these with custom script that replaces the script in the default installation exit.

The following installation exits are available in the base system:

Installation Exit	Description
Login	Takes a username and password pair and authenticates with the user object
Logout	Takes the user to the welcome page upon signing out; can be overridden by LogoutRedirect
LogoutRedirect	Takes the user to a specified URL upon signing out
ExternalAuthentication	Authenticates using header, parameter, or cookie; can be overridden by DigestSingleSignOn and PGPSingleSignOn
DigestSingleSignOn	Authenticates using header, parameter, or cookie and decrypts Digest encryption
PGPSingleSignOn	Authenticates using header, parameter, or cookie and decrypts PGP encryption

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Installation Exit	Description
ValidatePassword	Active by default, starting with the Helsinki release; allows customers to define their own password validation; can be overridden by ValidatePasswordStronger
ValidatePasswordStronger	Requires passwords be at least 8 characters long and contain a digit, an uppercase letter, and a lowercase letter
GetIntegrationSessionTimeout	Implements the default integration session timeout behavior.

Login modifications

The following modification to the **Login** installation exit sets each user's session timeout value as the user is logging in. In this particular example, if the user name is *admin*, the session is set to timeout in 30 seconds.

```
gs.include("PrototypeServer");

var Login = Class.create();
Login.prototype = {
 initialize : function() {
 },

        process : function() {
          // the request is passed in as a global
          var userName = request.getParameter("user_name");
          var userPassword =
 request.getParameter("user_password");

          var authed = GlideUser.authenticate(userName,
 userPassword);
          if (authed) {
             //
 ************************************************************
             // customization - if the userName == admin, set
 the session
             // timeout to be 30 seconds. You can implement your
 own
             // session timeout algorithm here by checking to
 see if a user
             // belongs to a certain group or has a certain
 role.
             // Values of setMaxInactiveInterval exceeding 1440
 minutes are
             // treated as one day (1440 minutes).

           if (userName == "admin") {
              request.getSession().setMaxInactiveInterval(30);
             }
             //
 ************************************************************
             return GlideUser.getUser(userName);
          }

          this.loginFailed();

          return "login.failed";
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
        },

        loginFailed : function() {
          var message = GlideSysMessage.format("login_invalid");
          var gSession = GlideSession.get();
          gSession.addErrorMessage(message);

          var userName = request.getParameter("user_name");
          EventManager.queue("login.failed", "", userName, "");
        }

}
```

Session timeout can also be set according to IP address.

```
gs.include("PrototypeServer");

var Login = Class.create();
Login.prototype = {
 initialize : function() {
 },

        process : function() {
          // the request is passed in as a global
          var userName = request.getParameter("user_name");
          var userPassword =
 request.getParameter("user_password");

          var authed = GlideUser.authenticate(userName,
 userPassword);
          if (authed) {

          //
 ************************************************************
          // customization - if the user is logging in from a
 particular IP
          // range starting with XXX.XXX you can implement your
 own
          // session timeout algorithm here by checking the
 login IP
          //
          // Values of setMaxInactiveInterval exceeding 1440
 minutes are
          // treated as one day (1440 minutes).

          var clientIP =
 gs.getSession().getClientIP().toString();

          // if client IP starts with specified range
          if (clientIP.indexOf('XXX.XXX') == 0) {
             // set to 10 hours
             request.getSession().setMaxInactiveInterval(60 * 60
 * 10);
          }
          //
 ************************************************************
```

```
            return GlideUser.getUser(userName);
          }

          this.loginFailed();

          return "login.failed";
        },

        loginFailed : function() {
          var message = GlideSysMessage.format("login_invalid");
          var gSession = GlideSession.get();
          gSession.addErrorMessage(message);

          var userName = request.getParameter("user_name");
          EventManager.queue("login.failed", "", userName, "");
        }

}
```

Related topics

IP range based authentication

One way to secure a web-based application is to restrict access based on the IP address.

You can block access to a specific address or range of addresses that you suspect belong to malicious individuals. The instance allows you to control access by IP address.

Note:
Use the Adaptive Authentication (AA) pre-authentication context policy to enforce IP based authentications and restrictions for additional capabilities. For more information, see Adaptive authentication.

Notes and Limitations:

- The system won't let you lock yourself out, so if you try to add a rule such that your current address would be locked out, the system warns you and refuses your insert.
- If you're inside of a corporate intranet, be very careful about setting up your IP rules. The IP address you see on your own computer (like 10.10.10.25) generally bears no relationship to the IP address you will actually appear as out on the internet. Your company likely proxies and/or NATs your address into a predictable set of outbound addresses which you will likely need to ask your network team about.
- A user whose access is restricted based on an access rule gets a 403 error on their browser.
- Restricted users do not use transactions, semaphores, or count towards any server resource counts.
- This feature does not supersede or override your existing access control rules if, for example, you're running a VPN to our data center. It's an additional check that must be met in addition to any access controls we may have set up on your PIX.
- Allow rules always supersede deny rules. So if an address is both allowed (by one rule) and denied (by a second rule) it is, in fact, allowed.
- Asterisks and CIDR blocks are not currently supported.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Regarding forwarded proxy addresses, the allow rules are applied to each address in the chain and then the deny rules are applied to each address in the chain if none of the allow rules matched.
- IP range based authentication can effect the transfer of update sets. If IP address access control is enabled on the source instance, add the IP addresses of all application nodes supporting your instance as exceptions.

Note:
To find your instance IP information, Log in to ServiceNow - NOW Support, and Search for the **My IP Information** service catalog item.

Note:
To learn more about the *com.snc.ipauthenticator* and *glide.ip.authenticate.strict* properties, which restrict instance access to specific IP ranges, see the following topics in Instance Security Hardening Settings:

Restrict access to specific IP ranges plugin [Updated in Security Center 1.3]

IP address access control

Apply an IP access control to outbound traffic, inbound traffic, or bidirectional traffic. The system only blocks an IP address if a matching Deny rule exists and no matching Allow rule exists. By default, there are no restrictions on access to your instance.

Before you begin

Note:
Use the Adaptive Authentication (AA) pre-authentication context policy to enforce IP based authentications and restrictions for additional capabilities. For more information, see Adaptive authentication.

Role required: admin

Warning:
IP Address Control is configured only for external IPs and it will not block internal IP addresses from ServiceNow.

Procedure

1. Navigate to **All** > **System Security** > **IP Address Access Control** to see a list of your IP access controls.
   You might have to activate the IP Range Based Authentication [com.snc.ipauthenticator] plugin.
2. Complete the form.

Note:
To find your instance IP information, Log in to ServiceNow - NOW Support, and Search for the **My IP Information** service catalog item.

Field	Description
Type	Type of access control rule to include.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	○ *Allow*: Any IP address in this range can interact with this instance. ○ *Deny*: Any IP address in this range cannot interact with this instance unless it is listed in an Allow rule. Also, when adding deny rules, you cannot deny your own public IP address or your instance does not update a deny rule. **Note:** To support maintenance, upgrades, and Customer Service and Support, some ServiceNow internal IPs cannot be blocked by Deny rules.
Direction	Direction of the IP access control rule. ○ **Inbound**: Choose Inbound to allow or deny inbound transactions. These are transactions initiated from outside of your instance. ○ **Outbound**: Choose Outbound to allow or deny outbound transactions. These are transactions initiated from within your instance. ○ **Bidirectional**: Choose Bidirectional for the configuration to apply for both Inbound and Outbound.
Active	When selected, the form is active.
Description	Description of the access control.
Range Start	Starting range of IP addresses to allow or deny. **Note:** These rules also affect transferring update sets. To ensure that IP address access control does not cause update sets to fail, add the target instance as an exception.
Range End	Ending range of IP addresses to allow or deny. **Note:** To limit access to specific VPN addresses only, enter a Deny range of **0.0.0.0** through **255.255.255.255** into the **Deny** field, and only enter the specific allowed VPN ranges.

3. Click **Submit**.

Find denied IP addresses

Find Denied IP addresses in the instance's node log files.

Before you begin

Role required: admin.

About this task

Log entries for blocked IP address appear as follows: `2015-10-21 18:37:43 (175) http-30 WARNING *** WARNING *** Security restricted: Access restricted (xx.xx.xxx.xxx not authorized)`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
Denied IP addresses are the viewable instance's node log files, not viewable from the system logs.

Procedure

1. Navigate to **All** > **System Logs** > **Utilities** > **Node Log File Browser.**.
2. Browse the logs by criteria, such as time period and message.
3. You can also download log files when you know which log you are looking for, by navigating to **System Logs** > **Utilities** > **Node Log File Download**.

Lightweight Directory Access Protocol integration

An LDAP integration allows your instance to use your existing LDAP server as the primary source of user data.

Administrators integrate with a Lightweight Directory Access Protocol (LDAP) directory to streamline the user login process and to automate administrative tasks such as creating users and assigning them roles. An LDAP integration allows the system to use your existing LDAP server as the primary source of user data. Typically, an LDAP integration is also part of a single sign-on implementation.

The integration uses the LDAP service account credentials to retrieve the user distinguished name (DN) from the LDAP server. Given the DN value for the user, the integration then rebinds with LDAP with the user's DN and password. The password that the user enters is contained entirely in the HTTPS session. The integration never stores LDAP passwords.

The integration uses a read-only connection that never writes to the LDAP directory. The integration only queries for information, and then updates its internal database accordingly.

Note:
For detailed information about setting up the integration, see LDAP integration setup.

Note:
If your instance is using an LDAP integration and the Active Directory settings require users to reset their password upon login, your users will not be able to log in the instance. The instance cannot change any user's active directory password.

Features of LDAP integration

LDAP integration features include the following.

Scheduled LDAP refresh

A scheduled scan of your LDAP server is usually run once a night. It queries all applicable user records' attributes and compares them with the account on our servers. If there is a difference, we modify our user record with the changed attribute. The load placed upon the LDAP server during the refresh depends on how many records are queried, and the number of attributes being compared. We recommend scheduling the refresh during off-peak hours. A large refresh operation can affect other scheduled operations, such as running reports, and should be planned to minimize any conflicts.

LDAP listener

LDAP listener is our version of a persistent query (or persistent search). We issue a standing query for changes made to your LDAP server, and constantly listen for a

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

response. Assuming your server supports a persistent search, any changes made to any of your applicable LDAP accounts are returned to the LDAP listener and sent to your instance within approximately 10 seconds. This is an extremely useful tool, allowing us to have a nearly real-time copy of your users' account details, without having to wait for the next scheduled refresh.

On-demand LDAP login

After an LDAP integration is established, the instance can allow new users to log in to the system even if they do not yet have an account on the instance. When a new user attempts to log in to the instance, the integration checks to see if this user has an account in the instance. If the integration does not find an existing user account, it automatically queries the LDAP server for the username that was entered. If a matching LDAP account is found, the integration tries to authenticate with the password the user entered. If the password is valid, the instance creates an account for the user, populates the account with all applicable LDAP information, and logs the user in to the instance.

On-demand login uses the LDAP User Import transform map. For more information on transform map requirements, see LDAP transform maps.

LDAP data population

> **Note:**
> Functionality described in this integration is not available by default. This integration involves post-deployment customization performed by an experienced administrator or by ServiceNow professional services consultants.

An integration to the LDAP servers allows you to quickly and easily populate the instance's database with user records from the existing LDAP database. To prevent data inconsistencies, you can create, ignore, or skip incoming LDAP records.

You can also limit the data the integration imports by specifying LDAP attributes, thereby importing only the data that you want to expose to an instance. Typically, the LDAP attributes you specify become part of the integration transform map. If you do not specify any LDAP attributes, the integration imports all available object attributes from the LDAP server. The instance stores imported LDAP data in temporary import set tables, so the more attributes you import, the longer the import time. For more information, see Specify the LDAP attributes.

LDAP authentication

Use LDAP authentication to access using LDAP credentials.

When a user enters network credentials in the login page:

1. The instance passes the credentials to an LDAP server to find the instance.
2. With RDNs, it validates the user's DN string. It validates only if at least one of the LDAP OU configurations with `table=sys_user` has an RDN configured.
3. The LDAP server responds with an authorized or unauthorized message that the system uses to determine whether access should be granted.

By authenticating against your LDAP server, users access the platform with the same credentials that they use for other internal resources on your network domain. Also, you can reuse any existing password and security policies that are already in place. For example, the LDAP server may already have account lockout and password expiration policies.

When you enable LDAP, the system updates user records with these fields.

LDAP user record updates

Field	Description
Source	Identifies whether or not LDAP is used to validate a user. If the source starts with ldap, then the user is validated via LDAP. If the source does not start with ldap, then the password on the user record is used to validate the user upon login.
LDAP Server	Identifies which LDAP server authenticates the user when there are multiple LDAP servers.

Note:
The system does not support LDAP password authentication through a MID Server. An instance must be able to directly connect with an LDAP server to support password authentication.

Understand LDAP integration

An LDAP integration allows your instance to use your existing LDAP server as the primary source of user data.

LDAP integration prerequisites

- The directory services server must be LDAP v3 compliant
- Inbound network access through the firewall must be allowed (to the LDAP server)
- External IP or Name of the LDAP server
- User credentials with read-only access
- For LDAPS, a PKI certificate

LDAP integration timing

LDAP integrations are usually done before the instance Go Live, but can be integrated at any time.

LDAP server data integrity

Some users are concerned about a third party (the instance in this case) making changes (writing) to your LDAP server. In an LDAP integration, your instance does not write to the internal LDAP directory. The instance queries for information, and updates its database accordingly.

No changes are made to the internal LDAP server by the instance. The service account is read only.

Most changes (including additions) to your LDAP server are available to the instance within seconds, depending on how many components of the full LDAP integration are in place.

To keep LDAP records synchronized, schedule a periodic scan of the LDAP server to pick up changes.

The instance does not synchronize department records. Users and group memberships are kept up-to-date by the LDAP Listener mechanism and a daily full LDAP Browse, but the instance does not delete any of these entries once they disappear from LDAP.

If an entry were to be deleted, the entire history would also get deleted, and any references to it would be cleared or deleted. Configuration Items (CIs), SLA Agreements, Software Licenses,

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Purchase Orders, and Service Catalog Entries all have a reference to Department, and if Department is deleted, then those references get cleared. There are many references to Users, and so deleting a user would lose all history of what that user did. Currently, the decision to delete or not to delete is made by our customers.

Security

The connection is made from a single machine using a fixed IP address through a specific port on your firewall. Authentication is done with a read-only LDAP account of your choosing. You can use standard LDAP, or load the public side of an SSL certificate installed on your directory, in which case we can use LDAPS. To add another layer of security, we also offer the option of a point-to-point IPSEC VPN tunnel. Speak to your account manager for details and pricing.

Secure LDAP connections

Connection	Description
MID Server	To shield your LDAP server from external network traffic, install a MID Server on the local network and configure the system to communicate with the MID Server over a secure channel.
LDAPS	To establish an encrypted LDAPS connection, load the public side of your LDAP server's SSL certificate. The integration uses the certificate to encrypt all communication between the LDAP server and the instance.
VPN	To secure the LDAP server with an encrypted point-to-point IPSEC VPN tunnel, speak to your account manager for details and pricing.

Another security aspect to consider is the data shared in an LDAP integration. To limit the data exposed to your instance, specify attributes in your transform map. For more information, see LDAP transform maps.

Importing LDAP data to the instance

It is recommended that attributes are defined to import only required data. Defined attributes get mapped into the instance user database.

We cannot answer the question of which specific attributes are needed because this is determined by the scope of the project and business requirements.

Supported types of LDAP servers

The instance has successfully integrated with Microsoft Active Directory, Novell, Domino (Lotus Notes), and Open LDAP. We use JNDI to interface with the LDAP Server. As long as your LDAP server is LDAP v3 compliant, the integration is successful.

LDAP single-sign-on

Along with the data population functionality provided with the LDAP import, you can use the External Authentication functionality supported by the application to prevent your users from needing to sign on each time.

Multiple LDAP domains

The recommended method for handling multiple domains is to create a separate LDAP server record for each domain. Each LDAP server record must point to a domain controller for that domain. This means the local network must allow connections to each of the domain controllers.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

After expanding to more than one network domain, it is critical that you identify unique LDAP attributes for the application usernames and import coalesce values. A common unique coalesce attribute for Active Directory is objectSid. Unique usernames may vary based on the LDAP data design. Common attributes are `email` or `userPrincipalName`.

Handling query limits

By default, Active Directory 2000/2003 has an LDAP query limit (maxPageSize) of 1000 objects to prevent excessive loads and denial of service attacks. We have two methods of dealing with this limit.

The default method is to break up the query to return less than 1000 objects at a time. For example, query only for object starting with the letter 'a', then query for 'b' objects. The more efficient method for large environments is to enable paging. Paging is supported by default on all Microsoft Active Directory servers. It automatically splits the results into multiple result sets, so we don't have to split up the query into multiple requests.

LDAP query type

If an LDAP password is supplied then a "Simple Bind" is performed. If no LDAP password is supplied then "none" is used, in which case the LDAP server must allow anonymous login.

LDAP authentication

We use provided service account credentials for LDAP to retrieve the user DN from the LDAP server. Given the DN value for the user, we then rebind with LDAP given the users DN and the provided password.

Password storage

The password that the user enters is contained entirely in their HTTPS session. We do not store that password anywhere.

Setting up LDAP authentication

These fields on the user record pertain to LDAP:

- **Source**: The Source field identifies whether or not a user is validated using LDAP. If the source field starts with "ldap", then the user is validated via LDAP. If the Source field does not start with "ldap", then the password on the user record is used to validate the user upon login.
- **LDAP Server**: The instance supports multiple LDAP servers, so the LDAP Server field determines which server should be used to authenticate the user.

LDAP integration requirements

Review the requirements for LDAP integration, which include a PKI certificate an LDAP compliant directory services server.

LDAP integration requires:

- An LDAP v3 compliant directory services server
  - Allows inbound network access through the firewall (to the LDAP server)
  - (Optional) Accepts anonymous login
  - (Optional) Supports paging for large LDAP queries

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- The external IP address or fully-qualified domain name of the LDAP server. You can also use a MID server.
- A read-only LDAP account of your choosing
- For multiple domains, network access for each domain controller
- For LDAPS, a PKI certificate
- For LDAP listener, a Microsoft Active Directory server that supports persistent queries (ADNotify)

Supported LDAP servers

Using JNDI to interface with the LDAP server, the instance has successfully integrated with the following servers:

- Microsoft Active Directory
- Novell
- Domino (Lotus Notes)
- Open LDAP

LDAP query limits

By default, Active Directory 2000/2003 has an LDAP query limit (maxPageSize) of 1000 objects to prevent excessive loads and denial of service attacks. The system has two methods of dealing with this limit.

- The default method is to break up the query to return fewer than 1000 objects at a time. For example, query only for objects starting with the letter a, then query for b objects.
- The more efficient method for large environments is to enable paging, which is supported by default on all Microsoft Active Directory servers. Paging automatically splits the results into multiple result sets so the integration does not have to split up the query into multiple requests.

LDAP integration setup

Administrators can enable LDAP integration to allow sign-on of users from their company LDAP directory.

LDAP typically uses one of these types of communication channels.

LDAP communication channels

Connection	Description	LDAP import support?	LDAP authentication support?
MID Server connection	Communicates over HTTP on port 80 by default. This communication channel does not require a certificate. The connection between the MID Server and the instance is over HTTPS (port 443). You can use the MID Server to import data over LDAP, but you cannot use the MID Server for LDAP authentication. Proceed to Define the LDAP Server.	Yes	No

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

LDAP communication channels (continued)

Connection	Description	LDAP import support?	LDAP authentication support?
Standard LDAP integration	Communicates over TCP on port 389 by default. This communication channel does not require a certificate. Proceed to Define the LDAP Server.	Yes	Yes
SSL-encrypted LDAP integration (LDAPS)	Communicates over TCP on port 636 by default, This communication channel requires a certificate. Proceed to Install the LDAP X.509 SSL certificate to obtain and upload the certificate.	Yes	Yes
VPN connection	Communicates over an IPSEC tunnel. Purchase or create an IPSEC tunnel on your local network. Proceed to Define the LDAP Server.	Yes	Yes

If using a MID Server, the MID Server connects to the instance and the MID Server also connects to the LDAP server. In both cases, the MID Server initiates the connection:

1. First, the MID Server connects to the LDAP server via LDAP on Port 389.
2. Then, the MID Server initiates an HTTPS encrypted connection to the instance on Port 443 to push the data to the instance.

For more information about VPNs, Mid Servers, and LDAP, see You Don't Need A VPN Part II on the community.

Install the LDAP X.509 SSL certificate

You can install an X.509 certificate for your LDAP integration.

Before you begin

Role required: admin

Procedure

1. Purchase or generate an SSL certificate on your LDAP server.
2. Navigate to **LDAP** > **Certificate** and click **New**.
3. Fill in the form fields:

Field	Description
Name	The certificate name.
Expiration notification	Select this option to send a notification to the users selected in the **Notify on expiration** field. By default, this is enabled.
Notify on expiration	Select the users to revive the notification regarding certificate expiration. If no users are selected, the logged in user is added by default, along with the last two logged in users with the administrator role.
Warn in days to expire	The number of days before expiration that the instance send the notification. Enter a value of at least 20. Instances upgraded to Istanbul and later releases have this value set to 20 unless a greater value is specified.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Active	A check box to indicate that this certificate is active.
Format	The format of the certificate.
Type	The certificate container. The instance recognizes certificates from trust stores, Java keystore, and PKCS#12 keystores.
Valid from	The instance automatically adds the certificate valid from date to this field. Attach the certificate to the X.509 certificate record to populate this field.
Expires	The instance automatically adds the certificate expiration date to this field. Attach the certificate to the X.509 certificate record to populate this field.
Expires in days	The calculated number of days to expiration.
Short description	A description for the certificate.
Issuer	The instance automatically adds the certificate issuer to this field. Attach the certificate to the X.509 certificate record to populate this field.
Subject	The instance automatically adds the certificate subject to this field. Attach the certificate to the X.509 certificate record to populate this field.
PEM Certificate	Enter the value of the X509 certificate.

Note:
The integration does not currently sign the certificate in communications between the instance and the IdP.

4. Click **Save**.

What to do next
Click **Validate Stores/Certificates** to test the trust store and certificate.

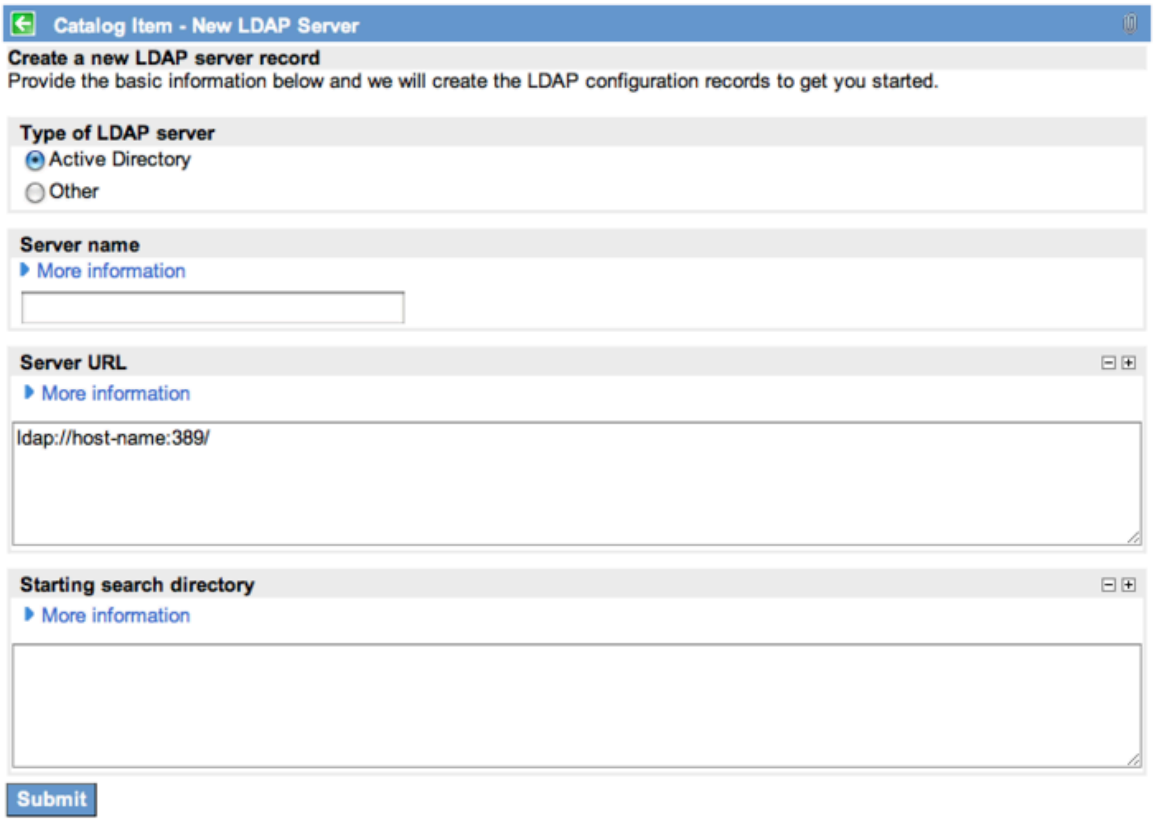
Define an LDAP server

Create a new LDAP server record in the instance.

Before you begin
Role required: admin.

Procedure
1. Navigate to **All** > **System LDAP** > **Create New Server**.
2. Fill in the form fields.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



In the **Server URL** field, the valid URLs of all servers appear separated by a space. Servers are first ordered by operational status, with servers that are **Up** listed first, then ordered by the **Order** value that you specify. The first server listed is the primary LDAP server. The others are redundant servers.

> **Note:**
> There is a slight delay between the change in the actual operational status and the display.

Alternatively, you can add a redundant LDAP server by navigating to an existing LDAP server record and inserting a row in the LDAP Server URLs embedded list.

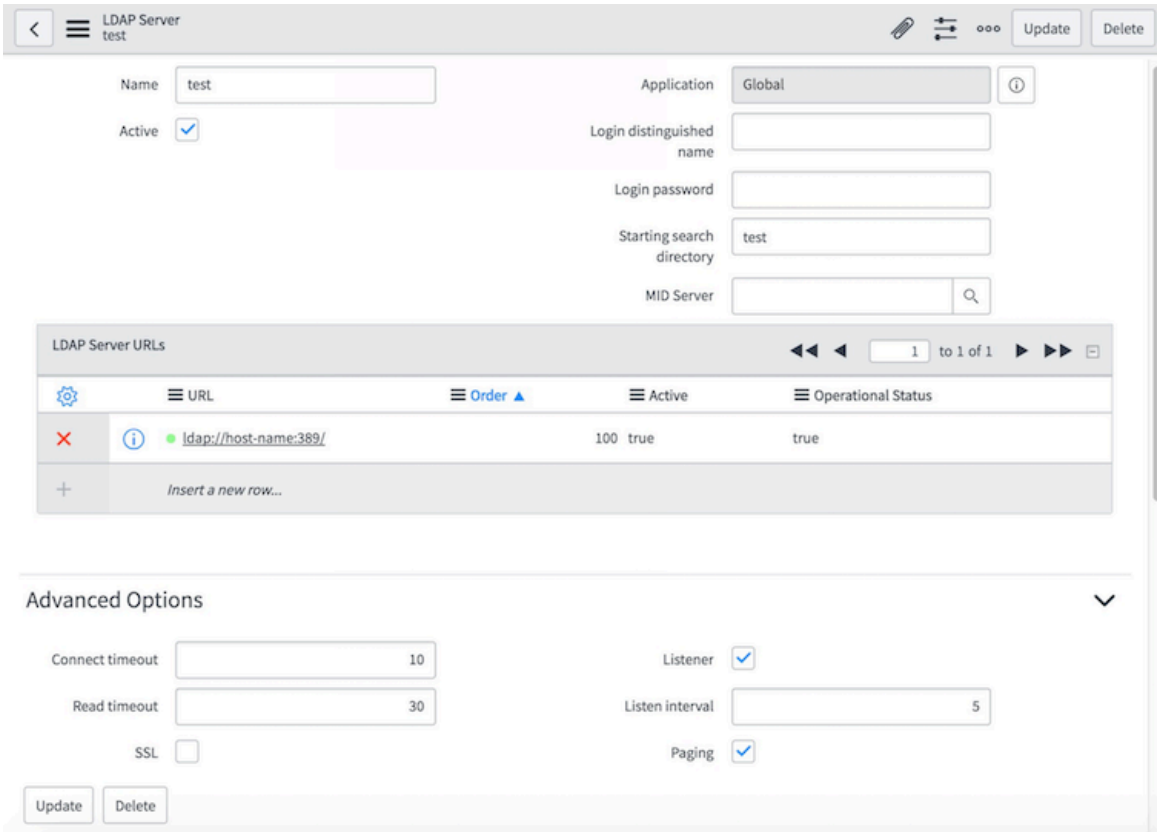
3. Click **Submit**.

> **Note:**
> You can also modify an existing LDAP server record by navigating to **System LDAP** > **LDAP Servers** and making the needed changes.

4. Make changes to the fields as necessary.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

LDAP server form



Field	Description
Name	Enter the name of the server.
Active	Select this check box if the server is active.
LDAP Server URLs	Enter the URLs of the primary and backup LDAP servers. Servers are first ordered by operational status, with servers that are Up listed first, then ordered by the Order value that you specify. The first server listed is the primary LDAP server. The others are redundant servers.
Server URL	Enter the URL of the server. Configure the form to add this field if necessary. It is a calculated read-only field that shows the list of LDAP servers that you can also see in the **LDAP Server URLs** field, separated by a space, and ordered by operational status and the order values of the URLs.
Login distinguished name	Enter the distinguished name (DN) of the user authenticating the LDAP connection. To access an LDAP directory server, the username must be in the full distinguished name format: `servicenow@service-now.com`
Login password	Enter the server's password.
Starting search directory	Enter the relative distinguished name (RDN) of the default search directory. All queries to this LDAP server will start from this RDN.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
MID Server	Select the MID Server you want to use to connect to the LDAP server. Using a MID Server to establish an LDAP connection prevents you from having to expose the LDAP server to external network traffic. It also eliminates the need to establish a VPN tunnel between your LDAP server and ServiceNow data centers. **Note:** ○ The MID Server user must have the user_admin role in order to be able to read LDAP server configuration records. ○ The following are not available with the MID Server: ▪ LDAP authentication ▪ SSL connection
Connect timeout	If a MID Server is configured, the connection times out after 10 seconds, regardless of this setting. This setting is hard-coded and cannot be altered.
Read timeout	Specify the number of seconds the integration has to read LDAP data. The integration stops reading LDAP data after the connection exceeds the read timeout. If you enable an SSL connection, you can also set a read timeout value with the *com.glide.ssl.read.timeout* system property. If you enter timeout values for both this field and the system property, the lowest timeout value takes precedence.
SSL	Select this check box to require the LDAP server to make an SSL-encrypted connection. If you selected a MID Server, this field is not available. If you use an LDAPS integration and the default SSL port is 636, no further configuration is necessary; SSL is automatically enabled. If the LDAPS integration uses another SSL port, define the alternate SSL connection properties. **Note:** Be sure a network administrator configures the local firewall to allow the application server to access the LDAP server. If the LDAP server is located within an internal network, the firewall forwards (or NATs) the application server's IP address through the firewall on the correct port.
Listener	Select this check box to enable the integration to periodically poll Microsoft Active Directory servers or LDAP servers that support persistent search request control. Additionally, if you selected a MID Server, the listener functionality is available for that MID Server. See Enable an LDAP listener and set system properties for more information.
Listen interval (timeout value)	Specify the listener timeout value in the number of minutes that the integration listens for LDAP data with every connection. The integration stops listening for LDAP data after the connection exceeds the listen interval.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Paging	Select this check box to have the LDAP server split up LDAP attribute data into multiple result sets rather than submit multiple queries.

Note:
If you provide an LDAP password, the integration performs a Simple Bind operation. If you do not provide an LDAP password, the LDAP server must allow anonymous login or the integration cannot bind to the LDAP server.

Result
When an LDAP Server record is set to active, the system automatically tests every connection to validate it.
Validations include:

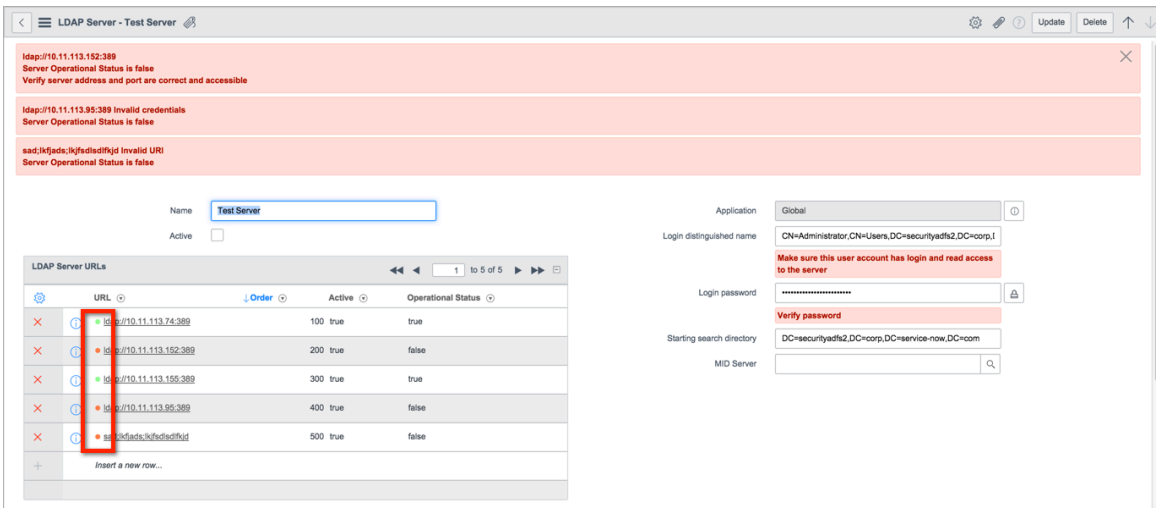
- The LDAP server is accessible at the provided URL and port
- The LDAP server URL is properly formatted
- The login credentials are valid

Starting with the Fuji release, the system displays colored dots next to each server URL:

LDAP server connection icons

Color	Description
Green	The server if active and operational.
Gray	The server is neither active nor operational.
Red	The server is active but not operational.

LDAP server connection status



Enable an LDAP listener and set system properties

Enabling a listener is optional. If enabled, a listener notifies the system to process LDAP records soon after there is an update on the LDAP server.

Before you begin
Role required: admin.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

About this task

A listener is a dedicated process that periodically searches for changes on the LDAP server.

The listener can be deployed on a Microsoft Active Directory server that supports persistent queries (ADNotify), or on an LDAP server that supports persistent search request control (with OID 2.16.840.1.113730.3.4.3).

If the LDAP server supports a persistent search, the LDAP listener recognizes any user and group changes made to any of the applicable LDAP accounts and forwards them to your instance within approximately 10 seconds. This allows the instance to have a nearly real-time copy of your users' account details without having to wait for the next scheduled refresh. The LDAP listener can only synchronize objects that map to the User [sys_users] and Group [sys_user_group] tables.

Note:
If a user is added via the listener, but the user does not meet the requirements as defined by the OU filter, then the instance ignores the record on the LDAP server. If it meets the criteria, the user is added to the instance.

To enable a listener:

Procedure

1. Navigate to **All** > **System LDAP** > **LDAP Servers**.
2. Select the LDAP server to configure.
3. Select the **Listener** check box.
4. Click **Update**.

Note:

The system only imports user records that match the LDAP OU filter. Incoming user records that do not meet the filter requirements are flagged as invalid and ignored by the import. Administrators can enable verbose LDAP logging to determine if incoming records are not matching the LDAP OU filter.

5. **Optional:** Navigate to the System Properties [sys_properties] table and set LDAP listener system properties.

LDAP listener properties

Property	Description
glide.ldap.listener.use_background_transaction	When true, the LDAP listener is started as a background running the LDAP listener as a background transaction, t Listener Start/Stop Transaction can cancel the transactio duration is reached, 5 minutes by default. This behavior listener from waiting indefinitely. **Note:** This property applies only to LDAP connections that do not use a MID Server. Use *glide.ldap.listener.mid.use_backgro* to control the behavior of LDAP connections that go Server.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property	Description
	○ Type: true | false ○ Default value: false ○ Location: Add to the System Properties [sys_properties
glide.ldap.listener.mid.use_background_transaction	When true, the LDAP listener is started as a background running the LDAP listener as a background transaction, t Listener Start/Stop MID Transaction can cancel the trans maximum duration is reached, 5 minutes by default. This LDAP listener from waiting indefinitely. **Note:** This property applies only to LDAP connections that Use *glide.ldap.listener.use_backgrou* to control the behavior of LDAP connections that do Server. ○ Type: true | false ○ Default value: false ○ Location: Add to the System Properties [sys_properties
glide.ldap.listener.mid.one_listener	When true, only a single ECC queue message is created the LDAP listener through a MID Server. When false, mul messages can be created, leading to the creation of mul stop the LDAP listener. ○ Type: true | false ○ Default value: true ○ Location: Add to the System Properties [sys_properties

Specify the LDAP attributes

Specify the attributes included in LDAP server queries by using the LDAP server **Attributes** field. This can enhance performance as well as security.

Before you begin
Role required: admin

About this task
By default, the system loads all of the attributes for each object that it has permission to read from your LDAP server. Using the **Attributes** field, you can specify and thereby limit the attributes the LDAP query returns. Using this approach for large LDAP imports can greatly improve the speed of those imports.

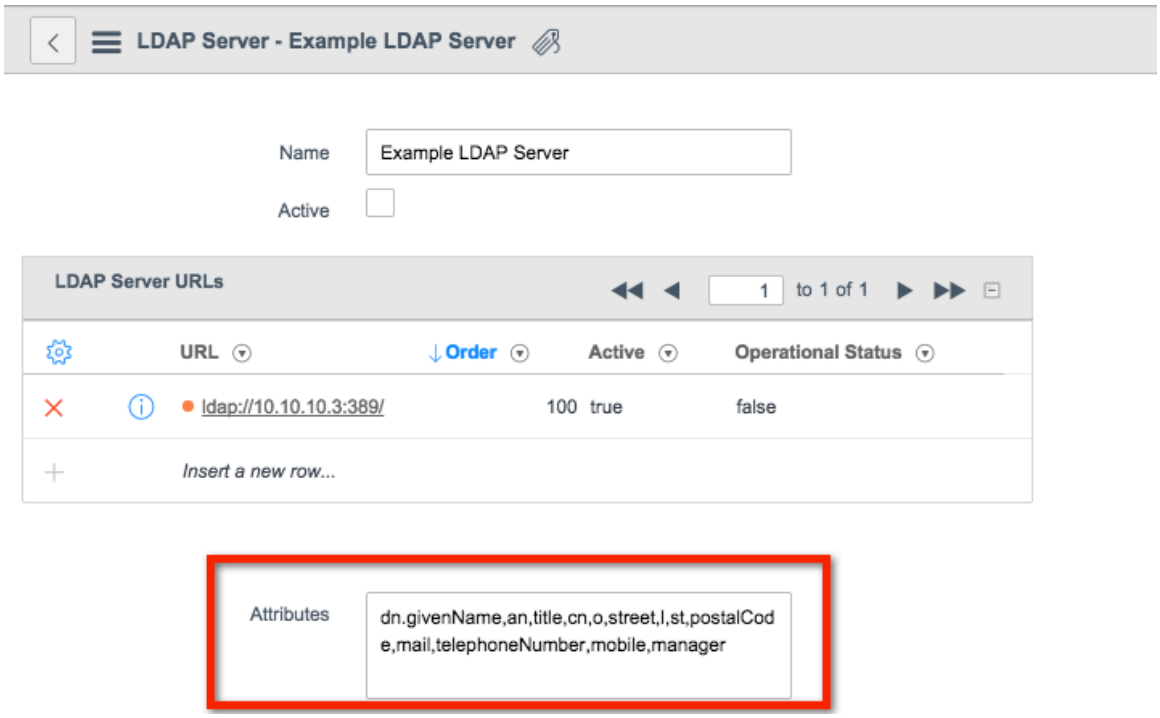
Procedure

Explicitly define attributes where possible.

If there is information that you do not want exposed to the instance, exclude the attribute. If you do not specify LDAP server attributes, user transactions may freeze for extended periods of time when new attributes are added to an LDAP server object because the system will be busy loading data from the new attributes.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
To use the manager lookup scripts described in Select or Create a Transform Map for LDAP Data, specify **manager** and **dn** (distinguished name) in the **Attributes** field. Neither attribute is required to be a part of a transform map.



Test an LDAP connection

The instance tests the connection automatically every time a user opens the LDAP Server form. Alternatively, you can manually test the connection to the LDAP server from the LDAP server form.

Before you begin
Role required: admin

About this task
By default, error messages appear on the LDAP server form if there are any issues connecting to the LDAP server.

Note:
Employees can also verify connectivity between the instance and the LDAP server. Contact Technical Support for assistance verifying LDAP connectivity.

To manually test a connection:

Procedure

1. Navigate to **All** > **System LDAP** > **LDAP Servers**.
2. Select the LDAP server to test.
3. Under **Related Links**, click **Test connection**.
4. Under **Related Links**, click **Browse** to verify that the appropriate LDAP directory structure is visible to the system.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

5. **Optional:** If the connection was successful, click **Browse** to view the source LDAP directory structure that is visible to the instance.

   Note:
   The **Filter** and **RDN** fields on the left of the Browse window are ignored when you use the search field on the right.

Result

The instance changes the operational status of LDAP servers depending on the result of the connection test.

- If your instance establishes a connection to a server that has a **Operational Status** value of **down**, the **Operational Status** value is automatically changed to **up**. This functionality is supported for both automatic and manual connection tests.
- If a connection cannot be established to a server that has a **Operational Status** value of **up**, the **Operational Status** value is automatically changed to **down**. This functionality is supported for automatic connection tests only, not manual tests.

Define LDAP organizational units

An organizational unit (OU) definition specifies the LDAP source directories available to the integration.

Before you begin

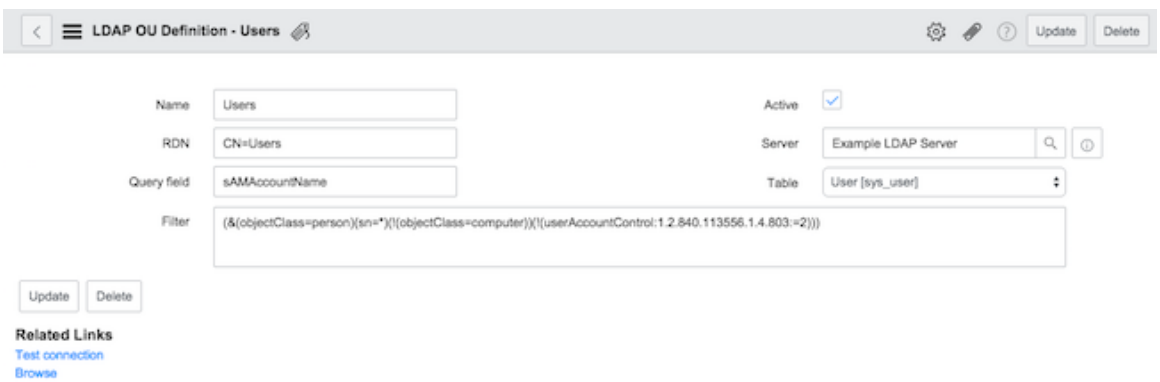
Role required: admin.

About this task

OU definitions can contain locations, people, or user groups. Every LDAP server definition contains two sample OU definitions: one for importing groups into the system and the other for users.

Procedure

1. Navigate to **All** > **System LDAP** > **LDAP Servers**.
2. Select the LDAP server to configure.
3. In the **LDAP OU Definitions** related list, select either the **Groups** or **Users** sample OU definition.
4. Complete the LDAP OU Definition form (see table).
5. Click **Update**.
   The system automatically tests the connection to the LDAP server.
6. Under **Related Links**, click **Browse** to view the LDAP directory records that the OU definition returns.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

OU Definition form

Field	Description
Name	Specify the name the integration uses when referencing this OU. The name you enter here becomes an LDAP target in the data source record.
RDN	Specify the relative distinguished name of the subdirectory you want to search. This RDN is combined with the start-searching directory from the LDAP server definition to identify the subdirectory containing information for this organizational unit. For example, the sample OU definition uses the RDN value of `CN=Users` to search the LDAP directory `CN=Users`, `DC=service-now`, `DC=com` and any directory below this point. This field must match a subdirectory in your LDAP system.
Query field	Specify the name of the attribute within the LDAP server to query for records. The query field must be unique in both single and multiple domain instances. For best results, use email addresses or other credentials that uniquely identify the user in a multiple domain instance. Active Directory uses the **sAMAccountName** attribute. Other LDAP servers tend to use the **cn** attribute. **Note:** The **Query field** must map to the **User ID** field in the User [sys_user] table. For example, if an Active Directory user logs in as `joe.example`, there must be a user record with a **User ID** value of **joe.example** and an LDAP record with an **sAMAccountName** value of **joe.example**.
Active	Select this check box to activate the OU definition and to allow administrators to test importing data. However, the integration can only bring data into the system from active OU definitions.
Table	Specify the table that receives the mapped data from your LDAP server. For users, select **User (sys_user)**, and for groups, select **Group (sys_group)**.
Filter	Enter an LDAP filter string to select specific records to import from the OU. The more specific the LDAP filter query, the more efficient the query is. For example, the Users LDAP OU definition uses the following filter to select records that are classified as a person, have an **sn** attribute value, are not computers, and are not flagged as inactive: `(&(objectClass=person)(sn=*)(!(objectClass=computer)) (!(userAccountControl:1.2.840.113556.1.4.803:=2)))` You can find a description of LDAP filter syntax by searching the internet for `LDAP Filters RFC`.

Example: Example organizational unit definitions

Suppose you have an LDAP server with the following directory structure:

dc=my-domain,dc=com

- ou=Groups
  - cn=Development
  - cn=HR
  - cn=Sales

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- ou=Users
  - ou=Development
  - ou=HR
  - ou=Sales

Further suppose that you want to exclude the HR group and HR users from the application. Do the following:

1. Create an LDAP server record with a starting search directory of dc=my-domain,dc=com.
2. Create an OU definition record for ou=Groups with a filter to exclude cn=HR.
3. Create an OU definition record for ou=Users with a filter to exclude ou=HR.

If you do not specify additional attributes or filters with an OU definition, the LDAP query returns the entire sub-tree from the starting directory and RDN.

In these examples, an OU definition with the RDN value of ou=Groups and no filter would have returned all groups. Likewise, an OU definition with the RDN value of ou=Users and no filter would have returned all users and child organizational units.

Create a data source for LDAP

Each LDAP organizational unit (OU) definition has its own related list of data sources.

Before you begin

Role required: admin

About this task

Note:
Both the **LDAP Server** and **LDAP OU Definition** must be active for the test load action to function properly. When the test load is activated for the first time, the system samples up to 20 records to determine the length of the import set fields. If the sampled records do not contain values for the **User ID** field, the system sets the field length for all subsequent imports to the default length of 40. The import truncates any imported data that exceeds the import set table field length. Additionally, the **User ID** field is truncated to a maximum of 40 characters. Be aware that the 20 loaded records cannot be transformed and are for testing purposes only. If the test records contain values for the **User ID** field, the field length is set based on the field length of the longest user ID in the test records.

To create a new data source:

Procedure

1. Navigate to **All** > **System LDAP** > **LDAP Servers**.
2. Select the LDAP server to configure.
3. In the **LDAP OU Definitions** related list, select an item, such as **Groups** or **Users**.
4. In the **Data Sources** related list, click **New**.
5. Complete the Data Source form (see table).
6. Click **Submit**.
7. Under **Related Links**, click **Test Load 20 Records** to test whether the data source can bring LDAP data into the import table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Data Sources form

Field	Description
Name	Specify the name the integration uses when referencing this data source.
Import set table name	Enter the name of the staging table where the system temporarily places the imported LDAP records and attributes. Review this table to view imported LDAP records. You can use the same import set table name for all LDAP data sources.
Type	Select **LDAP** to indicate the imported data is LDAP data. After you select the type **LDAP**, the form displays the **LDAP target** field.
LDAP target	Select the LDAP OU definition associated with this data source.

Auto provision LDAP users

You automatically provision users who are in the LDAP server but not yet in your instance.

Before you begin

Role required: admin

Procedure

Create the following properties in the System Properties [sys_properties] table:

LDAP properties

LDAP property	Description
glide.ldap.authentication	Enables LDAP authentication by using LDAP to authenticate users. Set this property to **true** (the default value).
glide.ldap.user.autoprovision	Enables LDAP the system to automatically create users in the User [sys_user] table when the user exists in LDAP but is not yet in the instance. Set this property to **true** (the default value).

Both of these properties must be set to **true** for auto-provisioning to work.

LDAP integration via MID Server

Administrators can integrate using an LDAP data source over a Management, Instrumentation, and Discovery (MID) Server.

The MID Server enables communication and movement of data between the ServiceNow AI Platform and external applications, data sources, and services. For details on installing a MID Server, see MID Server installation.

Using a MID Server to establish an LDAP connection prevents you from having to expose the LDAP server to external network traffic. It eliminates the need to establish a VPN tunnel between your LDAP server and datacenters. The MID Server user must have the user_admin role to be able to read LDAP server configuration records.

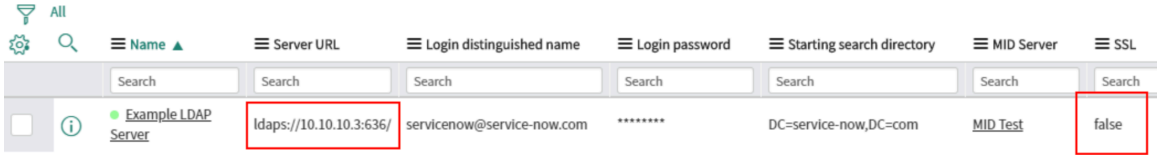
Note:
The MID Server does not allow using the UI action `<instance>/sys_ui_action.do?sys_id=1b4f7ef30a0001060058e223c9a5744c` to refresh user and group records from LDAP.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

A MID Server connection communicates over HTTP on port 80 by default. This communication channel does not require a certificate. The connection between the MID Server and the instance is over HTTPS (port 443). The instance connects to the LDAP server directly, using LDAP or LDAPS. This connection can either be over the internet or through a VPN tunnel.

Note:
LDAP cannot communicate via the MID Server with password authentication.

For a secure communication over SSL, you must add an SSL certificate for the MID Server. Change the LDAP server URL from LDAP to LDAPS and change to port 636.



Note:
If you create a new LDAP server, the MID Server SSL flag sets to false by default. You can ignore this behavior.

To set connection properties for a specific LDAP server, see Define an LDAP server.

Configure LDAP connection monitoring

Change or disable LDAP connection monitoring and notifications.

Before you begin
Role required: admin

About this task
The instance automatically sends an email to users configured in the LDAP Admins group when an LDAP server connection fails. This uses the email notification, which is launched by the **LDAP Connection Test**scheduled job. This email notification is enabled by default.

Note:
The instance does not send the email notification unless there is at least one member in the LDAP Admins group. Make sure to populate this group with the users you want to receive the email.

By default, the scheduled job tests the connection every 15 minutes. To change this interval or disable monitoring:

Procedure

1. Navigate to **All** > **System Definition** > **Scheduled Jobs**.
2. Open **LDAP Connection Test**.
3. Do one of the following:
   - Change the interval in the **Repeat Interval** field.
   - Disable monitoring by clearing the **Active** check box.

Import binary data through a MID Server

As an administrator, you can import binary large object (BLOB) data with an LDAP integration through the MID Server.

Before you begin
Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

About this task

Procedure

1. Add the name of the LDAP column you want to import binary data from to the system property `glide.ldap.binary_attributes`.
2. Add a MID Server property with the Name `glide.ldap.binary_attributes` and the same value you set for the system property.

Troubleshooting LDAP integration via MID Server

You may encounter issues in the following areas while integrating LDAP via MID Server.

You can troubleshoot these issues by viewing the outputs found in the External Communication Channel (ECC) Queue (**Discovery** > **Output and Artifacts** > **ECC Queue**).

Test Connection Issues

When defining OUs within the server, there is a **Test connection** related list that is used to verify the LDAP connection. When you click this link, the ECC Queue should show a single output message with a topic name of **LDAPConnectionTesterProbe**. After the test has completed on the MID Server, the ECC Queue should show an input message with the same topic name. If the **Name** column for the input message shows **true**, the test was successful. Drill down into the record to view the payload and ensure it does not contain error messages.

Test Connection

Created	Agent	Topic	Name	Source	Queue	State	Processed
2013-07-29 13:24:17	mid.server.local_mid	LDAPConnectionTesterProbe	true	04a952038f21010036bf21ca47e79a30	input	processed	2013-07-29 13:24:19
2013-07-29 13:24:04	mid.server.local_mid	LDAPConnectionTesterProbe		04a952038f21010036bf21ca47e79a30	output	processed	2013-07-29 13:24:17

Browse Issues

When defining OUs within the server, there is a **Browse** related list that is used to view the LDAP directory records that the OU definition returns. When you click this link, the ECC Queue should show a single output message with a topic name of **LDAPBrowseProbe**. After data has been returned from the MID Server, the ECC Queue should show an input message with the same topic name. If the **Name** column for the input message shows **true**, the test was successful. Drill down into the record to view the payload and ensure it does not contain error messages.

Load Import Issues

When uploading data (for example, using the Test Load 20 Records feature), the ECC Queue should show a single output message with a topic name of **LDAPProbe**.

After data has been returned from the MID Server, the ECC Queue should show another input message called **LDAPProbeCompleted**. The **Name** column for this input message shows the total number of records returned.

An additional input messages, also named **LDAPProbe**, is displayed. The **Name** column for this input message displays the highest record number in the batch. If the total number of records returned is 258 and the batch size is 200 (the default), two LDAPProbe (200, 258) incoming messages will be received, and one LDAPProbeCompleted (258) incoming message will be received.

Drill down into the record to view the payload and ensure it does not contain error messages.

Import Load

Created	Agent	Topic	Name	Source	Queue	State	Processed
2013-07-29 13:09:48	mid.server.local_mid	LDAPProbeCompleted	11	ed0a0d7a8f32010036bf21ca47e79a56	input	processed	2013-07-29 13:09:51
2013-07-29 13:09:48	LDAPProbeResult	LDAPProbe	11	ed0a0d7a8f32010036bf21ca47e79a56	input	processed	2013-07-29 13:09:51
2013-07-29 13:09:36	mid.server.local_mid	LDAPProbe		ed0a0d7a8f32010036bf21ca47e79a56	output	processed	2013-07-29 13:09:46

Also keep an eye out for an output message called **LDAPProbeError**.

Error message

All > Created on Today > Topic = LDAPProbeError

Created	Agent	Topic	Source	Queue	State	Processed	Error string
2014-02-20 14:52:55	mid.server.localdublinmid	LDAPProbeError	MID Server reported error: java.lang.Exc...	output	error	2014-02-20 14:53:02	No message handler for this message.

Click the link in the **Name** column to view the details of the error.

LDAP paging

LDAP paging does not work if the paging size on the LDAP server is less than 1000. Set the MID Server property *`glide.ldap.max_results`* to a value less than or equal to the LDAP server paging size.

LDAP fails to import binary data

To import binary data via LDAP, such as a user photo, you must include the binary attribute in the MID Server property *`glide.ldap.binary_attributes`*. For the user photo example, the attribute may be `jpegphoto`.

Import and map data

LDAP import maps match fields in your LDAP database to fields in your instance.

Note:
LDAP mapping has a performance effect, so the recommended approach is to schedule it during off-peak hours, or process a few records at a time to maintain system availability.

Define a transform map that only imports the needed or required attributes. Depending on the version of the instance you are using, the method for specifying LDAP mapping relationships varies.

The easiest way to know whether or not you are running a version which uses the System LDAP application for LDAP integration is to find the application from the application navigator.

The **Run Business Rules** option is applied only for the target table. Only transform maps associated to the target table run the business rules associated with different tables. If you are updating a user group and have business rules running on a user group table, the group must have roles defined.

LDAP import mapping options

System LDAP application?	Map
Yes	Use a transform map to specify your mapping.
No	Use a LDAP legacy import map to specify your mapping, or the default LDAP transform that is included in baseline instances. Remember to adjust the **Coalesce** field to match against the correct fields.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Scheduled imports

A scheduled import allows administrators to import LDAP data on a regular schedule. By default, the LDAP integration includes two sample scheduled imports:

- Example LDAP User Import
- Example LDAP Group Import

Neither example is active by default. Change these scheduled imports to meet your company's business needs.

LDAP transform maps

The transform map moves data from the import set table to the target table (User or Group).

The LDAP integration uses standard import sets and transform maps. You can also create custom LDAP transform maps.

Important:
Whether you select or create custom LDAP transform maps, there should be one active transform map for a set of source and target tables. Enabling multiple transform maps for the same source and target tables can produce duplicate entries in the target table unless you coalesce against the matching fields.

Default LDAP transform maps

By default, the system provides two transform maps for LDAP data.

Default LDAP transform maps

Transform Map	Source Table	Target Table	Description
LDAP User Import	[ldap_import]	[sys_user]	Default transform map for creating user records from LDAP credentials as part of LDAP on-demand login. Contains mappings for an Active Directory LDAP server.
LDAP Group Import	[ldap_group_import]	[sys_user_group]	Default transform map for creating group records from LDAP OUs. Contains mappings for an Active Directory LDAP server.

Note:
By default, the system does not have a transform map for LDAP department records.

Requirements for custom LDAP transform maps

If you choose to create a custom transform map, the transform map must meet the following mapping requirements.

Requirements for custom LDAP transform maps

Source Table	Source Field	Target Table	Target Field	Coalesce	Description
`ldap_import`	`u_source`	`sys_user`	source	false	The **u_source** field identifies the LDAP DN of the

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Requirements for custom LDAP transform maps (continued)

Source Table	Source Field	Target Table	Target Field	Coalesce	Description
					imported user or group. The system uses this field to determine that a user requires LDAP authentication, to find a user's manager, and to put users into groups.
`ldap_import`	Select one of the following fields: • `u_samaccountname` • `u_dn` • `u_cn`	`sys_user`	`user_name`	true	If LDAP integrates to Active Directory, select **u_samaccountname** as the source field. If other LDAP directories are used, select **u_dn** or **u_cn** as the source field.

Differences between LDAP transform maps and legacy import maps

When specifying LDAP mapping relationships using transform maps, there is a major difference in how reference fields are set for manager and department.

When using a transform map, it is necessary to use a transform script to create references. This is because the value associated with an LDAP attribute like "manager" is the distinguished name (DN) of the manager.

Without some extra logic in place, the result is the creation of a user record with a manager name that is the distinguished name of that user in LDAP. The integration includes a transform script to facilitate the creation of these references. The default transform map "LDAP User Import" includes transform scripts for these references.

Existing mapping relationships

When updating legacy import maps to transform maps, you can retain the LDAP mapping relationships that existed prior to the addition of the System LDAP application. The LDAP server has a **Map** field that is a reference to the legacy import map.

Note:
By default this field is hidden, so you have to configure the form to display it.

If you want to transition to using a transform map, clear the reference to the legacy import map.

LDAP import map settings

Verify and use attributes to limit the fields the integration imports from the LDAP source. Additionally, it is important to map the user_name field to the LDAP attribute that contains the user's login ID. For Active Directory this is usually the sAMAccountName attribute. If you would like to import and coalesce on a binary attribute (such as objectSID or objectGUID), you have to create a custom transform script.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
Any value mapped to the user_name field must be unique.

If you do not specify a transform map (such as LDAP User Import), the integration uses the following default mappings:

LDAP import default mapping

User field or variable	LDAP attribute
user_name	sAMAccountName
email	mail
phone	telephoneNumber
home_phone	homePhone
mobile_phone	mobile
first_name	givenName
last_name	sn
title	title
department	department
manager	manager
middle_name	initials
u_memberof	groups
u_member	members
u_manager	manager

LDAP data transformation

If an LDAP attribute contains simple data, the transform map links an imported LDAP attribute to an appropriate field in the target table (User or Group). For example, sample data in the sAMAccountName attribute maps to the **User ID** field in the User table.

If the imported LDAP data maps to a reference field, the instance searches for an existing matching record. If no matching record exists, the instance creates a new record for the reference field unless the field mapping specifies otherwise.

For example, suppose the LDAP attribute l maps to the **Location** reference field in the User table. Whenever the import brings in an attribute value that does not match an existing location record value, the transform map creates a new location record. The new location record has the same value as the imported attribute, and the imported user record now has a link to the new location record.

However, there are times when LDAP attribute returns a distinguished name (DN), which is essentially a reference to another record within the LDAP directory. For example, the manager attribute typically contains the distinguished name for the manager of the current LDAP directory entry. An imported DN typically uses a long text string such as: cn=Beth Anglin,ou=Users,dc=my-domain,dc=com.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Warning:
Make sure your target fields are long enough to contain a DN. Many text fields use the default length of 40, which may not be long enough for some DN values. The ServiceNow system truncates any value that exceeds the field length.

Administrators do not typically want the system to create new users from the DN value because the new user has no association with an existing user. Instead, administrators want the import to locate the manager's existing user record and associate it with the newly imported user. The `LDAPUtils` script include contains the `setManager` and `processManagers` functions that can parse a DN and search for an existing user. For best results, use these functions to create a custom transform map.

For example, the `LDAP User Import` transform map script calls the `setManager` function:

```
//
// The manager coming in from LDAP is the DN value for the
 manager.
// The line of code below will locate the manager that matches
 the
// DN value and set it into the target record.  If you are not
// interested in getting the manager from LDAP then remove or
// comment out the line below
ldapUtils. setManager (source , target ) ;
```

In some cases, the integration imports a user's record before importing the associated manager's user record. To handle such cases, you may want to call the `processManagers` function after the transform completes. For example, the **LDAP User Import** transform map uses an `onComplete` transform script to call the `processManagers` function.

```
// It is possible that the manager for a user did not exist
 in the database when // the user was processed and therefore
 we could not locate and set the manager field. // The
 processManagers call below will find all those records for
 which a manager could  // not be found and attempt to locate
 the manager again. This happens at the end of the  // import
 and therefore all users should have been created and we should
 be able to  // locate the manager at this point
ldapUtils. processManagers ( ) ;
```

Remove or comment out the `setManager` and `processManagers` function calls if your LDAP integration does not use the manager attribute.

LDAP scripting

Create custom transform maps, scripts, and business rules to specify requirements when importing data.

Custom transform maps should include `onStart` and `onAfter` transform scripts.

The `onStart` script should call the `LDAPUtils` script include and start logging. For example, the **LDAP User Import** transform map has an `onStart` script that uses this code:

```
gs.include ( "LDAPUtils" ) ; var ldapUtils  = new LDAPUtils
 ( ) ;
ldapUtils. setLog (log ) ;
```

The `onAfter` script should call the `addMembers` function. For example:

```
ldapUtils.addMembers (source , target ) ;
```

Set disabled Active Directory users to inactive

Use the following script to automatically deactivate users when the associated AD user is disabled.

Before you begin

Role required: admin

About this task

You can identify disabled Active Directory users by checking the value of the `userAccountControl` attribute. This rule executes whenever the `userAccountControl` value changes and deactivates user accounts if the **User Account Control** signifies a disabled AD account.

Use the following script to automatically deactivate users when the associated AD user is disabled.

Procedure

1. Configure the User form and create a new integer field called **User Account Control**.
2. Add mapping for userAccountControl (external) to the new field.
3. Create a new business rule with the following properties:

Disable AD Users business rule

Business rule field	Value
Name	Disable AD Users
Table	User [sys_user]
When	Before
Condition	current.u_user_account_control.changes()

The Script field should contain the following:

```
var disabledFlag = 2;
//perform a bitwise comparison on userAccountControl to see if
 the 2 bit flag is enabled
if (current.u_user_account_control & disabledFlag) {
  gs.log('Disabling user: ' + current.user_name +
 'userAccountControl=' + current.u_user_account_control);
  current.active='false';
  current.locked_out='true';
}
```

Assign LDAP field values

You can use a script to assign a value to any field for which there is a field mapping.

For example, to assign a value to the sys_user.company field, create a field map for the company field and add a transform script of:

```
company = "Don's Sporting Goods";
```

Exclude particular LDAP users

If you cannot completely filter the LDAP user list using LDAP filter properties, you can exclude users with a map script.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

After you have run the logic to identify a user that should not be imported, set the user_name field to an empty string and this user will not be imported.

```
user_name='';
```

One way to identify users to filter out is to look for a string in the `distinguishedName` attribute. For example, this script excludes accounts that are not in a Users OU. You might use this script if you have too many Users OU to include in the target OU LDAP Option.

```
//vdn is a variable mapped to distinguishedName
gs.include("LDAPUtils");
var vdn = source.getElement(this.distinguishedName);
if (vdn.indexOf('OU=Users')<0) {
  user_name='';
  gs.log('LDAP Import Skipping User: ' + vdn);
}
```

A more complex method of filtering is to use regular expressions.

```
//vcn is a variable mapped to cn
//vdn is a variable mapped to distinguishedName
//c is the regular expression string
gs.include("LDAPUtils");
var vdn = source.getElement(this.distinguishedName);
var vcn = source.getElement(this.cn);
var c = /^[a-z][a-z][a-z][0-9][0-9][0-9]$/;
var nvcn = vcn.toLowerCase();
//test to see if the cn is in the form of 3 letters followed by
 3 numbers, only import these
if (c.test(nvcn)) {
 user_name = nvcn;
} else {
 gs.log("LDAP import rejected username: " + vcn + " for DN: " +
 vdn);
 user_name = "";
}
```

Set choice action for reference field imports

The LDAP transform map determines how fields in the Import Set table map to fields in existing tables such as Incident or User.

Before you begin

Role required: admin

About this task

If the LDAP transform map updates a field in the import set table, the integration automatically creates a new record whenever there is a new record in the LDAP data. If the LDAP transform map updates a reference field storing data from another table, the administrator can choose to create, ignore, or reject new LDAP records.

For example, if the integration receives a new department record that does not match any existing department, you may want to update all of the other LDAP record fields without creating a new department record in the instance. The transform map allows you to set the record creation options for each reference field.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **System LDAP** > **Transform Maps**.
2. In the Field Maps related list, select one of the following actions from the **Choice action** field:
   - **create** – creates a new reference field record if a matching record does not exist.
   - **ignore** – ignores new records in the reference field and completes processing of all other fields in the transform map.
   - **reject** – stops the transform for the entire record.

Note:
The field map only displays the **Choice action** field for reference fields.

Verify LDAP mapping

After creating an LDAP transform map, refresh the LDAP data to verify the transform map works as expected.

Before you begin
Role required: admin

Procedure

1. Navigate to **All** > **System LDAP** > **Scheduled Loads**.
2. Click your LDAP import job.
3. Click **Execute Now**.

LDAP integration troubleshooting

If you are integrating your LDAP server and have questions, these items may help you troubleshoot the issue.

Preliminary checks

- If the LDAP is unavailable, users cannot log in to the instance. A good practice is to have local accounts for administrators so that if the LDAP is down, administrators can still access the instance.
- Check the service account to ensure that it is not expired or locked out.
- Check the format of the username. Instead of using just the username, try using the domain with the username, or username@domain.
- Verify that you have changed the `system_id` entry on the `ldap_server_config` record. If you modify the `system_id` unintentionally with an update set, `system_id` points to the wrong node for the target instance and does not work.

Error codes

The LDAP log file lists industry standard error codes for both LDAP and Active Directory (AD). The LDAP log file is contained in the wrapper file. The LDAP error codes are two-digit numbers, while the Active Directory error codes are three-digit numbers. For a list of the most-common error codes, see LDAP Error Codes.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Multiple domain integration

You can integrate multiple domains within the same forest or in completely non-trusted domains. It is recommended that you create a separate LDAP server record for each domain. Each LDAP server record must point to a domain controller for that given domain. This means you will have to allow connections to each of the domain controllers. Multiple AD forests through LDAP with one LDAP account is not supported.

When you expand to more than one domain, it is critical that you identify unique LDAP attributes for the application usernames and import coalesce values. A common unique coalesce attribute for Active Directory is `objectSid`. Unique usernames will vary based on your LDAP data design. Common unique attributes are `email` or `userPrincipalName`.

Incoming records

See LDAP transform maps to set how the integration processes incoming LDAP records that are missing matching values in reference fields.

Common authentication errors

- User Cannot Log In (Invalid DN)
- Invalid CN
- Invalid Connection

Automatic LDAP connection tests

You can manually test connections to LDAP servers or allow ServiceNow to automatically test the connections.

The system tests the connection automatically:

- Every time a user opens the LDAP Server form.
- Through the LDAP Connection Test scheduled job, which runs every 15 minutes by default.

  You can change how often this scheduled job runs. If this scheduled job is not able to establish a connection, a new one-time schedule job retries the connection test after either five minutes, or half the **Repeat Interval** value in the scheduled job, whichever occurs first.

Error messages appear on the form if there are any issues connecting to the LDAP server. Also supported are test connections for servers behind a MID server.

View the LDAP monitor

You can view current information about LDAP servers and listeners using LDAP monitor.

Before you begin
Role required: admin

About this task
The available states are:

- Active
- Inactive
- Error
- Active (Shutting down...)
- Error (Shutting down...)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

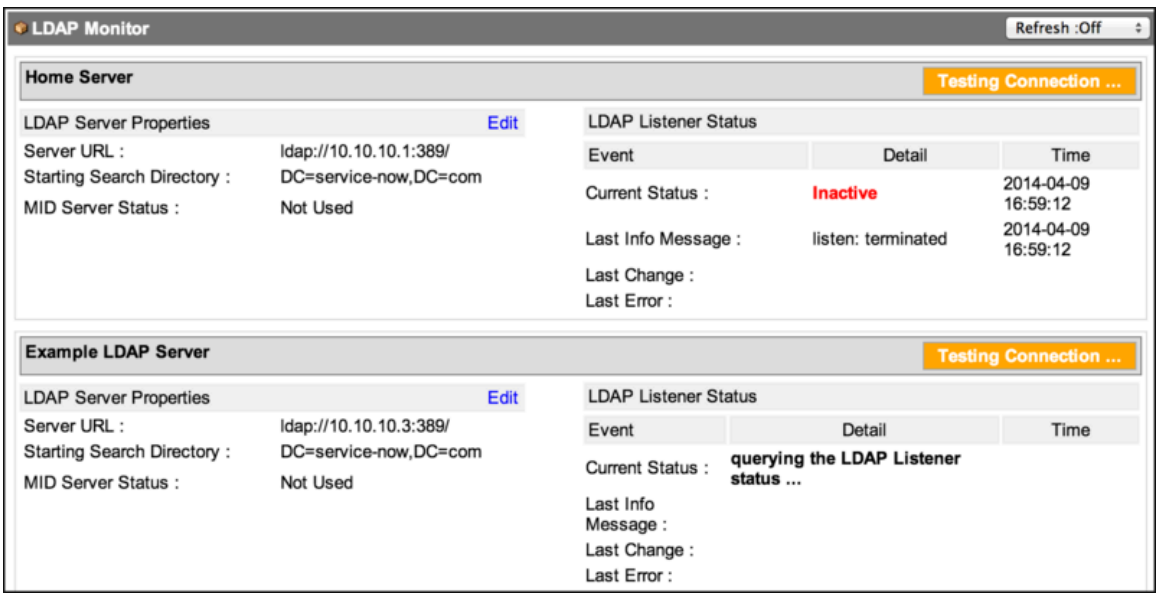
In addition to its current state, the monitor also shows:

- The last message detected by the listener, such as waiting for LDAP changes, error connecting, and so forth.
- The last LDAP user change, such as new user, updated user, and so forth.
- The last error that occurred.

To view LDAP monitor:

Procedure

Navigate to **All** > **LDAP** > **System LDAP** > **LDAP Monitor**.



See the table for descriptions of the properties and fields in the screen.

LDAP monitor

Field	Description
Refresh	You can configure the refresh rate by clicking the **Refresh** field in the LDAP Server Monitor header bar, and selecting the number of seconds between each data refresh. You can also select **None** to suppress refreshing.
Connection Status	The server connection indicator is located on the right side, above the LDAP Listener Status fields. When the server is connected, the box is green and shows *Connected*. When the server is not connected, the box is red and shows *Not Connected*. When the server connection is being tested, the box is yellow and shows *Testing Connection*.
LDAP Server Properties	
Edit	As you monitor LDAP servers, you can make changes to the properties by clicking **Edit** in the LDAP Server Monitor screen.
Server URL	The combination of the server name and server port where the LDAP Server is listening. Frequently, the port is set to one of the following: • 389: the default port for connecting to LDAP in clear text • 636: the standard port for connecting to LDAP via an SSL connection

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Example value: ldap://10.10.10.3:389/ Your LDAP Server may have more than one URL address. This does NOT establish multiple directory structures from which you can import data, which is done by creating another LDAP Server entry, but does provide for redundancy when you have multiple LDAP Servers to avoid a single point of failure. The LDAP URL addresses are separated with a space character, and the system automatically tries each server address in turn until a valid connection can be made.
Starting search directory	The starting directory or RDN (Relative Distinguished Name) where the system begins searching for users or groups. Example value: DC=service-now,DC=com No data ABOVE this point is available for import. The instance has visibility into the specified directory and directories BELOW it in the LDAP hierarchy.
MID Server Status	The current connection status of the MID Server.
LDAP Listener Status	
Current Status	This indicates whether the listener is active.
Last Info Message	This shows the last message the LDAP server received relating to user and group changes, and the time the message was received.
Last Change	This shows the last change made to the LDAP server, and the time it was made.
Last Error	This shows the last error that occurred on to the LDAP server, and the time it occurred.

LDAP error codes

The LDAP Log file lists industry standard error codes for both LDAP and Active Directory (AD).

Standard error codes

Standard LDAP errors

Error / data code	Text	Description
0	LDAP_SUCCESS	Indicates the requested client operation completed successfully.
2	LDAP_PROTOCOL_ERROR	Indicates that the server has received an invalid or malformed request from the client.
3	LDAP_TIMELIMIT_EXCEEDED	Indicates that the operation's time limit specified by either the client or the server has been exceeded. On search operations, incomplete results are returned.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Standard LDAP errors (continued)

Error / data code	Text	Description
4	LDAP_SIZELIMIT_EXCEEDED	Indicates that in a search operation, the size limit specified by the client or the server has been exceeded. Incomplete results are returned.
5	LDAP_COMPARE_FALSE	Does not indicate an error condition. Indicates that the results of a compare operation are false.
6	LDAP_COMPARE_TRUE	Does not indicate an error condition. Indicates that the results of a compare operation are true.
7	LDAP_AUTH_METHOD_NOT_SUPPORTED	Indicates that during a bind operation the client requested an authentication method not supported by the LDAP server.
8	LDAP_STRONG_AUTH_REQUIRED	Indicates one of the following: In bind requests, the LDAP server accepts only strong authentication. In a client request, the client requested an operation such as delete that requires strong authentication. In an unsolicited notice of disconnection, the LDAP server discovers the security protecting the communication between the client and server has unexpectedly failed or been compromised.
9		Reserved.
10	LDAP_REFERRAL	Does not indicate an error condition. In LDAPv3, indicates that the server does not hold the target entry of the request, but that the servers in the referral field may.
11	LDAP_ADMINLIMIT_EXCEEDED	Indicates that an LDAP server limit set by an administrative authority has been exceeded.
12	LDAP_UNAVAILABLE_CRITICAL_EXTENSION	Indicates that the LDAP server was unable to satisfy a request because one or more critical extensions were not available. Either the server does not support the control or the control is not appropriate for the operation type.
13	LDAP_CONFIDENTIALITY_REQUIRED	Indicates that the session is not protected by a protocol such as Transport Layer Security (TLS), which provides session confidentiality.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Standard LDAP errors (continued)

Error / data code	Text	Description
14	LDAP_SASL_BIND_IN_PROGRESS	Does not indicate an error condition, but indicates that the server is ready for the next step in the process. The client must send the server the same SASL mechanism to continue the process.
15		Not used.
16	LDAP_NO_SUCH_ATTRIBUTE	Indicates that the attribute specified in the modify or compare operation does not exist in the entry.
17	LDAP_UNDEFINED_TYPE	Indicates that the attribute specified in the modify or add operation does not exist in the LDAP server's schema.
18	LDAP_INAPPROPRIATE_MATCHING	Indicates that the matching rule specified in the search filter does not match a rule defined for the attribute's syntax.
19	LDAP_CONSTRAINT_VIOLATION	Indicates that the attribute value specified in a modify, add, or modify DN operation violates constraints placed on the attribute. The constraint can be one of size or content (string only, no binary).
20	LDAP_TYPE_OR_VALUE_EXISTS	Indicates that the attribute value specified in a modify or add operation already exists as a value for that attribute.
21	LDAP_INVALID_SYNTAX	Indicates that the attribute value specified in an add, compare, or modify operation is an unrecognized or invalid syntax for the attribute.
22-31		Not used.
32	LDAP_NO_SUCH_OBJECT	Indicates the target object cannot be found. This code is not returned on following operations: Search operations that find the search base but cannot find any entries that match the search filter. Bind operations.
33	LDAP_ALIAS_PROBLEM	Indicates that an error occurred when an alias was dereferenced.
34	LDAP_INVALID_DN_SYNTAX	Indicates that the syntax of the DN is incorrect. (If the DN syntax is correct, but the LDAP server's structure rules do not permit the operation, the server returns code 53: LDAP_UNWILLING_TO_PERFORM.)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Standard LDAP errors (continued)

Error / data code	Text	Description
35	LDAP_IS_LEAF	Indicates that the specified operation cannot be performed on a leaf entry. (This code is not currently in the LDAP specifications, but is reserved for this constant.)
36	LDAP_ALIAS_DEREF_PROBLEM	Indicates that during a search operation, either the client does not have access rights to read the aliased object's name or dereferencing is not allowed.
37-47		Not used.
48	LDAP_INAPPROPRIATE_AUTH	Indicates that during a bind operation, the client is attempting to use an authentication method that the client cannot use correctly. For example, either of the following cause this error: The client returns simple credentials when strong credentials are required...OR...The client returns a DN and a password for a simple bind when the entry does not have a password defined.
49	LDAP_INVALID_CREDENTIALS	Indicates that during a bind operation one of the following occurred: The client passed either an incorrect DN or password, or the password is incorrect because it has expired, intruder detection has locked the account, or another similar reason. See the data code for more information.
49 / 52e	AD_INVALID CREDENTIALS	Indicates an Active Directory (AD) AcceptSecurityContext error, which is returned when the username is valid but the combination of password and user credential is invalid. This is the AD equivalent of LDAP error code 49.
49 / 525	USER NOT FOUND	Indicates an Active Directory (AD) AcceptSecurityContext data error that is returned when the username is invalid.
49 / 530	NOT_PERMITTED_TO_LOGON_AT_THIS_TIME	Indicates an Active Directory (AD) AcceptSecurityContext data error that is logon failure caused because the user is not permitted to log on at this time. Returns only when presented with a valid username and valid password credential.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Standard LDAP errors (continued)

Error / data code	Text	Description
49 / 531	RESTRICTED_TO_SPECIFIC_MACHINES	Indicates an Active Directory (AD) AcceptSecurityContext data error that is logon failure caused because the user is not permitted to log on from this computer. Returns only when presented with a valid username and valid password credential.
49 / 532	PASSWORD_EXPIRED	Indicates an Active Directory (AD) AcceptSecurityContext data error that is a logon failure. The specified account password has expired. Returns only when presented with valid username and password credential.
49 / 533	ACCOUNT_DISABLED	Indicates an Active Directory (AD) AcceptSecurityContext data error that is a logon failure. The account is currently disabled. Returns only when presented with valid username and password credential.
49 / 568	ERROR_TOO_MANY_CONTEXT_IDS	Indicates that during a log-on attempt, the user's security context accumulated too many security IDs. This is an issue with the specific LDAP user object/ account which should be investigated by the LDAP administrator.
49 / 701	ACCOUNT_EXPIRED	Indicates an Active Directory (AD) AcceptSecurityContext data error that is a logon failure. The user's account has expired. Returns only when presented with valid username and password credential.
49 / 773	USER MUST RESET PASSWORD	Indicates an Active Directory (AD) AcceptSecurityContext data error. The user's password must be changed before logging on the first time. Returns only when presented with valid user-name and password credential.
50	LDAP_INSUFFICIENT_ACCESS	Indicates that the caller does not have sufficient rights to perform the requested operation.
51	LDAP_BUSY	Indicates that the LDAP server is too busy to process the client request at this time but if the client waits and resubmits the request, the server may be able to process it then.

Standard LDAP errors (continued)

Error / data code	Text	Description
52	LDAP_UNAVAILABLE	Indicates that the LDAP server cannot process the client's bind request, usually because it is shutting down.
52e	AD_INVALID CREDENTIALS	Indicates an Active Directory (AD) AcceptSecurityContext error, which is returned when the username is valid but the combination of password and user credential is invalid. This is the AD equivalent of LDAP error code 49: LDAP_INVALID_CREDENTIALS.
53	LDAP_UNWILLING_TO_PERFORM	Indicates that the LDAP server cannot process the request because of server-defined restrictions. This error is returned for the following reasons: The add entry request violates the server's structure rules...OR...The modify attribute request specifies attributes that users cannot modify...OR...Password restrictions prevent the action...OR...Connection restrictions prevent the action.
54	LDAP_LOOP_DETECT	Indicates that the client discovered an alias or referral loop, and is thus unable to complete this request.
55-63		Not used.
64	LDAP_NAMING_VIOLATION	Indicates that the add or modify DN operation violates the schema's structure rules. For example, The request places the entry subordinate to an alias. The request places the entry subordinate to a container that is forbidden by the containment rules. The RDN for the entry uses a forbidden attribute type.
65	LDAP_OBJECT_CLASS_VIOLATION	Indicates that the add, modify, or modify DN operation violates the object class rules for the entry. For example, the following types of request return this error: The add or modify operation tries to add an entry without a value for a required attribute. The add or modify operation tries to add an entry with a value for an attribute which the class definition does not contain. The modify operation tries to remove a required attribute without removing the auxiliary

Standard LDAP errors (continued)

Error / data code	Text	Description
		class that defines the attribute as required.
66	LDAP_NOT_ALLOWED_ON_NONLEAF	Indicates that the requested operation is permitted only on leaf entries. For example, the following types of requests return this error: The client requests a delete operation on a parent entry. The client request a modify DN operation on a parent entry.
67	LDAP_NOT_ALLOWED_ON_RDN	Indicates that the modify operation attempted to remove an attribute value that forms the entry's relative distinguished name.
68	LDAP_ALREADY_EXISTS	Indicates that the add operation attempted to add an entry that already exists, or that the modify operation attempted to rename an entry to the name of an entry that already exists.
69	LDAP_NO_OBJECT_CLASS_MODS	Indicates that the modify operation attempted to modify the structure rules of an object class.
70	LDAP_RESULTS_TOO_LARGE	Reserved for CLDAP.
71	LDAP_AFFECTS_MULTIPLE_DSAS	Indicates that the modify DN operation moves the entry from one LDAP server to another and requires more than one LDAP server.
72-79		Not used.
80	LDAP_OTHER	Indicates an unknown error condition. This is the default value for NDS error codes which do not map to other LDAP error codes.
775	USER_ACCOUNT_LOCKED	Indicates users are unable to log in because the user account is locked.

Customized error codes

Customized LDAP error codes

Error / data code	Text
10000	LDAP_ERROR_GENEREL
10001	LDAP_ERROR_MAL_FORMED_URL
10002	LDAP_ERROR_UNAUTHENTICATED_BIND

10403	LDAP_ERROR_SSL_CERT_EXPIRED
10500	LDAP_ERROR_INVALID_SEARCH_FILTER_EXCEPTION

Send a one-time password when the LDAP server is down

An LDAP property is available to send a one-time password to a user if the user is unable to log in because the LDAP server is down. You can also configure another property to control how long the password is valid.

Before you begin

Role required: admin

To receive a one-time password, the user must have notifications enabled on their user profile. The notification is an email message only. SMS messages are not supported.

About this task

Both properties are enabled by default. The default value for property that controls password validity is 10 minutes.

Procedure

1. Open the list of system properties by entering `sys_properties.list` in the filter of the application navigator.
2. Find the *`glide.ldap.onetime.password.enabled`* property.
3. Set the property to `true`.
4. To change the password validity time for a user, set the following property to an integer number of minutes: *`glide.authenticate.onetime.password.validity`*.

LDAP record synchronization

Administrators can synchronize inactive, disabled, or deleted LDAP records with their LDAP records.

LDAP record synchronization is the process of detecting inactive records on the LDAP server and updating the corresponding LDAP records. Detecting inactive LDAP records involves defining consistent data indicators for each user object, importing LDAP data, and evaluating the data indicators.

A data indicator can be:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- A date field
- Membership in a specific OU (identify by parsing the *dn* attribute), using the *useraccountcontrol* attribute
- A combination of these indicators

Imported data comes into the instance through import set tables where the data can be evaluated and processed.

The import process can use LDAP refresh filterson multiple import jobs to divide different types of user records and segregarte records for separate processing.

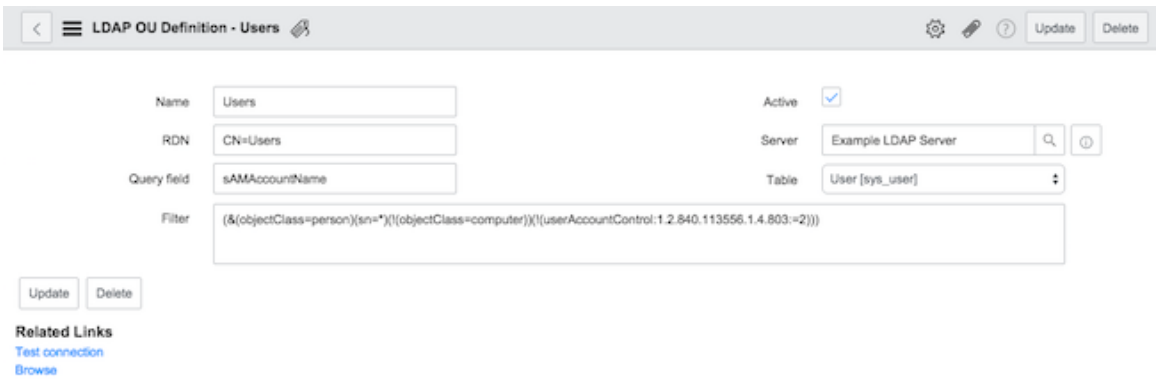
LDAP refresh filters

Filters on the LDAP refresh process can be used to specify processing that ignores inserts of disabled users.

You can loosen the LDAP OU filter to bring all of the data in to your import set table (including inactive users) and then specify processing that ignores inserts of disabled users. The sample 'Users' OU definition that the instance provides in its out-of-box LDAP sample contains a filter.

This filter is important because it defines which user records are brought into the import set table to be evaluated. While achieving a smaller data load, a limitation of this filter is that it filters out inactive users, so the inactive user records are not imported into the import set temporary tables. Since there is not visibility of the inactive user records, there is no ability to evaluate the record indicators.

LDAP OU filter



To use filtering within the main LDAP refresh process, change the filter to bring in all of the user records. The result is that all the records will be loaded into the import set temporary table where they can be evaluated and transformed.

Note:
There is a precaution here: because the filtering brings in all the records, you may end up with a vast amount of older inactive LDAP accounts that should not be inserted into the instance. A user record should never be created for a disabled user.

LDAP extraction

An LDAP extraction process can be implemented to detect disabled users.

An extract from your LDAP source can filtered for disabled users using an active flag that can be set for every record in the import to 'false'. Specify ('target.active=false') and copy into the **Script** field directly on the Table Transform Map record.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Benefits

Benefits to this method include:

- Simple scripting
- Existing user records are not involved in processing
- Inactive users are not loaded into a temporary import table
- No performance impact

Drawbacks

Drawbacks to this method include:

- An additional process is created
- The extract set must be placed in a location where your data source can access it

Alternative method

LDAP refresh filters use multiple import jobs to divide different types of user records, segregating records for separate processing.

Inactive LDAP user accounts

Detect that an existing, current, user account is inactive or has been disabled or deleted from an Active Directory (AD) LDAP.

A common LDAP integration issue is how to detect disabled or deleted users in an Active Directory (AD) and then deactivate them in the instance. In an Active Directory LDAP, a filter is usually set to exclude inactive users when refreshing, so the instance is not aware of users that are disabled or deleted in AD. The issue is how to detect that an existing, current user is inactive or has been deleted from AD.

For more information on locating inactive accounts, see Find inactive LDAP accounts by using the userAccountControl field.

Note:
The recommended approach is to deactivate user records and all other types of records, not delete them. Each record is linked to other records, and deleting a record destroys all the relationships to those other records. Deactivating records keeps those relationships in place.

Find inactive LDAP accounts by using the userAccountControl field

Identify when an Active Directory (AD) user is deleted (or made inactive).

Before you begin

Role required: admin

About this task

One method is to track the active status of AD users and create a business rule to update corresponding accounts when an AD account is inactive.

Procedure

1. Create a new string field on the User [sys_user] table to track the value of the AD **userAccountControl** field.
   For example: `u_ad_user_account`.
2. Create an LDAP transform script to set the field value.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Example

```
target.u_ad_user_account = source.userAccountControl
```

3. Update the LDAP filter to show disabled AD accounts.

   Example
   Here is an example of a filter.

   ```
   (&(objectClass=person)(sn=*)(!(objectClass=computer))(!
   (userAccountControl:1.2.840.113556.1.4.803:=2)))
   ```

   Here is an example of a replacement filter you can use.

   ```
   (&(objectClass=person)(sn=*)(!(objectClass=computer)))
   ```

4. Create an onChange business rule to set the active field to false whenever the u_ad_user_account field has the value 514.
   '514' indicates an inactive account.

LDAP script examples

The following script examples assume you use an Active Directory (AD) for your LDAP server.

userAccountControl attribute values script

This example tests the source for the userAccountControl attribute values associated with a disabled user (514 or 546).

```
//Deactivate LDAP-disabled users during transform based on
 'userAccountControl' attribute
if(source.u_useraccountcontrol == '514' ||
 source.u_useraccountcontrol == '546'){
   target.active=false;
   target.locked_out=true;
}
```

Here is an example using a bitwise check:

```
if(source.u_useraccountcontrol & 2){
   active = false;
}
```

userAccountControl attribute script

This example examines the userAccountControl attribute but does not test for specific values. It also contains the option of reactivating LDAP user accounts.

```
/*
* Deactivate LDAP-disabled users during transform based on
 'userAccountControl' attribute
* Convert the userAccountControl attribute back to a hex value
*/
var ctrl = parseInt(source.u_useraccountcontrol, 10);
ctrl = ctrl.toString(16);

/*
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
* The only digit we care about is the final one
* A final hex digit value of '2' in 'ctrl' means disabled
*/
if(ctrl.substr(-1) == "2"){

   //Deactivate and lock the user account
   target.active = false;
   target.locked_out = true;

   //Ignore any insert of a disabled record
   if(action == 'insert'){
      ignore = true;
   }
}
/* Optional: Uncomment else block to reactivate and unlock the
 user account
else {
   target.active = true;
   target.locked_out = ctrl.substr(-2, 1) == "1";
}
*/
```

onBefore transform map script

Here is an example of a onBefore transform map script. The script identifies disabled records and records being inserted. If an insert of a disabled user is occurring, then the operation transform ignores the record.

```
//Ignore any insert of a disabled record as defined by the
 'userAccountControl' attribute
var uc = source.u_useraccountcontrol;
if((uc == '514' || uc == '546') && action == 'insert'){
   ignore = true;
}
```

DN member script

This script example introduces flexibility by not relying on the 546 and 514 userAccountControl values, but instead checking whether the user is a member of a particular Distinguished Name (DN). You can use this script either in the **Script** field of the 'Table Transform Map' record or in an onBefore transform map script.

```
//Deactivate LDAP-disabled users during transform based on OU
 membership in 'dn'
if(source.u_dn.indexOf('OU=Disabled Accounts') > -1){
   target.active = false;
   target.locked_out = true;
}
```

Active Directory Application Mode (ADAM)

Active Directory Application Mode (ADAM) is an Lightweight Directory Access Protocol (LDAP)-compliant directory service.

Note:
A basic level of understanding with Microsoft Windows Server and Active Directory is needed for understanding this topic. You must also have administrator permissions on the server you are configuring for ADAM.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

These are sample procedures. Due to installation and environment variations, we cannot offer direct support. We recommend working with a Microsoft consultant.

ADAM has a simple install and runs as a service on Windows operating systems. It can be fully customized and distributed as an application component or used as a stand-alone LDAP directory. ADAM uses the same technologies found on Active Directory Domain Controllers (including replication and delegation features) and has its own administration and customization features. It can be run as a Windows service. ADAM can be installed on Windows XP, 2000, 2003, and 2008 operating systems. ADAM is included as part of Windows Server 2003 R2 and Windows Server 2008. A download is available at http://www.microsoft.com/downloads http://www.microsoft.com/downloads for earlier operating systems.

Security

Some company security policies prohibit external vendors and partners from connecting directly to an Active Directory (AD) Domain Controller. If exposing certain AD objects or attributes to an external vendor or partner is prohibited, access to objects and attributes can be blocked using AD Security Access Control Entries (ACE or ACL). Depending on security requirements, this method can introduce complexity in the integration. Consolidating multiple domains and forests is recommended. If all LDAP imports and authentications need to be channeled through a single source, ADAM can be used as a consolidated source. With the release of Windows 2008 this functionality has been renamed to Light-Weight-Directory Service, LDS. Installation and configuration is similar to Windows Server 2003 R2.

Recommended Knowledge

For this task, you must understand AD, object classes and attributes. To have a successful integration, you need to be knowledgeable of the current AD object structure, familiar with Active Directory delegations, and have a strategy on how to use ADAM and for what purposes. If you are not familiar with AD or ADAM, work with your AD administrator to configure a new ADAM environment.

Trusts

If *`userProxy`* objects is used, the computer hosting ADAM needs to be a member of the domain that has the AD accounts, or a member of a trusted domain.

Internal Connectivity

If *`userProxy`* objects is used, the ADAM computer must be able to connect to the related Domain Controllers to perform proxy authentication.

Configuring an instance with ADAM

The first install copies the ADAM files to your computer, registers requires components, and creates the application shortcuts.

Before you begin

Role required: admin

About this task

By default, all of the application files are installed to `%systemroot%\ADAM`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Windows Server 2003 R2 - ADAM can be installed using the **Control Panel > Add and Remove Programs > Optional Component Manager**.
- Windows Server 2000 & Windows XP - Downloaded http://www.microsoft.com/downloads from Microsoft.

Create the first instance service which functions as the first directory service hosted by ADAM. Do one of the following:

Procedure

- Run `adaminstall.exe` from the ADAM folder.
- Use the **Create an ADAM instance** shortcut from the **Start Menu > Programs > ADAM** folder.

1. Select the **A unique instance** install option.

   Note:
   You can use this option to install an instance replica on a second server to provide a fault tolerant system.

2. Complete the fields.

ADAM Instance

Field	Description
Instance Name	used primarily to identify the Windows Service name and display name
Ports	sets the port numbers to be used for LDAP and LDAPS Listeners. The default LDAP port is 389, LDAPS is 636. If these ports are in use on the server, the setup wizard selects new ports. Work with your network administrator to determine the best ports to use
Application Directory Partition	creates an application directory partition. Not needed at this step, we recommend creating the new partition now. A good practice is to use the same distinguished name as your forest or domain, but replace the highest level domain with adam instead of com or local. For example, if your forest partition is *dc=myCompany,dc=com*, you could create the ADAM partition as *dc=myCompany,dc=adam*
File Locations	selects the location(s) for the ADAM partition data.
Service Account Selection	selects a service account that the instance runs as. For stand-alone services, you can use the default network service account. If you plan on using replicas, you need to use an account that has access to all ADAM instances.
ADAM Administrators	the delegation on the ADAM directory that leverages Windows integrated authentication. This is how the initial access is granted for administration. Once the initial account is granted rights, this user or group delegates rights to other Windows users or ADAM users. You can select the default to only grant admin access to the current user, or grant access to a different user or group based on your needs.
Import LDIF Files	the files to import. MS-UserProxy is the most important file to import, but it's worth adding all available files since there is little overhead to the schema and you won't have to worry about extending it later if your needs expand. Confirm the details and the wizard complete the configuration.

Set up the ADAM console

Set up the ADAM console. Even though there are many similarities between ADAM and Active Directory, the administration can be very different since there is no **Users and Computers** management console.

Before you begin

Role required: admin

About this task

Most of the general administration is performed using the ADAM ADSI MMC console available from the **ADAM** start menu. The first time you run the ADAM ADSI console, you must connect to the partition you created.

Procedure

1. Right-click the **ADAM ADSI Edit** item in the left frame.
2. Give the new connection a name and update the server name and port fields with the information used when you created the instance.
3. Select **distinguished name** or **naming context** and specify the distinguished name of the application partition you created earlier.
   You can connect to the *Configuration and Schema* partitions for advanced configuration options.
   You should now be able to see into the partition and the default containers for LostAndFound, NTDS Quotas, and Roles. The Roles container has not been configured yet.

Related topics

Create containers and organizational units for ADAM

Logically group objects stored in ADAM into containers and organizational units (OU) just as they would be in Active Directory.

Before you begin

Role required: admin

Procedure

1. Right-click the root partition and navigate to **New** > **Object** > **organizationalUnit**.

   Note:
   You can also view the list of other objects that are available. This list varies based on the schema extensions installed when you imported the LDF files.

2. When prompted for a value, enter the name of the OU such as `Users`.
   The screen displays a **More Attributes** button.
3. Use the button to assign values to additional attributes.
   For the OUs and containers, no additional values are needed.
   After creating the OUs, the new OUs are listed as a child of the root object.

Delegation with ADAM

Once the OU structure is created, define the permission delegations to properly secure the objects to limited users.

As with Active Directory, there are two general ways to grant permissions:

- Add users to a group that already has the appropriate permissions assigned.
- Define new permissions on the ADAM objects.

For this task, we discuss object level permissions. Refer to the Group Administration section for information on group memberships.

Since we don't have a Users and Computers console for ADAM, all object level permissions are defined using the Active Directory utility *DSACLS.exe*. This file is found in the ADAM program directory. When running ADAM utilities it is best to launch the ADAM Tools Command Prompt. This ensures the proper versions of the tools. DSALCS is used to view and set object access rights.

Example: "`dsacls \\localhost:50010\dc=myCompany,dc=adam`" displays the permissions assigned to the root of partition *dc=myCompany,dc=adam* running on the localhost, port 50010. DSACLS is a complex tool used to create complex delegation. Run *"DSACLS /?"* for usage notes.

Create containers and organizational units for ADAM

Use ADAMSync to populate ADAM

http://www.microsoft.com/downloads/en/details.aspx?familyid=9688f8b9-1034-4ef6-a3e5-2a2a57b5c8e4&displaylang=en%7C

Populating ADAM Objects

ADAM Objects include User Objects, UserProxy Object, and Group Objects.

User Objects

Users can be created using the ADAM ADSI Edit console just as we did for OU creation. Users can also be administered using AD command line tools, which is beyond the scope of this document. The only mandatory attribute for new user objects is the *cn*, which is a short name or the user's full name. There are also a wide range of optional attributes similar to Active Directory user attributes. You can access the full list of attributes by selecting properties from the user object.

UserProxy Objects

For ServiceNow LDAP integration we recommend you use *UserProxy* objects in ADAM which creates a proxy account that links to the related AD user account. This allows you to have ADAM authenticate logon credentials using AD usernames and passwords from the domain without ServiceNow directly connecting to the Domain Controller. *UserProxy* objects are very similar to AD and ADAM User objects except that do not store passwords and has an *objectSID* attribute that contains the SID from the linked AD User object. This is how the proxy works. *UserProxy* objects are created using the *ADSIEdit* console or command line tools, but this can be tedious. It is recommended that you use an automated process as defined below.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Group Objects

Groups are created using the ADSIEdit console and AD command-line tools. Group concepts are similar to AD and are used to integrate groups and members to ServiceNow. The biggest difference is ADAM groups can contain members from ADAM or from trusted AD Domains.

Automating ADAM Object Creation

If you are interested in synchronizing Active Directory accounts to ADAM, we recommend you use Microsoft *ADAMSync* tool. This is the most common use of ADAM for ServiceNow LDAP integration.

About Permission Delegation

ADAM contains some built-in groups with default permissions. These groups are found in the container *cn=roles,dc=myCompany,dc=adam*. These are similar to domain level groups and have rights to objects in the current partition. Similar to AD Forests you can also set a higher level of permissions using the default groups in *cn=roles,cn=configuration,dc=myCompany,dc=adam*. You must connect to the configuration partition in *ADSIEdit*. The Administrators group by default includes the account specified during the setup. This member is not always visible since it's inherited through the configuration groups. Administrators have full control of all partition objects. The Readers group does not contain any members by default and has read access to all objects in the partition. The Users group is a dynamic group just as it is in Active Directory. Transitively it includes all ADAM users created in the partition.

Testing and troubleshooting ADAM setup

The primary tool used for testing is LDP. This allows you to fully test user authentication.

Most of the object management can be completed using the ADAM ADSI Edit console which will provide access to the entire collection of objects and attributes. The highest level of control and troubleshooting ADAM services is using the Windows service created during the instance setup. The service name will vary and depends on the name of the instance created. This service must be running in order for the ADAM service to run. If you are experiencing connection problems, you should review the network configurations to ensure you have the appropriate network access to connect to the server and ADAM port. For each ADAM instance installed, a Windows Event Log is created. This is also a great tool for troubleshooting ADAM services.

The Windows Security Event Log is also helpful when troubleshooting *userProxy* authentications. All *userProxy* logon attempts are logged in the Security Log and reference the remote client device address, the distinguished name of the user trying to log on, and the result or status code.

Backup and recovery with ADAM

All ADAM data can be backed up using standard file system backup methods.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Redundancy

ADAM has built-in replication utilities based on the same technology as AD. A full read and write replica of an ADAM partition can exist on the same or different computer. You can use this replica in a variety of ways to provide a fault-tolerant LDAP integration with the instance. One option is to expose both partitions to the instance through the firewall and define both servers in the LDAP Properties server field.

Active Directory Application Mode (ADAM)

http://www.microsoft.com/downloads/en/details.aspx?familyid=9688f8b9-1034-4ef6-a3e5-2a2a57b5c8e4&displaylang=en%7C

Use LDAPS with ADAM

The default configuration for *userProxy* object authentication is to enforce LDAPS (secure LDAP) communications. LDAPS requires SSL certificates to secure the network traffic.

To remove this requirement make the following change using the *ADSIEdit* console connected to the configuration partition.

```
Object: CN=Directory Service, CN=Windows NT, CN=Services,
 CN=Configuration
Attribute: msDS-Other-Setings
Value: change RequiresSecureProxyBind from 1 (enforced) to 0
 (disabled)
```

Restart the ADAM service to use the new setting.

To support secure binds and encrypt the user and password information being transmitted, a SSL certificate must be installed on the server and any LDAP client. Since there is limited and controlled uses to the ADAM service, it is feasible to use a self-signed certificate which would meet the needs without incurring certificate costs or building a Certificate Authority (CA) infrastructure. If you already have a CA, you can issue a certificate. Otherwise, create a self-signed certificate.

Creating a Self-Signed Certificate

To use the *selfssl* utility, Internet Information Services (IIS) must be installed. This service can be removed after you generate the certificate. You can get the selfssl.exe utility from the IIS Resource Kit. If IIS is already installed, create a new website so that the current sites will not be impacted during the certificate generation. Selfssl needs to temporarily attach the new self-issued certificate to a valid web site.

Selfssl is a command-line tool and has the following common parameters.

Selfssl Parameter Descriptions

Parameter	Description
/T	Adds the cert to 'Trusted Certificates' on the local machine
/N:cn	Set the common name of the certificate. This must match the fully qualified domain name of the server running the web service using the certificate
/K	Sets the strength of the key size in bits
/V	Number of days the cert is valid

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Selfssl Parameter Descriptions (continued)

Parameter	Description
/S	Web site ID to attach the certificate to
/P	IP port of the web service

The common name attribute should match the external name or address that the instance will use to connect to your ADAM computer. You will need to get the IIS Website site id unless you are using the default website which is 1 and does not need to be defined in the selfssl command. A sample command to generate a certificate for myCompany would be:

```
selfssl /N:CN=myCompany.externaldomain.com /K:1024 /V:3650 /
S:12345 /P:50001 /T
```

This statement creates a certificate that is valid for 10 years. Set the value to any duration, but be aware the new certificate must be generated and submitted to the instance before the old one expires. We recommend making a note of the expiration date on the certificate.

Once the certificate is generated you can remove it from the website, or delete the entire web site if you created a temporary site.

Assign the certificate to ADAM

Install an SSL certificate on the server and any LDAP client to support secure binds and encrypt the user and password information being transmitted.

Before you begin
Role required: admin

About this task
Because there is limited and controlled uses to the ADAM service, it is feasible to use a self-signed certificate to meet your needs without incurring certificate costs or building a Certificate Authority (CA) infrastructure.

Procedure

1. Open the Certificates MMC console and create two console connections, one for Local Computer Certificates, and the other for Local Computer Services Certificates on the new ADAM service.
   The new certificate can be found under `Certificates (Local Computer)\Personal\Certificates`.
2. Copy the certificate to the container for the ADAM service `Certificates - Service (ADAM Service Name)\ADAM_ADAM Service Name\Trusted Root Certificates\Certificates` and copy the certificate to `Certificates - Service (ADAM Service Name)\ADAM_ADAM Service Name\Personal \Certificates`.
3. Open the details tab on the certificate that you copied, note the Valid from date stamp, and assign read access to the certificate key file.
   Go to `C:\Documents and Settings\All Users\Application Data \Microsoft\Crypto\RSA\MachineKeys` and identify the certificate with the matching

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

time stamp. Assign Read & Execute rights to the service account running ADAM. By default, this is **Network Service**.

4. Restart the ADAM service to activate the new certificate.

Related topics

http://www.microsoft.com/downloads/en/details.aspx?familyid=9688f8b9-1034-4ef6-a3e5-2a2a57b5c8e4&displaylang=en%7C

Export the public key certificate

LDAPS clients, including the instance need the public key certificate in order to make a secure connection to ADAM.

Before you begin

Role required: admin

About this task

From the server certificate consoles you used above, export a public key to be used by the clients.

Procedure

1. Select the certificate, right-click, and select **all tasks/export**.
   Do not export the private key. Select the default DER encoded binary X.509 format and specify the export file name.
2. Install the public certificate on the LDAP clients that connect to the server using LDAPS.
   When prompted, add the certificate to the *Trusted Root Certificate Authorities* store.

Related topics

http://www.microsoft.com/downloads/en/details.aspx?familyid=9688f8b9-1034-4ef6-a3e5-2a2a57b5c8e4&displaylang=en%7C

Active Directory Application Mode (ADAM) Access Account

The system requires a user account to read the Active Directory Application Mode (ADAM) object information that is imported into the application instance.

Create the account by using one of the following methods:

- Create a local ADAM user account and assign it a password and assign permissions.
- Assign permission to a Windows domain account on the ADAM partition.
- Use a *userProxy* account.

When using ADAM as an LDAP source, you must specify the fully qualified distinguished name (FQDN) of the ADAM account in the instance's LDAP server's **Login distinguished name** field.

Related topics

Active Directory Application Mode (ADAM)

Test the LDAPS connections

Test the LDAPS connections. There are two console connections, one for Local Computer Certificates, and the other for Local Computer Services Certificates on the new ADAM service.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin
Role required: admin

Procedure

1. Run *LDP.exe* from the ADAM install folder c : \windows\adam.
   Verify that the ADAM version is selected because this is not the standard Windows LDP client.
2. Open a new connection by using the **Connection/Connect** menu.
   The server name must match the CN that is assigned to the certificate.
3. Enter the **LDAPS port** and select the **SSL** check box.
   The results of a successful connection are some general server information and no errors.
4. Bind (log in) to the service.
   To replicate typical LDAP client connections, select the Simple bind option. Enter a valid ADAM user or *userProxy* distinguished name in the user field and the associated password.
   If you see a return message stating 'Authenticated as:....' then you have successfully connected using LDAPS.

Related topics

Use ADAMSync to populate ADAM

Administrators use MS ADAMSync to populate LDAP directories that use MS ADAM.

Note:

This document assumes you have at least a basic level of understanding with Microsoft Windows Server, Active Directory, and ADAM and that you already have a functional Active Directory Application Mode (ADAM) instance with a partition.

These are sample procedures. Due to the complexity and the fact that it is running in your environment, we cannot offer direct support. We recommend you work with Microsoft or a Microsoft consultant if you run into any trouble.

Once ADAM has been installed and the first partition has been created, you can populate it with objects.

The following options are available:

- Manual object creation using GUI or scripts. This option is inefficient and slow.
- Integrate with Active Directory using Microsoft Integration Information Server. This option ultimately provides the most flexibility and functionality but does require some advanced configurations. There is a free version of MIIS available that is compatible with Active Directory, ADAM, andMicrosoft Global Address Lists from Exchange. Unless you already have experience with MIIS we advise that you don't attempt to implement a new environment for LDAP integration only.
- Use ADAMSync, a synchronization tool that Microsoft provides with ADAM. This is the option that is explained here.

Define ADAM user accounts

Define user accounts in ADAM. One user account is used for the instance to connect with and the other user account is for ADAMSync.

Before you begin
Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

About this task

These accounts can be local ADAM User objects, UserProxy objects, or a Windows account from a trusted domain.

The *ADAM User* account requires read-only access to the directory structure you are importing to your instance. The best way to accomplish this is to add the account to the member attribute on the Readers group found in cn=roles,dc=myCompany,dc=adam.

New ADAM User accounts are disabled by default. You will need to enable the new accounts and set a password.

Procedure

1. Enable users by changing the attribute msDS-UserAccountDisabled to FALSE.
2. Right-click the user object and reset the password.
3. Test the new accounts by using LDP as defined in Active Directory Application Mode (ADAM) to make sure they can connect.
   Use the **LDAP** > **View/Tree** option, leaving the Base DN blank to make sure that you can view the objects in the directory by using the new accounts. The Configuration, Schema, and the domain partition should be visible in the left pane. Traverse the domain partition. If you are using a new local ADAM account, it will show 'No Children' which means that you don't have read access to the objects. Verify the Setup group memberships and re-test.

   ADAMSync uses the *ADAMSync User* account to manage objects in the ADAM partition. This account requires admin level rights since it will create, update, and delete ADAM objects.

   ADAMSync uses the *ADAMSync AD* account to read the AD objects that will be synchronized to ADAM.

Set up ADAMSync

ADAMSync is included with Windows Server 2003 R2. Download and install ADAMSync if you are using a different OS.

Extending the schema

The ADAM schema needs to be extended to support ADAMSync.

1. Run the following command from c:\windows\adam to import the ADAMSync schema extensions. You may have to change the server:port and add credentials if the current user doesn't have access. See the AdamSyncMetadata.ldf file for details.

```
ldifde -i -f MS-AdamSyncMetadata.LDF -s localhost:50000 -j . -c
 "cn=Configuration,dc=X" #configurationNamingContext
```

2. Do the same with MS-AdamSchemaW2k3.ldf to support Windows 2003 attributes.

```
ldifde -i -u -f MS-AdamSchemaW2K3.LDF -s localhost:50000 -j .
 -c "cn=Configuration,dc=X" #configurationNamingContext
```

Recommended schema changes

Here are some additional schema changes we recommend.

1. Open a new MMC console and add the ADAM Schema Snap-in.
2. Connect to the ADAM instance.
3. Expand the Classes folder and locate the userProxy class, open **Properties**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Verify the following optional attributes on the Attributes tab, add any that do not already exist.
   - company
   - department
   - givenNane
   - mail
   - physicalDeliveryOfficeName
   - sAMAccountName
   - sn
   - telephoneNumber
   - title
   - userAccountControl
   - userPrincipalName
5. Restart the ADAM Service to enable the new settings.

Install the ADAM configuration file

Install the ADAM configuration file through the Windows command line.

Before you begin
Role required: admin

Procedure

1. Install the configuration file.

```
C:\WINDOWS\adam>adamsync /install localhost:50000
MS-AdamSyncConf-SNC.XML
```

2. Run the synchronization file to log to the console.

```
C:\WINDOWS\adam>adamsync /sync localhost:50000
"ou=users,dc=service-now,dc=adam" /log -
```

3. Review the results by using the ADSIEdit console.
   You should see the new objects and attributes that were created by ADAMSync.
4. Run ldap to test the UserProxy authentication.
   Automating the sync process

   Set up the sync process as a Windows Scheduled Task. You must either provide the credentials in the config file, command line, or run the Scheduled Task with an account that has access.

   Special notes
   - You can create multiple configuration files and scheduled jobs to sync ADAM from multiple sources.

     This example imports the sAMAccountName attribute which can be used as the application logon. If you are going to sync source you need to make sure you have a unique attribute

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

value that can be used for the logon credentials. sAMAccountName is guaranteed to be unique within a domain, but not across multiple domains.

- If you are using Microsoft Exchange, we recommend excluding cn=SystemMailbox* objects as part of the object-filter configuration.

Example ADAM configuration files

All of the configurations for ADAMSync are stored in xml files.

Default configuration file with comments

There is a default configuration file called MS-AdamSyncConf.xml included with the ADAMSync install. Make a copy of this file so you have a base example to refer to in the future. This example is the default configuration file with comments added.

```
<?xml version="1.0"?>
<doc>
 <configuration>
<!-- Sync File Description -->
<description>MyCompany ADAMSync Configuration</description>
  <security-mode>object</security-mode>;
<!-- source-ad-name = fqdn of the domain controller -->;

 <source-ad-name>;fully.qualified.domain.name.of.domain.controll
er</source-ad-name>;
<!-- source-ad-partition = root AD domain partition -->;

LDAP filters configuration file

You can provide any level of filtering in the object-filter value in the configuration file. Use standard LDAP query syntax with the following xml escape characters in place of the standard operators.

- AND = "&" replace with &
- OR = "|" (vertical line) replace with |
- NOT = "!" replace with !

Reference configuration file

Here's an actual configuration file that can be referenced as a sample.

```
<?xml version="1.0"?>;
<doc>;
 <configuration>;
<description>;SNCTest ADAMSync Configuration</description>;
  <security-mode>;object</security-mode>;
```

Configure Microsoft Active Directory for secure LDAPS communication

Use certificate pairs to enable Microsoft Active Directory (AD) LDAPS communications.

Note:
These procedures were designed and tested using Windows 2003 R2 Standard Edition and work with all versions of Windows 2003.

Secure LDAP (LDAPS) communication is similar to SSL (HTTPS) communication in that both encrypt the data between servers and clients. To accomplish this, the server and clients share common information by using certificate pairs. The server holds the private key certificate and the clients hold the public key certificate. These certificates are required to enable Microsoft Active Directory (AD) LDAPS communications.

To configure LDAPS for Active Directory you must:

- Ensure that the Active Directory domain is set up and that the instance is able to connect to the Active Directory server through the firewall.
- Verify that there is a Certificate Authority (CA) that can issue a certificate for the domain controller (DC). If you don't already have a CA infrastructure there are two options.
  - Setup a stand-alone CA to issue the certificate
  - Request a third party certificate
- If you already have a CA in place, you can generate a certificate from an internal CA.

All certificates have a defined expiration date which can be viewed in the certificate properties. If the certificate expires, all LDAPS traffic fails, and your users can no longer log into the instance. To resolve this, a new certificate must be issued and installed on your instance.

The default expiration for Microsoft CA certificates is one year. External CA certificates are usually purchased in one year increments. Note when your certificate expires, or use the application's Expiration Notification function (located in **System LDAP** > **Certificates**). Ensure that you have a new certificate ready before the old one expires. This gives you time to install and test the new certificate before the old one expires.

Set up a stand-alone certificate authority for active directory

The first step to configure Microsoft Active Directory for SSL access is to set up a stand-alone Certificate Authority (CA).

Before you begin
Role required: admin

About this task
Do not worry about addition resource utilization because both of the required services (IIS & CA) can be disabled after issuing the certificate(s).

Procedure

1. Install Internet Information Server (IIS).
2. Install Certificate Authority Services in stand-alone mode.
3. Verify the Certificate Services web application is installed and active.

What to do next
Using the IIS Manager console, expand the local computer and select *Web Sites*. The state of **Default Web Site** should be *Running*. You should also see a *CertSrv* application listed under the

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Default Web Site. If the site is not running or the application is missing, you must resolve the issue before you proceed.

Generate a certificate from an internal certificate authority

When you configure Microsoft Active Directory for SSL access, you must generate an internal certificate and request the external certificate.

Before you begin

Role required: admin

About this task

These steps apply to Microsoft CA services. If you have a different internal CA platform, see your local CA administrator for assistance.

Procedure

1. From the domain controller (DC) you want to create a certificate for, browse to `http://localhost/certsrv` or specify the CA server name if it is on a remote server.
2. From the Welcome page, click **Request a certificate** and select *advanced certificate request*.
3. On the Advanced Certificate Request page, select **Create** and submit a request to this CA.
4. Complete the Advanced Certificate Request as follows:

Advanced Certificate Request fields

Field	Entry
Name	The fully qualified domain name (FQDN) of the DC that is requesting the certificate.
E-Mail	The email address of the person responsible for the certificate.
Company	Your company name.
Key Options settings	
Create new key set	Select it.
CSR	Microsoft RSA SChannel Cryptographic Provider.
Key Usage	Exchange.
Key Size	1024 is recommended. The instance supports up to 2048.
Automatic key container name	Select it.
Store certificate in the local computer certificate store	Select it.

5. Click **Submit**.
   You are directed to a page that provides your **Request ID**, make note of this ID.
6. To process the pending request, complete the following:
   a. Open the Certificate Authority management console.
   b. Expand the server node and select **Pending Requests**.
   c. Locate the Request ID for the request you just submitted, right-click, and select *All Tasks/ Issue to approve the request and issue the certificate*.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

7. To retrieve the issued certificate, complete the following:
   a. From the DC you made the request from, browse to `http://localhost/certsrv`, or specify the CA server name if it is on a remote server.
   b. Select `View the status of a pending certificate request`.
   c. Select the link to the new certificate.
   d. Select the link to **Install this certificate**.

What to do next
You need to request a third party certificate. Certificates from external CAs can be purchased for as little as $30 per year. For detailed procedures on requesting a certificate from an external CA, see Microsoft article 321051. After it is received, installed, and tested, follow the export procedure.

Test the LDAPS connectivity locally

Test the LDAPS connectivity after installing the internal and third party certificates when you configure Microsoft Active Directory for SSL access.

Before you begin
Role required: admin

Procedure
1. Ensure that Windows Support Tools are installed on the domain controller (DC).
   The Support Tools setup (suptools.msi) can be found in the `\Support\Tools` directory on your Windows Server CD.
2. Navigate to **Start** > **All Programs** > **Windows Support Tools** > **Command Prompt**.
   On the command line, enter `ldp` to start the tool.
3. From the *ldp* window, select **Connection** > **Connect** and supply the local FQDN and port number (636).
   Also select the *SSL*.
   If successful, a window displays and lists information related to the Active Directory SSL connection. If the connection is unsuccessful, try restarting your system and repeat this procedure.

Export the public key certificate to trust the LDAP certificate

Export the public key certificate and import it into the application when you configure Microsoft Active Directory for SSL access.

Before you begin
Role required: admin

About this task
If your Certificate Authority is not a trusted third party vendor, you must export the certificate for the issuing CA so we can trust it, and, by association, trust the LDAP server certificate. For MS Certificate Services users, you can view the certificate path by viewing the certificate in the console used to export; select the **Certificate Path** tab. You must export all certificates in the chain. You can find the CA certificate in the same folder as the LDAP certificate by looking for the name in the Certificate Path. Submit all certificates for importing to your instance.

Procedure
1. From a current or new MMC console, add the Certificate (Local Computer) snap-in.
2. Open the `Personal/Certificates` folder.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. Locate the new certificate.
   The Issued to column shows the FQDN of the domain controller.
4. Right-click the certificate and select *All Tasks/Export*.
5. Export to DER or Base-64 format.
   Name the file using the format `MyCompany.cer`. This is the public key certificate the needs to be used on the instance to communicate securely with your domain controller.
6. Test LDAPS locally before you submit the certificate to the instance.

What to do next
After completing this procedure, import the public key certificate into the application.
See Install the LDAP X.509 SSL certificate to upload the certificate into the application.

LDAP global catalog usage

A DC can be granted the Global Catalog (GC) role. Global Catalog (GC) role is an LDAP-compliant directory consisting of a partial representation of every object from every domain within a forest.

Administrators configure Active Directory to host Lightweight Directory Access Protocol (LDAP) directory information using one of the following hosting methods.

- The common method of hosting LDAP directory information is to use the default LDAP or LDAPS (secure LDAP) on ports 389 or 636. These standard LDAP ports always exist on a Domain Controller (DC) and are rarely changed. Accessing this directory partition provides access to all of the objects within the domain that is hosted on the DC. There is no way to access objects from other domains using this method.
- A DC can also be granted the Global Catalog (GC) role. Global Catalog (GC) role is an LDAP-compliant directory consisting of a partial representation of every object from every domain within the forest. This LDAP directory can be accessed on port 3268, with LDAPS on port 3269. LDAPS and the default LDAP ports' certificate requirements are the same.

Global Catalog LDAP dependencies

- The domain controller that your instance connects to must have the Global Catalog role enabled.
- Firewall rules must allow inbound traffic to the domain controller on port 3268 (LDAP) or 3269 (LDAPS).

Special notes

- Not all attributes are replicated to the GC partition. Common attributes such as first name, last name, email, phone number, description, and address are included. Additional attributes can be added to the GC but should be limited to minimize the impact to forest replication traffic.
- Standard LDAP integrations usually use sAMAccountName as the instance's UserID and as the coalesce key in the LDAP import map since this is guaranteed to be unique within a domain. This attribute is no longer unique when viewing an entire forest of domains. A new unique attribute needs to be identified and as the UserID and the coalesce key. These do not need to be the same attribute and may vary based on your forest design. Consult your Active Directory administrator. Typically, the userPrinicpalName is a unique attribute across domains but this may not be a user-friendly name to login with, but it could be used for the unique identifier on imports. A common attribute that is used for the UserID is email address. These decisions impact the LDAP Properties and LDAP Mapping.
- The value used for the coalesce key on the LDAP import map must be unique and exist on every object being imported. If it is not unique or does not exist, incorrect records are updated with changes.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- If you already have an LDAP integration and wish to change it to a GC, change the import coalesce key. The new key values must be imported before you can change the coalesce key.
- If you make any changes to your LDAP integration that break your integration, your first step should be to revert those changes. After that, contact Customer Service and Support with complete information about what you're attempting.

OpenLDAP minor schema modification

In OpenLDAP 2.3 systems that use the back-bdb (Berkley backend), administrators make a minor modification to their schema to facilitate the integration.

> **Warning:**
> The customization described here was developed for use in specific instances, and is not supported by Now Support. This method is provided as-is and should be tested thoroughly before implementation. Post all questions and comments regarding this customization to our community forum.

In OpenLDAP 2.3, back-bdb has limited support for inequality indexing (ordering). It is implemented only for generalizedTime and ChangeSequenceNumber syntax. It cannot be supported on syntax that support substrings. Search filters containing inequalities are processed using the presence index.

We recommend creating a custom attribute for this purpose, instead of changing what is already indexed or present in the schema (for example, *servnowid*).

Modify the OpenLDAP schema

Modify the OpenLDAP schema. These steps detail a schema modification to OpenLDAP 2.3 provided by one of our customers that helped them integrate with their instance.

Before you begin

Role required: admin

About this task

> **Warning:**
> The customization described here was developed for use in specific instances, and is not supported by Now Support. This method is provided as-is and should be tested thoroughly before implementation. Post all questions and comments regarding this customization to our community forum.

To modify the OpenLDAP schema for integration with the instance:

Procedure

1. Create a custom attribute.

   Example

```
attribute ( 1.3.6.1.4.1.3403000.2.1.8

     NAME 'servnowid'
  ORDERING caseIgnoreOrderingMatch
  EQUALITY caseIgnoreMatch
  SYNTAX '1.3.6.1.4.1.1466.115.121.1.15' )
```

2. Include the attribute in the selected objectclass OID.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Example

```
objectclass ( 1.3.6.1.4.1.3403000.2.2.1
     NAME 'BcfUserIdentifiers' SUP top AUXILIARY
  MAY ( uniqid $ unixid $ servnowid ) )
```

In OpenLDAP 2.3, you can dynamically change the server configurations, but you can only extend the schema. You cannot modify or delete the existing schema. Instead of creating another objectclass for this attribute in the dynamic configuration, use the static configuration file, slapd.conf.

3. In slapd.conf, include indexing for the new attribute in the bdb section of your main database backend.

Example

```
database bdb (configs here) ....

index servnowid pres

(other indexes here) .....
```

4. As root, run slapindex to index this attribute to make it available in search filters.
Make sure that the OpenLDAP daemon is not running or is in read-only mode before starting slapindex.

Record LDAP deletions

By default, the instance does not delete any entries after they disappear from LDAP.

Deleting an entry, also referred to as a record, also deletes the entire history and references to the deleted entry.

For example, configuration items (CIs), SLA agreements, software licenses, purchase orders, and service catalog entries all have a reference to Department, and if a department is deleted, then the integration clears all references to the department. Also, deleting a user results in losing all history of what that user did.

Decide whether to retain or Delete all records from a table according to your organization's needs.

Limit concurrent sessions

You can limit the number of concurrent interactive sessions for a user or role on an instance across all nodes.

Learn the features and business value of limit concurrent sessions.	Understand how to Activate limit concurrent sessions.
Set Set the limit concurrent sessions for a user or role.	Disable Know about the how to disable limit concurrent sessions.

Explore limit concurrent sessions

You can limit the number of concurrent interactive sessions for a user or role on an instance across all nodes.

Concurrent interactive sessions refer to the number of sessions a user can have active per ServiceNow instance. An active instance session occurs with every new login to a specific ServiceNow instance. By default, there are no limitations on the number of active instance sessions a user can have.

With the Jakarta release, you can limit the number of active concurrent sessions per user. When the user logs in after hitting the maximum number of sessions active, the oldest active session terminates and a new interactive session becomes active. If a user tries to access a closed session through a browser, the user is redirected to the login page.

Note:
The **Limit concurrent sessions** plugin must be active to enable a maximum session limit. Limits are set through the glide.authenticate.max.concurrent.interactive.sessions property. A maximum limit value applies to any user or role that has the limit property active. A user or a role connected to the user must have the limit_concurrent_sessions value set to true for the limit on sessions to initiate. For the Jakarta release, this feature does not support sessions created through the native mobile app or non-interactive mechanisms.

A typical use case if a maximum concurrent session of 1 is set:

1. The user accesses the initial ServiceNow instance through Chrome.
2. After the user successfully logs in, ServiceNow creates session 1 (S1) for the user.
3. The user decides to initiate another access to the ServiceNow instance through Firefox.
4. After the user successfully logs in, ServiceNow creates session 2 (S2) for the user.
5. Since the user has a maximum concurrent session limit of 1, the S1 session invalidates when S2 is created.
6. When the user goes back through Chrome to access the S1 ServiceNow instance, the user is redirected to the login page as S1 is invalid.

Concurrent session limits work with all the ServiceNow authentication mechanisms: SAML, LDAP, and local database authentication. It also works with Multi-factor authentication and all interactive ServiceNow authentication mechanisms. The source of the session is viewable through the **sys_user_session** table, under the column **Type**. The values can be:

- Web Browser
- Mobile Browser
- ServiceNow Mobile App
- Non-interactive (SOAP, WSDL, OAuth)

Activate and configure limit concurrent sessions plugin

You can activate the Limit Concurrent Sessions plugin (com.glide.limit.concurrent.sessions) if you have the admin role.

Before you begin

Role required: admin

About this task

Procedure

1. Navigate to **All** > **System Definition** > **Plugins**.
2. Find and click the Limit Concurrent Sessions plugin.
3. On the System Plugin form, review the plugin details and then click the **Activate/Upgrade** related link.
4. Click **Activate**.
5. To enable this feature and set a maximum limit of concurrent sessions, go to the **Plugin Files** tab, find the following properties, and change the setting values.

Option	Description
glide.authenticate.limit.concurrent.interactive.sessions	You can enable the ability to limit concurrent sessions by setting the value to **True**. By default, this property is set to **False**, which means there is no limit on the number of interactive sessions a user can have active. **Note:** To disable this feature, set this property back to **False**.
glide.authenticate.max.concurrent.interactive.sessions	You can set the maximum number of concurrent active interactive sessions a user can have on the instance across all nodes.

6. **Optional:** You can also amend the following properties, if necessary.

Option	Description
glide.authenticate.session.types.to.limit.concurrency	This property limits session types. By default, only the web browser sessions have a limit. Session types include: ○ Web Browser (1) ○ Mobile Browser (2) ○ ServiceNow Mobile App (3) ○ Non-interactive (10)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Option	Description
	You can configure and set the value to '1' for web browser, '2' for mobile browser, or '1,2' for both. **Note:** Only web and mobile browser sessions can have a limit. There are no limits for sessions that originate from the Service Now mobile app or non-interactive ses sions.
glide.authenticate.limit.concurrent.session s.across.all.nodes	This property restricts the limit of concurrent sessions per node instead of restricting them across all nodes of a ServiceNow instance. By default, the value is set to true, which limits user sessions across all nodes. If the property is set to false, only the sessions on that node and not the ones on the other nodes are sub ject to the limit.

7. Click **Update** to have the settings take effect.

What to do next

Set a concurrent session limit by user or role.

Security options

You can control several aspects of user login and authentication security:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Feature	Description	Related topics
Log in and log out controls	Control several dimensions of the log in and log out process for users, such as specifying a landing page that the user sees upon login and control how users log out.	• Define login scenarios • Configure the logout confirmation prompt • Installation exits • Specify lockout for failed login attempts
Authentication security	Control the password reset process and features like the Remember Me option. You can also use IP address-based controls for access to the instance and implement a nonce to be used with single sign-on digest authentication.	• Configure your password policy • Password Reset • Remember me • IP range based authentication • Implement a nonce

Define login scenarios

You can direct all users to the same page after login.

Before you begin

Role required: admin

About this task

When users log on to an instance directly, such as going to http://{instance_name}.service-now.com/, the system does the following:

1. Accesses the value in the property *glide.entry.page.script*. The default value of the property is derived from a script include named *CMSEntryPage*.
2. Directs the user to the instance login page if the entry page requires a login.
3. Applies login rules, if any, to the user.

To force the system to direct all users to the same page after login:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Content Management** > **Configuration** > **Configuration Page**.
2. Select a value for the *Login page* field, or create a new page as desired.

   If this page is not the site default page, it always redirects here. If it is a site default page, it applies login rules. If this value is null, the system uses navpage.do as the entry page. Do not enter a login page here; otherwise, users need to log in twice.

   Logging Into an Instance to access a record:

   When users log into an instance to access a record by its globally unique identifier (sys_id), such as http://{instance}.service-now.com/incident.do?sys_id={sys_id}, then the system does the following:

   a. Directs the user to a login page if not already logged in.

   b. Directs the user to the appropriate record if they are allowed to access it. If the user does not have access rights to the record, a denial of access message appears.

   Logging Into the Service Portal or a CMS site:

   When users log on the Service Portal or a CMS site, such as http://<instance>.service-now.com/site-name/page.do, the system does the following:

   - If there is a value in the *Login page* field on the Service Portal or the CMS site form, it directs the user to that login page and applies login rules, if any, to the user.
   - If there is no login page specified, it directs the user to the value in the *Home page* field on the Service Portal or the CMS site form.

   Logging Into the Service Portal or a CMS Site to access a record:

   When users log on to the Service Portal or a CMS site to access a record, such as http://{instance}.service-now.com/ess/incident_detail.do?sysparm_document_key=incident,{sys_id}, the system follows the same procedure and finally takes the user to the record. If the user does not have access rights to the record, a denial of access message appears.

Logins and the employee self-service portal

The system keeps track of the first starting page that a user is trying to access even if the user wants to log in to the Employee Self-Service Portal.

Consider the following scenarios.

Example 1:

1. A user is not logged in, and then tries to access a record using a specific SYS ID in the URL.
2. The system redirects the user to the login page.
3. Rather than logging in, the user tries to access another site, such as the Employee Self-Service (/ess) Portal.
4. The system redirects the user to the login page again.
5. The user logs in and is redirected to the record that the user was first trying to access rather than the Employee Self-Service Portal.

Example 2:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

1. A user is not logged in, and then tries to access a record using a specific SYS ID in the URL through the Employee Self-Service (/ess) Portal.
2. The system redirects the user to the login page.
3. Rather than logging in, the user tries to access another record through the Employee Self-Service Portal.
4. The system redirects the user to the login page again.
5. The user logs in and is redirected to the first record rather than the second.

Specify a login landing page

By default, users see their homepage upon login. You can specify a different login landing page by using a system property or the content management system.

Before you begin
Role required: admin

About this task
To specify a login landing page for all users, change the property value on the sys_properties table.

Procedure
1. Type `sys_properties.list` in the navigation filter.
2. Locate the **glide.login.home** system property.
3. In the **Value** field, enter the name of the page that all users see upon login.

   Use `<page name>.do`; you may omit the `http://''instance''.service-now.com/` portion of the URL. To determine the page name or the URL of a page in the system, you can point to a link. Some possible pages are `welcome.do` and `incident.do`.

   To specify a dashboard landing page, set the property to `$dashboards.do?dashboard=<SYS_ID>`. Replace <SYS_ID> with the sys_id of the dashboard.

   To direct users to service portal, set the property to `/sp`

   Note:
   This property is system-wide, so setting it affects all users. To set a login specifically for users with no roles, you can apply these same steps and use the **glide.entry.loggedin.page_ess** property.

   You can also specify a login landing page with the content management system.

Specify lockout for failed login attempts

The system provides inactive script actions that enable you to specify the number of failed login attempts before a user account is locked and to reset the count after a successful login.

Before you begin
Role required: password_reset_admin

Procedure

Navigate to **All** > **System Policy** > **Script Actions** to view or activate the scripts.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
Starting with the Kingston release, following a zBoot, the script actions **SNC User Lockout Check with Auto Unlock** and **SNC User Clear** are activated.

To learn more about properties that affect failed login attempts, see Managing failed login attempts (instance security hardening) in the Instance Security Hardening Settings.

Script action	Description
SNC User Lockout Check with Auto Unlock	• Uses the value of the `glide.user.max_unlock_attempts` property to set the limit for failed login attempts. • Unlocks the user account after the time period that is specified for the `glide.user.unlock_timeout_in_mins` property. If no value is specified, then the system unlocks the user account after the default period of 15 minutes.
SNC User Lockout Check	Tracks the number of failed login attempts and locks the user account after a specified number of failed login attempts (default: 5).
SNC User Clear	Updates the user record after a successful login: Resets the number of failed login attempts and updates the date of the last login.

What to do next
Each time a user attempts to log in, the action is recorded in an event log. You can view a log of failed login attempts.

1. Navigate to **System Policy** > **Event Logs**.
2. Filter for **login.failed** in the **Name** field. You can view the attempted login name, date, and IP address logged for the attempt.

Make UI pages public or private

You can make pages public if you want your users to see the pages without logging in.

Before you begin
Role required: admin

About this task
Most pages are only viewable by logged in users. A limited number of pages are public so that users do not have to log in to view them, such as the welcome page, the front page, and the login and logout pages.

Warning:
Several base system public pages are required for the functionality of many features. Do not disable base system public pages.

Procedure
1. In the application navigator filter, type `sys_public.list`.
2. Click **New**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. In the sys_public table, create a record with the following values.

Field	Description
Page	The name of the page. For example: $sp
Active	When selected, the page is publicly accessible. Deselect the Active option when you want the page to be private.

4. Click **Save**.
   By setting active to true, the page is public, so anyone visiting `<instance_name>/sp` or `<instance_name>/$sp.do` can access the page.

Password complexity requirements

Passwords in your ServiceNow® instance must meet complexity requirements.

Explore

Learn the features and business value of Password complexity requirements.

Enable

Understand how to enable Password complexity requirements.

Configure

Configure the Password complexity requirements.

Reference - Unsupported password characters

Know about the unsupported password characters.

Explore Password complexity requirements

Passwords in your ServiceNow® instance must meet complexity requirements.

The Passwords complexity requirements policy setting determines whether passwords must meet a series of strong-password guidelines.

Password complexity requirements are enforced when a password is changed or created.

Password complexity requirements adhere and work based on the following:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- If the *glide.apply.password_policy.on_login* property is enabled, the password policy check is enforced against the user during login. During login, the user must adhere to the password policy and change the password for the instance.
- The password policy requirements are based on the Basic Multilingual Plane (BMP) that contains characters for all modern languages. ServiceNow instances are shipped with BMPs of around 10,000 characters.
- Passwords within the permissible BMPs can be set for your instance. Passwords that do not adhere within these BMPs are not allowed.

If needed, you can require that passwords are changed regularly, at least every 90 days.

Requirements and banned characters

To enable a secure network environment, it is necessary for users to use strong passwords that include combination of letters, numbers, and symbols. These combinations help to prevent unauthorized users who usually use manual or automated methods to guess weak passwords.

The password to your instance must meet the following requirements:

- Minimum 8 characters.
- Maximum 100 characters.
- Contains lower case and upper case characters
- Contains special characters.
- Contains digits.

You can ban a list of common bad passwords, such as the following:

- Predictable and repeating sequences such as "123456", "qwerty", "!@#$%^", "aaaaa", and so on.
- Employee name or user names.
- Relevant brand or product names.
- Locations, such as company headquarters, city, country, and so on.
- Company-specific internal terms or abbreviations.
- Emojis.

Note:
User, brand, or company-specific characters that cannot be used in the password can be configured in the Password Policy or Exclude Password page.

Enable password policies on your instance

Implement password policy controls at login. Force users to change their password if the password does not meet the password policy criteria.

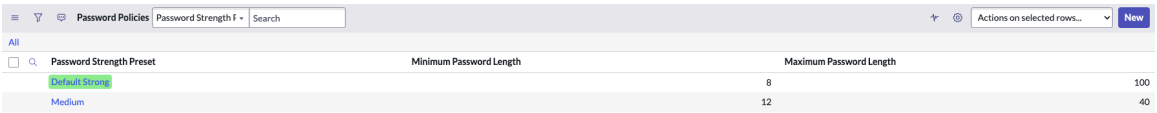
Before you begin
Role required: admin

About this task
The Password Policy plugin (com.glide.password_policy) is enabled by default. The policy goes into effect when a user changes or resets the password.
The **Password Strength Preset** field is automatically set to **Default Strong**. If you want to add new criteria, you can perform the following procedure.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

If you customized your instance through the *ValidatePasswordStronger* installation exit or your Password Reset credential store *pwd_cred_store* property, then see password policy properties to know how to implement a password policy for your instance.

Note:
The active password policy is highlighted for the Instance as shown.



To change the password policy navigate to **All** > **Password Reset** > **Credentials Stores**, select the credentials and change the **Password policy** field to the required policy input.

Procedure

1. Navigate to **All** > **Password Policy** > **Password Policies**.
2. Click **New**.
   The Password Policy form appears.
3. Specify the **Name** for your password policy.
4. In the Password Policy Criteria section, select one of the following presets from the **Password Strength Preset** field.

   Note:
   Password policy is applied based on the selected preset.

5. On the form, fill in the remaining fields.

Password Policy form

Field	Description
Minimum Password Length	Minimum length of the password. This option is displayed for all the presets except for **Advanced**. Set this field to a minimum of 8–10 characters.
Maximum Password Length	Maximum length of the password. This option is displayed for all the presets except **Advanced**. Set this field to a maximum of 100 characters.
Minimum Uppercase Character(s)	Minimum number of uppercase characters in the password, from 0 to 10.
Minimum Lowercase Character(s)	Minimum lowercase characters in the password, from 0 to 10.
Minimum Numeric Character(s)	Minimum numeric of characters in the password, from 0 to 10.
Minimum Special Character(s)	Minimum number of special characters in the password, from 0 to 10.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Included Special Characters	Allow a restricted set of special characters without any delimiter. For example, if you enter `$,!`, then users can only use "$" and "!" as special characters in the password. No other special characters can be used. A password with other special characters is not allowed.
Excluded Special Characters	Allow a restricted set of special characters without any delimiter. For example, if you enter `@$!`, then users cannot use '@', '$' and '!' as special characters in their passwords. **Note:** This option is available if the *glide.password_policy.use_excluded_spec* property is enabled.
Disallow User Data	Option to disallow user data that is authentication-related.
Sequence Length Threshold	The sequence length of your password.
Repetition Length Threshold	The repetition length of your password. **Note:** ○ Both the sequence length threshold and repetition length threshold can have a maximum of eight characters. These fields enable you to restrict weak combinations of passwords that have predictable and repeating sequences such as "123456", "qwerty", "!@#$%^", "aaaaa", and so on. ○ If **Password Strength Preset** is set to **Default Strong**, then the length for both sequence length threshold and repetition length threshold is set to four characters.
Test Your Password	Specify your actual password in this field.

6. Click **Test Your Password**.
7. After the password is tested as valid, click **Submit** to submit the password.

Note:
Always test your password before submitting.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Password policy properties

The password policy properties enable you to administrate password policies, exclude list passwords, and apply a password policy during login.

Navigate to **Password Policy** > **Properties** to view and edit the password policy properties.

Property	Description
glide.enable.password_policy	Enables a password policy for your instance. The policy goes into effect when a user changes or resets a password. This property is automatically set to **true**. **Note:** • If your instance is customized, via the *ValidatePasswordStronger* installation exit or your Password Reset credential store [pwd_cred_store], then you must create this property and add it to your system properties. • Prior to the Orlando release, if your instance was customized with the *ValidatePasswordStronger* installation exit, then you had to create the Password Policy property to make the Password Policy work. • Starting with the Orlando release, there is no installation exit customization. The Password Policy properties work by default. These properties can be manually turned off.
glide.enable.blacklist_password	Prohibits using specific passwords. The administrator can insert passwords into the Excluded Password table. This property is automatically set to **true**.
glide.apply.password_policy.on_login	Forces users to change the passwords during their next login if the existing passwords are not in compliance with the current password policy. This property is automatically set to **false**. Setting the value to **true** enforces a password policy during login. **Note:** Enabling this property might force a significant number of users who are not in compliance with the new password policy to change their passwords.
glide.password_policy.user_excluded_special_char	Enables users to use the excluded special character option on the Password policy form.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property	Description
glide.validate.sys_user.password.field	Enables validation on the user password against the password policy when an admin is editing the sys_user form or list view.
glide.password.policy.generate.password.field.disabled	Disables the **Password** field on the set password pop-up on the sys_user form.
glide.user.show.password.field	Enables the **Password** field on the sys_user form.
glide.password_policy.debug	Enables debug logging for the password policy.

Configure your password policy

Password policy criteria enables you to secure your password and adhere to the minimum password complexity requirements.

Before you begin

Role required: admin

About this task

The Password Policy [com.glide.password_policy] plugin is enabled by default. It goes into effect when a user changes or resets the password. If you customized your instance, through the ValidatePasswordStronger installation exit or your Password Reset credential store [pwd_cred_store], see password policy properties.

Procedure

1. Navigate to **All** > **Password Policy** > **Password Policies**.

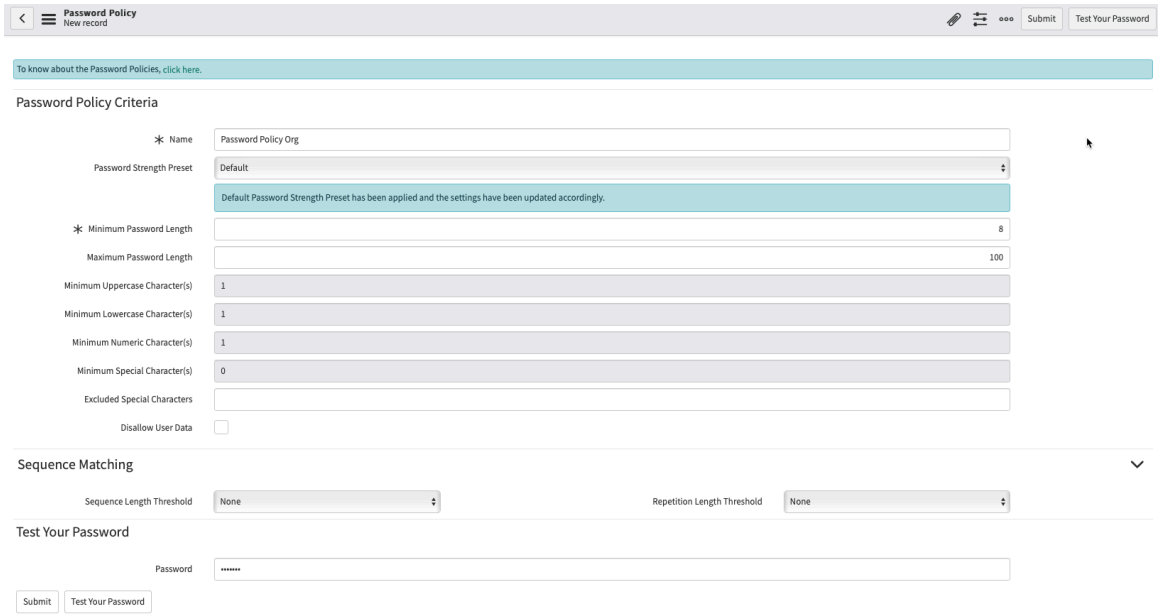
   Note:
   Default Strong preset in enabled as a default password acceptance criteria. In case, if you want to add a new criteria, you can perform the following steps.

2. Click **New**.

   The Password Policy New record page, has the following sections that you must specify for setting your password:

   - **Password Policy Criteria**
   - **Sequence Matching**
   - **Test Your Password**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



3. Specify the **Name** for your password policy.
4. In the **Password Policy Criteria** section, select the preset from the **Password Strength Preset**. The presets available are as follows:

Password Strength Preset and its description

Password Strength Preset	Description
Default	Selecting **Default** auto-populates the password characters required as follows: ○ One Minimum Uppercase Character ○ One Minimum Lowercase Character ○ One Minimum Numeric Character
Medium	Selecting **Medium** auto-populates the password characters required based on characters as follows: ○ One Minimum Uppercase Character ○ One Minimum Lowercase Character ○ One Minimum Numeric Character ○ One Minimum Special Character
High	Selecting **High** auto-populates the password characters as follows: ○ One Minimum Uppercase Character ○ Two Minimum Lowercase Character ○ One Minimum Numeric Character ○ Three Minimum Special Character
Default Strong	Selecting **Default Strong** auto-populates the password characters required based on characters as follows:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Password Strength Preset	Description
	○ One Minimum Uppercase Character ○ One Minimum Lowercase Character ○ One Minimum Numeric Character ○ One Minimum Special Character
Custom	Selecting **Custom** auto-populates the password characters required based on characters as follows: ○ One Minimum Uppercase Character ○ One Minimum Lowercase Character ○ One Minimum Numeric Character ○ One Minimum Special Character You can also customize the **Password Policy Script** that is displayed.
Advanced	Selecting **Advanced** displays **Password Rule Script** and **Password Strength Script**. Based on your requirement you can customize these scripts.

Note:
Password policy is applied based on the selected preset.

5. Specify the fields described in the table:

Password Policy form

Field	Description
Minimum Password Length	Minimum length of the password. This option is displayed for all the presets except **Advanced**. **Note:** **Minimum Password Length** is a required field and recommended setting it to a minimum of 8–10 characters.
Maximum Password Length	Maximum length of the password. This option is displayed for all the presets except **Advanced**. **Note:** **Maximum Password Length** is an optional field and recommended to set it to a maximum 100 characters.
Minimum Uppercase Character(s)	Minimum number of uppercase characters in the password, from 0 to 10.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Minimum Lowercase Character(s)	Minimum lowercase characters in the password, from 0 to 10.
Minimum Numeric Character(s)	Minimum numeric of characters in the password, from 0 to 10.
Minimum Special Character(s)	Minimum number of special characters in the password, from 0 to 10.
Included Special Characters	Allow a restricted set of special characters without any delimiter. For example, if you enter "$,!" users can only use "$" and "!" as special characters in the password. No other special characters can be used, and a password with other special characters is not allowed.
Excluded Special Characters	Allow a restricted set of special characters without any delimiter. For example, when '@ $!' is entered, users should not be able to use '@', '$' and '!' as special characters in their passwords. **Note:** This option is available if the glide.password_policy.use_excluded_special_char property is enabled.
Disallow User Data	It is enabled to disallow the user data.

6. In the Sequence Matching section, specify the **Sequence Length Threshold** and **Repetition Length Threshold**.

   Note:

   - Both the sequence length threshold and repetition length threshold can have a maximum of eight characters. These fields enable you to restrict weak combinations of passwords that have predictable and repeating sequences such as "123456", "qwerty", "!@#$%^", "aaaaa", and so on.
   - For **Default Strong**, the length for both sequence length threshold and repetition length threshold is selected as four characters.

7. In the **Test Your Password** section, specify your password.
8. Click **Test Your Password**.
9. Once the password is valid, click **Submit** to submit the password.

   Note:
   Always test your password before submitting.

Configure password for a user

Set your user's password for the instance based on the password policy that is configured.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin

Users created for setting the password for their first login. For more information, see Create a user.

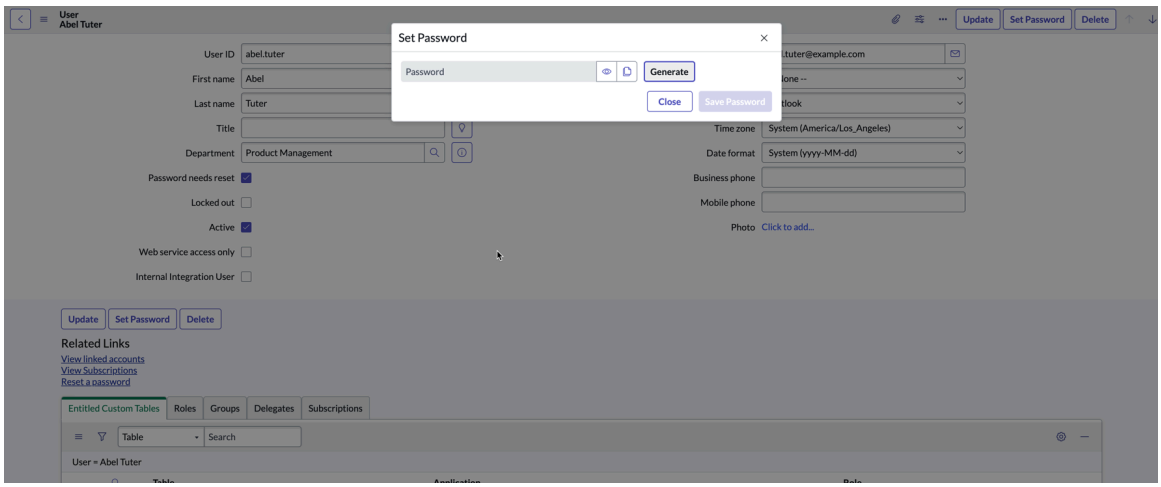
To populate the **Password** field directly on the user form, enable the **Enable to show the password field on the sys_user Form** (glide.user.show.password.field). To know more about the properties, see Password policy properties.

Role required: admin

Procedure

1. Navigate to **All** > **User Administration** > **Users**.
2. Select the user from the list in the Users page.
3. To set the password based on the password policy, click **Set Password**.

   The Set Password pop-up is displayed.

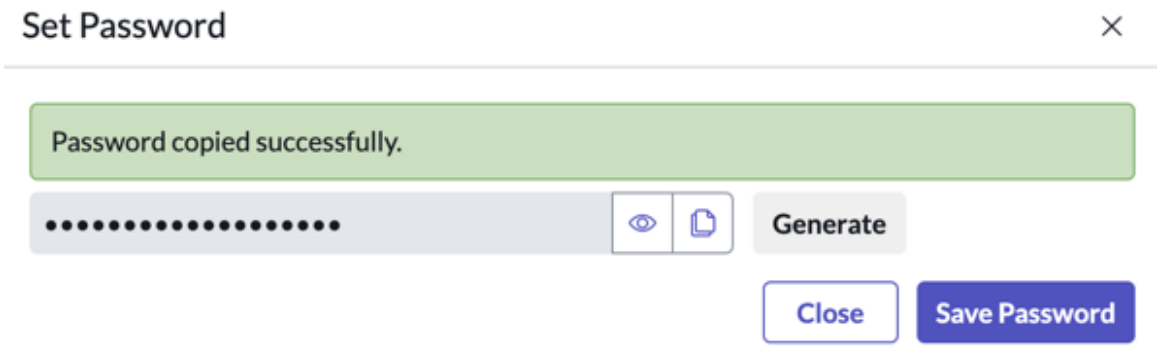


4. In the Set Password, perform the following.
   a. Click **Generate** to generate the password.

   b. Click the **View** icon to view the password.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

c. Click the **Copy** icon to copy the password to share to the user.



5. Click **Save Password**.

   The password is set for the user. Also the Password needs rest check-box is automatically enabled.

   The user during the first login must use the same password for login and change the password upon login adhering to the password policy configured by the administrators.

Exclude passwords through password policies on your instance

Add passwords to the Excluded Password table to prohibit specific passwords from being used by users on your instance.

Before you begin

Role required: admin

About this task

You can ban as many passwords as necessary. Some of the examples are as follows:

- Predictable and repeating sequences, such as "123456", "qwerty", "!@#$%^", "aaaaa", and so on.
- Employee name or user names.
- Relevant brand or product names.
- Locations, such as a company headquarters, city, country, and so on.
- Company-specific internal terms or abbreviations.
- Emojis.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Password Policy** > **Excluded Passwords**.
2. To add a password to your exclude list, click **New** and enter the password.
3. Navigate to **Password Policy** > **Exclusion List Management** to govern your users' password and prevent users from using bad password for the instance.

   The **Exclusion List Management** has about 5000 commonly used passwords.

Unsupported password characters

There are password characters that are not supported. Users cannot use these characters, based on ServiceNow password complexity requirements.

To enable a secure network environment, it is necessary for users to use strong passwords that include combination of letters, numbers, and symbols. These combinations help to prevent unauthorized users who usually use manual or automated methods to guess weak passwords.

- The password policy requirements are based on the Basic Multilingual Plane (BMP) that contains characters for all modern languages. ServiceNow instance is shipped with BMPs of around 10000 characters.
- Password characters within this permissible BMPs can be set for your instance, the password characters that do not adhere within this BMPs are not allowed.

Note:
User or company-specific characters that cannot be used in the password can be configured in the exclude password list.

For more information about the password policy properties, see password policy properties.

Password Reset

The default self-service Password Reset process enables a user to reset the password without assistance from service desk agents.

Example: The default self-service password reset flow

1. If a user does not remember the password, the user can click the **Forgot Password?** link on the login screen.
2. The Password Reset application starts. On the **Identity** page, the user identifies himself or herself by entering a **Username**.
3. On the **Verify** page, the user proves that they are the person who is associated with the username. In this example, the user enters the email address that is associated with the user profile. The admin can configure a different verification method or can require additional verifications, for example, a personal question that only the user can answer.
4. The **Reset** page tells the user to check email for instructions.
5. The user opens the email and clicks the **here** link to reset the password. The link is valid for a period that you specify (use the **password_reset.request.expiry** property).
6. The **Reset Password** page guides the user to reset the password.

The default self-service Password Reset process (`com.glideapp.password_reset`) defines:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- The URI that specifies where users are redirected when they click **Forgot Password?**. By default this value is **/$pwd_reset.do?sysparm_url=ss_default**, which is the same value used in the *glide.security.password_reset.uri* property. In previous releases, this value was set to **/reset_password.do**.
- The **Enable Password Reset URL** option, which specifies that the user should receive an email with a link to reset their password after they click **Forgot Password?**.
- The Personal Data - Enter Email Address verification flow that specifies the three-step password reset flow.

See Configure your Password Reset process for instructions on accessing this form and configuring the fields.

Note:

- This feature works for locally authenticated users who enter the username and password specified in their user record. Users logging in to the instance via an SSO solution or an LDAP integration cannot reset passwords using the example self-service Password Reset process.
- The end user must enable and configure notification preferences. See Subscription-based notifications. Administrators can xmodify the email that is sent to the end user.

Modify the Password Reset notification email text

Users of the self-service Password Reset process receive an email notification when they request password reset. You can modify the text of the email and other aspects of the notification.

Before you begin
Role required: admin

About this task
This process is relevant only if users are Subscription-based notifications.

Procedure

1. Navigate to **All** > **System Notification** > **Notifications**.
2. Select the **Password Reset URL** notification.
3. Modify the text of the email in the **What it will contain** section.
   For information on configuring other aspects of the notification, see Create an email notification.

Configure Password Reset properties

You can specify properties that configure the Password Reset experience for end users.

Before you begin
Role required: password_reset_admin

About this task
While there are no range limits for the values you can enter for properties, consider using only positive integer values starting at 1. When you determine the limit for the upper range of a property, consider the task that the user is performing.

For example, you would not want to allow 100 attempts for users to verify their identity. A more common value is 3 attempts. Similarly, you may not want to force users who are completing the

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

enrollment process to spend time selecting and answering 30 security questions. The more commonly used number of security questions is between 5 and 7.

Procedure

1. Navigate to **All** > **Password Reset** > **Properties**.
   For information about the Password Reset properties, see Password Reset global properties.
2. Update settings as needed and then click **Save**.

Remember me

When the **Remember me** check box is selected at login, a cookie is stored on the user's computer. This cookie automatically authenticates the user upon subsequent visits.

If the user logs out, the cookie is destroyed. The default value of the **Remember me** check box is controlled by one property, and whether or not the check box appears on the login page is controlled by a different property.

Two properties, *glide.ui.user_cookie.life_span_in_days* and *glide.ui.user_cookie.max_life_span_in_days* control the glide_user system generated cookie expiration value. When a user accesses an instance with 'remember me' enabled, the access resets the cookie expiration period until the maximum (glide.ui.user_cookie.max_life_span_in_days) life span limit is reached.

Note:
To learn more about these properties, see the following topics in Instance Security Hardening Settings:

- Minimize absolute session timeout duration [Updated in Security Center 1.3]
- Minimize session window timeout duration [Updated in Security Center 1.3]

Change the default value of the Remember me check box

You can change the default value of the **Remember me** check box.

Before you begin
Role required: admin

Procedure

1. Navigate to **All** > **System Properties** > **UI Properties**.
2. Locate the *Default value of "Remember me" checkbox on login page* property (*glide.ui.remember.me.default*).
3. To set the default value of the **Remember me** check box to **No**, clear the property check box.
4. To restore the default value of the **Remember me** check box to **Yes**, select the property check box.

Remove the Remember me check box

You can remove the **Remember me** check box so users do not have access to this feature.

Before you begin
Role required: security_admin

Note:
To learn more about this property, see Remove remember me in Instance Security Hardening Settings.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Elevate your role to security_admin.
2. Navigate to **System Properties** > **UI Properties**.
3. Locate the *Remove "Remember me" checkbox from login page* property (*glide.ui.forgetme*).
4. Select the property check box.
   This setting removes the **Remember me** check box, invalidates existing cookies, and disables Remember me functionality entirely.
5. To restore the **Remember me** check box to the login page, clear the property check box.

Configure the logout confirmation prompt

You can enable a logout confirmation prompt to prevent users from inadvertently logging themselves out.

Before you begin
Role required: admin

About this task

Note:
The following procedure only works in UI versions earlier than Core UI, which is the most recent and most commonly used one.

Procedure

1. Navigate to **All** > **System Properties** > **System**.
2. Locate the **Prompt user to confirm a logout request** property and select the check box.
3. When the user clicks the **Logout** button, a confirmation dialog box displays.

Implement a nonce

You can implement a nonce to be used with single sign-on digest authentication.

To use a nonce with the unencrypted token or encrypted token methods of single sign on, these steps apply with only a few minor changes.

Note:
The nonce is used only for login requests, not for any other type of request. If the system receives a nonce value after login, the nonce is not consumed.

Benefits

The usage of a nonce prohibits a malicious user from performing a replay attack in order to log into your system.

Nonce process flow

When a customer has implemented the digested token Single Sign-on and wishes to add the security of a nonce, they follow a certain process flow.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

1. A user logs into the customer's portal.
2. The customer generates the required SSO parameters and appends a random nonce to the end. For example, if the customer were forwarding the authentication response via the query string, it may look something like this:

```
SM_USER=itil&DE_USER=V1QuWMmxSfBgfRS099X0cAjKo5Q=&NONCE=1407743018
```

The instance receives this request and retrieves the authentication variables. Before attempting to verify the integrity of the authentication response, the instance checks the nonce against an internal table (u_authentication_nonce) to verify that it does not yet exist. If the nonce does not exist within that table, the nonce is then added to the table and the authentication process is allowed to continue. However, if that nonce value already exists within the table, the authentication attempt is cancelled and an error code of `failed_missing_requirement` is returned, which typically takes the user back to the login page.

Implement a nonce

Add a cryptographic nonce to the authentication header to ensure that it can only be used once.

- Create a system property called *`glide.authenticate.header.nonce_key`* and set its value to whatever variable name you're using for the nonce, such as NONCE or NCE.
- Create a new table called `u_authentication_nonce`. Add a field to the table called `u_nonce`.
- Go to **System Properties** > **Installation Exits** and create an item called `DigestSingleSignOnNonce` which overrides ExternalAuthentication (*`glide.authenticate.external_property`*).
- Add the following code to the script portion of the newly created DigestSingleSignOnNonce.

```
gs.include("PrototypeServer");

var DigestSingleSignOnNonce = Class.create();
DigestSingleSignOnNonce.prototype = {

 process : function() {

  var headerKey =
 GlideProperties.get("glide.authenticate.header.key",
 "SM_USER");
  var headerDigestKey =
 GlideProperties.get("glide.authenticate.header.encrypted_key",
 "DIGEST");
  var headerNonceKey =
 GlideProperties.get("glide.authenticate.header.nonce_key",
 "NCE");
  var fieldName =
 GlideProperties.get("glide.authenticate.header.value",
 "user_name");
  var fkey =
 GlideProperties.get("glide.authenticate.secret_key");

  // Look in the Headers
  var data = request.getHeader(headerKey);
  var encdata = request.getHeader(headerDigestKey);
```

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
 var nonce = request.getHeader(headerNonceKey);

 // If not, then check the URL Parameters
 if (data == null || encdata == null || nonce == null) {
  data = request.getParameter(headerKey);
  encdata = request.getParameter(headerDigestKey);
  nonce = request.getParameter(headerNonceKey);
 }

 // then maybe its a cookie
 if (data == null || encdata == null || nonce == null) {
  var cookies = request.getCookies();
  data = GlideCookieMan.getCookieValue(cookies, headerKey);
  encdata = GlideCookieMan.getCookieValue(cookies,
headerDigestKey);
  nonce = GlideCookieMan.getCookieValue(cookies,
headerNonceKey);
 }

 // if found run encryption
 if (data != null && encdata != null && nonce != null) {
  try {

   // Replace all spaces with plus(+)'s, converted in url
   encdata = encdata.replaceAll(' ', '+');

   // ----- Encrypt the username|nonce
   var key = this.getDigest( data + "|" + nonce, fkey);

   // Check for match of received encoded data
   // and your encoding of user name
   if (encdata == key) {
    var ugr = new GlideRecord("sys_user");
    ugr.initialize();
    if (!ugr.isValidField(fieldName)) {
     GlideLog.warn("External authorization is set to use
field: '"+ fieldName + "' which doesn't exist");
     return "failed_missing_requirement";
    }
    ugr.addQuery(fieldName, data);
    ugr.query();
    if (!ugr.next()) {
     var userLoad = GlideUser.getUser(data);
     if (userLoad == null)
      return "failed_authentication";

     ugr.initialize();
     ugr.addQuery(fieldName, data);
     ugr.query();
     if (!ugr.next())
      return "failed_authentication";

    }

    if (this.processNonce(nonce)){
     var userName = ugr.getValue("user_name");
     return userName;
```

© 2026 ServiceNow, Inc. All rights reserved.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
     }
     else return "failed_missing_requirement";
     }
    else {

     return "failed_authentication";
    }
   } catch(e) {
    gs.log(e);
    return "failed_authentication";
   }
   // Encoded data didn't match recieved Encoded data
  } else {

   return "failed_missing_requirement";
  }
 },

 getDigest : function( data, fkey ) {
  try {
   // default to something JDK 1.4 has
   var MAC_ALG = "HmacSHA1";
   return SncAuthentication.encode(data, fkey, MAC_ALG);

  } catch (e) {
   gs.log(e.toString());
   throw 'failed_missing_requirement';
  }
 } ,

 processNonce : function( sentNonce ) {
  var ngr = new GlideRecord("u_authentication_nonce");

  ngr.addQuery("u_nonce", sentNonce);
  ngr.query();
  if (ngr.next()) {
   gs.log("This SSO entry has already been processed! (Nonce: "
 + sentNonce + ")");
   return false;
  }
  var ngrNew = new GlideRecord("u_authentication_nonce");
  ngrNew.initialize();
  ngrNew.u_nonce = sentNonce;
  ngrNew.insert();
  gs.log("Inserted new nonce: " + sentNonce);
  return true;
 }
};
```

- Once you've saved your new installation exit, go to the DigestSingleSignOn installation exit and make sure that it is set Active=false.

Your instance should now be configured to implement a nonce.

Multi-factor Authentication enforcement

Enforcement of MFA for non-SSO logins to ServiceNow from the Yokohama release.

MFA enhances security by requiring users to provide two or more evidence to prove their identity during login. MFA protects accounts from threats like phishing and account takeovers.

MFA being a critical security tool against various identity takeover-related attacks. ServiceNow enforces MFA by default post-Yokohama upgrade and making it mandatory for non-SSO log ins (users performing login with only username and password or LDAP based authentication) to ensure a better security posture and reduce the risk of breaches.

MFA enforcement is carried though a MFA policy that is activated by default from Yokohama or upgrade to Yokohama. The MFA is enforced the **Enforce MFA for non-SSO logins** policy is `Active` and honored through the MFA Context.

Note:

- The policy is enabled for all **non-snc_external** users performing local (username and password) or LDAP based authentication.
- The instance admin can modify the enforcement scope by changing the MFA context policy, policy criteria, or policy conditions.

Here's more details about MFA enforcement:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Enforced to all production and non-production instances.
- Enforced to all the **non-snc_external** users and **non-SSO** login.
- Integration with Basic auth and OAuth resource owner password credential grant does not require MFA from Yokohama.

To know more about the changes due to enforcement, see Changes due to the Multi-factor Authentication enforcement.

To know more about MFA, see Exploring Multi-factor Authentication.

Frequently asked questions - Multi-factor Authentication enforcement

Changes due to the Multi-factor Authentication enforcement

Information about the changes that are expected due to the MFA enforcement.

MFA enforcement changes that are expected as follows:

- No impact on integration.
- Users who have already enrolled MFA continue to be challenged with MFA during local login.
- If a user has not set up MFA yet, after the Yokohama upgrade, they'll be initially exempted from undergoing MFA for a certain period during which they can enroll MFA.
- If the user fails to self-enroll, then they have MFA enforced on the completion of the exemption period (default 30 days) and must set up MFA.
- After 90 Days, MFA will be enforced by default. There will be no self-enrollment period for first-time logins after 90. Administrators can configure this period.

As an administrator, you can prepare for the MFA enforcement based on the following:

- Review the MFA Context Policy configuration and adjust the policy conditions according to your business requirements.
- Add the exempted group provided by default, if there are any other users who must be exempted.
- Review the MFA Enforcement Properties and adjust based on your requirements. To learn more, see Multi-factor Authentication enforcement properties.

Example: MFA enforcement scenario after 30 days of the MFA enforcement

- **Scenario 1 for Acme Corp**: In the instance, if the user doesn't have an active MFA policy. Imagine Sarah uses local authentication to access an instance. On upgrading to the Yokohama release during login, a message to enroll in MFA is displayed. There's 30 days to complete this setup. If Sarah doesn't complete the setup, after 30 days, the account requires MFA to log in, and won't be able to access it until MFA is set up.
- **Scenario 2 for Acme Corp**: In the instance, Anita was already MFA along with local authentication. Anita continues to require MFA without the 30-day self-enrollment window.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **Scenario 3 for Acme Corp**: In the instance, Olivia uses Single Sign-On (SSO) for authentication. There's no impact on the login experience, and Olivia isn't enforced for MFA.
- **Scenario 4 for Globex Corp**: In the instance, if a user already had an MFA policy requiring - MFA for all local login attempts outside the company's trusted network. On upgrading to the Yokohama or a later release, MFA enforcement behavior for user logins remain the same.

Multi-factor Authentication enforcement properties

Configure the properties for MFA enforcement.

To set the MFA enforcement properties, navigate to **sys_properties.list** to validate or change the MFA enforcement properties.

MFA enforcement properties

Field	Description
glide.authenticate.multifactor.setup.bypass.count	Number of times a user can bypass setting up multi-factor authentication (Max possible bypass count is 3, beyond that it will treated as 3).
glide.authenticate.multifactor.self_enroll_days	Indicates number of days a user will be given an option to self enroll for MFA, post which user will be automatically challenged with MFA. Any value exceeding 90 will be treated as 90 days only.
glide.authenticate.multifactor.enforce.max_enroll_days	Indicates the maximum number of days a new user will be given an option to self-enroll for MFA, post which all new user's performing non-SSO logins are automatically challenged with MFA. Any value exceeding 270 is treated as 270 days only.
glide.authenticate.multifactor.enforce.debug	MFA Enforcement debug logger. Helps in debugging the flows for MFA logins. **Note:** This property doesn't exist on the instance, you have to create and enable the property, if needed.
glide.authenticate.hybrid_user_tracking.enabled	Property for enabling tracking of hybrid users. The user accounts which are not marked as 'Web service access only' in corresponding sys_user record, but still performs integrations (For example, API logins) using the username and password, will be tracked in the 'User Login Info' table when this property is enabled. **Note:** This property doesn't exist on the instance, you have to create and enable the property, if needed.

MFA enforcement properties (continued)

Field	Description
glide.authenticate.hybrid_user_tracking.debug	A debug property for the tracking of hybrid user API logins.Side **Note:** This property doesn't exist on the instance, you have to create and enable the property, if needed.

Troubleshooting Multi-factor Authentication enforcement

Troubleshooting information due to the MFA enforcement.

ServiceNow enforces MFA by default post-Yokohama upgrade and making it mandatory for non-SSO logins (users performing login with only username and password or LDAP based authentication) to ensure a better security posture and reduce the risk of breaches.

MFA enforcement is carried though a MFA policy that is activated by default from Yokohama or upgrade to Yokohama. Following are some of the troubleshooting task that you can perform if there's any change to the MFA behavior:

- Debug using the troubleshooting tools
- Navigate to the Log location and Debug properties
- Understand the MFA scenarios based on your users experience while using MFA
- Understand the MFA issue due to upgrade from a previous release

Debug MFA

Use the either of the following tools or a combination to understand the debug information:

- **Splunk** - to see the debug logs.
- System logs or Node logs.
- **HAR** logs to analyze the debug logs for the MFA.

Log location and Debug properties

Navigate to the following location to know more about logs:

- For system logs, navigate to **All** > **System Log** > **System Logs**.
- For node logs, navigate to **All** > **System Logs** > **Utilities** > **Node Log File Browser**.

The system debug logs and instance node logs are required for the debug purpose. Following are the debug properties that are required to be enabled:

- `glide.webauthn.debug.enabled`
- `glide.log.default_log_debug`
- `glide.authenticate.policy.debug`
- `glide.authenticate.hybrid_user_tracking.debug`

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

MFA issue based on scenarios

Scenario 1: User is not able to login using any of their second factor

Reset the MFA for the your users and delete the old user records from the following tables:

- `user_multifactor_auth`
- `sys_user_public_credential`
- `sys_user_multi_factor_setup`

Scenario 2: Admin is not able to login using any of their second factor

Another user with admin access can reset the MFA for any blocked admin user. If still the issue exist, reach out to ServiceNow Support.

Scenario3: Error observed during the MFA Setup or Validation

Check the warning "Associated Error Codes/Warning: Your 6-digit verification code is incorrect. Try again with the correct code".

Perform the following steps:

- In case of TOTP Authenticator App, if the date and time of the Authenticator MFA device and instance are not in sync (±30 sec), then the TOTP code is not accepted. Verify the device and instance date and time.
- In case of email, configure the user level notification, outbound email configuration, and user correctly in the `sys_user` table.
- In case of SMS, configure the Twillio or other SMS service provider integration correctly and set to active. Verify if the user's mobile number is configured correctly in the `sys_user` table.

Frequently asked questions - Multi-factor Authentication enforcement

Details about some of the FAQs due the MFA enforcement.

MFA being a critical security tool against various identity takeover-related attacks. ServiceNow enforces MFA by default post-Yokohama upgrade and making it mandatory for non-SSO logins (users performing login with only user name and password or LDAP based authentication).

MFA enforcement is carried though a MFA policy that is activated by default from Yokohama or upgrade to Yokohama. You can check the following links to learn more about MFA enforcement related questions:

- MFA reset

MFA enforcement requirements – What and Why

FAQ related to MFA enforcement and why it’s important.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

1. What is the MFA?

   Multi-factor Authentication (MFA) is a security process that requires you to provide two or more forms of verification before they can access an account or system. To learn more, see Exploring Multi-factor Authentication.

2. Why is the MFA enforcement mandate?

   MFA is mandated to protect your account and data security. Cyberthreats are ever-changing, and passwords alone no longer provide sufficient protection against unauthorized access.

   - With MFA enabled, even if attackers have your password, the attackers still need a second form of verification. This additional layer significantly blocks most unauthorized attempts, keeping your information more secure.
   - Setting MFA as the default, minimize the risk of security breaches and safeguarding your account automatically. This means you get enhanced peace of mind without having to make any extra security decisions.

3. Why is it important to enable MFA?

   Enabling MFA boosts your account security. Passwords alone aren't enough because passwords can be exposed in data breaches. With MFA, even if someone knows your password, they can't access your account without a second verification step.

4. Why does ServiceNow require MFA?

   ServiceNow is mandating MFA to protect you from these threats. It's a simple yet effective way to reduce unauthorized access. By requiring MFA, there's a strong layer of protection to every account, reducing security risks for you and all users.

5. What is the MFA requirement for existing customers?

   For existing customers upgrading their instance to the Yokohama or a later release:

   - If the instance doesn't already have the **Adaptive Authentication** – Multi-factor Authentication context turned on, automatically it's enabled as a default MFA policy.
   - All the internal users (users who don't have snc_external role) logging in with local or LDAP authentication must set up MFA within 30 days of their first successful login. During this time, you can log in normally but see a message at the time of login to enroll in MFA.
   - After 30 days, MFA will be required by default, and users won't be able to log in without completing the MFA setup.

6. What is the MFA requirement for new customers?

   For any instance using the Yokohama release or later, MFA is enabled by default for all internal users. It also applies to users who don't have the `snc_external` role and are logging in with local or LDAP authentication. From the first login, the users are required to set up and use MFA.

MFA enforcement scope

FAQ related to MFA enforcement scope and why it's important.

1. Which user, login, and environment types require MFA?

   From the Yokohama release onwards, with the new default secure MFA policy MFA enforced for the following scenarios:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- All the users except the users having **snc_external** role.
- All the users performing user name and password based local or Lightweight Directory Access Protocol (LDAP) authentication.
- All customer instances, including production, subprod, and test instances, that didn't already have an active MFA policy before the upgrade.

The instance admin can modify the enforcement scope by changing the MFA context policy, policy criteria, or policy conditions.

2. Is MFA required for Single-Sign-On (SSO) logins?

   No. With the default secure MFA policy, MFA isn't required for SSO (SAML, OIDC, Certificate Based Authentication) login.

   Customers can collaborate with their Single Sign-On (SSO) provider (Identity Provider, or IdP) to enforce multi-factor Authentication (MFA) on the IdP side. If enforcing MFA on the IdP side isn't feasible, customers also have the option to enable the ServiceNow platform's MFA for SSO logins by following the instructions provided in Multi-factor Authentication with Single Sign-On.

3. Is MFA required for external users?

   No. With the default secure MFA policy, MFA isn't required for users having the snc_external role.

   - Admins can modify this behavior and enforce MFA for external users by updating the MFA policy conditions.
   - External users who were already undergoing MFA before the upgrade to Yokohama or later release continues to have MFA.
   - External users can visit their profile and self-enroll for MFA.

4. Is MFA required for Mobile App login?

   Yes. The MFA policy is applied to both web and mobile app log in with user name and password based non-SSO login.

5. Is MFA required for non-production and test environments?

   Yes. MFA is enforced for all customer instances, including production, non-production, dev, and test environments, if there's no active MFA policy existed on the instance before upgrading to Yokohama or later versions.

6. Is MFA required for developer instances?

   Yes. MFA is enforced for all developer instances that are on Yokohama or later release versions.

7. Is MFA required for API authentication?

   No. From Yokohama or a later release, MFA is only required for the user name and password-based interactive user logins. This means API authentication with basic auth works without requiring MFA. It's recommended to customers use alternative secure API authentication methods such as OAuth or mTLS. More details here.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

a. Clone

b. Update set retrieval

c. RPA

> **Note:**
> To enforce MFA for API authentication, set the `glide.authenticate.multifactor.for_integrations` system property to `true`. MFA is enforced only for users who have already enrolled in MFA. Users who have not enrolled are not affected.

8. Is there any impact on the clone setup process due to MFA?

   No, the clone setup process continues to work with user name and password and doesn't require MFA.

9. Is there any impact on the update set retrieval due to MFA?

   No, the update set retrieval continues to work with user name and password and doesn't require MFA.

10. Is there been any impact on RPA bots accessing ServiceNow instances?

    Yes, if the RPA bot uses the interactive user name and password login to access the ServiceNow instance, it must perform MFA. Admins can add RPA bot accounts to the **MFA Exempted User Group** if they want to relax MFA for RPA bot accounts.

11. Is MFA required for the OAuth-based integrations?

    The OAuth Resource owner password credential (ROPC) works with user name and password without requiring MFA. For Authorization code grant type MFA is required as part of the user login flow before giving the OAuth consent.

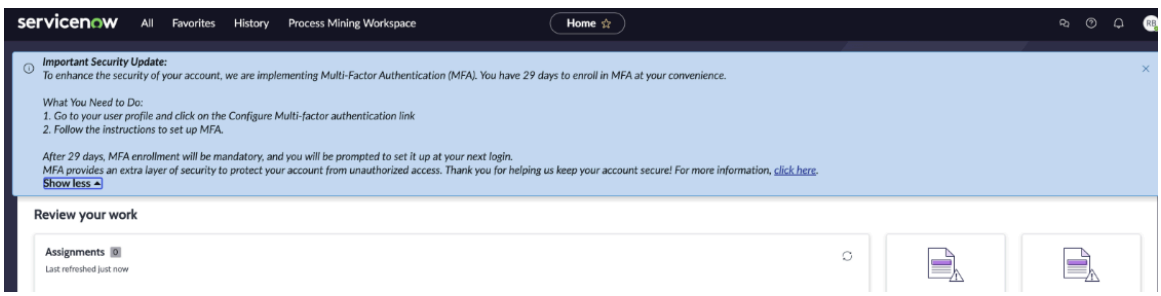
MFA enforcement timeline

FAQ related to MFA enforcement timelines and why it's important.

1. When is MFA enforced?

   According to the MFA policy, eligible users who haven't completed the MFA setup has a 30-day self-enrollment period. The behavior is controlled using the system property `glide.authenticate.multifactor.self_enrolment_period`. The property's default value is 30 days. It can be updated to a maximum of 90 days.

   All internal users (users who don't have a `snc_external` role) logging in with local or LDAP authentication must set up MFA within 30 days of their first successful login. During this time, you can log in normally but see a message at the time of login to enroll in MFA.



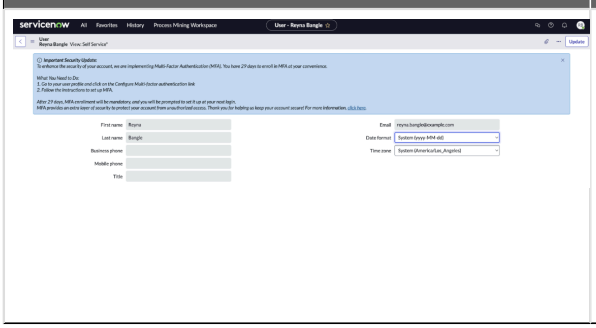
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

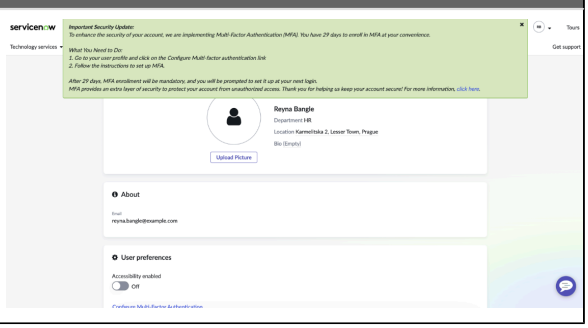
After 90 days of upgrading to Yokohama or a later release, if an internal user (user without the `snc_external` role) logs in with local or LDAP authentication for the first time, they'll be required to use MFA immediately. You don't have the 30-day MFA self-enrollment window. This period is governed by a system property: `glide.authenticate.multifactor.enforcement.max_relaxation_period`. The maximum value for this property is 270 days.

2. How can the MFA enforcement timeline adjusted?
   - By updating the value of the property `glide.authenticate.multifactor.self_enrolment_period`, admins can provide a smaller or larger self-enrollment window. Set the property value to 0. The users are required to complete the MFA setup after their first login attempt with local or LDAP login after upgrading to Yokohama or a later release. The maximum duration of the self-enrollment window can be 90 days. Property value set higher than 90 will be treated as 90.
   - By updating the value of the property `glide.authenticate.multifactor.enforcement.max_relaxation_period` admin can decide how many days post upgrade to the Yokohama or a later release you get the MFA self-enrollment window.
3. How are end users informed about this upcoming change?

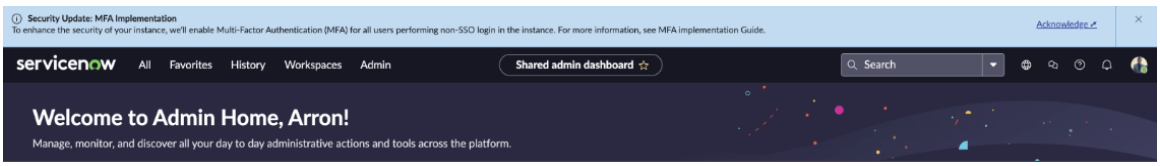
   End users performing local or LDAP authentication who will be enforced with MFA will see an information message after logging in. The same message is available when users visit their profile.

Enforcement Message

On the User Profile	On Employee Service Center
	


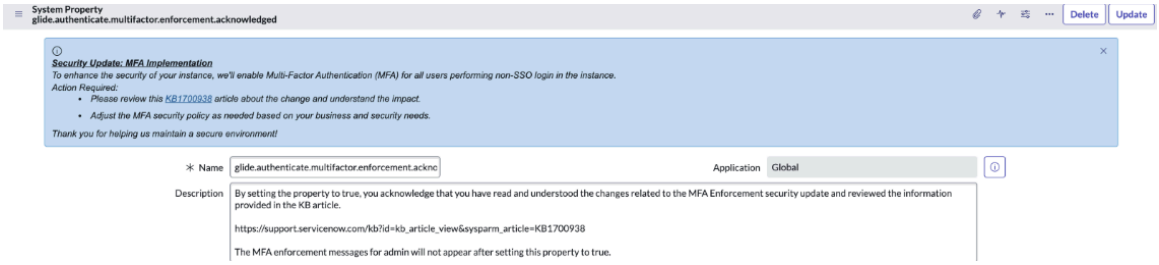


This message won't appear for non-admin users performing SSO logins. The admin role will see a different information message after a successful login irrespective of the authentication method used for logging in.



This message continues to be displayed until one of the admins acknowledges the update by setting the `glide.authenticate.multifactor.enforcement.acknowledged` property value to true.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



4. How to turn off the message displayed to end users about completing the MFA setup when they log in?

   Admins can update the value of the `glide.authenticate.multifactor.enforcement.show_user_info_message` system property to false to turn off the MFA enrollment information message shown to end users after login.

5. How to turn off the message displayed to administrators about the MFA enforcement?

   The information message regarding MFA enforcement shown to admin users after login, stops appearing when one of the admins acknowledges it by updating the value of the `glide.authenticate.multifactor.enforcement.acknowledged` system property to true.

6. There's already an MFA policy defined using adaptive authentication based on the security needs of my organization in the instance. Is the policy impacted by the mandate?

   No, if the instance already has an active Adaptive authentication—MFA context policy, the new default secure MFA policy isn't enforced. If the instance had MFA property enabled (`glide.authenticate.multifactor`) but the MFA policy wasn't active, then the default secure MFA policy for enforcing MFA for all internal users (users who don't have `snc_external` role) performing user name and password-based local or LDAP login is enabled.

MFA enforcement exception

FAQ related to MFA enforcement exception and why it's important.

1. How can the MFA mandate be relaxed for specific users?

   In the Yokohama release, a new user group, MFA Exempted User Group record is added. Based on the default condition, there's an MFA policy added, any user who is a member of this group is enforced with MFA.

   To relax MFA for specific users, follow the procedure:

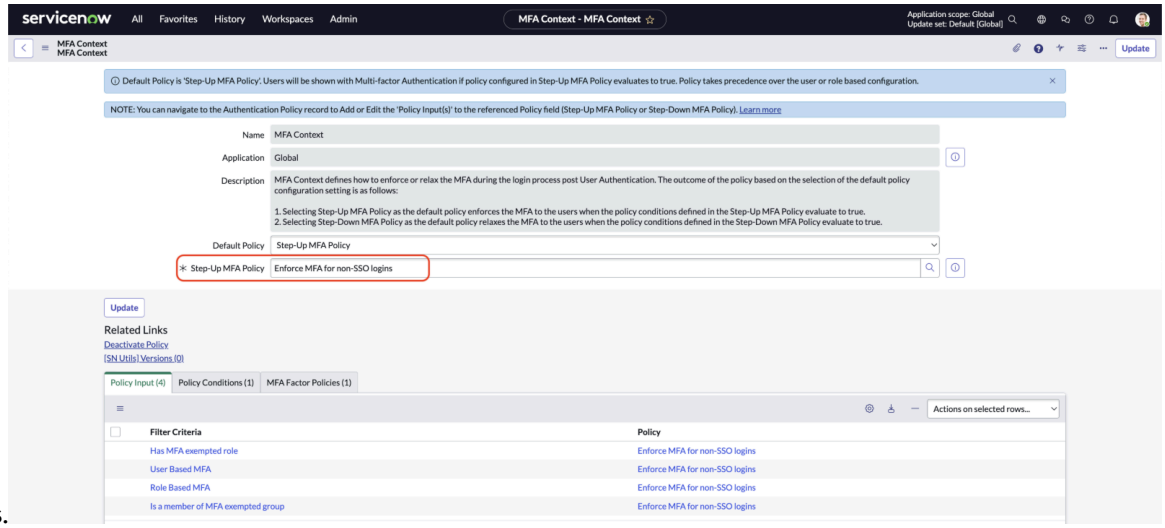
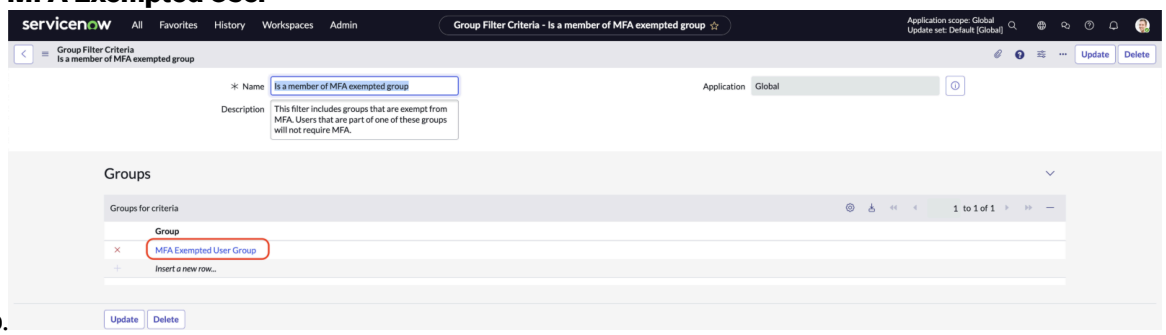
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

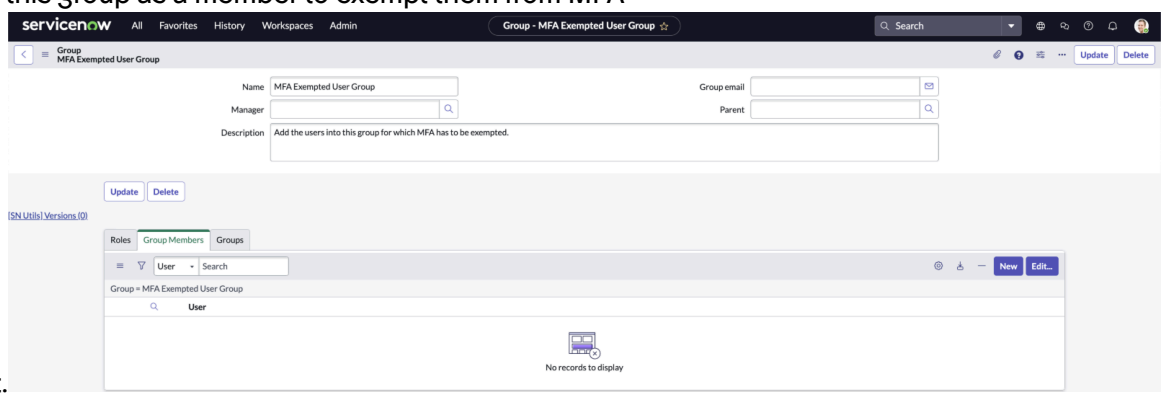
- Navigate to **MFA context**. The Step-Up MFA Policy associated with the MFA context record should be “Enforce MFA for non-SSO logins.



- Under the **Policy Input** related list, select the **Is a member of MFA exempted group** filter criteria record.
- Select **MFA Exempted User Group**.



- Add users to this group as a member to exempt them from MFA enforcement.

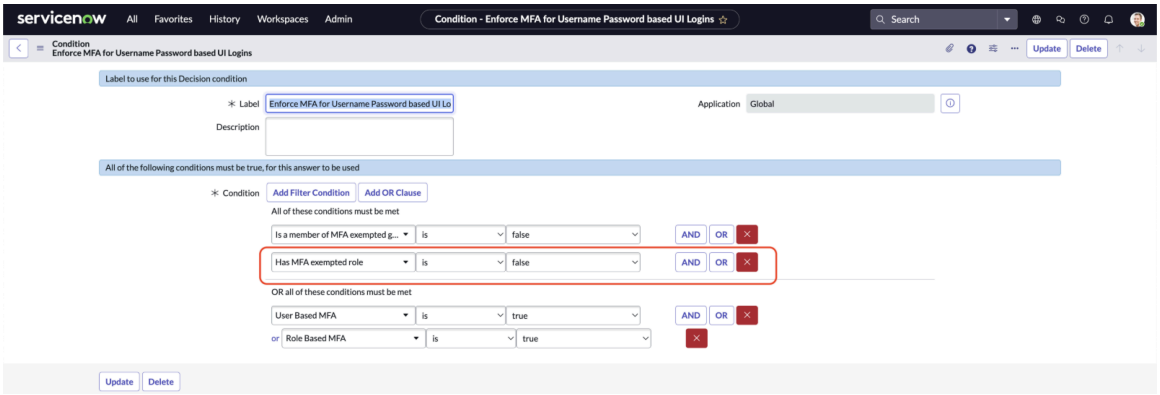


Note:
If you have a different policy associated with the MFA context, you can add “Is a member of MFA exempted group” filter criteria to your policy and modify the policy conditions to exempt users of this group from MFA enforcement.

2. How can the MFAs mandate be relaxed for certain roles?

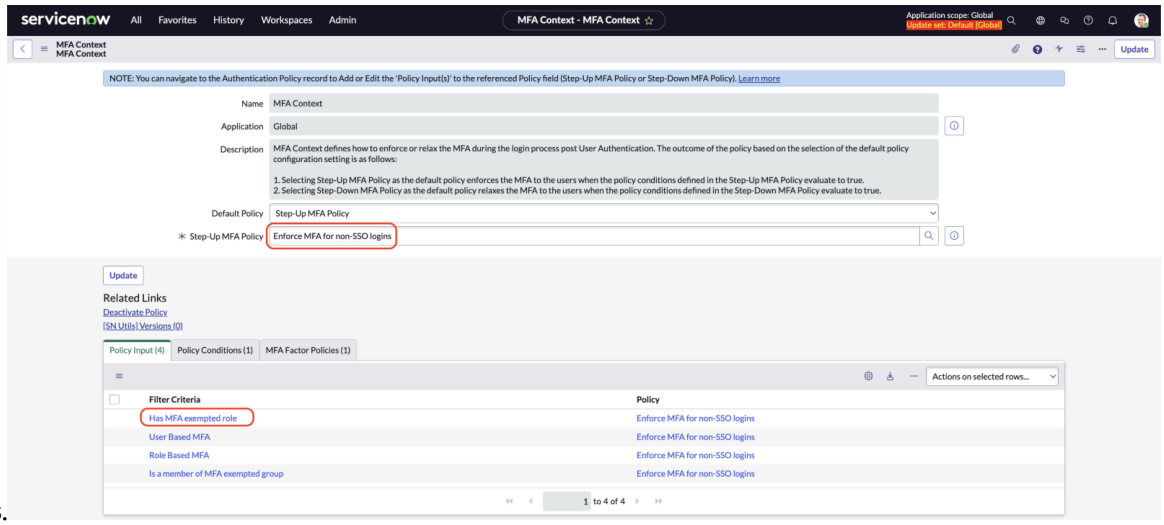
In the Yokohama release, an empty new role **Has MFA exempted role** filter criterion is added. There are conditions added to the MFA policy to exempt users who have the roles part of exempted role criteria from the MFA enforcement.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

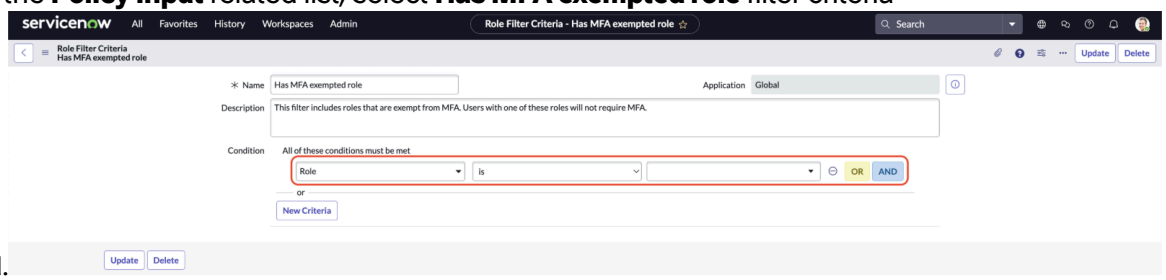


To relax MFA for specific roles, follow the procedure:

- Navigate to **MFA context**. The Step-Up MFA Policy associated with the MFA context record should be **Enforce MFA for non-SSO logins**.



- Under the **Policy Input** related list, select **Has MFA exempted role** filter criteria record.



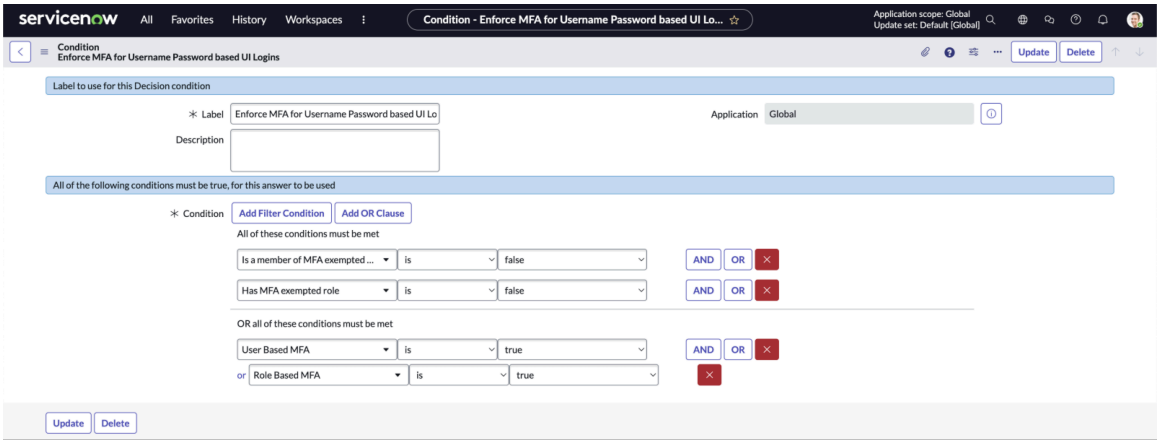
- Add the roles that you want to add to the condition. You can add multiple roles using the OR operator.

> **Note:**
> If you have a different policy associated with the MFA context, you can add **Has MFA exempted role** filter criteria to your policy. Modify the policy conditions to exempt users with exempted roles from the MFA enforcement.

3. How can the MFAs mandate be relaxed for certain groups?

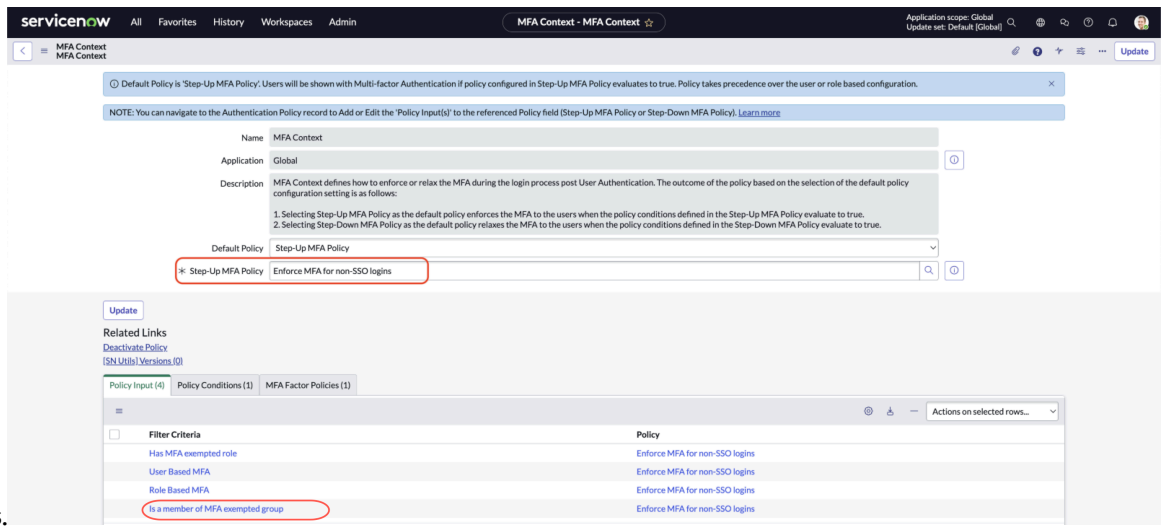
In the Yokohama release, a user group **MFA Exempted User Group** is added. Based on the default, condition added to the MFA policy, the user or group who is a member of this group isn't enforced with MFA.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



To relax MFA for specific groups, follow the procedure:

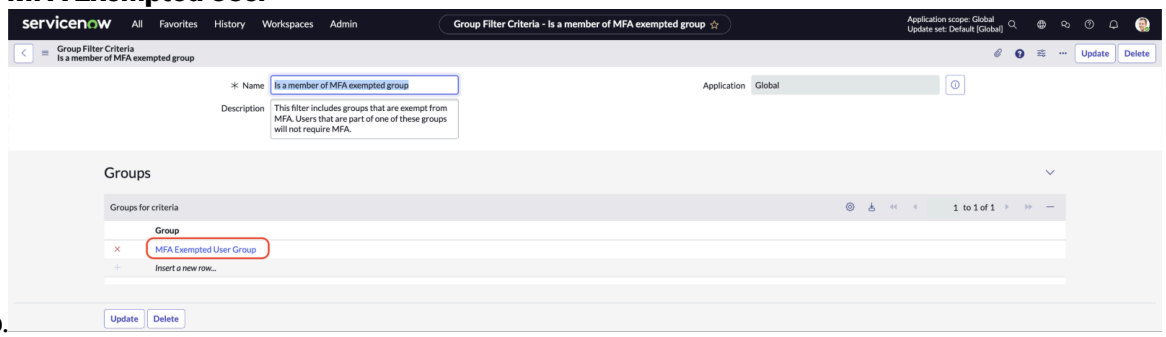
- Navigate to **MFA context**. The Step-Up MFA Policy associated with the MFA context record should be **Enforce MFA for non-SSO logins**.



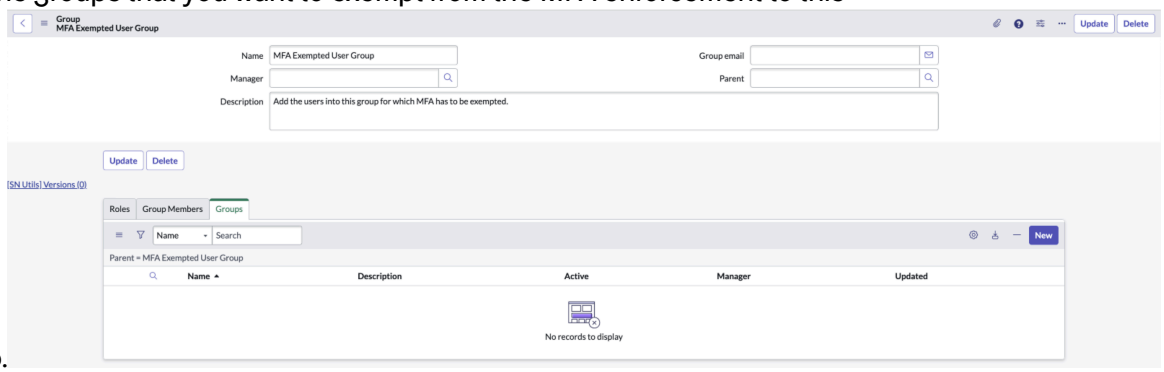
- Under the **Policy Input** related list, select the **Is a member of MFA exempted group** filter criteria record.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Select **MFA Exempted User Group**.

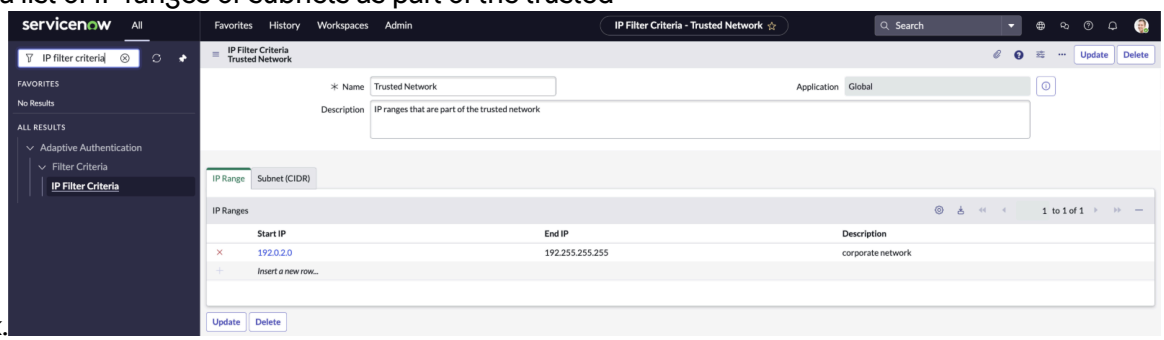


- Add the groups that you want to exempt from the MFA enforcement to this group.

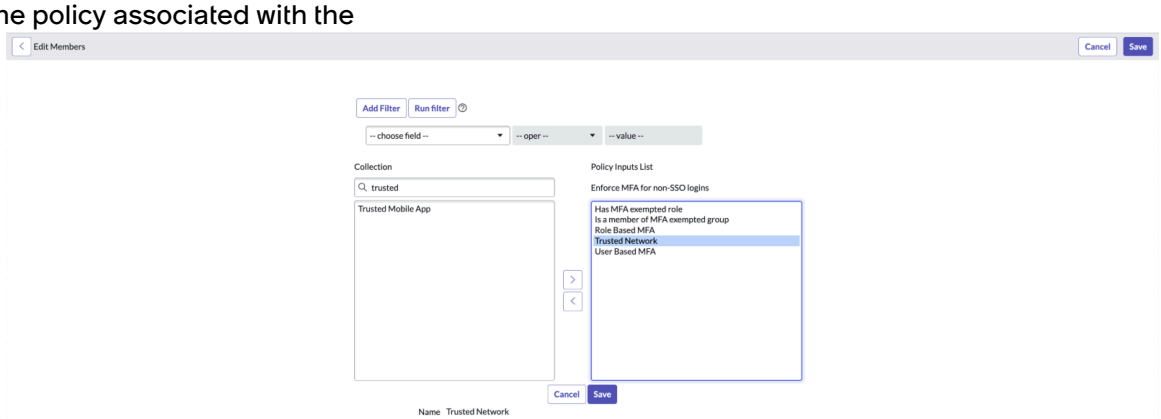


4. How can the MFAs mandate be relaxed for trusted networks?

- Navigate to **Adaptive Authentication** > **Filter Criteria** > **IP Filter Criteria**.
- Create a criterion to specify a trusted network. You can specify a list of IP ranges or subnets as part of the trusted network.

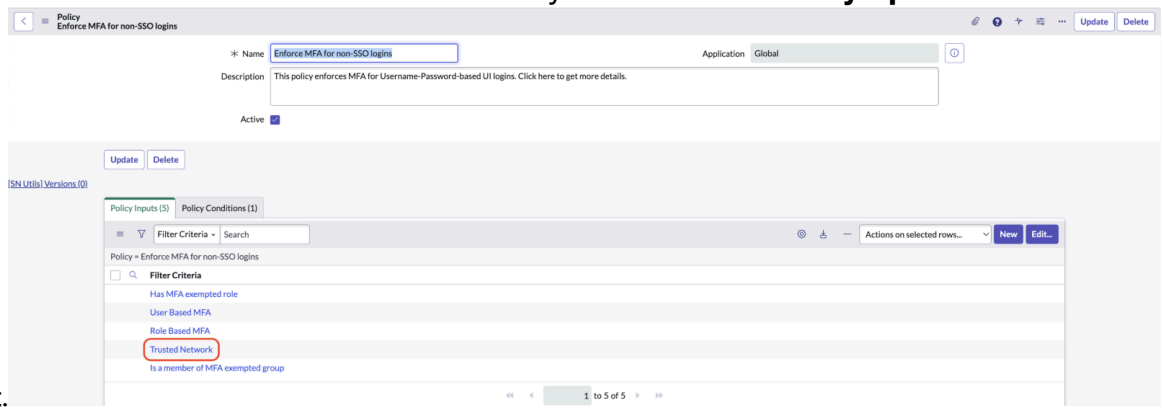


- Navigate to **Adaptive Authentication** > **Auth Policy Contexts** > **MFA context**.
- Open the policy associated with the context.

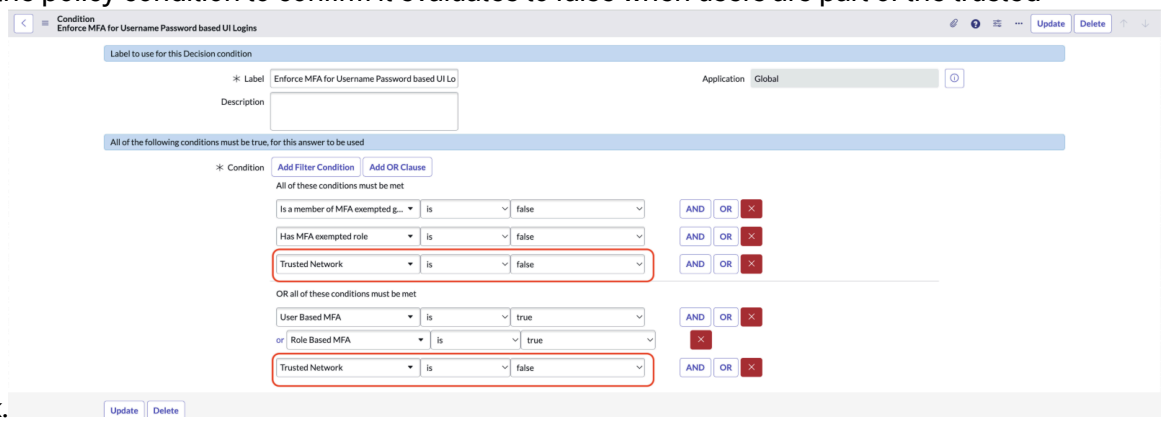


© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Select the edit to add the **IP Filter Criteria** that you created to the **Policy inputs-related** list.



- Modify the policy condition to confirm it evaluates to false when users are part of the trusted network.



> **Note:**
> If you have a different policy associated with the MFA context, you can add the IP filter criteria created as part of Step 1 to your policy and modify the policy conditions to exempt MFA enforcement on the trusted network.

5. How can the MFAs mandate be relaxed for trusted locations?

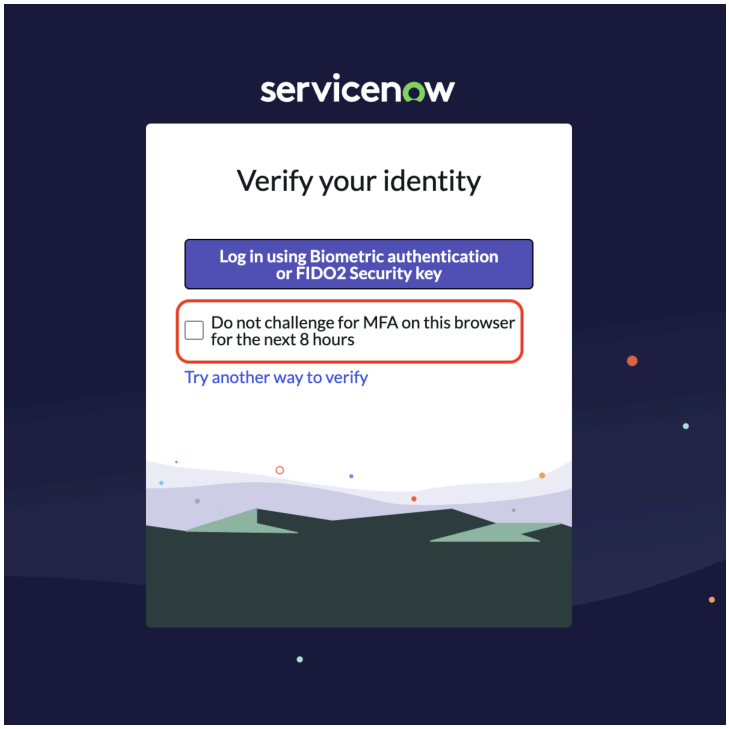
You can use Location Filter Criteria which is available with the **Zero Trust – Location Based Access** (requires an additional subscription) plugin.

6. How to control the frequent MFA enforcement?

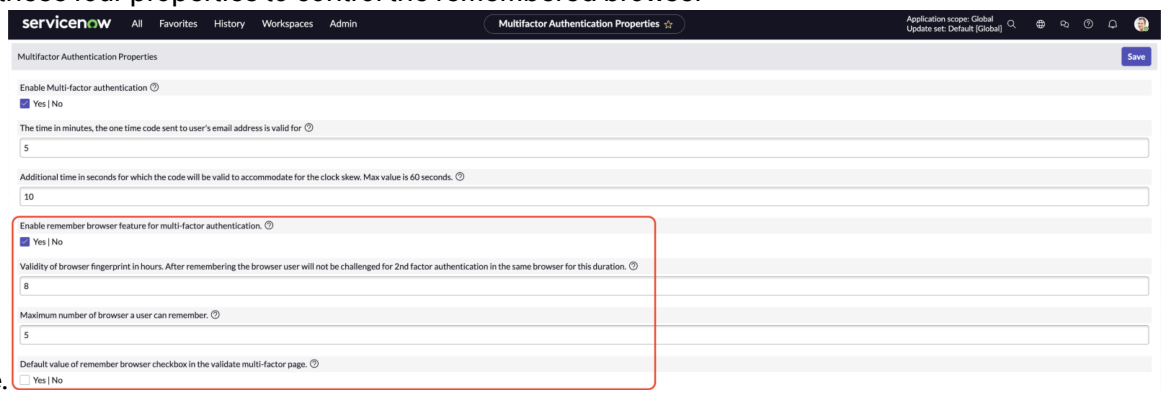
Use the Location Filter Criteria which is available with the **Zero Trust – Location-Based Access** (requires an additional subscription) plugin.

On the MFA validation page, there's a check box to remember a browser. MFA isn't enforced on the remembered browser:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



- The duration specified by this system property. `glide.authenticate.multifactor.browser.fingerprint.validity`. The default value of the property is 8 hours. This duration can be increased by up to 24 hours. Similarly using the `glide.authenticate.multifactor.remember.browser.default` system property the default value of the check box can be set to true.
- Navigate to **Multi-factor Authentication** > **Properties** and adjust these four properties to control the remembered browser feature.



7. How does MFA work for accounts shared by users?

Single accounts shared by multiple users are a security risk. It isn't recommended to share an account with multiple users.

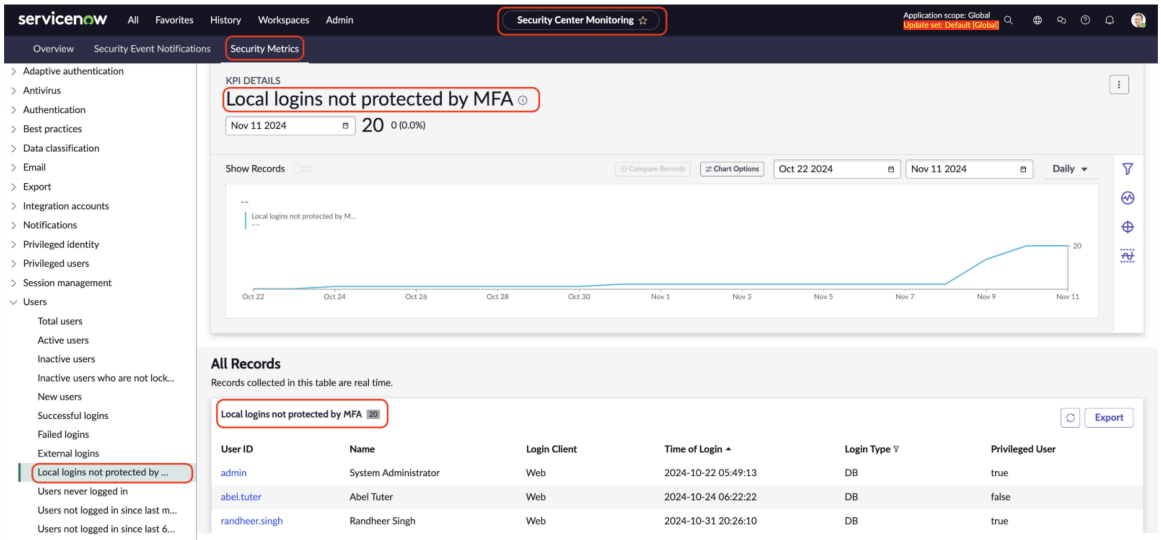
MFA metrics

FAQ related to understanding the MFA metrics.

1. How can I check the count of local logins which are not undergoing MFA?

You can navigate to **Security Center** > **Security Console** > **Security Metrics**. Under metrics for users click on local login not protected by MFA.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



2. How can I check the number of users who still need to complete the MFA setup and are performing local login?

   You can navigate to **Security Center** > **Security Console** > **Security Metrics**. Under metrics for users click on local login not protected by MFA.

MFA types

FAQ related to MFA types and why it's important.

1. What are the types of verification methods that are available for MFA with ServiceNow?

   ServiceNow base system supports these verification methods.

   a. Passkey

   b. TOTP Authenticator apps such as Google Authenticator, Okta verify, Microsoft Authenticator, Authy, DUO

   c. Biometric Authenticator (FIDO2) such as Windows Hello, Apple Touch ID, Face ID, android fingerprint sensor.

   d. Hardware Security Keys (FIDO2) such as YubiKey, Thetis

   e. Email One-time password (OTP)

   f. SMS OTP - Multi-factor authentication with SMS com.snc.authentication.sms_mfaplugin installation and factor configuration are required to enable SMS OTP-based MFA.

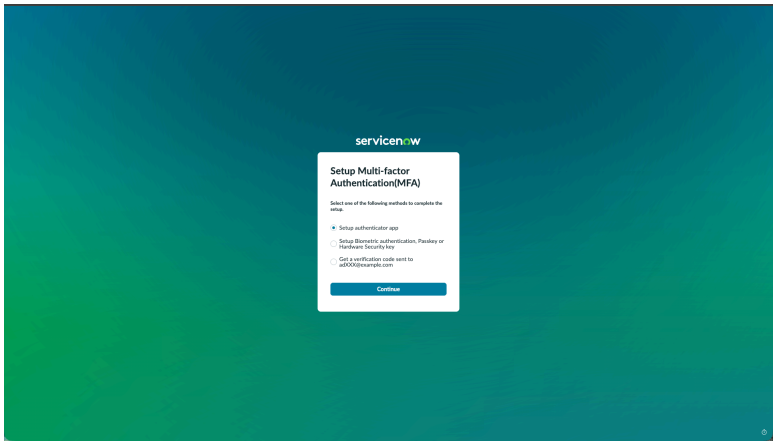
2. Can a user configure multiple MFA factors or verification methods?

   Yes, you can enroll for multiple MFA factors by visiting their user profile. For example, you can enroll a laptop with biometric authenticator, use the mobile phone with a passkey, and have an authenticator app setup.

3. What steps do users must perform to complete the MFA setup?

   User can perform either of the following MFA options.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Refer the Multi-factor authentication documentation for more information about MFA setup.

4. Can the SMS and Email OTP-based MFA limited to certain users?

   Admin can set up MFA factor policies for email and SMS OTP-based MFA factors to limit these factors to certain user groups or roles.

5. The users don't have a mobile phone where they can set up an authenticator app. How can these users enable MFA?

   From the Xanadu release onwards, you can use a Biometric authenticator, passkeys, FIDO2 hardware security keys, and email OTP-based MFA without requiring an authenticator app setup on the mobile phone.

6. As an end user how to set up MFA?

   Refer the Using Multi-factor authentication documentation for more information about MFA setup.

MFA reset

FAQ related to MFA reset and why it's important.

1. Lost the authenticator app setup. How can I reset?

   It's better if the users enroll in multiple factors so that they aren't locked out due to MFA. For example, you can have the TOTP authenticator app, passkey, and email OTP-based MFA.

   In case users are unable to use any of the enrolled MFA factors the administrator can reset the MFA by following these steps.

   a. Clearing the Authenticator app setup:
      - Navigate to **All** > **Multi-factor Authentication** > **User Multi-factor Setup**.
      - Search for the user in the table.
      - Delete the record associated with the user

   b. Clearing the FIDO2 authenticators and passkeys:
      - Navigate to **All** > **Multi-factor Authentication** > **Web Authentication** > **User Public Credentials**.
      - Search for the user in the table
      - Delete the records associated with the user

   c. Clearing other multi-factor setups associated with the user

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Navigate to **All** > **Multi-factor Authentication** > **User Multi-factor Setup**.
- Search for the user in the table
- Delete the records associated with the user

In case no one including the admin can access the instance. The admin can perform a self-service MFA reset using a catalog item available at Now support.

2. How to avoid administrators from lockout due to MFA?

   The administrators enroll for multiple MFA factors so that they aren't blocked from accessing the instance.

   In case no one including the admin can access the instance. The admin can perform a self-service MFA reset using a catalog item available at Now support.

Exploring Multi-factor Authentication

Multi-factor Authentication (MFA) is an authentication method that requires users to provide information other than their basic credentials.

MFA is a security process that requires a user to provide two or more different verification factors to access a service or account. It adds an extra security layer of protection to your service beyond just a password, which makes it harder for unauthorized individuals to gain access.

By requiring multiple factors, MFA significantly enhances security and helps protect against various cyberthreats, including phishing and identity theft. Here's some insight about how MFA works:

- **First factor**: The user using their user name and password for login.
- **Second factor**: The user is prompted for a second factor that's with the user (An identity verification method such as an authenticator app or security key).

Further, these factors can be typically categorized into secured and less-secured based on their level of protection against common security threats.

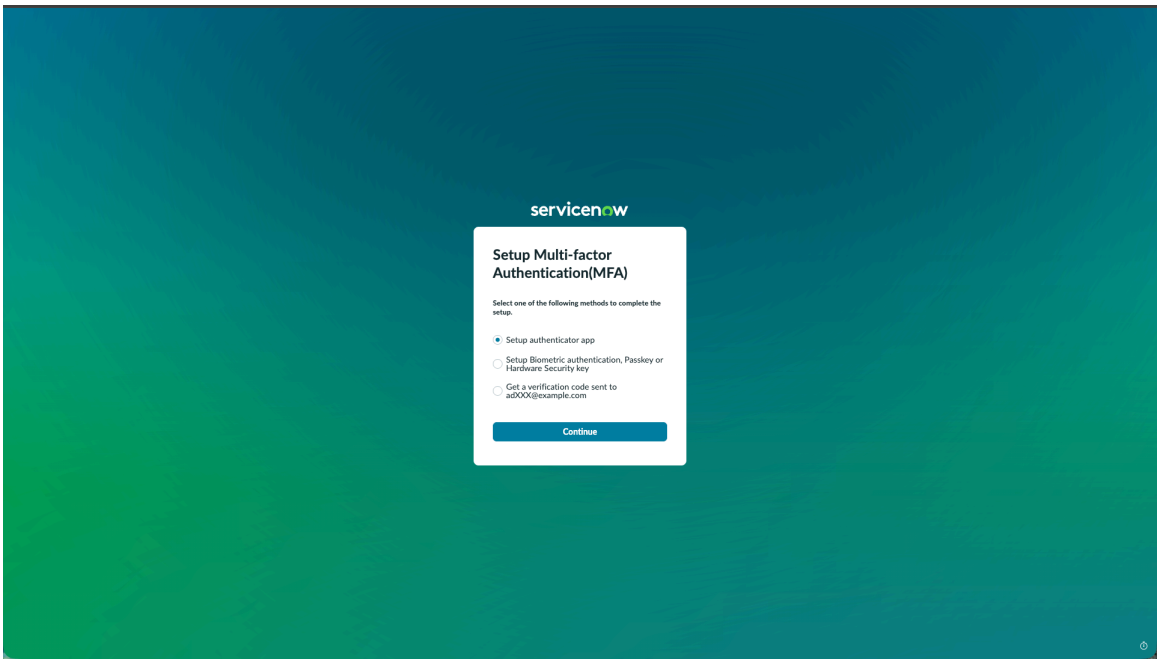
- Secured Factors:
  - FIDO (Fast Identity Online): This factor uses hardware tokens or biometric authentication methods, providing a high level of security by confirming that the user has a physical device or unique biometric trait to verify their identity.
  - **TOTP (Time-Based One-time Password):** This factor generates a one-time password that is valid for a short period, usually 30 seconds. It's typically delivered through a mobile app, adding an extra layer of security by requiring the user to have access to a specific device and app.
- Less-Secured Factors:
  - **EMAIL:** This factor sends a verification code or link to the user's email address. While convenient, it's less secure because email accounts can be compromised.
  - **SMS:** This factor sends a verification code via text message to the user's phone number. It's also less secure due to the potential for SIM swapping and other mobile phone vulnerabilities.

To enhance security, it's recommended to prioritize the use of secured factors like FIDO and TOTP over less-secured factors like EMAIL and SMS.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:

- MFA is activated by default on ServiceNow.
- MFA is enabled using *glide.authenticate.multifactor* property. If you want to disable this property, you must provide a business justification about why you want to disable MFA.



ServiceNow's MFA supports verification methods such as Authenticator App, Fast IDentity Online 2 (FIDO2), Passkey, and time-based One-time Password (OTP). Following are the details of available verification methods:

- **Authenticator App**: Apps that generate unique, temporary verification codes. For example: Okta, Google Authenticator, Microsoft Authenticator, and so on
- **FIDO2**: Physical devices that use public-key cryptography to validate user identities. For example: Hardware Keys (YubiKey), Biometric scanners (Apple's Touch ID).
- **Passkey**: Log in with a passkey by unlocking the device with a biometric sensor, PIN, or pattern.
- **OTP**: The secret key and the current time to generate a unique password that is only valid for a short period. For example: SMS (OTP) and Email (OTP).

You can use MFA along with the following:

- Local Database Authentication (native ServiceNow authentication) or Lightweight Directory Access Protocol integration
- SSO SAML or SSO OIDC. For more information, see Multi-Provider single sign-on (SSO).

Multi-factor Authentication system properties

Configure Multi-factor authentication

Configure multi-factor authentication (MFA) to improve your users security posture when using ServiceNow.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Firstly, to implement MFA, determine the MFA verification methods based on business and user needs.

After identifying the needs, with ServiceNow's MFA, you can select the right method or the combination of it for your users. Further, you can also use the various multi-factor authentication properties to enable, disable, and configure MFA to further enhance the user's MFA experience based on the authentication criteria.

Here's some of the important topics related to configuring MFA:

- Multi-factor Authentication verification methods
- Multi-factor Authentication system properties
- Multi-factor Authentication criteria

Multi-factor Authentication context

The Multi-factor Authentication (MFA) policy context uses a policy to define how and when MFA is enforced during the login process.

MFA context record

The MFA policy context defines whether your users must provide a second form of authentication when logging in. This context does not deny access to your instance as the post-authentication and pre-authentication policies. The policy you select in this context takes precedence over user or role-based configurations for multi-factor authentication.

To access the MFA context, navigate to **All** > **Multi-factor Authentication** > **MFA Context**.

Use the fields in the Post-authentication policy context record to define how your instance uses your policy.

Note:

- If the default policy is **Step-Up MFA Policy**, users will be shown with Multi-factor Authentication if policy configured in **Step-Up MFA Policy** evaluates to true. Policy takes precedence over the user or role based configuration.
- MFA with SSO login will only be available if `glide.authenticate.mfa.with.multisso.enabled` Property is set to true.
- You can navigate to the Authentication Policy record to Add or Edit the 'Policy Input(s)' to the referenced Policy field (**Step-Up MFA Policy** or **Step-Down MFA Policy**).
- MFA context policy applies only for user log ins. It does not apply for API authentication, basic auth, and OAuth resource owner password credential grant.

MFA context form

Field	Description
Name	Name of the policy context. This field is static and cannot be changed.
Description	Description of the context
Default Policy	Defines the default behavior of this context when evaluating the policy. Select from the following options. **Step-Up MFA Policy** Enforces MFA to users when the policy conditions defined in the **Step-Up MFA Policy** field evaluate to true.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

MFA context form (continued)

Field	Description
	Step-Down MFA Policy Enforces MFA by default. MFA is not enforced only when the policy conditions defined in the **Step-Down MFA Policy** field evaluate to true.
Step-Up MFA Policy	The policy used for this context uses. This field appears only when the **Default Policy** field is set to **Step-Up MFA Policy**.
Step-Down MFA Policy	The policy used for this context uses. This field appears only when the **Default Policy** field is set to **Step-Down MFA Policy**.

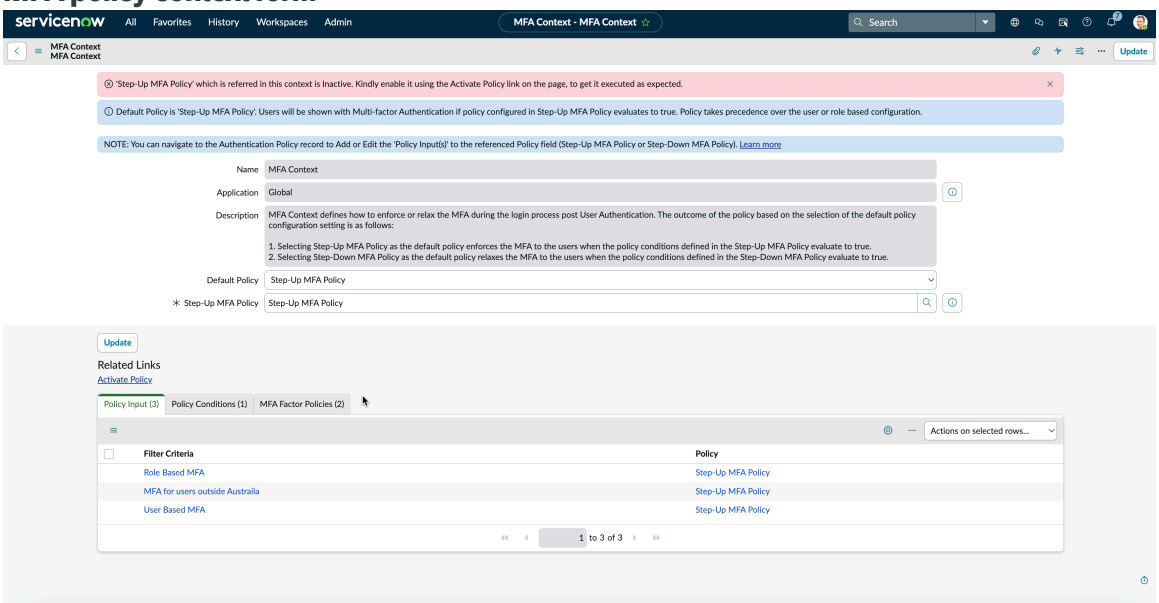
Policy inputs and conditions

The **Policy Input** and **Policy Conditions** tabs display the inputs and conditions of the policy selected in the **Step-Up MFA Policy** or **Step-Down MFA Policy** field. These tabs serve as a reference, but cannot be used to change the policy inputs or conditions. To modify your policy settings, navigate to the policy using the reference icon ( ) next to the **Step-Up MFA Policy** or **Step-Down MFA Policy** field.

Note:
Policy conditions can be created from here, but as a good practise it is recommended to add new policy conditions from policy page.

This example shows an MFA context record configured using a step-up MFA policy. This default policy means that MFA is enforced only when the conditions defined in the policy evaluate to true. The context uses a policy called **Step-Up MFA policy**. That policy has a set of inputs and conditions that are displayed in the **Policy Input** and **Policy Condition** tabs.

MFA policy context form



MFA factor policies

MFA factor policies are a critical component of an organization's security posture, enabling you to enforce additional verification steps beyond passwords. These policies define the

authentication methods that users must employ to access providing a flexible and customizable approach to authentication. For more information, see Multi-Factor Authentication factor policies.

Multi-factor Authentication verification methods

ServiceNow's MFA supports verification methods such as Authenticator App, Fast IDentity Online 2 (FIDO2) and Time-based One-Time Password (TOTP).

The users can use the following options in addition to their user name and password to fulfill multi-factor authentication requirements. The users can setup MFA factors such as Authenticator applications, Biometric scanners, Hardware Keys, and SMS independently.

Authenticator Applications

An authenticator application is third-party software that generates temporary passcodes. Users can use these passcodes along with their password to log in into an instance that requires multi-factor authentication (MFA). For more detail on these applications, see Authenticator Applications.

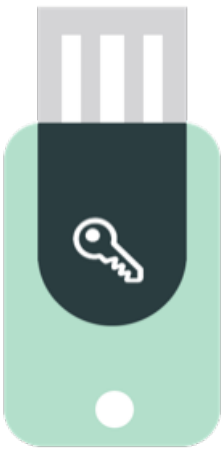
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Hardware Keys and Biometric scanners (Web Authentication)

The *Integration - Web Authentication* (com.snc.integration.webauthn) plugin allows hardware key or biometric reader authentication on your instance.

Biometric authenticators use fingerprint or facial recognition to identify users. Your users can use these authenticators on their devices as part of the multi-factor login process. For details on registering biometric authenticators, see Register a biometric authenticator.

Hardware keys are physical hardware that you can use to authenticate. Hardware keys are inserted into a port on your device to provide authentication. For details on registering hardware keys, see Register a hardware security key.



Passkey

Passkey authentication is a secure, password less method of log in, where the users use a passkey by unlocking their device with a biometric sensor, PIN, or pattern.

SMS

Admin can configure ServiceNow instance to require users who attempt to log in to the instance using SMS based OTP.

When users attempt to log in to ServiceNow, SMS OTP is sent to the mobile number associated with the sys_user record. Users can enter the six-digit verification code that it sent to the mobile device and verify their identity. For more information, see SMS as an MFA factor.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Email

Admin can configure ServiceNow instance to require users who attempt to log in to the instance using Email based OTP.

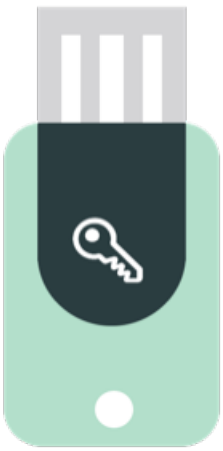
When users attempt to log in to ServiceNow, Email OTP is sent to the email address of the user. Users can enter the six-digit verification code that it sent to the email address and verify their identity. For more information, see Email as an MFA factor.

Related topics

- Web Authentication - MFA
- Multi-factor Authentication verification methods
- Email as an MFA factor

Web Authentication - MFA

Use the **Integration - Web Authentication (com.snc.integration.webauthn)** to allow hardware key or biometric reader authentication on your instance.



Hardware keys are physical hardware that you can use to authenticate. Hardware keys are inserted into a port on your device to provide authentication. For details on registering hardware keys, see Register a hardware security key.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Biometric authenticators use fingerprint or facial recognition to identify users. Your users can use these authenticators on their devices as part of the multi-factor login process. For details on registering biometric authenticators, see Register a biometric authenticator.

Configuring Multi-factor Authentication with Biometrics

Administrators can use the User Public Credentials list to view and manager user created credentials.

When a user registers an authenticator application, biometric authentication, or hardware key, you instance creates a record on the **User Public Credentials**[sys_user_public_credential] table. Use this table to see which users have registered an authenticator, as well as what types, and when they were registered and used. You can also mark these records as inactive to prevent the credentials to prevent users from using these credentials.

The **Integration - Web Authentication (com.snc.integration.webauthn)** plugin must be activated for Web Authentication (FIDO2).

Note:
The **Integration - Web Authentication (com.snc.integration.webauthn)** plugin is installed by default.

User public credential form

Field	Description
Credential Nickname	Nickname for the credential. This nickname is chosen by the user when they register an authenticator.
User	User associated with the credential
Active	Whether the credential is active. Administrators can set a record to inactive to prevent a user from authenticating with this credential.
Authenticator	The type of authenticator registered by the user.
Registration Time	The date and time the user-created this credential
Last Used Time	The last date and time the user logged in with this credential.

Restricted authenticator types

If you have restricted an authentication method, such as biometric authenticators, users will not be able to create new credentials of that type. However, any credentials created before you made

this restriction will continue to work. You can disable records on the **User Public Credentials** table to prevent these credentials from being used after they have been created.

Authenticator configuration options

Use the Authenticator Configuration page to manage authenticator options on your instance.

Navigate to **Multi-factor Authentication** > **Web Authentication** > **Authenticator Configuration** to view and edit the default configuration options.

Authenticator Configuration form

Field	Description
Allowed authenticator type	Type of authenticators allowed to be registered. Select from: • **Platform** authenticators are attached or integrated into a device. Fingerprint readers or facial recognition available on mobile devices (such as Apple FaceID or TouchID) fall under this category. • **Roaming** authenticators can be removed from a computer or other client device and used elsewhere. Hardware keys fall under this category.
Attestation Type	Setting the value to direct or indirect will require importing authenticator metadata to attest to the provenance of an authenticator during registration. • None • Direct • Indirect
Platform self-attestation	Whether self-attestation is enabled for platform authenticators.
Cross platform self-attestation	Whether self-attestation is enabled for roaming authenticators.
User verification	Select from **Preferred** or **Required**. If required, web authentication flow prompts users for verification using PIN or Biometrics.
Verify user presence	Whether web authentication flow requires the user presence verification.
Resident key	Select from **Preferred** or **Required**. If required, the authenticator persists the public key credentials within the authenticator storage.
Timeout (In ms)	Maximum time limit for completing web authentication registration and authentication. Time is in milliseconds.

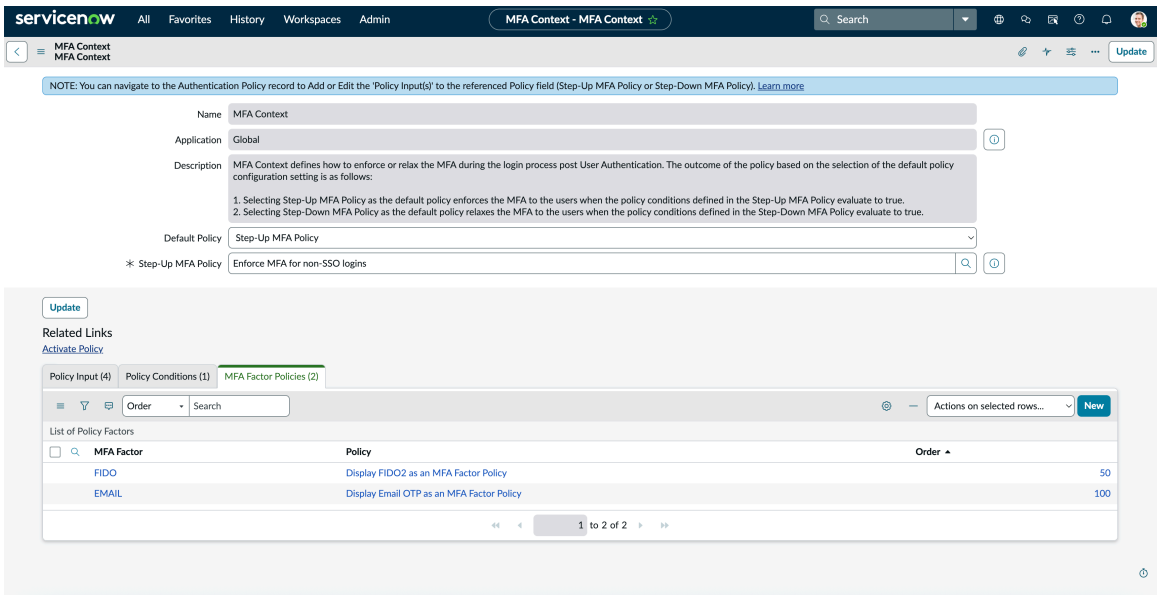
Multi-Factor Authentication factor policies

Use the MFA factor policies to specify the types of authentication factors that you would like to permit for your instance.

MFA factor policies are a critical component of an organization's security posture, enabling you to enforce additional verification steps beyond passwords. These policies define the authentication methods that users must employ to access your organization's resources, providing a flexible and customizable approach to authentication.

Implementing MFA factor policies is essential for enhancing the security of your organization's systems and data. These policies provide an additional layer of protection against cyberthreats, making it more difficult for attackers to gain unauthorized access.



To use the MFA factor policies you have to configure the policy inputs and policy conditions along with an MFA Context. To know more, see Multi-factor Authentication context.

Following are the MFA factor policies available in ServiceNow that enables you to specify the types of authentication factors that are permitted or required:

- FIDO2
- SMS
- Email

To get the most out of MFA factor policies, you need to understand how to configure and manage them effectively. This includes defining the authentication methods, specifying policy inputs and conditions, and configuring policy enforcement (MFA Context). By understanding and implementing MFA factor policies, you can significantly improve the security and integrity of your organization's systems and data.

Related topics

Multi-factor Authentication context

FIDO2 as an MFA factor

SMS as an MFA factor

Email as an MFA factor

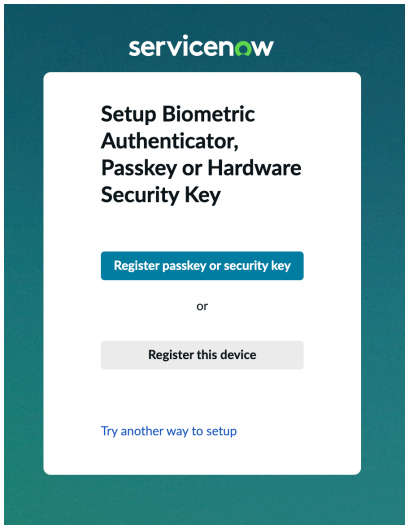
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

FIDO2 as an MFA factor

You can configure FIDO2 as an MFA factor policy to enforce MFA for yours.

FIDO2 is a password-less authentication standard that enables users to authenticate using a physical security key or biometric authentication. It provides a more secure alternative to traditional MFA methods, reducing the risk of phishing and other cyberattack.

The FIDO2 factor policy enhancement provides a secure authentication method to your multi-factor authentication (MFA) policies. You can configure FIDO2 as an MFA factor policy option, providing a higher level of security compared to traditional methods like Email and SMS.



You can configure FIDO2 factor policy and when the users satisfies the factor policy condition, the during log in to ServiceNow, FIDO2 setup is displayed for the users who haven't already added registered Hardware key or Biometric on their profile.

If the registration is completed, then second factor validation screen is displayed to log in.

Note:
FIDO2 can also be self-enrolled by the users. To know more about how to self-enroll, see Set up Multi-factor authentication on your user profile.

Key Benefits

The following are some of the key benefits of using FIDO2 as an MFA factor:

Exclusive FIDO2 Authentication

Ensure high-privilege accounts can only authenticate using FIDO2's strong authentication capabilities (biometrics, passkeys, or hardware security keys).

Exclusion of less secure methods

Suppress other authentication methods when FIDO2 is the only matching policy.

Forced enrollment

Require users to register a FIDO2 key if not already enrolled.

Granular control

Apply strict enforcement to specific roles or groups using policy-based targeting.

As a higher-security factor, FIDO2 has exclusive enforcement capabilities. When it's the only matching policy for a user:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Overrides other enroll-enrolled factors.
- Forces FIDO2 registration, if the user isn't enrolled.
- Becomes the exclusive authentication option.

Example Configurations and User Behaviors

The following table illustrates how different user scenarios are handled based on their roles and enrolled factors.

Example Factor Policy Conditions:

- **FIDO2 Factory Policy**: Condition is "ITIL role should be true".
- **EMAIL Factor Policy**: Condition is "ASSET role should be true".

Example user	Has roles	Already enrolled factors	Matching policies	Behavior
andrew.och	**ITIL**	None	FIDO2	User is redirected to MFA setup with FIDO2 only. After registration, FIDO2 is the only authentication option.
abel.tuter	**ITIL**	Authenticator	FIDO2	User is redirected to MFA setup with FIDO2 only, even if the user has Authenticator as self-enrolled factor. **Note:** If the user hasn't registered to any MFA factor, then the user is redirected to MFA setup with FIDO2.
aileen.motterm	**ASSET**	Authenticator	Email	Sees Email and Authenticator options during log in. The user can choose either factor or optionally register FIDO2.
abraham.lincoln	**ASSET**, **ITIL**	Authenticator	Email and FIDO2	Sees Email and Authenticator option during log in. The user can register FIDO2 during validation. After registration, the user can see all the 3 factors.

By configuring FIDO2 as an MFA factor policy, you can significantly enhance the security of your authentication processes.

Configure FIDO2 as an MFA factor

Configure policy input and condition to display FIDO2 as an MFA factor policy for authentication.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **Multi-factor Authentication** > **MFA Context**.
2. Select the **MFA Factor Policies** tab.
3. Select the **Display FIDO2 as an MFA Factor Policy**.

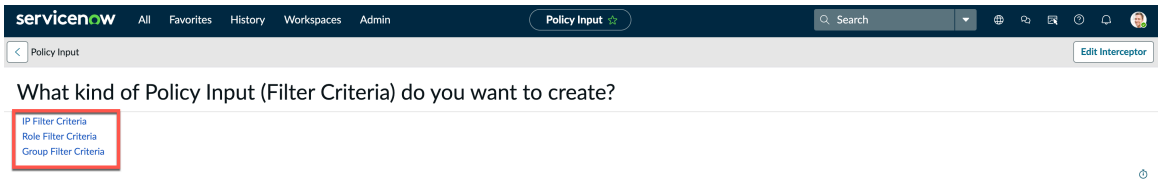
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Select **New** to add **Policy Inputs**.
5. Select the filter criteria that you want to create.

   Following are the types of filter criteria:

   - IP Filter Criteria
   - Role Filter Criteria
   - Group Filter Criteria

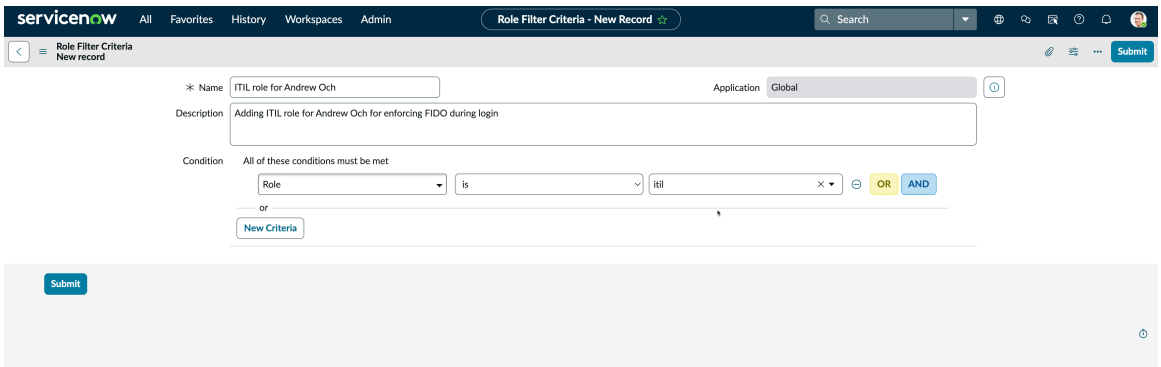
   For example, Role Filter Criteria.



6. Select **Role Filter Criteria**, fill the fields for the role filter criteria and submit the record.

   The new policy is created. For more information, see Role Filter Criteria.

   Let's take an example of using **ITIL** role for the user (**andrew.och**) as the policy input and submit.



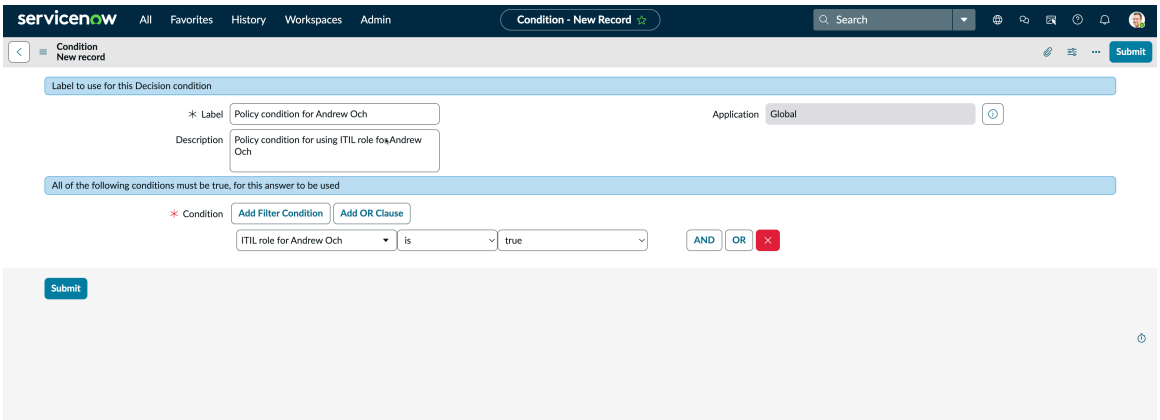
7. On the Policy - Display FIDO2 as an MFA Factor Policy page, select **Policy Conditions**.
8. Select **New** to add policy conditions.
9. On the form, fill in the fields.

Condition form

Field	Description
Label	Name to identify the condition.
Description	Description of the condition.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Condition	Logical combination of multiple policy inputs (filter criteria) that is used to evaluate authentication requests. Select the role-based filter criteria policy that was created for the condition.



10. Select **Submit**.

    Based on the policy input and condition, if the user (**andrew.och**) tries to log in to the instance, the user is shown as the FIDO screen to either enroll and register.

    To know more about different configuration example and user behaviors, see Example Configurations and User Behaviors.

11. **Optional:** Repeat step 8 to create additional policy conditions.

    Note:
    If you create multiple policy conditions, the final output of the access policy depends on the logical OR output of the all policy conditions. Based on the conditions the policy is evaluated.

SMS as an MFA factor

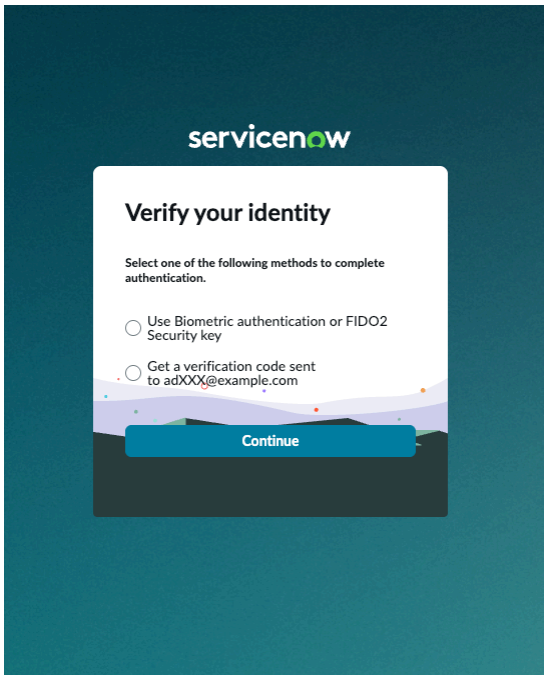
Multi-factor authentication (MFA) with SMS as a factor for your authentication.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Admin can configure ServiceNow instance to require users who attempt to login the instance using SMS based OTP.

When users attempt to login to ServiceNow, SMS OTP is sent to the mobile number associated with the sys_user record. User's can enter the six-digit verification code that it sent to the mobile device and verify their identity.

You can configure MFA with SMS using the out of the box Twilio as well. For more information, see Multi-factor authentication Providers.



Further the MFA with SMS can be controlled based on the policy input and conditions using filter criteria. Following are the types of filter criteria:

- IP Filter Criteria
- Role Filter Criteria
- Group Filter Criteria

Activate the MFA with SMS plugin

For MFA with SMS, install the Multi-factor authentication with SMS (`com.snc.authentication.sms_mfa`) plugin.

Before you begin

Role required: admin

About this task

The following items are installed with Multi-factor authentication with SMS:

- Adaptive Authentication (`com.snc.adaptive_authentication`
- Notify - Twilio Direct Driver (`com.snc.notify.twilio_direct`)

Dependent Plugin: Integration - Multifactor Authentication (`com.snc.integration.multifactor.authentication`)

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
You can load the demo data when installing the plugin if you are configuring a custom provider for generating the SMS.

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the Multi-factor authentication with SMS plugin (`com.snc.authentication.sms_mfa`) using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

   Note:
   When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

   You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Configure SMS as an MFA factor

Configure policy input and condition to display SMS OTP as an MFA factor policy for authentication.

Before you begin

Plugin required: Multi-factor authentication with SMS (`com.snc.authentication.sms_mfa`).

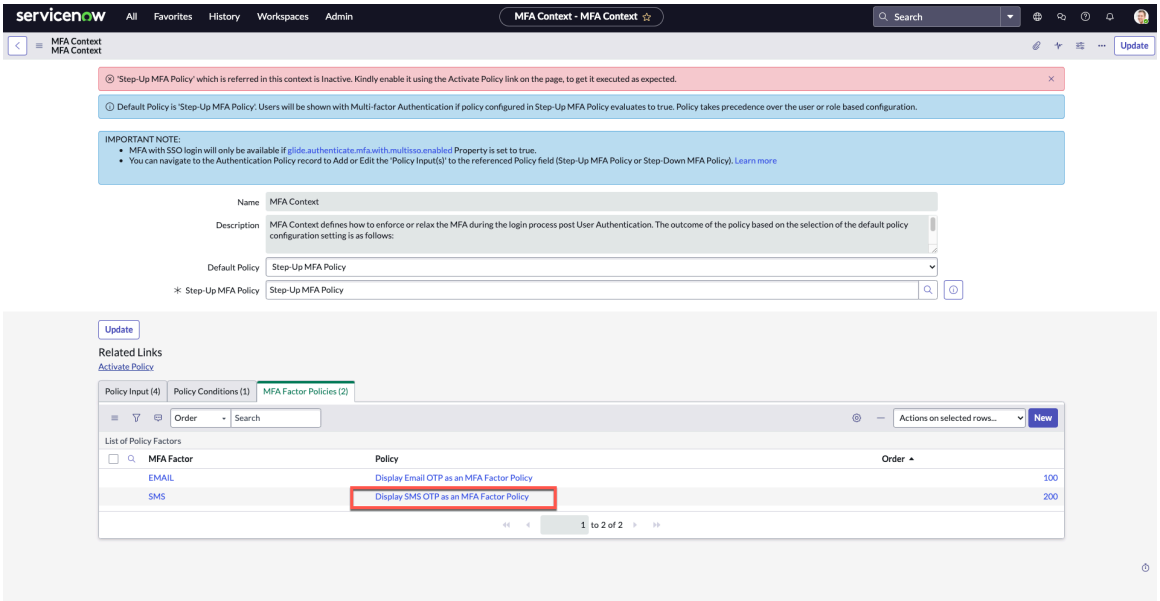
Role required: admin

Note:
The MFA context policy must be evaluated as `true` to apply the SMS factor policy.

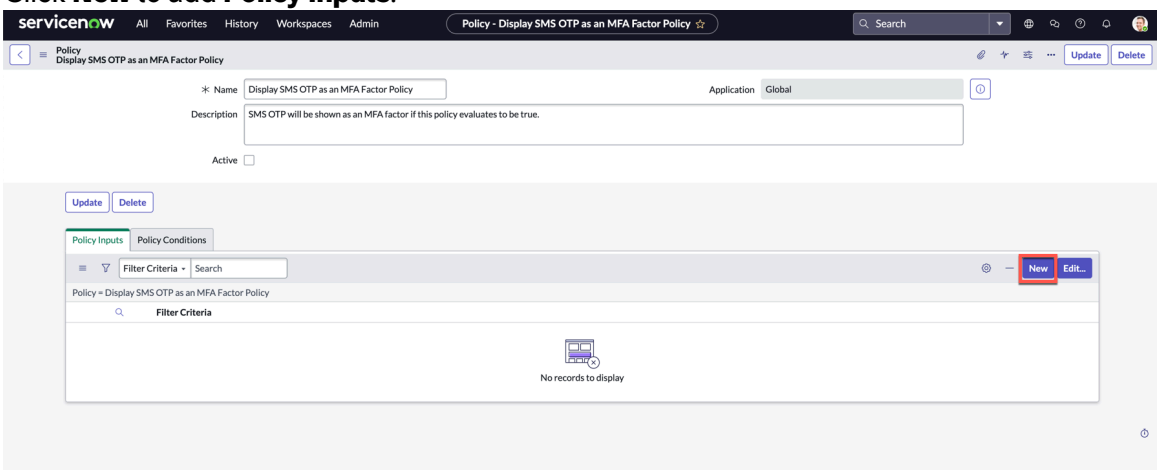
Procedure

1. Navigate to **All** > **Multi-factor Authentication** > **MFA Context**.
2. Click the **MFA Factor Policies** tab.
3. Select the **Display SMS OTP as an MFA Factor Policy**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



4. Click **New** to add **Policy Inputs**.

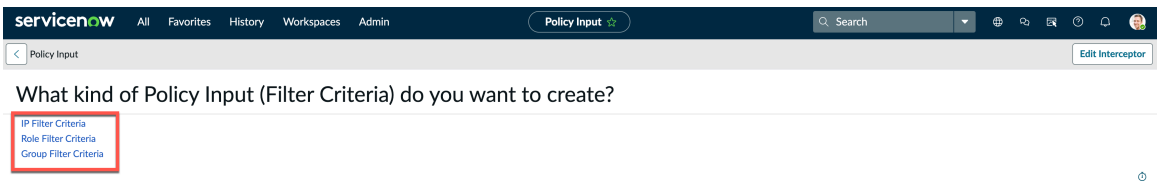


5. Select the filter criteria that you want to create.

Following are the types of filter criteria:

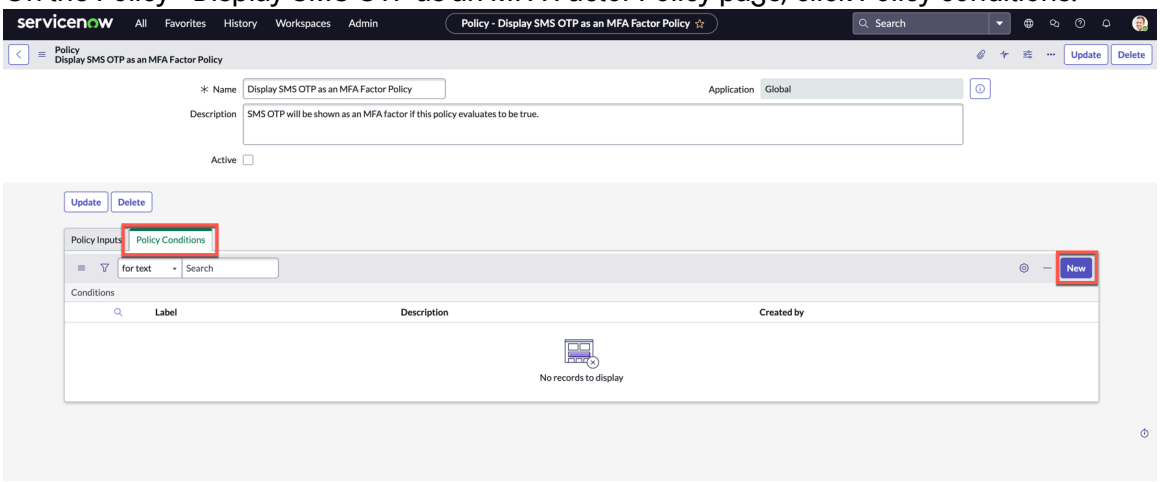
- IP Filter Criteria
- Role Filter Criteria
- Group Filter Criteria

For example, Role Filter Criteria.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

6. Click **Role Filter Criteria**, fill the fields for the role filter criteria and submit the record. The new policy is created. For more information, see Role Filter Criteria.
7. On the Policy - Display SMS OTP as an MFA Factor Policy page, click Policy conditions.



8. Click **New** to add **Policy Conditions**.
9. On the form, fill in the fields.

Condition form

Field	Description
Label	Name to identify the condition.
Description	Description of the condition.
Condition	Logical combination of multiple policy inputs (filter criteria) that is used to evaluate authentication requests. Select the role-based filter criteria policy that was created for the condition.

10. Click **Submit**.
11. **Optional:** Repeat step 8 to create additional policy conditions.

> **Note:**
> If you create multiple policy conditions, the final output of the access policy depends on the logical OR output of the all policy conditions. This means that the policy evaluates to true if any one of your policy conditions is met.

Based on the role filter (users) policy and the conditions specified for the role is matched, the SMS as MFA factor is shown as an option for authentication for the users.

Multi-factor authentication Providers

Use MFA providers to configure SMS and Email based authentication to ensure every user can login securely.

On the ServiceNow AI Platform, you can configure MFA providers with the mechanism of using multi-factor authentication such as Email and SMS.

You can use the following provider configuration available for MFA within the ServiceNow AI Platform:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Email Provider Configuration
- Twilio Provider Configuration
- Infobip Provider Configuration.

Note:
Twilio and Infobip Provider Configuration are auto-populated by enabling the Load Demo Data when installing the Multi-factor authentication with SMS (`com.snc.authentication.sms_mfa`) and Notify - Twilio Direct Driver (`com.snc.notify.twilio_direct`) plugins.

You can also create your own provider configuration for enabling the multi-factor authentication with SMS and Email.

Note:
The Infobip Provider configuration is provided as a part of demo data, you can edit the fields based on your requirements for configuration your own provider.

Configure MFA Provider

Configure SMS and Email with the Provider to ensure every user can login securely.

Before you begin

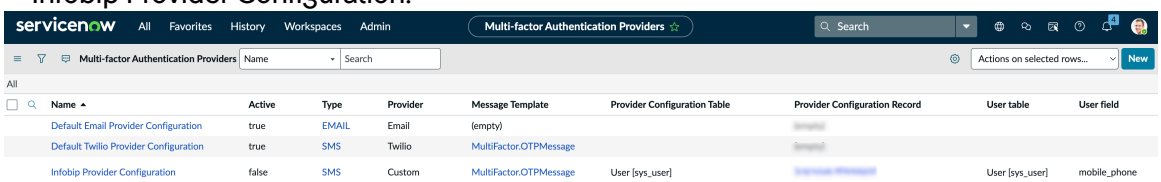
Role required: admin

Procedure

1. Navigate to **All** > **Multi-factor Authentication** > **Providers**.

   Following provider configuration are available for MFA within the ServiceNow AI Platform:

   - Email Provider Configuration
   - Twilio Provider Configuration
   - Infobip Provider Configuration.



2. To create a new provider, click **New**.
3. On the form, fill the fields.

Condition form

Field	Description
Name	Name of the record.
Type	Description of the record.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Provider	Choose **Twilio** or **Custom**. **Note:** To configure Twilio, see Configure Notify with Twilio. When choosing **Custom**, you need to specify the following fields: ○ Provider Configuration Table ○ Provider Configuration Record ○ Script ○ User table ○ User field
Message Template	The message template for the record.
Active	Option to make the provider configuration active.

4. Click **Submit**.

   Based on the message template and provider configurations, the SMS or Email is sent to users as a factor for authentication during the login process.

Vonage Provider custom configuration (Tutorial)

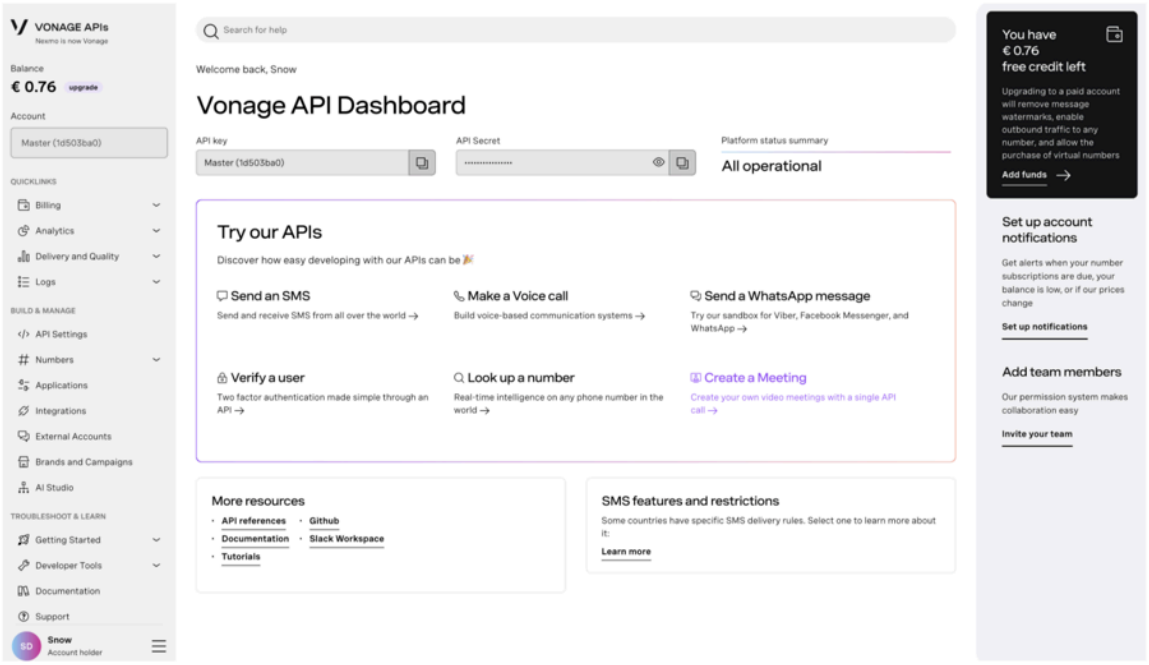
Configure a SMS with Vonage Provider to ensure every user can login securely.

Before you begin
Role required: admin

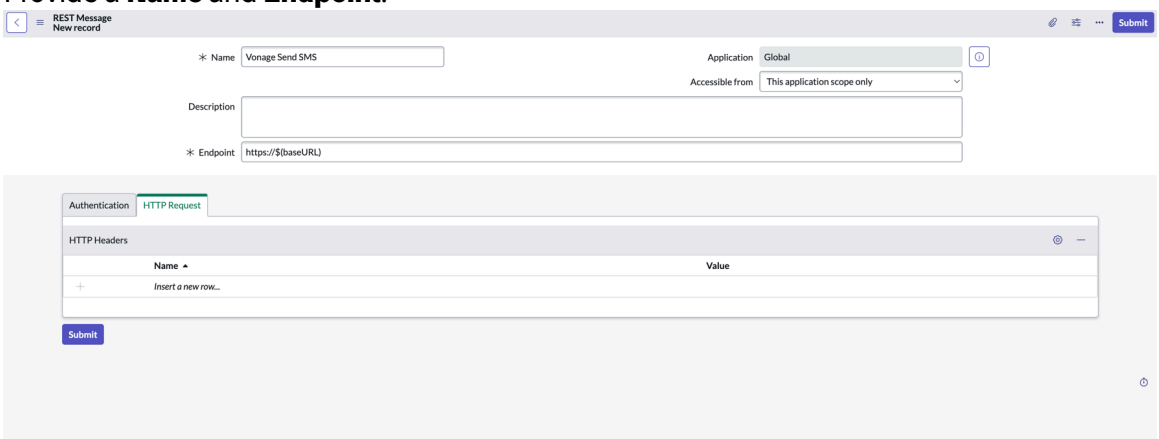
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **System Web Services** > **Outbound** > **REST Message** and perform the REST message configuration based on the information from Vonage API Dashboard.

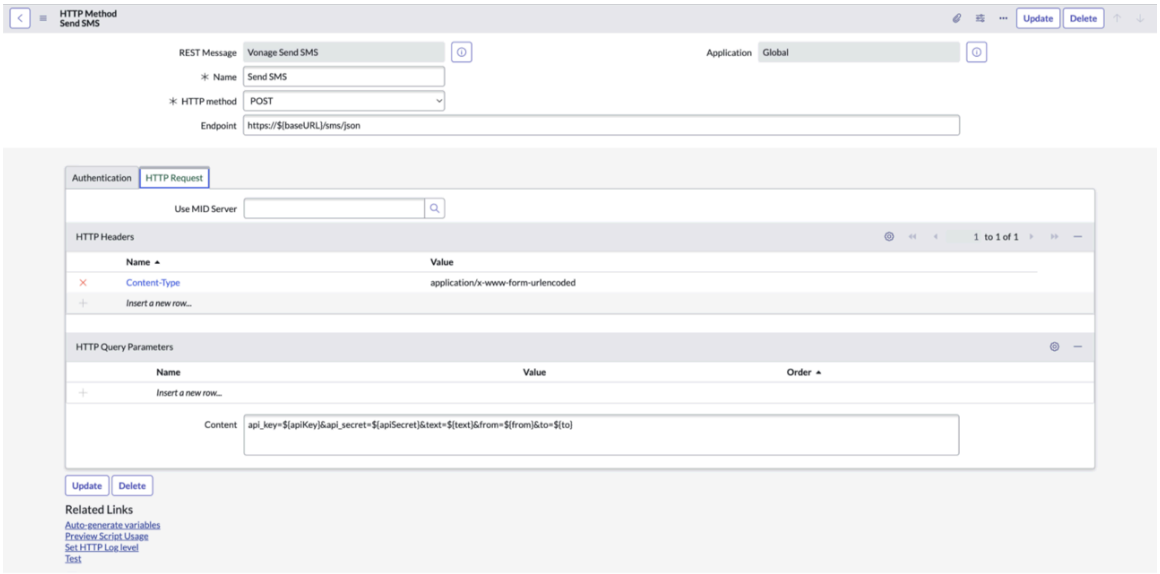


2. Click **New** to create a new **REST Message**.
3. Provide a **Name** and **Endpoint**.



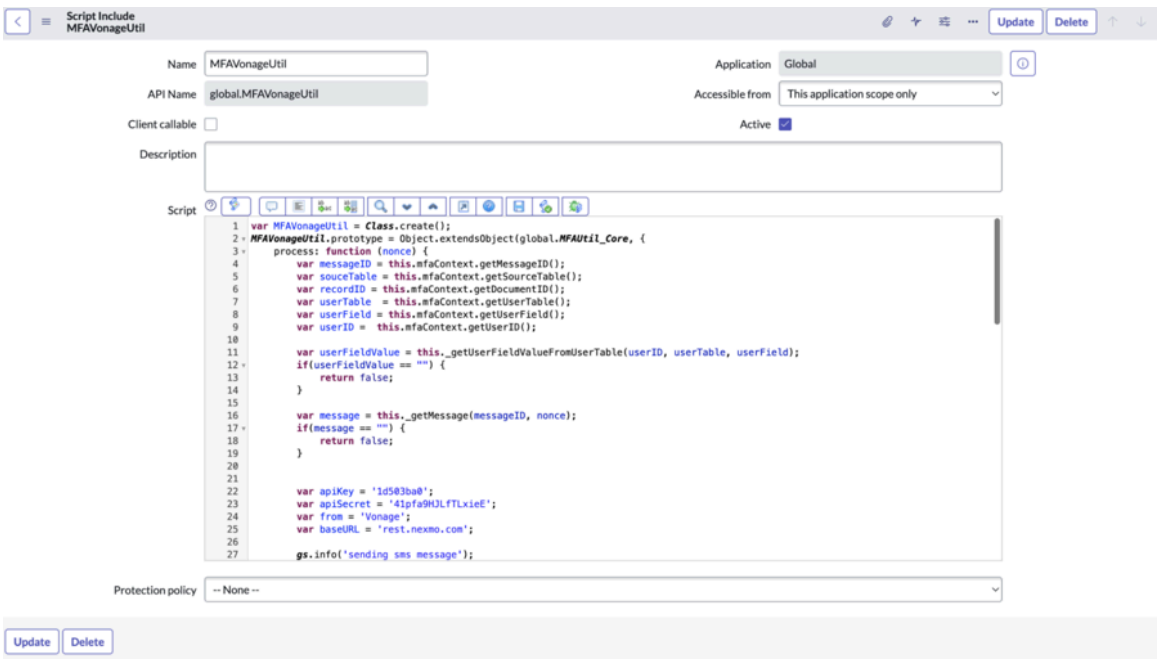
4. Click **Submit**.
5. Open the created record, in the **HTTP Methods** related list, click **New** and select the HTTP method as **POST**.
6. Fill the following fields:
   - Endpoint: `https://${baseURL}/sms/json`
   - Content:`api_key=${apiKey}&api_secret=${apiSecret}&text=${text}&from=${from}&to=${to}`
   - Content-Type: `application/x-www-form-urlencoded`

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



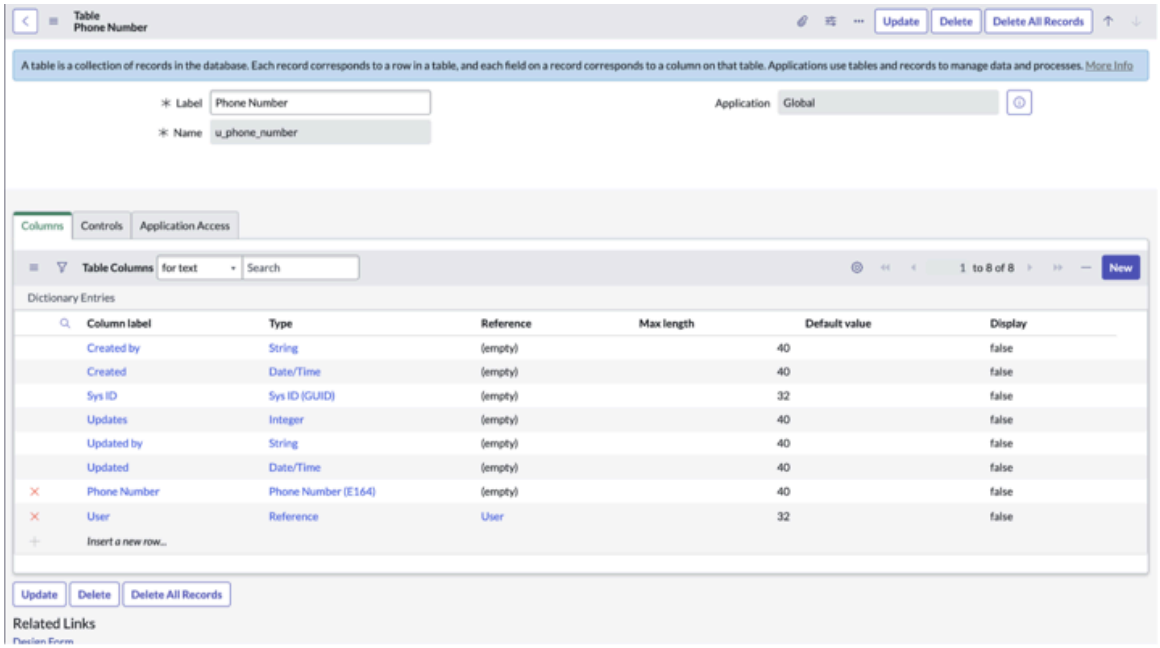
7. Update the record.
8. Click **Auto-generate variables** from the **Related Links** section.
9. Import SI shared in the folder and copy the apiKey and secret from the Vonage API dashboard.

> **Note:**
>
> The apiKey and secret are located in your Vonage account settings in the Vonage Dashboard.

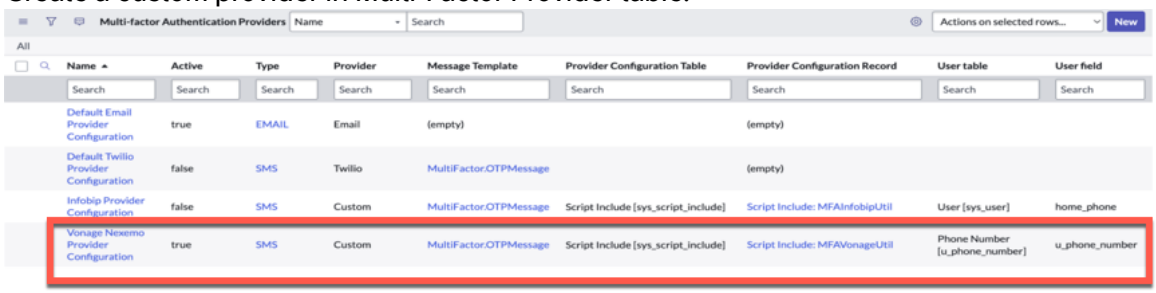


10. Create a custom Table Phone Numbers with two columns, For example:
    - **Column Label**: User, **Type**: Reference, **Reference**: User (sys_user).
    - **Column Label**: Phone Number, **Type**: Phone Number(E164).

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



11. Create a custom provider in Multi-Factor Provider table.



To know more about provider configuration, see Configure MFA Provider.

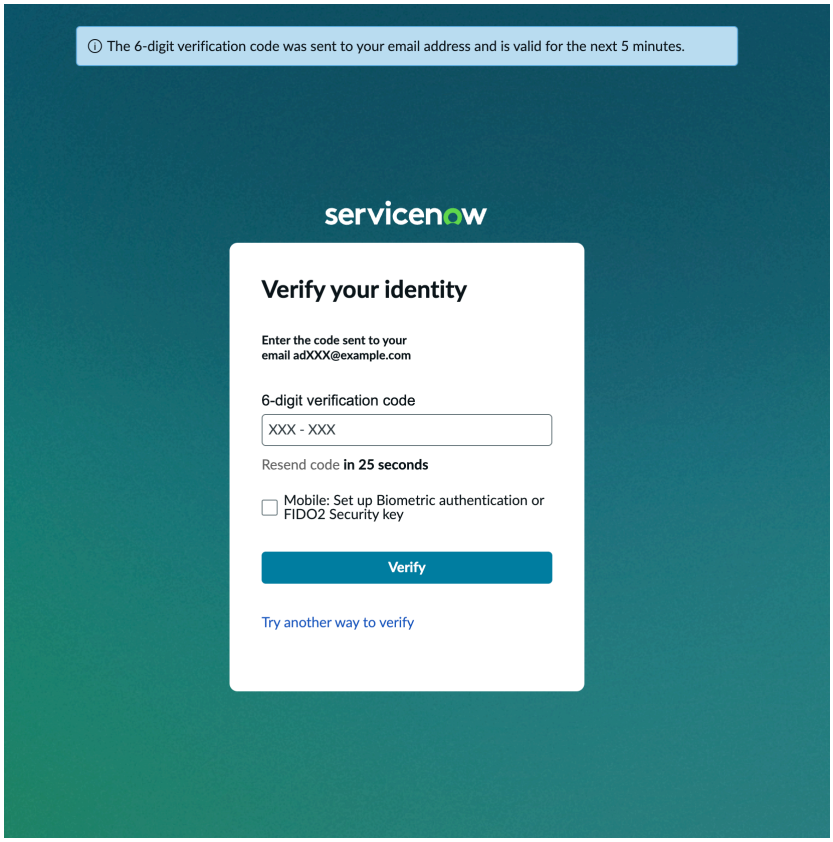
Email as an MFA factor

Multi-factor authentication (MFA) with Email as a factor for your authentication.

Admin can configure ServiceNow instance to require users who attempt to login to the instance using Email based OTP.

Note:
MFA with Email is activated with the Integration - Multifactor Authentication (`com.snc.integration.multifactor.authentication`) plugin by default. You need to configure the policy inputs and conditions.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



When users attempt to login to ServiceNow, Email OTP is sent to the Email address associated. User's can enter the six-digit verification code that it sent to the email address and verify their identity.

Configure Email as an MFA factor

Configure policy input and condition to display Email OTP as an MFA factor policy for authentication.

Before you begin

Role required: admin

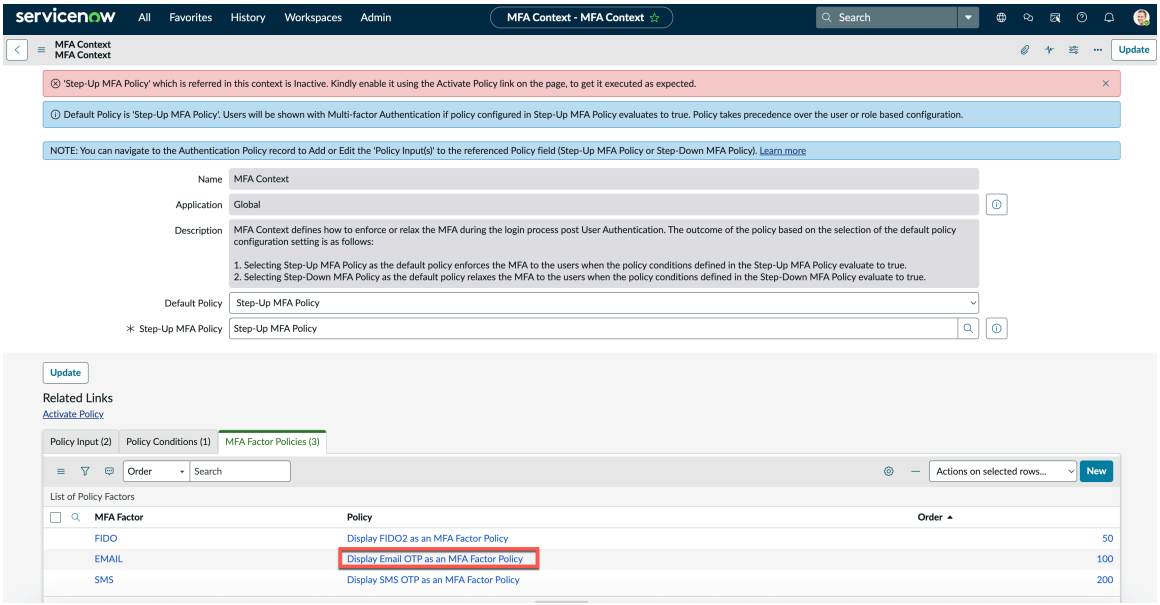
Procedure

1. Navigate to **All** > **Multi-factor Authentication** > **MFA Context**.
2. Click **MFA Factor Policies** tab.

> **Note:**
> The **EMAIL** as **MFA Factor with a Policy** is available by default. You can edit the policy and specify the policy inputs and conditions.

3. Select the **Display Email OTP as an MFA Factor Policy**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

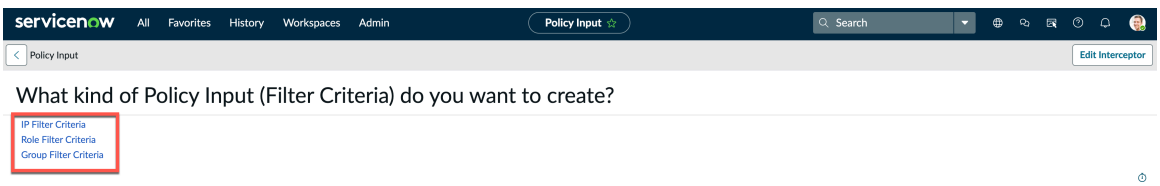


4. Click **New** to add **Policy Inputs**.
5. Select the filter criteria that you want to create.

   Following are the types of filter criteria:

   - IP Filter Criteria
   - Role Filter Criteria
   - Group Filter Criteria

   For example, Role Filter Criteria.



6. Click **Role Filter Criteria**, fill the fields for the role filter criteria and submit the record. The new policy is created. For more information, see Role Filter Criteria.
7. On the Policy - Display Email OTP as an MFA Factor Policy page, click **Policy conditions**.
8. Click **New** to add **Policy Conditions**.
9. On the form, fill in the fields:

Condition form

Field	Description
Label	Name to identify the condition.
Description	Description of the condition.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Condition	Logical combination of multiple policy inputs (filter criteria) that is used to evaluate authentication requests. Select the role based filter criteria policy that was created for the condition.

10. Click **Submit**.
11. **Optional:** Repeat step 8 to create additional policy conditions.

> **Note:**
> If you create multiple policy conditions, the final output of the access policy depends on the logical OR output of the all policy conditions. This means the policy will evaluate to true if any one of your policy conditions is met.

Based on the role filter (users) policy and the conditions specified for the role is matched, the Email MFA factor is shown as an options for authentication for the users.

Multi-factor Authentication system properties

Use system properties to enable and customize MFA to meet your security requirements.

Multi-factor Authentication properties

Property	Description
glide.authenticate.multifactor	Enable Multi-factor Authentication. **Note:** To enforce MFA for API authentication, set the `glide.authenticate.multifactor.for_integ` system property to `true`. MFA is enforced only for users who have already enrolled in MFA. Users who have not enrolled are not affected.
glide.authenticate.multifactor.setup.bypass.count	Number of times that a user can choose to skip the setup of MFA. The default is 0.
glide.multifactor.onetime.code.validity	Number of minutes that the reset code is valid. See Log in with Multi-factor Authentication. The default is 5. **Note:** This property is for email OTP validation time.
glide.authenticate.multifactor.clock_skew	Number of additional seconds that the reset code is valid. The maximum is 60. The default is 10. The instance validates the code entered by the user against the single app-generated

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Multi-factor Authentication properties (continued)

Property	Description
	code that is generated at the `current time`. You can skew the time window with this property and allow one or more codes to be generated during a time window to be considered valid. The property's value is used in the following calculation: `current time - X/2` and `current time + X/2`, where X is the value of this property. If you use the value of `10`, for example, the instance considers any codes that the app generates within the time range `[the current time - 5 seconds]` and `[current time + 5 seconds]` to be valid. Use this property to prevent login issues where the user is unable to enter the correct code in the default time allotted.
glide.authenticate.multifactor.remember.browser.enabled	Set to true to enable a user for MFA when they log in from a new device or browser. The default is yes.
glide.authenticate.multifactor.browser.remember.duration	After MFA is completed in a browser, the user is not challenged for MFA in the same browser for this duration. The default is 8 hours.
glide.authenticate.multifactor.remembered.browsers.max	The number of browsers MFA remembers for this user.
glide.authenticate.multifactor.remember.browser.default	Default value of the remember browser check box in the validate multi-factor page.
glide.webauthn.enabled)	Option to enable passwordless authentication (FIDO2 based MFA) methods such as hardware key and biometric authentication.
glide.authenticate.multifactor.email.otp.enabled	Option to enable email based OTP as a factor for MFA.
glide.auth.mfa.ui.v2.enabled	Option to enable MFA factor independently for the users without setting up an authenticator app.

Multi-factor Authentication criteria

Use MFA criteria to determine which users and roles must use two-step verification.

Multi-factor criteria

Use MFA criteria to determine which users and roles must use two-step verification. You can use one of these criteria or a combination of them to suit your business needs. You can use one of these criteria or a combination of them to suit your business needs.

Note:
It is recommended to use Adaptive Authentication policy based MFA.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

User-based multi-factor criteria

Use user-based multi-factor criteria to select individual users who are required to log in using MFA. Administrators update the **Enable Multifactor Authentication** field on a user record to enable or disable MFA requirements for a user. For details on this process, see Configure user-based multi-factor criteria.

Role-based multi-factor criteria

Use role-based multi-factor criteria to require MFA login for all users assigned to a specific role. The **Role-based multi-factor authentication** record on the **Multi-factor Criteria** [multi_factor_criteria] table contains the list of roles that require an MFA login. For details on maintaining this list, see Configure role-based multi-factor criteria.

Adaptive authentication policy-based multi-factor criteria

Use adaptive authentication to determine when your instance requires MFA. Adaptive authentication uses authentication policies to evaluate criteria like a user's IP address or user groups. For details on the adaptive authentication feature, see Adaptive authentication.

Configure user-based multi-factor criteria

Use user based multi-factor criteria to enable MFA for a user.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **User Administration** > **Users**.
2. Configure the list to show the **Enable Multi-factor Authentication** column.
3. Change the values of the **Enable Multi-factor Authentication** column for the selected users to **true**.

   When the user logs in with their user name and password, they are prompted to set up multi-factor authentication.

Configure role-based multi-factor criteria

Use role based multi-factor criteria to enforce Multi-factor authentication for all users assigned to specific roles.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **Multi-factor Authentication** > **Multi-factor Criteria**.
2. In the **Multi-factor Criteria** list, open the **Role-based multi-factor authentication** record.
3. Use the **Multi-factor Roles** list to add or remove roles.

Option	Description
Add a role	Double-click **Insert a new row...** and enter or select a role name. Click the **Save Icon** ( ) to save the entry.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Option	Description
Remove a role	Click the delete icon ( ) to remove a role from the list.

4. Click **Update**.

Result
Your instance enforces multi-factor authentication for all users who are members of the roles listed in the **Multi-factor Roles** list.

Important:
The record must be active to enforce role-based multi-factor authentication.

Configure adaptive authentication policy-based multi-factor criteria

Use adaptive policies to determine which users must use two-step multi-factor (MFA) verification.

Before you begin
Role required: admin

Note:

- If the default policy is **Step-Up MFA Policy**, users will be shown with Multi-factor Authentication if policy configured in **Step-Up MFA Policy** evaluates to true. Policy takes precedence over the user or role based configuration.
- MFA with SSO login will only be available if `glide.authenticate.mfa.with.multisso.enabled` Property is set to true.
- You can navigate to the Authentication Policy record to Add or Edit the 'Policy Input(s)' to the referenced Policy field (**Step-Up MFA Policy** or **Step-Down MFA Policy**).

Procedure

1. Navigate to **All** > **Adaptive Authentication** > **Auth Policy Contexts** > **MFA Context**.
   The **MFA Context** policy context record opens.
2. Select the default policy in the **Default Policy** field.
   This selection determines how your instance uses the policy conditions to determine whether to require MFA.

Default policies

Default Policy	Definition
Step-Up MFA Policy	Select to enforce MFA when the policy conditions defined in **Step-Up MFA Policy** evaluate to true.
Step-Down MFA Policy	Select to bypass MFA when the policy conditions defined in the **Step-Down MFA Policy** evaluate to true.

3. In the **Step-Up MFA Policy** field, select a policy to use with this context.
4. Click **Update**.
   After saving the record, the **Policy Input** and **Policy Conditions** lists update to display the policy inputs and conditions associated with the policy selected in the **Step-Up MFA Policy** field.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Multi-factor Authentication with Single Sign-On

You can use MFA with an SSO provider for your ServiceNow instance.

Since many users in your organization are logging in to your corporate network and accessing your ServiceNow instance, there is a stronger need for a secure authentication.

MFA with the combination of SSO provides an enhanced security for your instance. This capability provides flexibility to conditionally enable MFA for users.

Note:

- ServiceNow MFA is enforced after the user is redirected after the successful authentication at the Identity Provider.
- MFA was not enforced with SSO prior to the San Diego release.

For example, if you would like to give your external users an extra security protocol, then you can enforce MFA to only those users. In this way, you can add additional authentication abilities and control your user access.

For SSO-based login such as SAML, OpenID Connect, and Digest, you can enforce MFA for authentication.

MFA with SSO can be configured on-demand based on your requirement. With the help of authentication schemes and identity providers, you can enforce MFA for specific users with a specific login mechanism.

You can enforce MFA for the following conditions:

- Authentication Scheme
- Identity Provider

MFA with SSO is offered as a part of the Adaptive Authentication plugin (com.snc.adaptive_authentication). To know more on how to set up Adaptive Authentication, see Adaptive authentication.

Configuring MFA with SSO

Enforce MFA with SSO for your users within or outside your organization.

Before you begin

The MFA with SSO feature is offered as a part of the Adaptive Authentication plugin (com.snc.adaptive_authentication). You must enable the Adaptive authentication property for using MFA with SSO feature. To know more on how to set up Adaptive authentication, see Adaptive authentication.

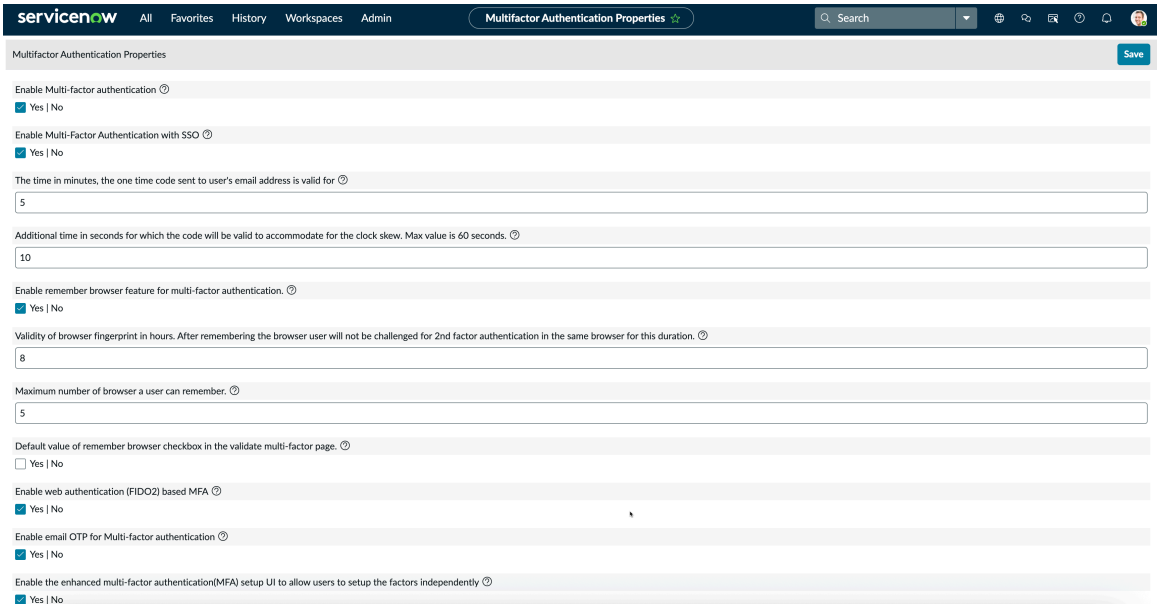
Note:
MFA with SSO login is available if the *glide.authenticate.mfa.with.multisso.enabled* property is set to **true**.

Role required: admin

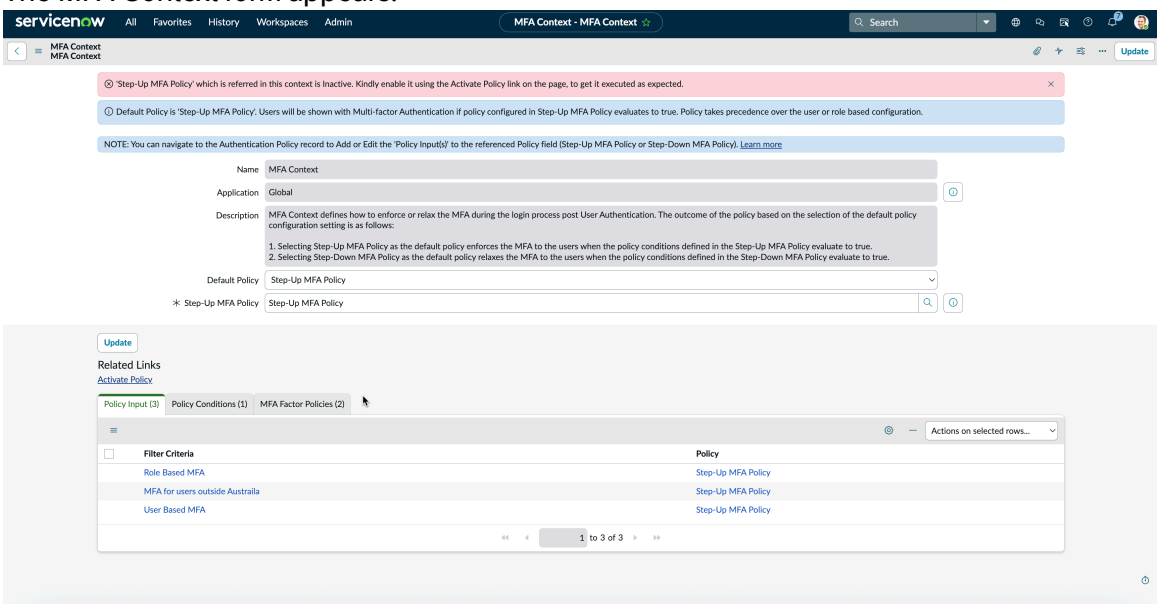
Procedure

1. Navigate to **All** > **Multi-factor Authentication** > **Properties**.
2. Enable the **Enable Multi-factor authentication** and **Enable Multi-factor Authentication with SSO** check boxes.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



3. Click **Save**.
4. Navigate to **Multi-factor Authentication** > **MFA Context**.
   The MFA Context form appears.



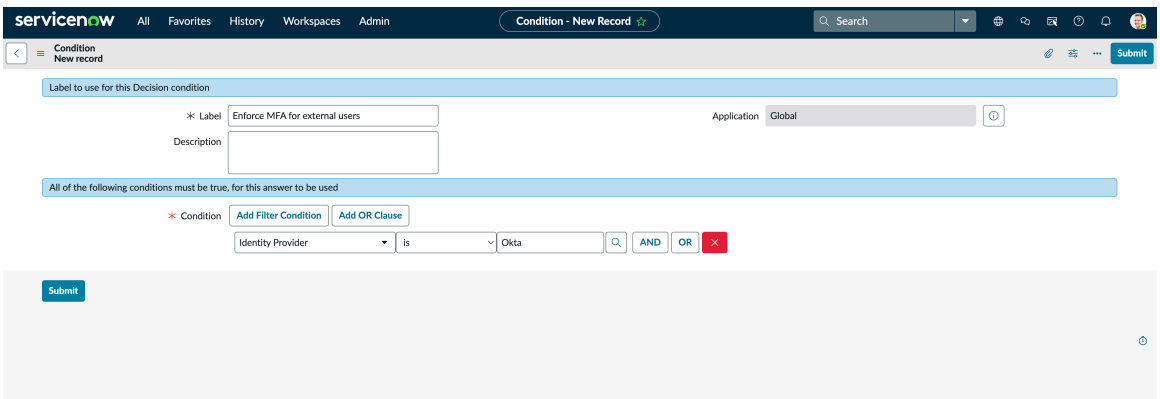
> **Note:**
> By default, the policy is **Step-Up MFA Policy**. Users are shown with Multi-factor Authentication if a condition configured in **Step-Up MFA Policy** evaluates to **true**. Policy takes precedence over the user or role-based configuration.

5. **Optional:** To edit a policy, go back to the Authentication Policy record, change the conditions, and come back.
   When you navigate to the Authentication Policy record, you can add or edit the 'Policy Inputs' to the referenced Policy fields, **Step-Up MFA Policy** or **Step-Down MFA Policy**.
6. To set a new policy condition, click **Policy Conditions**.
7. Click **New**.
8. On the form, fill in the fields.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Conditions form

Fields	Description
Label	Unique name for the condition that you want to create for the label.
Description	The policy condition description.
Conditions	The type of condition that you want to apply for the policy. You can add filter conditions and 'OR' clauses. **Note:** Adding various filter conditions and clauses enables you to challenge MFA for specific users.



Example

To set up your conditions, consider the following example. Assume that you want the authentication scheme with the identity provider as your condition for external users. You can set the conditions as follows:

a. Select **Authentication Scheme** and set the criteria as **Single Sign-On** or **Username and Password**.

   Based on this selection, the user is provided with an SSO-based login or login form to specify the user name and password.

b. Select **Identity Provider** and specify the provider as the IDP record for which you want to enable MFA. For example, **Okta**.

Based on this selection, if the user logs in with SSO, the user is not challenged with MFA. In contrast, if the user logs in using Okta, then the user is challenged with MFA.

9. Click **Submit**.

Reset Multi-factor Authentication (MFA) for users

Administrators can reset MFA for users who deleted the app, lost access to the device, or have no alternative MFA associated with their device.

Before you begin

Role required: admin

The following procedure describes how a ServiceNow® administrator can reset the MFA validation to unblock users and enable them to re-register MFA.

Procedure

1. Navigate to **All** > **Multi-factor Authentication** > **User Multi-factor Setup**.
2. Search for the user that you want to unblock.
3. Set the Validate to **false**.
4. Navigate to **All** > **Multi-factor Authentication** > **Web Authentication** > **User Public Credentials (sys_user_public_credential**.
5. Search for the user that you want to unblock.
6. Delete all the records for this user.
7. Navigate to **All** > **Multi-factor Authentication** > **User Recent User Factors**.
8. Search for the same user.
9. Delete all the records for this user.

Result

When the unblocked user enters the credentials and logs in, the **Enable multi-factor authentication (MFA)** page is displayed. The user can follow the steps on the page to re-register MFA.

Reference topic - Multi-factor Authentication

Reference topic related to the configuration of MFA.

User Multi-factor Authentications

To access the details about the user's MFA, navigate to **All** > **Multi-factor Authentication** > **User Multi-factor Setup**.

User Multi-factor Authentications

Field	Description
User	The username of the user
Bypasses remaining	The total number of bypasses that is remaining for the user.
Multi-factor secret	The details of the multi-factor secret.
Validated	Is the multi-factor validated. Changing the value to **false** invalidates the existing authenticator app setup.

Note:
The recently used MFA factors by the users is available in the User Recent Used Factors module. Navigate to **All** > **Multi-factor Authentication** > **User Recent User Factors**. For more information, see User Recent Used Factors.

Multi-factor Browser Fingerprints

To access the details about the user's browser fingerprints, navigate to **All** > **Multi-factor Authentication** > **Multi-factor Browser Fingerprints**.

Multi-factor Browser Fingerprints

Field	Description
User	The username of the user
Browser	The browser that the user used.
Browser Fingerprint	The browser fingerprint details.
Browser Fingerprint Cookie	The browser fingerprint cookie details.
Browser Fingerprint Cookie Expiry	The browser fingerprint cookie expiry details.

User Recent Used Factors

To access the details about the user's recently used factors, navigate to **All** > **Multi-factor Authentication** > **User Recent User Factors**.

User Multi Factor Setups

Field	Description
User	The username of the user
Multi Factor Type	The multi-factor type the user used for log in.
Is Recent Factor	The user's recent multi-factor detials.

MFA Metrics

View the different MFA metrics to understand the MFA adoption and usage.

MFA related metrics are available in Security Center. Security Center is a free application that you can download from the ServiceNow Store. For more information about Security Center, see Security Center landing page.

On Security Center, use the bar at the top of the page to navigate between the security monitoring console sections and select **Security Metrics** tab.

Following are the MFA metrics:

- Users enrolled for MFA: Total count of users enrolled to use MFA.
- Users using MFA bypass: Total count of users who are circumventing multi factor authentication.
- High privileged non-mfa user: Total count of high-privileged users that are not using MFA.
- Active MFA users: Total count of MFA users that are active on your instance.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Locked out MFA users: Total count of MFA users who are locked out on your instance.
- Local logins not protected by MFA: Users that logged in without MFA.

For more information about Security Metrics, see Security metrics.

Using Multi-factor authentication

Learn how to use multi-factor authentication tools to securely access your instance.

Login with MFA

ServiceNow requires authenticator applications that support Time-based One-time Passwords (TOTP). ServiceNow tests MFA with the following authenticators:

- Google Authenticator
- Microsoft Authenticator
- LastPass Authenticator
- Authy
- FreeOTP
- Duo
- Okta Verify

Note:

- Other authenticators not listed might also be compatible, but are not tested by ServiceNow.
- For information related to browser specific behavior change, see this KB article.

Register an authentication app

Authenticator App You can use authenticator apps to use a second factor of authentication.	If your administrator has enabled multi-factor authentication (MFA) on your instance, you are prompted for a second authentication after entering your user name and password. For details on the MFA login process, see Log in with Multi-factor Authentication.
Validation with Authenticator app Enter the code displayed on your authenticator app to login.	If you haven't configured a second form of authentication, you will see a configuration page after logging in to guide you through the process of setting up an authentication app. For details on this setup, see Set up Multi-factor authentication for the first time.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

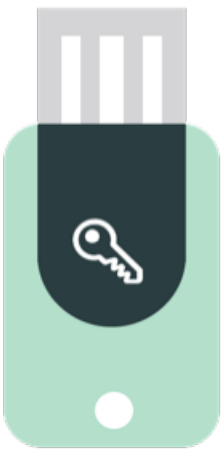
Register an authentication device

After you've configured an authentication app, you can register other methods for authentication.

Biometric authenticators

You can use biometric authenticators like fingerprint or facial recognition as your second MFA authentication. If your administrator allows this option, you can configure biometric authenticators using the steps in Register a biometric authenticator.

Hardware key authenticators



Hardware keys are physical security devices you can use for authentication. You can register a hardware device for use with your instance using the steps in Register a hardware security key.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Validation with Biometric or Hardware Key Use the biometric or hardware key to login.	Use the Biometric or Security Key to login. 
Register a phone number for OTP

SMS Use SMS based OTP to require users who attempt to login.	When users attempt to login to ServiceNow, SMS OTP is sent to the mobile number associated with the sys_user record. Users can enter the six-digit verification code that it sent to the mobile device and verify their identity. Validation with SMS Use the validation with SMS to login based on the OTP generated.	You need to enter the 6-digit code sent to the mobile number to login. The code sent is valid for the next 5 minutes. You can use resend code to again send the code.

Register an Email address for OTP

Email address Use Email based OTP to require users who attempt to login.	When users attempt to login to ServiceNow, Email OTP is sent to the email address associated to the user. User's can enter the six-

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

digit verification code that it sent to the mobile device and verify their identity.

Validation with Email Use the validation with Email to login based on the OTP generated.	You need to enter the 6-digit code sent to the email address to login. The code sent is valid for the next 5 minutes. You can use resend code to again send the code. 
Set up Multi-factor authentication for the first time

If your administrator enabled MFA on your profile but you have not yet set up the application, you can set it up upon login.

Before you begin

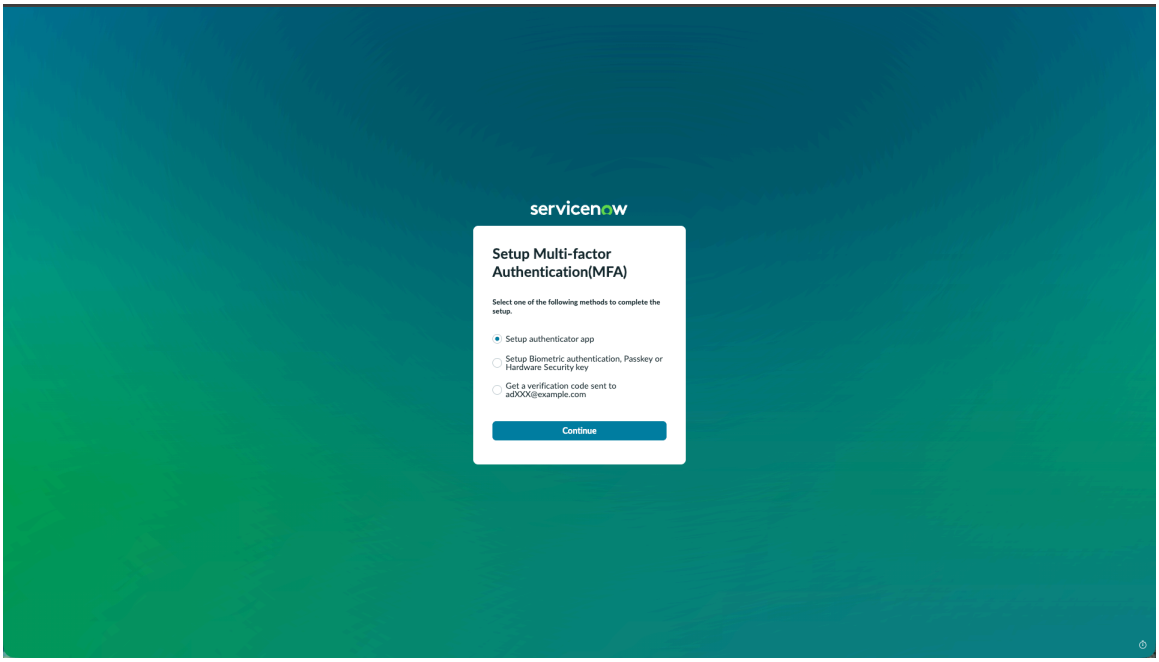
Role required: none

Procedure

1. Log in to your instance using your user name and password.

The multi-factor authentication set up screen intercepts your login.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Note:
If you want to skip the authentication set up now, click **Bypass Setup**. You can bypass multi-factor authentication for a limited number of times that your administrator allows. Eventually, you must configure multi-factor authentication.

2. Select one of the following methods to complete the mfa setup.

a. Setup authenticator app

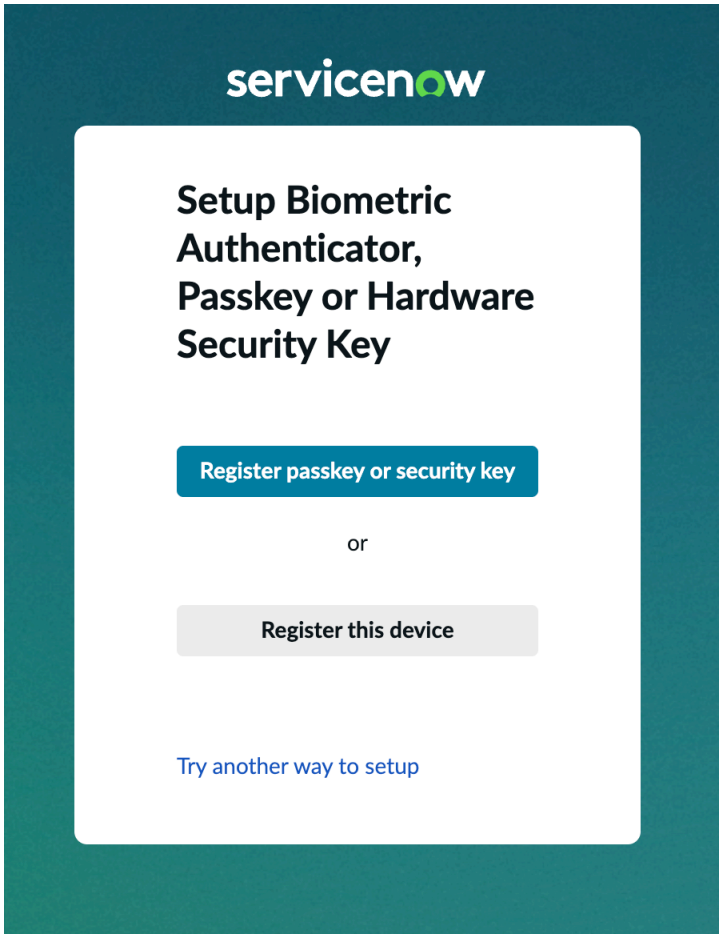
Follow the instructions on the screen to pair device and login.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

b. Setup Biometric authentication, Passkey or Hardware Security key

Select either of the option to complete the setup.

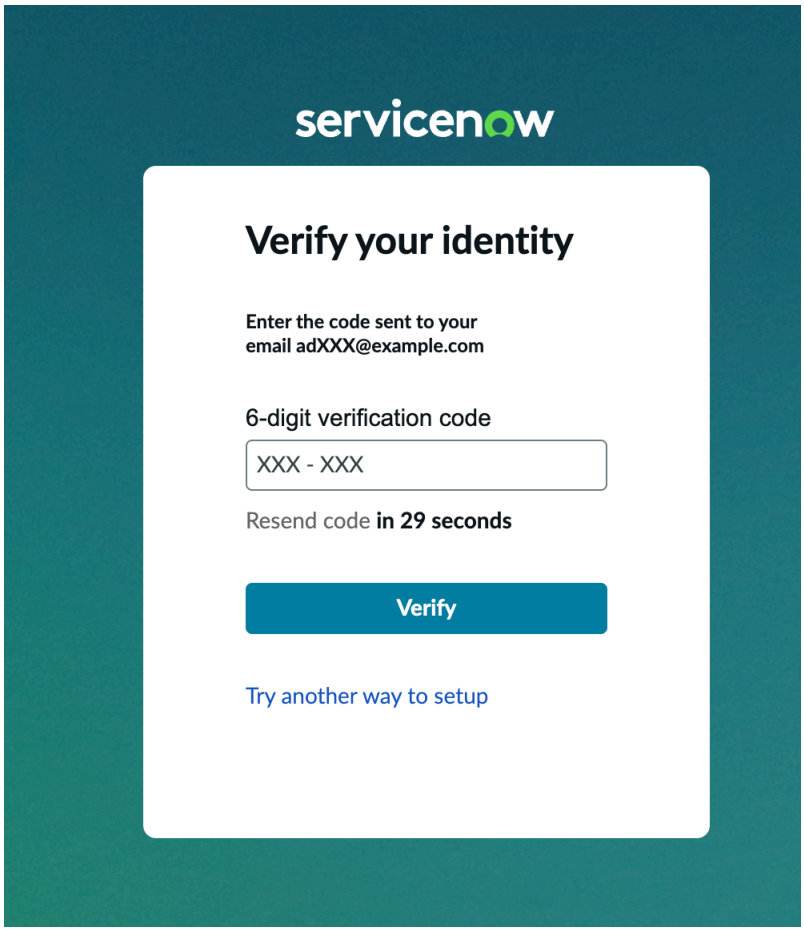
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



c. Get a verification code sent to your email

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Enter the verification code that is sent to your email.



After the successful completion of the either of the setup, you are logged in to the instance.

Set up Multi-factor authentication on your user profile

Enable multi-factor authentication for your account in your user profile settings.

Before you begin
Role required: none

Multi-factor authentication must be enabled on your instance.

Note:
Your administrator may require that you use multi-factor authentication. In this case, you are automatically prompted when you log in. See Set up Multi-factor authentication for the first time. Use the process below if your administrator allows you to opt-in to multi-factor authentication.

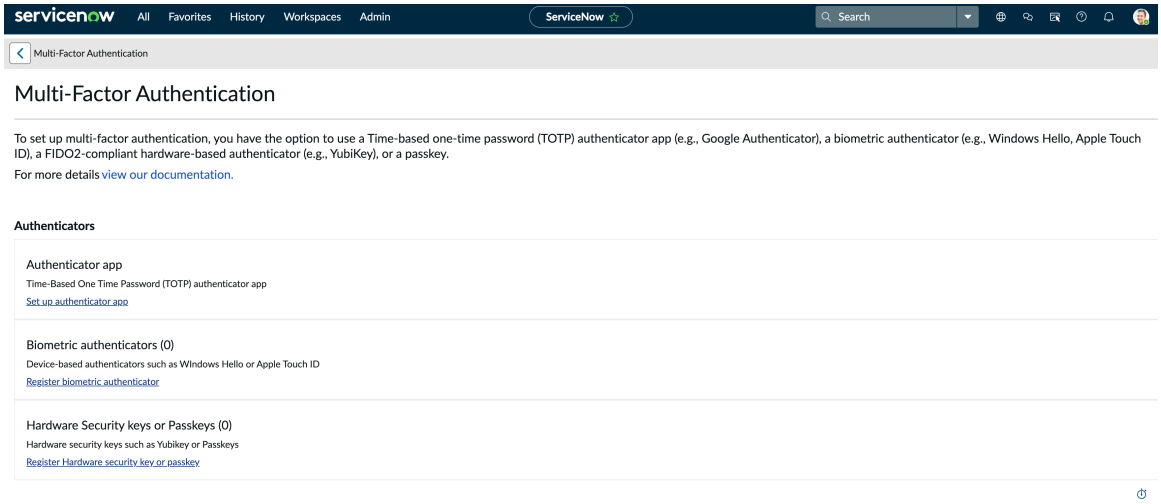
Procedure

1. Navigate to **All** > **Self-Service** > **My Profile**.

   Note:
   You can also access your profile by clicking on your user name in the instance header.

2. In your user profile, click **Configure Multi-factor Authentication** in the **Related Links** section.
3. Choose the MFA Authenticator type that you would like to use.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



MFA Authenticators

MFA Authenticators	Description
Authenticator App	Time-Based One Time Password (TOTP) authenticator app Select **Set up authenticator app** and follow the instructions on the screen to register for an authenticator app as the second factor for authentication. Biometric authenticators	Device-based authenticators such as Windows Hello or Apple Touch ID Select **Register biometric authentication** and follow the instructions on the screen to register for an authenticator app as the second factor for authentication. Hardware Security Keys	Hardware security keys such as YubiKey Select **Register hardware security keys** and follow the instructions on the screen

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

MFA Authenticators	Description
	to register for an authenticator app as the second factor for authentication. 
Result

Multi-factor authentication is enabled for your user account. You will be prompted to use multi-factor authentication the next time you log in.

Note:
You cannot disable multi-factor authentication on your account after you have enabled it. If you need to disable multi-factor authentication, contact your administrator.

Log in with Multi-factor Authentication

Login with MFA when it is enabled by your administrator on your instance.

Before you begin

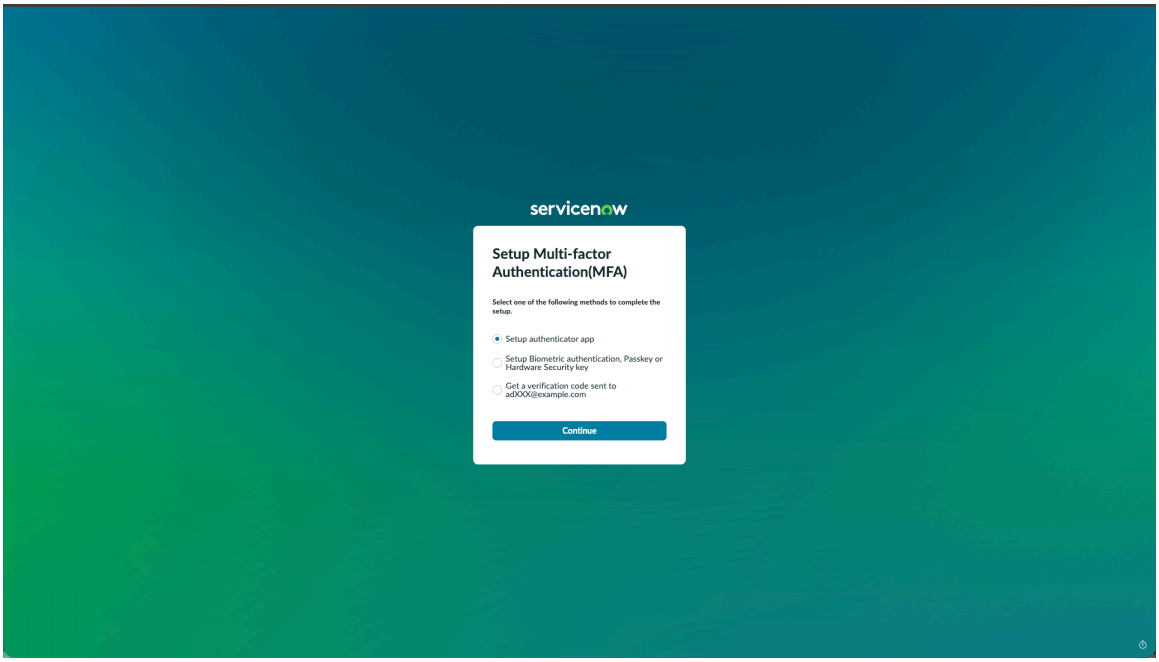
You must have MFA enabled for your profile. You can enable it yourself on your user profile or your administrator can enable it for you.
Role required: none

Note:
The last used MFA verification factor is automatically shown for the users in the subsequent log in.

Procedure

1. Go to the URL of your instance to open the login screen.
2. Enter your user name and password.
3. Click **Log in**.
   The multi-factor authentication screen appears.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



4. Select one of the methods to complete the MFA setup.
   For more information about each setup, see Set up Multi-factor authentication for the first time.

   If you wish to postpone the setup, select **Postpone setup**. The maximum number of time you can postpone the setup is displayed on the screen and this value is configured by your administrator.

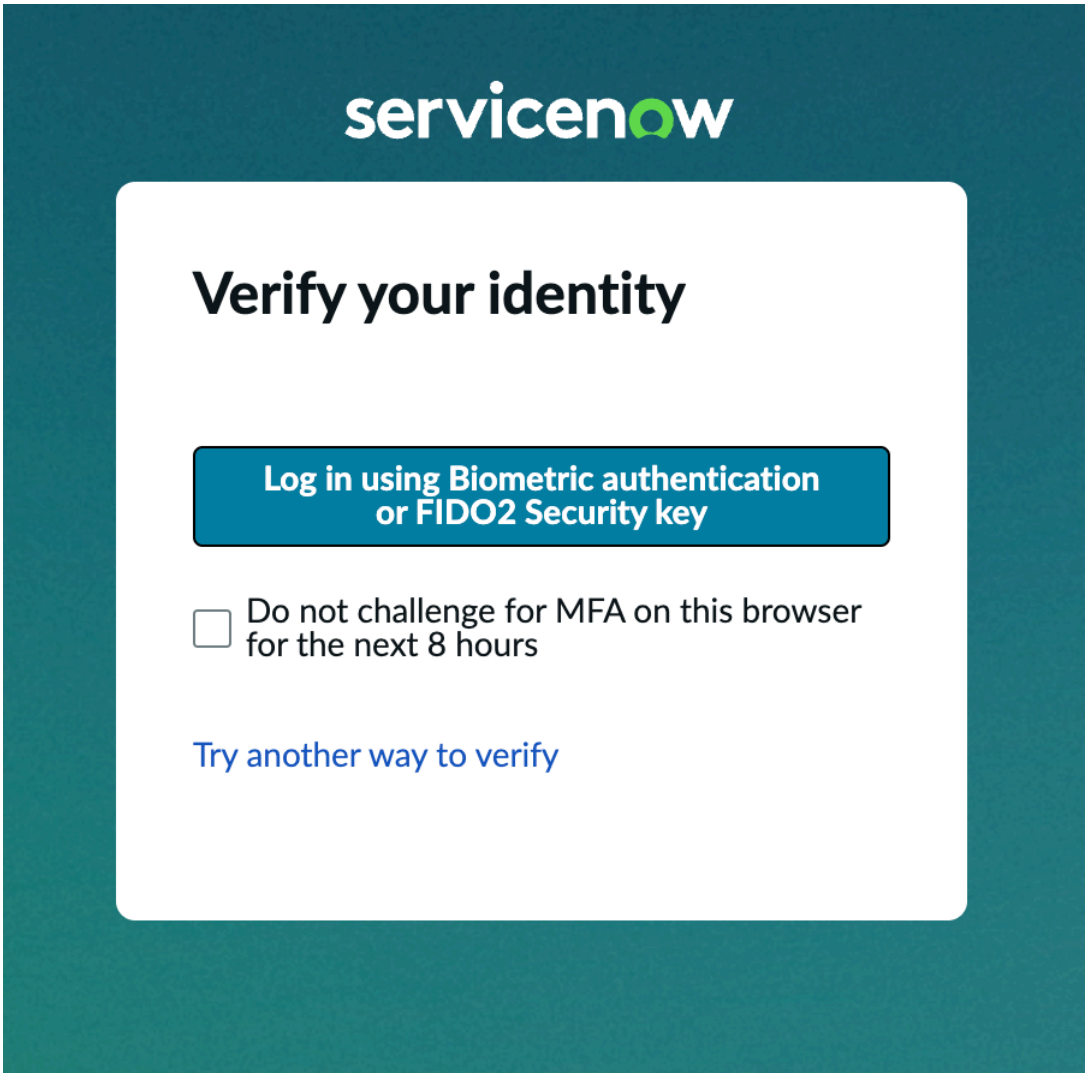
Result

If you have already setup MFA, the recently used factor is displayed when you login your instance after entering your username and password.

Example: Recently used MFA factor

If the recent used factor was Biometric login, then upon login using your username and password, you're directly displayed with the Biometric MFA setup screen.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



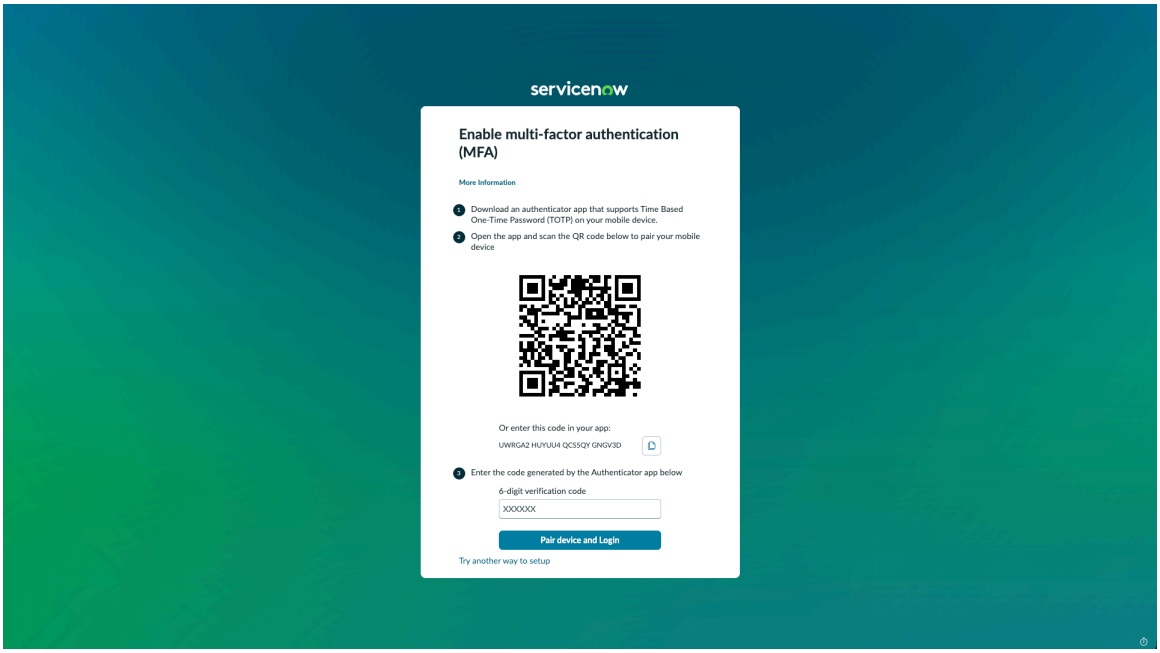
Authenticator Applications

Use third party authenticator applications to generate temporary MFA pass codes.

An authenticator application is third-party software that generates temporary pass-codes. You can use these pass-codes along with your password to login into an instance that requires multi-factor authentication (MFA).

If your administrator has enabled MFA on your instance, you see a prompt for a pass-code after entering your user and password during login.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



ServiceNow requires authenticator applications that support Time-based One-time Passwords (TOTP).

ServiceNow tests MFA with the following authenticators:

- Google Authenticator
- Microsoft Authenticator
- LastPass Authenticator
- Authy
- FreeOTP
- Duo
- Okta Verify

Note:
Other authenticators not listed might also be compatible, but are not tested by ServiceNow.

Change an Authenticator app

Generate a new code to change an Authenticator app on your device.

Before you begin

You must have MFA enabled for your profile. You can enable it yourself on your user profile or your administrator can enable it for you.
Role required: none

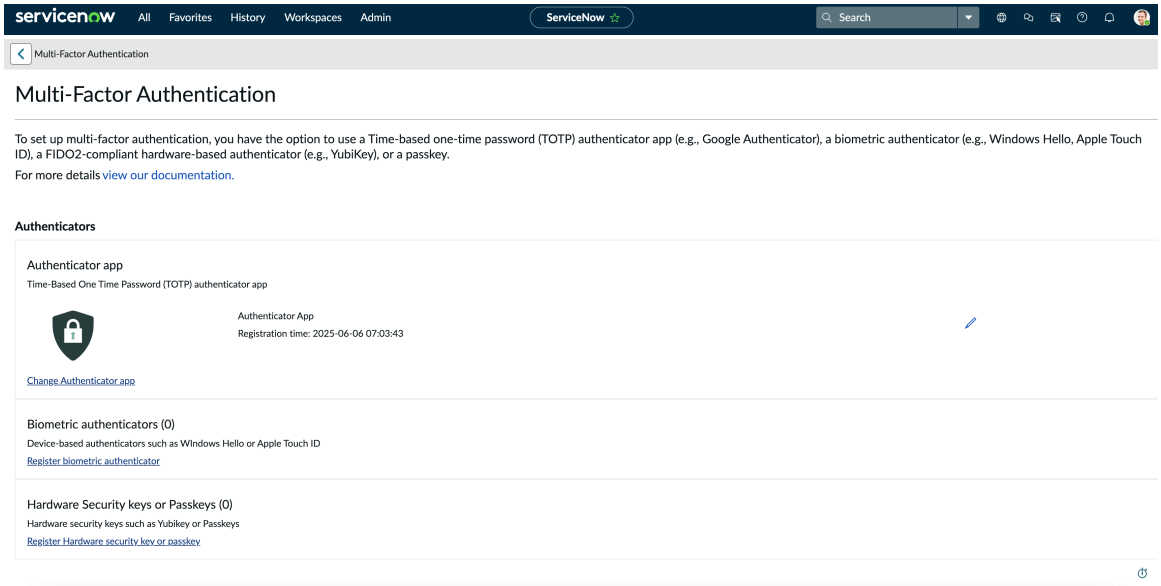
Procedure

1. Navigate to **All** > **Self-Service** > **My Profile**.

   Note:
   You can also access your profile by clicking on your user name in the instance header.

2. In your user profile, click **Muti-factor Authentication** in the **Related Links** section.
3. Under **Authenticator app**, select the edit icon.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

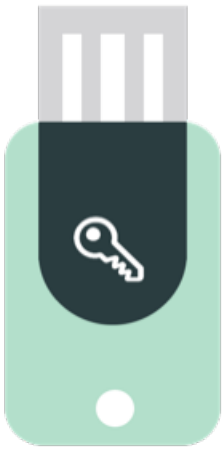


4. In the Change authenticator code window, click **Change**.
5. Follow the directions on the screen to register the authenticator app with the device.

Web Authentication

Your users can use hardware keys or their device's biometric readers (FIDO2) to authenticate to an instance.

Hardware keys



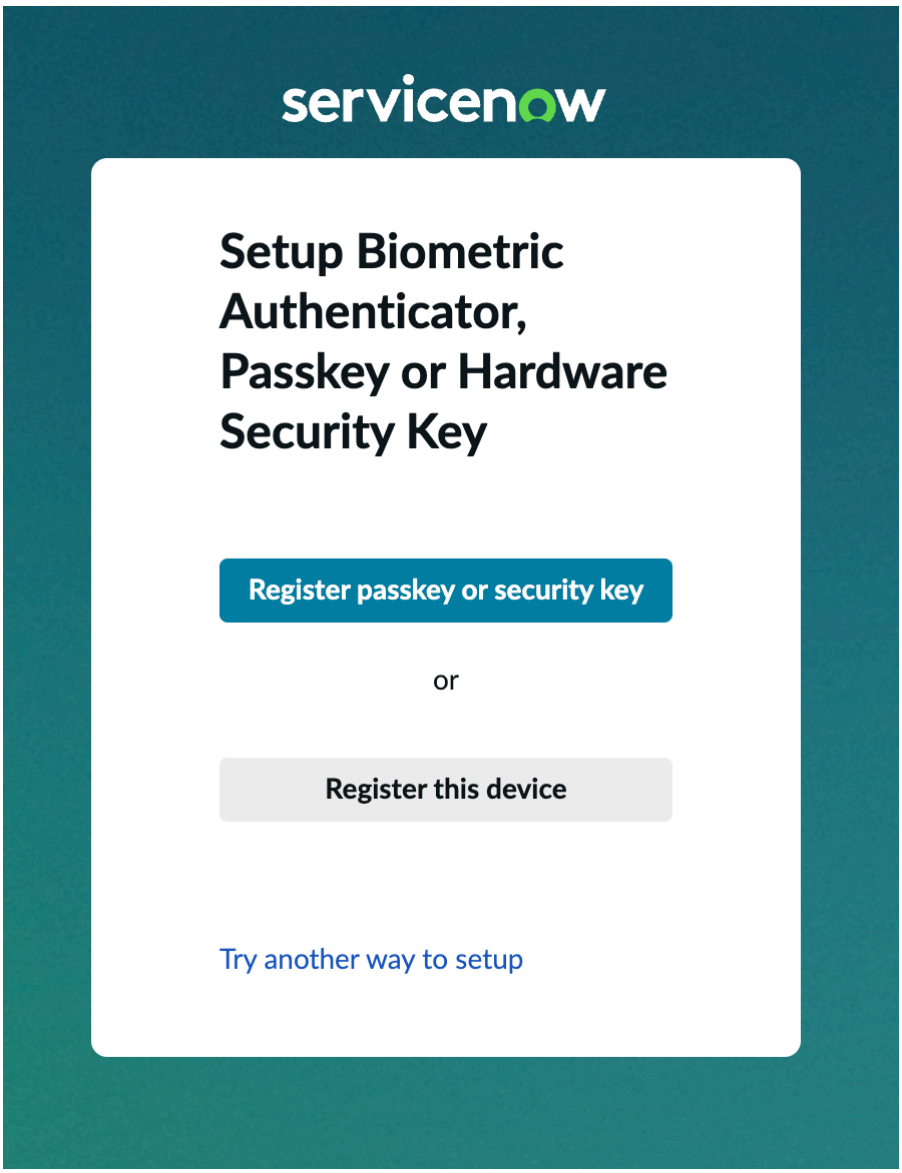
Hardware keys are physical hardware that you can use to authenticate. Hardware keys are inserted into a port on your device to provide authentication. For details on registering hardware keys, see Register a hardware security key.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Biometrics

Biometric authenticators use fingerprint or facial recognition to identify users. Your users can use these authenticators on their devices as part of the multi-factor login process. For details on registering biometric authenticators, see Register a biometric authenticator.

Choose the second factor that you wish to authentication and authenticate to your instance.



To configure the web authentication plugin, see .

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Register a biometric authenticator

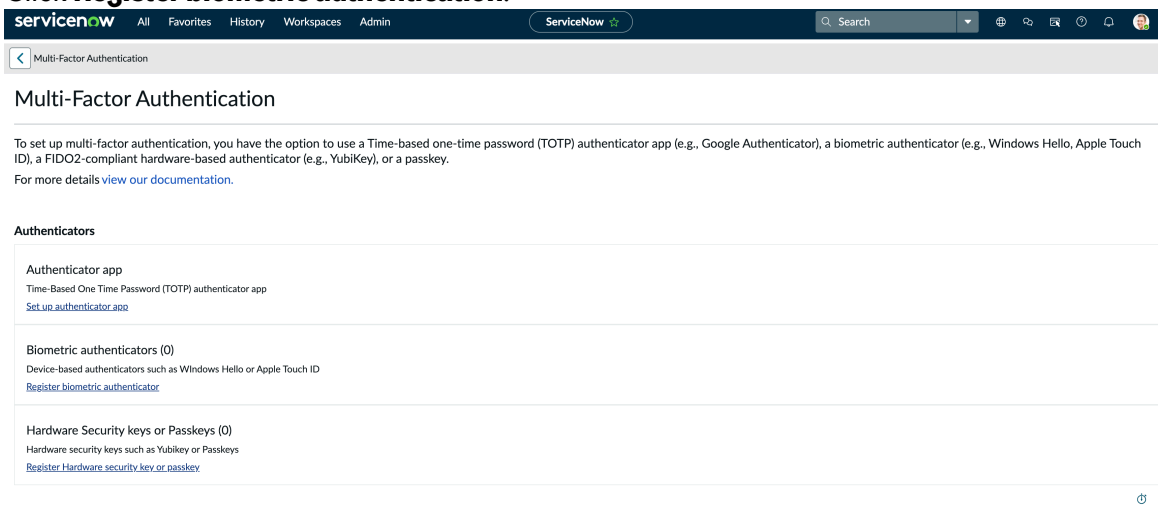
Register a biometric authenticator to use as part of your MFA login.

Before you begin

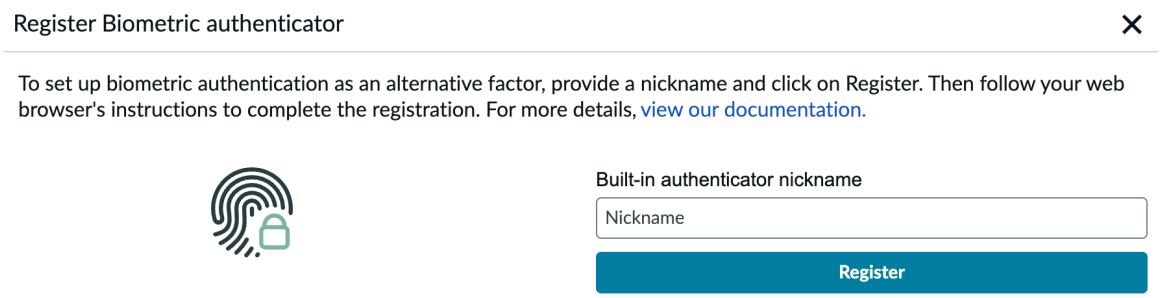
Role required: none

Procedure

1. Navigate to **All** > **Self-Service** > **My Profile**.
2. Under **Related Links**, click **Multi-factor Authentication**.
   The multi-factor authentication page opens.
3. Click **Register biometric authentication**.



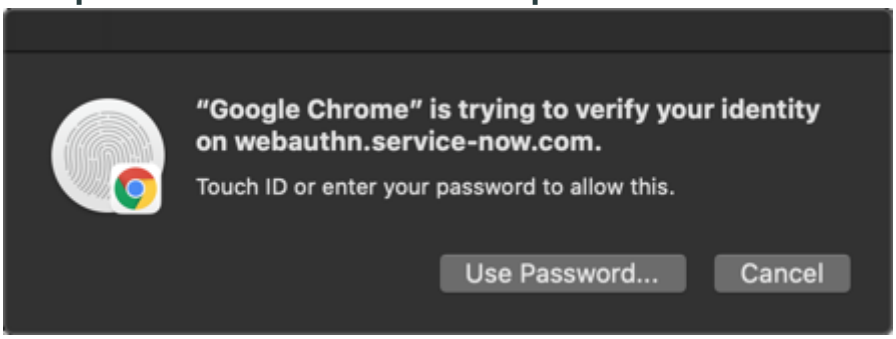
4. Enter a nickname for your authenticator and click **Register**.



5. When prompted, follow the instructions on the screen to authenticate with your biometric authenticator.
   This message will vary based on your specific authenticator.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Example of a biometric authentication request



After authenticating successfully, you see a confirmation window. Click X to close the confirmation.

Result

Your biometric authenticator is registered. You can see the biometric authenticator listed on the Multi-factor authentication page.

Register a hardware security key

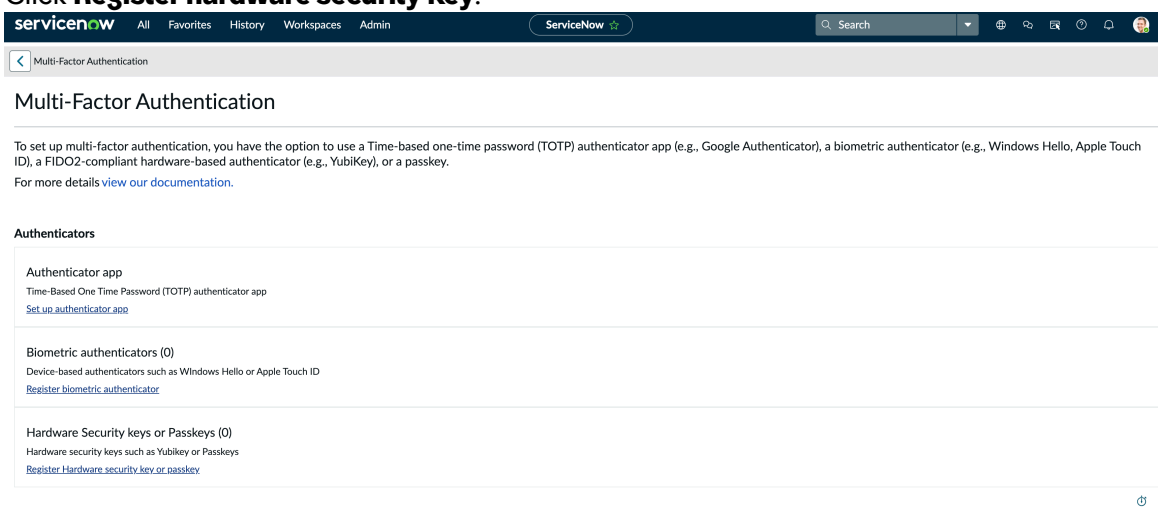
Register a hardware key to use as part of your MFA login.

Before you begin

Role required: none

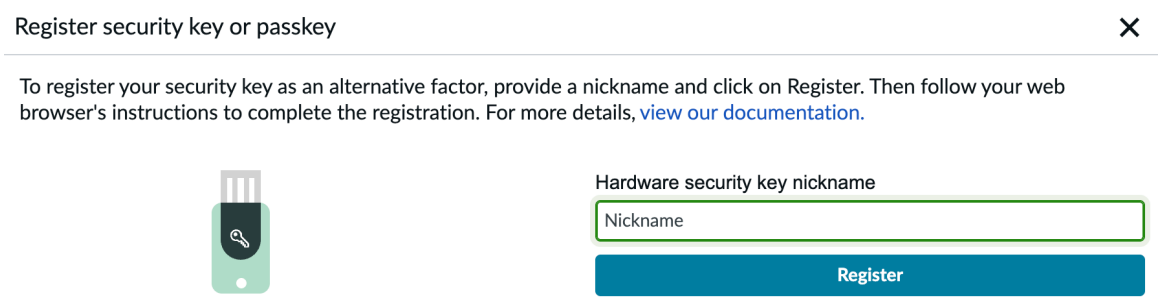
Procedure

1. Navigate to **All** > **Self-Service** > **My Profile**.
2. Under **Related Links**, click **Multi-factor Authentication**.
   The Multi-factor authentication page opens.
3. Click **Register hardware security Key**.



4. Enter a nickname for your hardware key and click **Register**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



5. When prompted, insert your hardware security key and activate it.
   After authenticating successfully, you see a confirmation window. Click X to close the confirmation.

Result

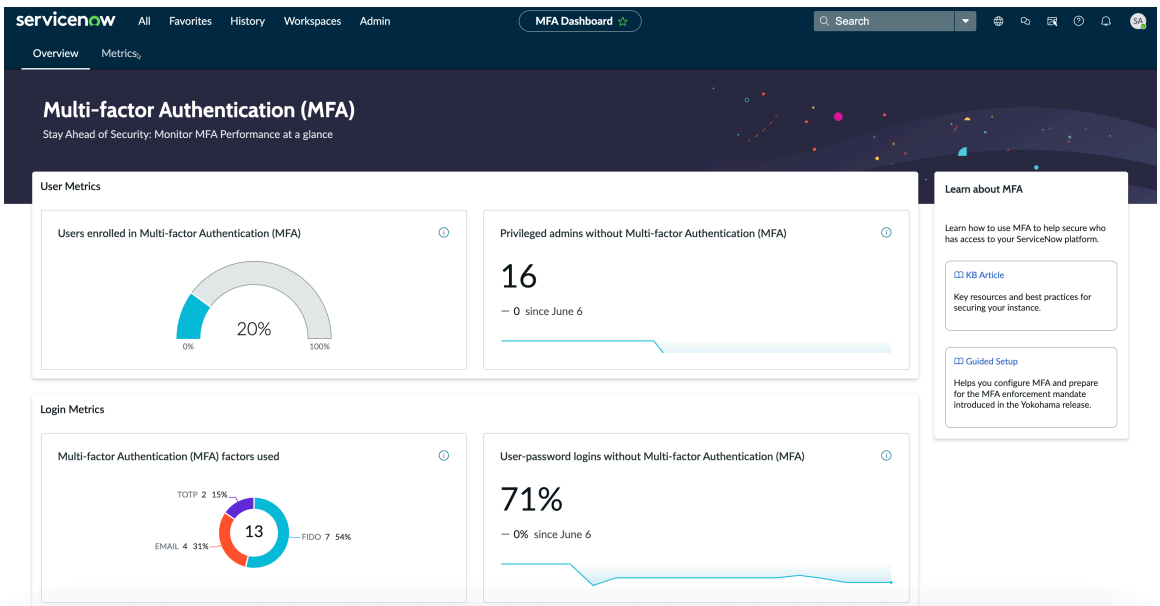
Your hardware key is registered. You can see the hardware key listed in the Multi-factor authentication page.

MFA Dashboard

View the different MFA metrics to understand the MFA adoption and usage.

The MFA enhances security by requiring an additional verification step during the login process. The MFA Dashboard helps you to monitor and manage MFA settings for your organization. This dashboard provides an overview of MFA user enrollment, privileged admins who haven't opted MFA, and compliance. You can use it to ensure that all users have MFA enabled for enhanced security.

To access the MFA Dashboard, navigate **All** > **Multi-factor Authentication** > **MFA Dashboard**.



Note:
You must enable MFA to view the metrics. For more information, see Multi-factor Authentication system properties.

Following are the types of metrics displayed on the MFA Dashboard:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- User Metrics
- Login Metrics

User Metrics

The following table provides details of the User Metrics in the MFA Dashboard.

User Metrics

Metrics	Description
Users enrolled in Multi-factor Authentication (MFA)	The percentage of users who can perform username-password based login and enrolled in MFA. This metric provides an insight on the adoption of MFA by the users over a period of time. **Note:** Ideally, the score should gradually increase and should be 100% over a period of time (Refreshed once a day to collect records for a day before).
Privileged admins without Multi-factor Authentication (MFA)	Privileged admins not using MFA is a significant risk to platform security. It's recommended that you get these people using MFA. **Note:** Privileged admins are the users who have at least one role from the sys_icenter_role_config table. (Refreshed once a day to collect records for a day before).

Login Metrics

The following table provides details of the Login Metrics in the MFA Dashboard.

Login Metrics

Multi-factor Authentication (MFA) factors used	Classification of MFA factors used during the username-password based login.
User-password logins without Multi-factor Authentication (MFA)	The percentage of username-password based logins without MFA. This metric provides an insight on the adoption of MFA over a period of time.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Login Metrics (continued)

	Note: Ideally, the score should gradually decrease and should be zero over a period of time (Refreshed once a day to collect records for a day before).

User Metrics

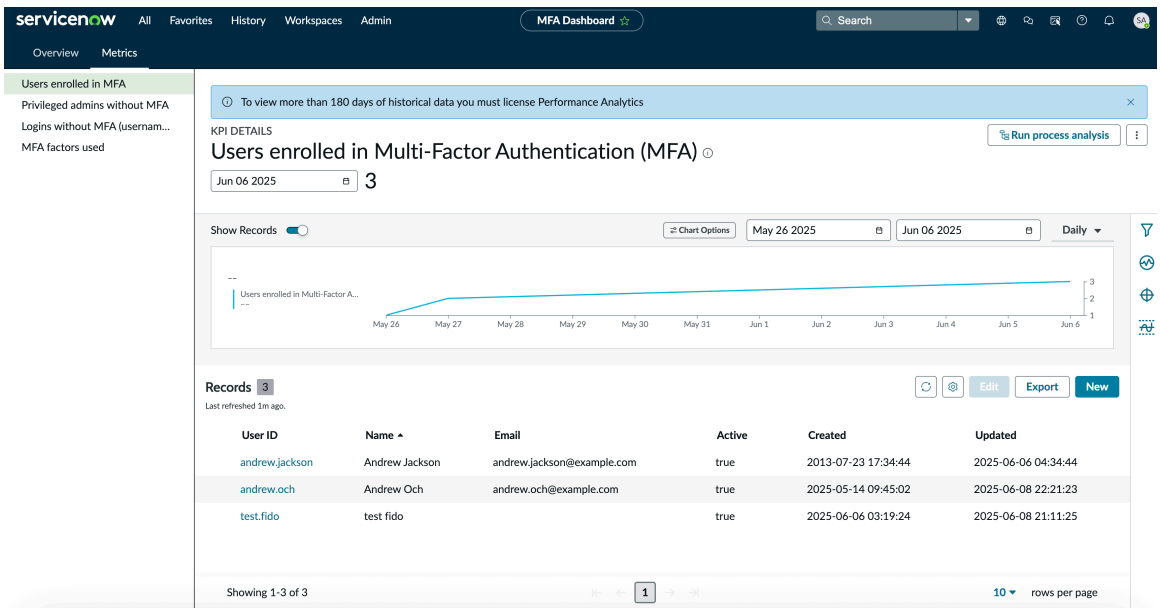
User Metrics displays the user MFA enrollment trends on ServiceNow.

User Metrics on the MFA Dashboard are as follows:

- Users enrolled in Multi-factor Authentication (MFA)
- Privileged admins without Multi-factor Authentication (MFA)

Users enrolled in Multi-factor Authentication (MFA)

The percentage of users who can perform username-password based login and enrolled in MFA. This metric provides an insight on the adoption of MFA by the users over a period of time.

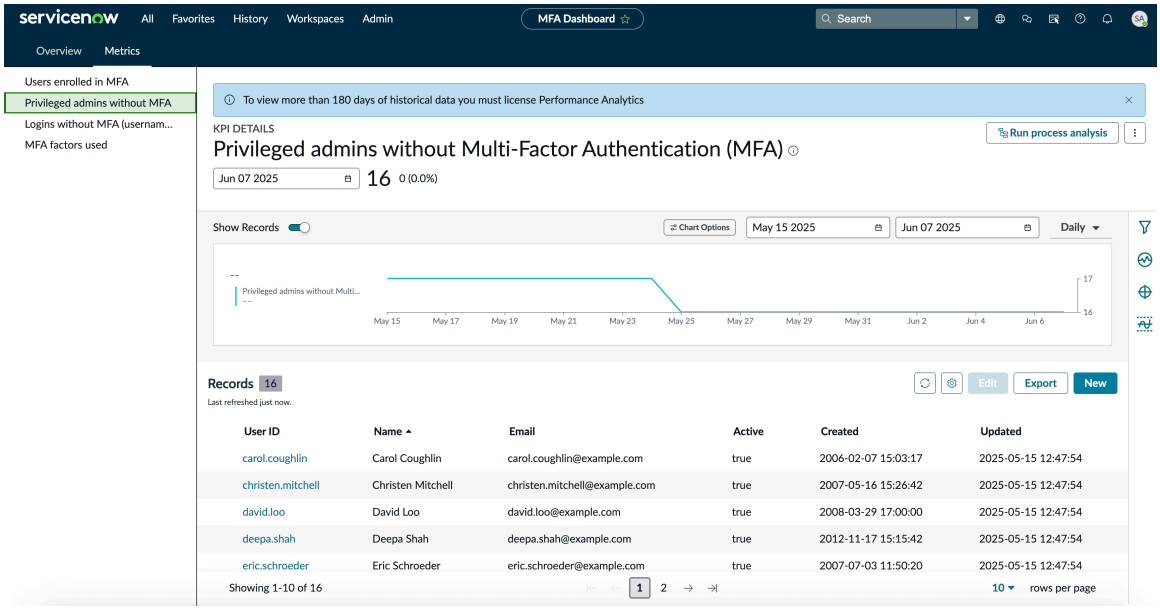


Note:
Ideally, the score should gradually increase and should be 100% over a period of time (Refreshed once a day to collect records for a day before).

Privileged admins without Multi-factor Authentication (MFA)

Privileged admins not using MFA is a significant risk to platform security. It's recommended that you get these people using MFA.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Note:
Privileged admins are the users who have at least one role from the **sys_icenter_role_config** table. (Refreshed once a day to collect records for a day before).

Log in Metrics

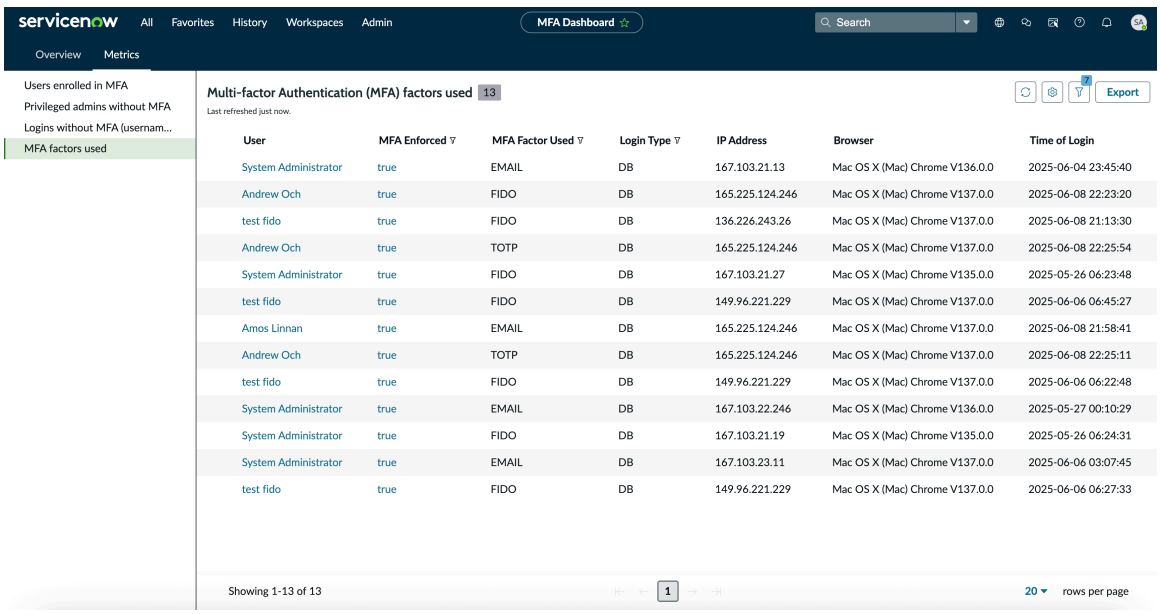
Log in Metrics displays the log in trends on the ServiceNow.

Log in Metrics on the MFA Dashboard are as follows:

- Multi-factor Authentication (MFA) factors used
- User-password logins without Multi-factor Authentication (MFA)

Multi-factor Authentication (MFA) factors used

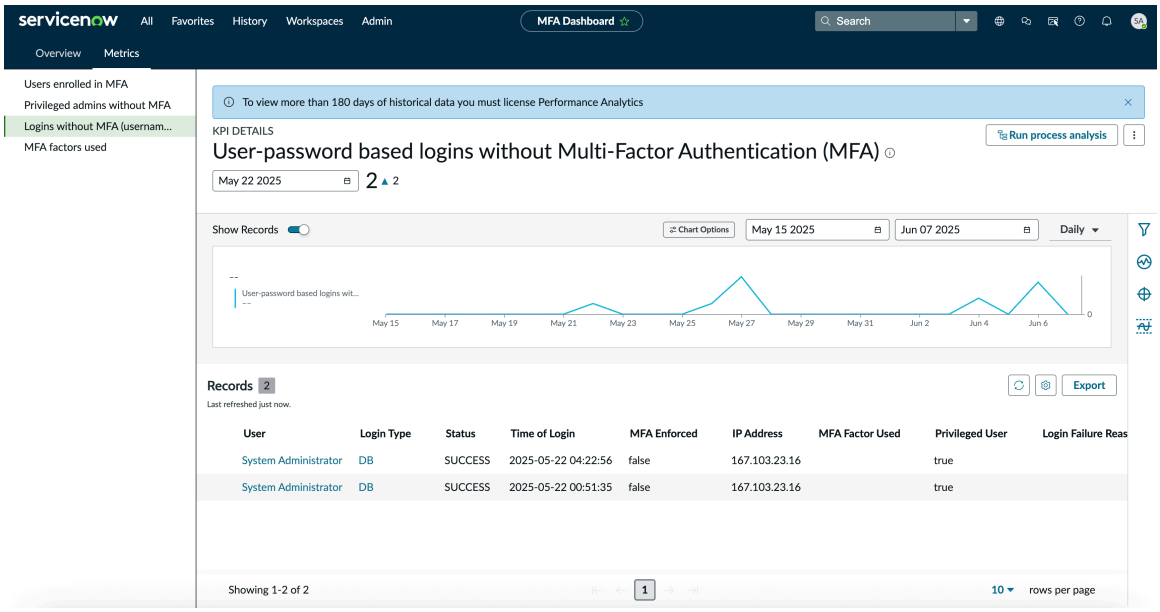
Classification of MFA factors used during the username-password based login.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

User-password logins without Multi-factor Authentication (MFA)

The percentage of username-password based log ins without Multi-factor authentication. This metric provides an insight on the adoption of MFA over a period of time.



Note:
Ideally, the score should gradually decrease and should be zero over a period of time (Refreshed once a day to collect records for a day before).

MFA Guided Setup

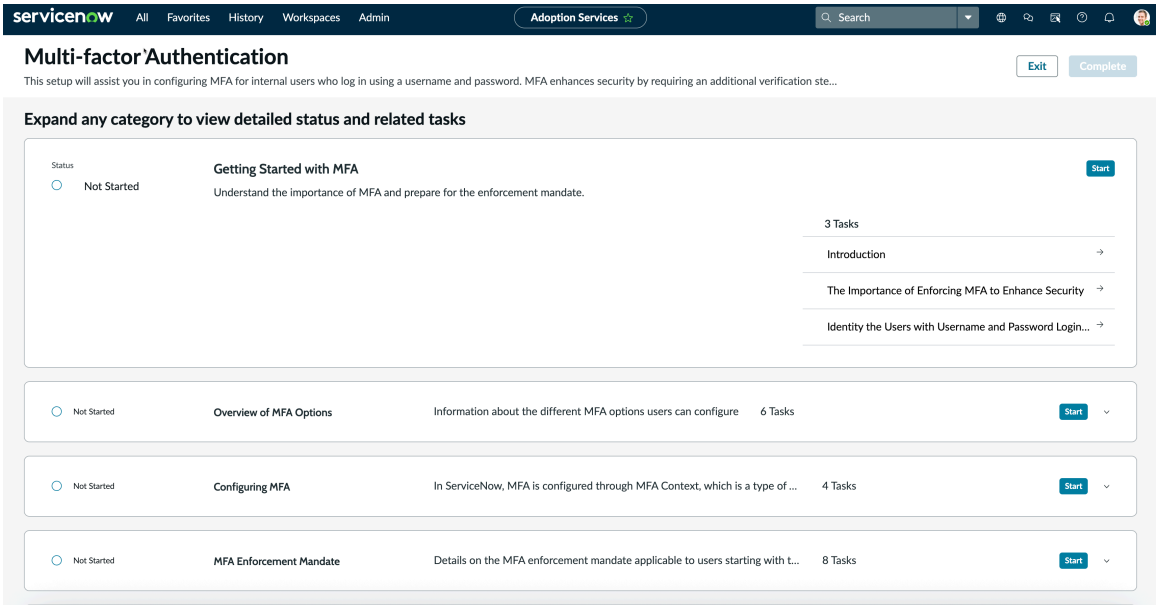
Use the MFA Guided Setup to step through the initial configuration of the MFA module and understand the requirements for MFA enforcements.

The MFA Guided Setup assists you to configure MFA for internal users who log in using a username and password.

To access the MFA Guided Setup, navigate to **All** > **Adoption Services** > **Guided Setup**. You can choose **All applications** and choose **Multi-factor Authentication**.

The Multi-factor Authentication guided setup opens in a new tab. Expand any category to view detailed status and related tasks on the page displayed.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Complete the following task to become familiar with the MFA configurations:

- Getting Started with MFA
- Overview of MFA Options
- Configuring MFA
- MFA Enforcement Mandate
- User Communication and Onboarding
- Monitoring

To know more about how to use the Guided Setup, see Guided Setup.

Multi-Provider single sign-on (SSO)

External SSO allows organizations to use several SSO identity providers (IdPs) to manage authentication as well as retain local database (basic) authentication.

Multi-Provider Single sign-on (SSO) is an authentication method that enables users to access multiple applications with one login and one set of credentials.

For using SSO, you must understand the following:

- *`Service Providers`*: When users trying to access the ServiceNow instance are redirected to an Identity Providers (IdP) to validate their credentials after successful validation users are allowed to access the instance. Here, ServiceNow acts as a service provider and relies on an Identity Provider (IdP) for handling user authentication and granting access to the instance.
- Identity Providers: IdPs are external systems that validates the users identity and credentials to access a system.

To establish an SSO with to access ServiceNow, you must activate Multi-Provider Single sing-on (SSO) you must install the *`Integration - Multiple Provider Single Sign-On Installer (com.snc.integration.sso.multi.installer)`* plugin. For more information, see Activate Multi-Provider SSO plugin.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

After successful installation of the plugin, you can customize the SSO properties, access tables and scripts that are shipped along with the plugin. For more information, see Multi-Provider SSO properties, tables, and scripts.

ServiceNow supports the following SSO methods:

- OpenID Connect
- SAML 2.0
- Digest Authentication (Token based authentication).

Choose the SSO method based on your requirement and learn more about how you need to prepare for configuring SSO. You must perform several steps to set up Multi-Provider SSO, including configuring properties, creating identity providers (IdPs), and configuring users to use SSO. For more information, see Multi-Provider SSO configurations.

After a successful configuration, the active IdPs in the instance are listed on the ServiceNow. You can list various SAML or OIDC Identity Providers (IdPs).

Note:
A maximum of 10 IdPs can be listed on the login page. The IdP options won't be visible if the instance has Domain Support - Domain Extensions Installer (*com.glide.domain.msp_extensions.installer*) plugin installed and enabled.

The Zurich release of ServiceNow include the following enhancements on SSO:

- **List SAML IdPs on login page**: Log in using SAML and OIDC IdPs that are listed on the login experience on both the platform and portal login pages, making it easier for users to select their preferred IdP. Earlier only OIDC IdPs were listed.
- **Select group for Auto-Provisioning**: Select specific groups during the auto-provisioning configuration for SAML and OIDC, ensuring users are assigned to the correct groups automatically.
- **Configure multiple OIDC record using the same well-known URL**: Simplify OIDC setup by allowing the creation of OIDC records using the same well-known URL, streamlining the configuration process.
- **Enhanced External logout complete page**: Display of login failure reason to the user. Provision to log in again to ServiceNow on the external logout complete page in case of successful logout.
- **Enhanced error message**: Display of generic error message when Single Logout (SLO) is unsuccessful, ensuring consistent and secure communication.
- **Notification enhancements for SAML Certificate and Encryption Keystore**: Receive timely notifications to the admins for SAML certificate and Encryption Keystore updates expiry, ensuring that your SSO configurations remain secure and up-to-date.

Example: Why organization needs SSO

A globally dispersed corporation might require one SSO provider for their employees, a different one for their vendors, and local database authentication for their administrators. Alternatively, a company might implement SAML 2.0 and a digest token authentication solutions on the same instance.

Activate Multi-Provider SSO plugin

This integration requires the Integration - Multiple Provider Single Sign-On Installer (com.snc.integration.sso.multi.installer) plugin.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin

Role required: admin.

The com.snc.integration.sso.multi.installer plugin can also be used for OIDC, SAML, and Digest.

Role required: admin

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the Integration - Multiple Provider Single Sign-On Installer (com.snc.integration.sso.multi.installer) plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

   Note:
   When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

   You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Multi-Provider SSO properties, tables, and scripts

The Integration - Multiple Provider Single Sign-On Installer plugin includes the following system properties, tables, and scripts.

Properties

Multi-Provider SSO adds the following system properties.

Multi-Provider SSO properties

Name	Description
glide.authenticate.multisso.debug	Enables (true) or disables (false) debug logging for the multi-provider SSO integratio • Type: true | false • Default value: false
glide.authenticate.multisso.enabled	Enables (true) or disables (false) multi-provider SSO. • Type: true | false • Default value: false

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Multi-Provider SSO properties (continued)

Name	Description
	Note: Setting this property to false will not disable multi-provider SSO if Account Recovery (ACR) is also enabled on the instance. To log in with a username and password ACR must also be disabled using the *glide.sso.acr.enable* property. For details on this property see Account recovery properties.
glide.authenticate.multissov2_feature.enabled	This property determines if the MultiSSOv2 version is enabled in the instance.
glide.authenticate.show.max.sso.login.option	This property determines the maximum number of SSO options displayed on the log screen. **Note:** The default value is 5. The maximum value of the property is 10.
glide.authenticate.show.max.sso.login.option	This property determines the maximum number of IdPs displayed on the login scree "glide.authenticate.show.max.sso.login.optio **Note:** The default value is 10.

Tables

Multi-Provider SSO adds the following tables.

Multi-Provider SSO tables

Name	Description
SSO Properties [sso_properties]	Stores data for each IdP, schema, common SSO data, and so on.
SAML 2 Update 1 Properties [saml2_update1_properties]	Stores data for SAML 2.0 Update 1 configurations such as SAML certificates.
Digest Properties [digest_properties]	Stores data for digest token authentication configurations.
SSO Federation [sso_federation]	Stores data for each SSO federation.
OIDC Identity Provider [oidc_identity_provider]	Stores data for Open ID connect based identity providers.

Scripts

Multi-Provider SSO adds the following scripts.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Multi-Provider SSO scripts

Name	Description
MultiSSO	Allows a customer to have an SSO type defined on a company basis.
MultiSSOLogin	Allows each domain to have their own login script.
MultiSSOLogout	Allows each domain to have their own logout script.
MultiSSO_OIDC_custom	Allows a user to define a custom Single Sign-on script for OIDC connection.
MultiSSO_OIDC_logout_custom	Allows a user to define a custom logout script for OIDC connection.
MultiSSO_Abstract_Core	Provides a base class for all multi-provider SSO classes.
MultiSSO_ClientHelper	Provides a client callable utility functions for multi-provider SSO.
MultiSSO_DigestedToken	Provides a base system logic for digested token authentication.
MultiSSO_SAML2_Update1	Provides logic to process SAML 2.0 Update 1 authentication for a multi-tenant single sign-on.

Multi-Provider SSO configurations

You must perform several steps to set up Multi-Provider SSO, including configuring properties, creating identity providers (IdPs), and configuring users to use SSO.

Refer the following topics to know more about each of the configurations.

- Multi-Provider SSO (SAML) IdP authentication flow
- Configure Multi-Provider SSO properties
- Create an external identity provider
- Configure users for Multi-Provider SSO

Configure Multi-Provider SSO properties

Configure SSO properties and also add a property to the System Properties table to configure an IdP inclusion list.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **Multi-Provider SSO** > **Administration** > **Properties**.
2. Select the **Enable Multi-Provider SSO** check box.
   This selection adds the link Use external login to the login page.
3. To update the user table with the users in the IdP, select the **Enable Auto Importing** option.
4. To enable the debug messages to appear at the bottom of the content frame, select the **Enable debug logging for the Multi-Provider SSO integration** check box.
   If enabled, the debug logging feature slows down performance and uses up disk space to generate logs.

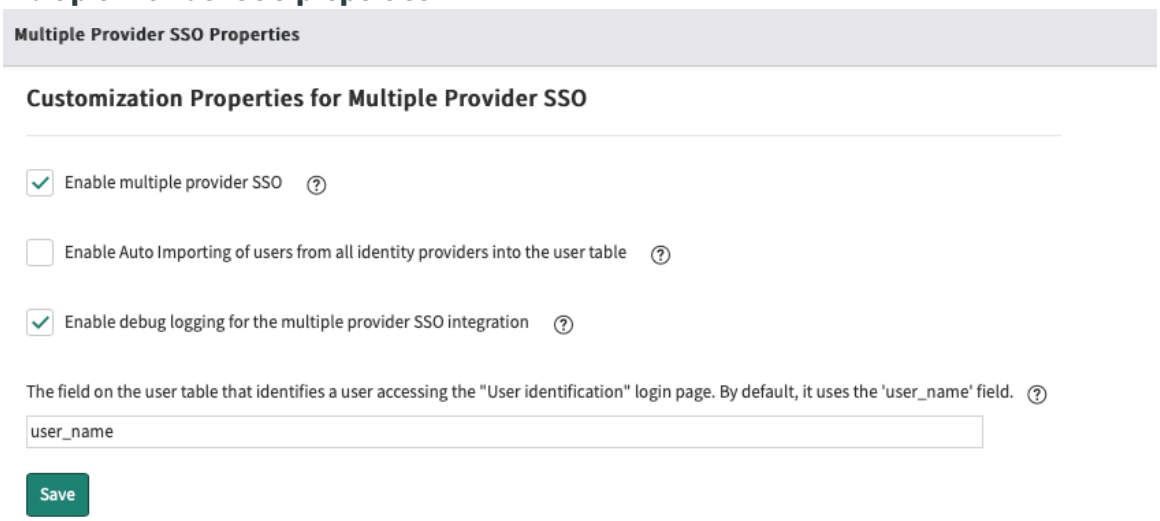
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

5. In the property **The field on the user table that identifies a user accessing the User identification login page**, enter the field on the User table that contains the value the IdP uses to identify the user. The default value is **user_name**.

   The default value is **user_name**.

   Multiple Provider SSO properties

6. Click **Save**.
7. Instruct your users to click the **Use external login** link when they log in to the instance.

Related topics

SAML user provisioning

Create an external identity provider

After you have configured the multi-provider SSO properties, you can update or create new SAML 2.0 or digest token identity provider.

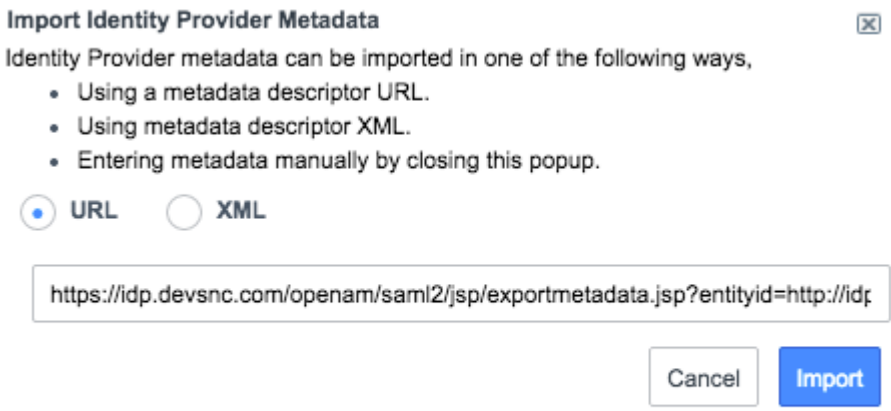
Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **Multi-Provider SSO** > **Identity Providers**.
2. To edit an identity provider record, click the record.
   - For digest token configurations, manually update the properties.
   - For SAML2 Update 1 configurations, automatically update the identity provider metadata with the **Import Identity Provider Metadata** related link or update the properties manually.
   - For OpenID Connect configurations, manually update the properties.
3. To create a new identity provider, click **New**.
   - For digest token configurations: Click **Digest SSO** and enter the digest properties for multi-provider single sign-on.
   - For SAML2 configurations: Click **MultiSSOV2_SAML2_custom** and import the identity provider metadata from a URL, as XML, or manually enter the identity provider information.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



- For OpenID Connect: Click **OpenID Connect** and enter client ID, client secret, and well known configuration URL.

4. To make the IdP the failover IdP that is used when the default IdP is not available, select the **Default** check box.

   If you have SAML 2 Update 1 active and you upgrade to the Fuji release, the SAML 2 Update 1 IdP is selected as the default failover. No default failover IdP is selected for new instances or if you are upgrading from a release on which SAML 2 Update 1 is not active.

   Note:
   The metadata import process automatically creates a certificate record for the identity provider. Navigate to the **x509 Certificate** module to see the certificate.

   Note:
   Certificates for single-sign on should always be in PEM format to work with SAML certificates.

5. If E-Signature is active, configure the Identity Provider form and add the **Assertion Consumer URL for eSignature authentication** field.
   In most cases, this URL is: `https://YOURINSTANCE.service-now.com/consumer.do`. However, if you employ a customized method of handling the SAML authentication for E-Signature, you can set up your own consumer URL. If you are only using SAML 2.0 Update 1 and not using Multi-Provider Single Sign-on, configure the assertion consumer URL with E-signature SAML properties.

Generate instance service provider (SP) metadata for SAML

As part of your SSO configuration, you can generate the instance SP metadata to provide to the IdP.

Before you begin
Role required: admin

About this task
The IdP needs the instance SP metadata to authenticate and forward requests.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Choose your installed SSO plugin:

Option	Description
Multi-Provider SSO	Navigate to **Multi-Provider SSO** > **Identity Providers**. Choose an IdP and click the **Generate Metadata** button. The integration automatically generates the instance's SP metadata from the system property settings.
SAML 2 SSO	Navigate to **SAML 2 Single Sign-on** > **Metadata**. The integration automatically generates the instance's SP metadata from the system property settings.

2. Copy the SP metadata in the text box.

   For example:

```
<EntityDescriptor xmlns="urn:oasis:names:tc:SAML:2.0:metadata"
 entityID="https://yourinstance.service-now.com">
  <SPSSODescriptor AuthnRequestsSigned="false"
 WantAssertionsSigned="true"
 protocolSupportEnumeration="urn:oasis:names:tc:SAML:2.0:protoc
ol">
  <SingleLogoutService
 Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-Redirect"
 Location="https://yourinstance.service-now.com/navpage.do" />

 <NameIDFormat>urn:oasis:names:tc:SAML:1.1:nameid-format:emailA
ddress</NameIDFormat>
  <AssertionConsumerService isDefault="true" index="0"
 Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"
 Location="https://yourinstance.service-now.com/navpage.do" />
  <AssertionConsumerService index="1"
 Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"
 Location="https://yourinstance.service-now.com/consumer.do"/>
 </SPSSODescriptor>
</EntityDescriptor>
```

3. Provide the instance SP metadata to the IdP.
   For example, SSOCircle allows a user to provide the SP metadata online.

Configure users for Multi-Provider SSO

Administrators can configure Multi-Provider SSO for individual users or for all users who belong to a company. You cannot configure Multi-Provider SSO for groups.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **Multi-Provider SSO** > **Identity Providers**.
2. Right-click an identity provider record and select **Copy sys_id**.
3. Copy the data to your clipboard.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Navigate to a user record or a company record.
5. Configure the form and add the **SSO Source** field.
6. In the **SSO Source** field, enter one of the following:
   - **SAML users**: enter **sso:** followed by the sys_id of the identity provider's record.
   - **SSO Federation users**: enter **federation:** followed by the sys_id of the federation record.
7. Click **Update**.

Test IdP connections

Testing the connection to an IdP validates the settings before enabling external authentication.

Before you begin

Role required: admin

About this task

The Jakarta release supports the test connection within a pop-up window. If your IdP does not work correctly with this option, you can turn off this default setting.
Refresh MultiSSO IDP Metadata job fetches and updates the certificate for the IdP while create, update, or testing the connection.

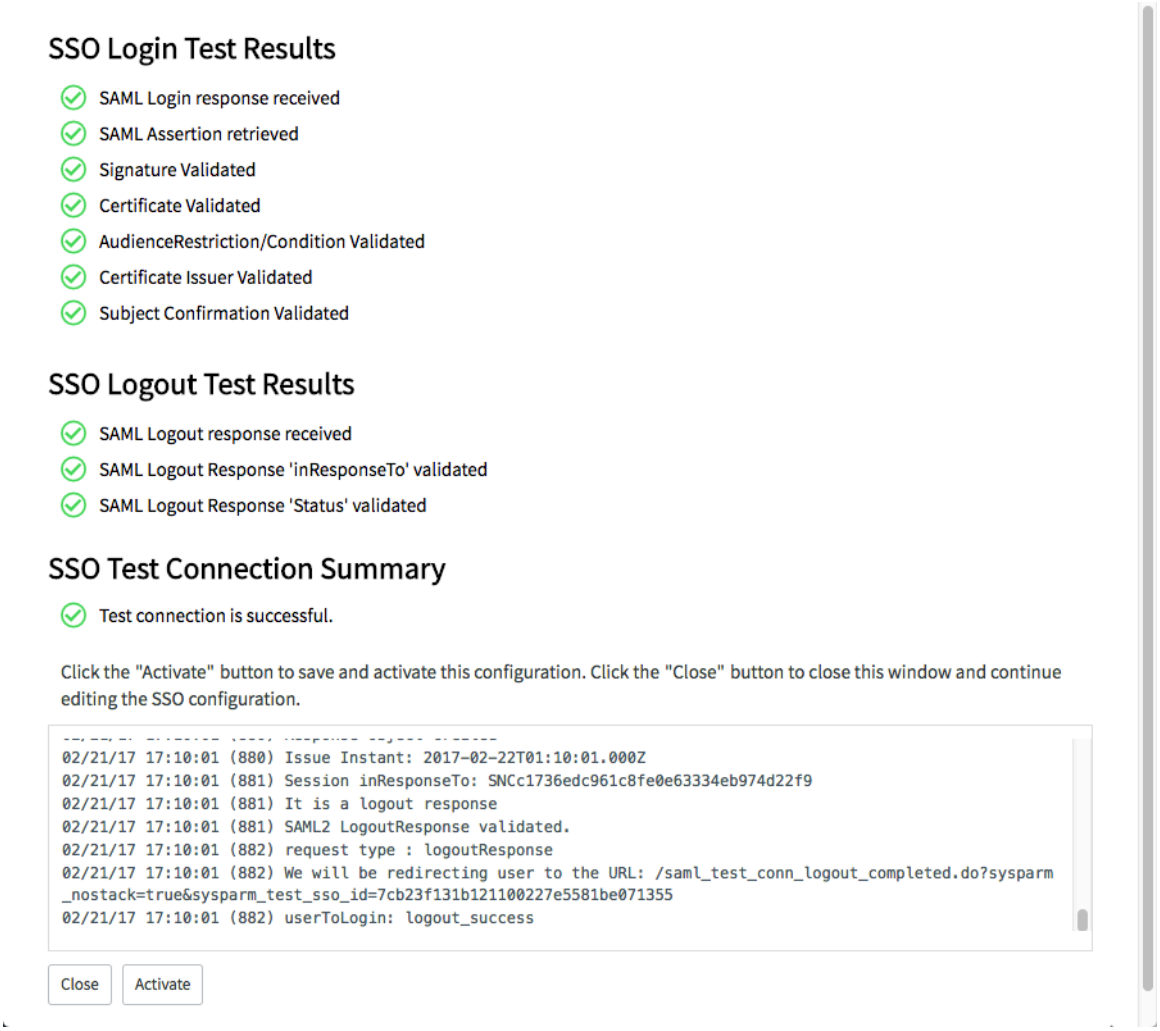
Note:
For some idp cases, If test connection is failed, they need to create glide.authenticate.multisso.test.connection.mandatory with the value as false and you can activate the idp without the test connection.

Procedure

1. Navigate to **All** > **Multi-Provider SSO** > **Identity Providers**.
2. Select a defined IdP or click **New** to define a new IdP.
3. **Optional:** Configure an identity provider if setting up a new IdP.
4. Click **Test Connection**, enter login credentials for the IdP to check login.
   You cannot activate the IdP until you have a successful test connection. If the test fails, you can update to save your configuration information, but you cannot activate this configuration.
5. Verify results using the **SSO Test Results/Summary** or the **Testing SSO Logs** section to see log messages.
   If there are any errors, refer to the Multi-SSO (SAML 2.0) errors and fixes

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

6. Click **Cancel** when testing is complete.



Common IdP connection errors

The following table describes some of the common IdP connection errors and their solutions.

Troubleshooting IdP test connections

Error messages	Solution
User Field validation failed. Invalid User Field '<field name>' is not a field on sys_user table.	Verify the contents of the User table field you selected matches the SAML NameID token.
Assertion issuer is invalid.	Verify **Identity Provider URL** contains a valid URL to your IdP. Each IdP URL must be unique.
AudienceRestriction validation failed.	Verify the **Audience URI** contains a valid URL to your instance.
Cannot logout of IdP's session.	Verify the **SingleLogoutRequest** URL contains a valid URL to your IdP's logout service.
Signature did not validate against the credential's key.	Verify the IdP has a valid certificate installed.

Troubleshoot script issues with SAML

Troubleshoot script issues with SAML. You might encounter script issues if SAML is already active at the time that you activate Multiple Single Sign-On and if you already customized the installation exits.

Before you begin
Role required: admin

Procedure

1. Back up the modified installation exit SAML2SingleSignon_update1 and script include SAML2_update1.
2. Revert both the installation exit and script include to the version that is available with the baseline system.
3. Activate or upgrade the **Integration - Multiple Provider Single Sign-On Installer** plugin. The system upgrades SAML and all necessary files to SAML 2 Update 1.
4. Open the Multiple SSO properties page and select the **Enable Multi-Provider SSO** check box to enable it.
5. Put the SAML2SingleSignon_update1 installation exit changes into the baseline script include **MultiSSO_SAML2_Update1 and the SAML2_update1** script include changes into the baseline SAML2_update1 script include.

Log in using Multi-Provider SSO

The recommended and most efficient method for users to log in using Multi-Provider SSO is to use a specifically configured URL.

Before you begin
Role required: admin

About this task
After multi-provider SSO is configured, you can send a URL to your users with the correct IdP in the parameter string. For example:

```
/login_with_sso.do?glide_sso_id=<sys_id of the sso configuration>
```

After a user successfully logs in to the IdP page, a cookie containing the IdP sys_id is added to the browser. The next time the user attempts to log in, the system redirects the user to log in to the IdP server, which automatically logs in to the instance.

If a URL parameter is not set or the browser cache has been cleared, users can also do the following:

Procedure

1. Click the **Use external login** link on the login page.

   The external login page appears. Users can click **Use local login** to return to the standard login page.

2. Enter the value for the specified field on the user table that you configured in Multi-Provider SSO properties.

   The user is redirected to the IdP server, where they log in.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Result

After users successfully log in to an IdP, they are automatically redirected to that IdP whenever they attempt to access the instance. To have a user access a different IdP, send the user a URL with the new IdP information in the parameter. The new IdP overwrites the old IdP in the cookie if the user successfully logs in. If the user does not log in successfully, the old IdP information is retained in the cookie.

Enable users to choose the identity provider for login

SSO federation support enables users to choose which IdP to log in to.

Before you begin

Role required: admin

About this task

SSO federations aggregate metadata from multiple IdPs and service providers, including your instance. Federations then publish the metadata as an XML file, which includes information like IdP names and IdP certificates. Administrators can then instruct the instance to read the XML file and automatically populate the SSO Properties table with all the necessary IdP information.

Procedure

1. Navigate to **All** > **Multi-Provider SSO** > **Federation**.
2. Click **New**.
3. Fill in the fields, as appropriate (see table).
4. Click **Submit**.
5. After you configure a federation, enable the Refresh SSO Metadata scheduled job, and then configure the users who you want to access the federation IdPs. Use the sys_ID of the federation record you just created.

   Use the sys_ID of the federation record that you just created.

   The instance populates the SSO properties table with the IdP information. When users who are configured to use the federation log in, they are redirected to the discovery service URL you configured. Then they select the IdP and provide the necessary credentials. Alternatively, you can send users a URL with the IdP in the parameter.

Allowing users to choose the identity provider for login

Field	Description
Name	Enter a descriptive name for the federation.
Active	Select the check box to enable the instance to pull the XML file from the federation.
Type	Select the type of authentication this federation supports.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Discovery Service URL	Enter the URL of the discovery service for this federation. This is the site where users are directed to select an IdP and log in.
Meta Data URL	Enter the URL of the XML file that holds the federation metadata.
x509 Certificate	Select the federation certificate.
Domain	Select the domain that the data will belong to.

Note:
The InCommon federated identity management IdP is preconfigured.

Use Service Portal with Multi-Provider SSO to redirect a URL

Service Portal uses a combination of system properties and script includes to determine how the system handles URL redirects for users logging in to the portal.

Before you begin
Role required: admin

About this task
If you are using the system property to automatically redirect to your primary Identity Provider (IdP), then Service Portal automatically redirects to that IdP. If you have multiple IdPs, Service Portal shows a link on the login page to **Use external login**.

Procedure
1. Configure the Service Portal login page
2. Redirect to Service Portal after login

Account recovery (ACR)

Administrators can configure account recovery (ACR) to perform recovery activities such as addressing SSO misconfiguration or expired certificates.

Note:
Enabling ACR disables the local interactive log-ins (username or password based) when SSO is enabled to your instances.

ACR provides the following capabilities:

- Bypass your single sign-on (SSO) login to address issues with SSO configuration as an administrator.
- Log in with using SSO to perform tasks with an administrator account configured as an account recovery.
- ACR flows enable the administrators to use self-service capabilities to address account recovery when there's a need for recovery, for example, SSO miss-configuration, expired certificates.
- Reduce unauthorized access to the instance and provide a strong foundation to use ACR outside SSO use cases.

Fresh Instance

For a fresh instance to use ACR, you must do the following:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Activate Mutli-SSO plugin (`com.snc.integration.sso.multi.installer`)
- Enable ACR (`glide.sso.acr.enabled`) - This is enabled by default in case of a fresh instance.
- Before enabling SSO property (`glide.authenticate.multisso.enabled`), the administrator must enroll as an ACR user.

  Note:
  Setting this property to false will not disable multi-provider SSO if Account Recovery (ACR) is also enabled on the instance. To log in with a username and password ACR must also be disabled using the *`glide.sso.acr.enabled`* property. For details on this property see Account recovery properties.

- Administrator must set a password for local login and register MFA before enrolling as an ACR user.

Upgraded Instance

For an upgraded instance to use ACR, you must do the following:

- Activate Mutli-SSO plugin (`com.snc.integration.sso.multi.installer`)
- Enable ACR (`glide.sso.acr.enabled`)

  Note:
  In case of upgraded instance, the administrator must enable ACR.

- Before enabling SSO property (`glide.authenticate.multisso.enabled`), the administrator must enroll as an ACR user.
- Administrator must set a password for local login and register MFA before enrolling as an ACR user.

Configure account recovery users

To use account recovery, you must register at least one admin account as an account recovery user. Single sign-on can't be activated on your instance until there is at least one account configured. For details on this process, see Configure an account recovery user from the Account Recovery Properties page.

Note:
If you're upgrading an instance already using single sign-on to Rome or a later release, single-sign on will continue to function without a recovery user configured.

Account recovery configuration

The account recovery feature is included with the **Integration - Multiple Provider Single Sign-On Installer (com.snc.integration.sso.multi.installer) plugins**. The feature is enabled by default. You can change this and other account recovery settings using system properties. For details on these properties, see Account recovery properties.

Account recovery policy context

After you've registered an account recovery user and enabled single sign-on (SSO), your instance restricts all local logins. This restriction is defined in the **SSO - ACR Context** auth policy context. For more information about the context, see Account recovery context.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

For details on how authentication policies and policy contexts, and how they work on your instance, see Adaptive authentication.

Configure an account recovery user

Configure an account recovery user to perform account recovery activities on your instance.

An account recovery user is a user account that administrators can use to perform account recovery tasks, such as addressing an SSO misconfiguration or addressing expired certificates.

Note:
If you are using account recovery on your instance, you must configure an account recovery user. This step is necessary before enabling multiple-provider single sign-on on an instance.

Configure an account recovery user from the Account Recovery Properties page

Configure an account recovery from the Account Recovery properties page.

Before you begin

Role required: admin

For a fresh instance to configure ACR, you must do the following:

- Activate Mutli-SSO plugin (`com.snc.integration.sso.multi.installer`)
- Enable ACR (`glide.sso.acr.enabled`) - This is enabled by default in case of a fresh instance.
- Before enabling SSO property (`glide.authenticate.multisso.enabled`), the administrator must enroll as an ACR user.
- Administrator must set a password for local login and register MFA before enrolling as an ACR user.

For an upgraded instance to use ACR, you must do the following:

- Activate Mutli-SSO plugin (`com.snc.integration.sso.multi.installer`)
- Enable ACR (`glide.sso.acr.enabled`)

  Note:
  In case of upgraded instance, the administrator must enable ACR.

- Before enabling SSO property (`glide.authenticate.multisso.enabled`), the administrator must enroll as an ACR user.

  Note:
  Setting this property to false will not disable multi-provider SSO if Account Recovery (ACR) is also enabled on the instance. To log in with a username and password ACR must also be disabled using the *`glide.sso.acr.enabled`* property. For details on this property see Account recovery properties.

- Administrator must set a password for local login and register MFA before enrolling as an ACR user.

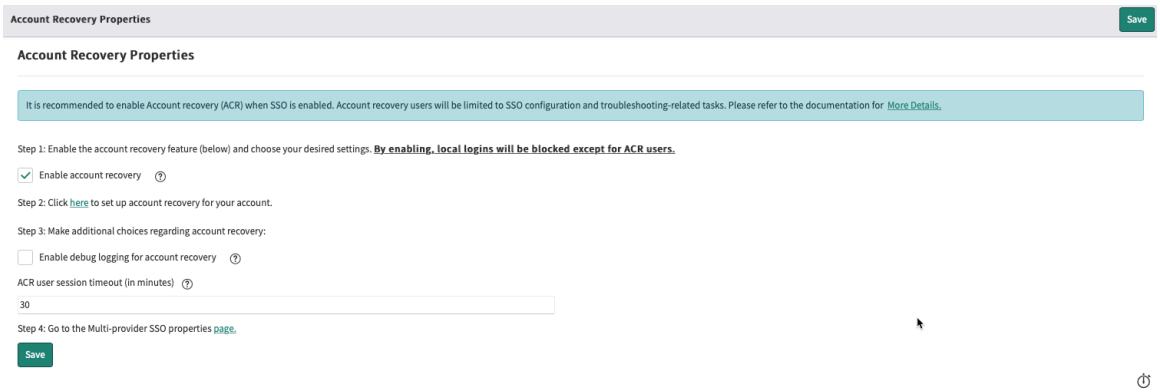
Procedure

1. Navigate to **All** > **Account Recovery** > **Properties**.
2. Click **Enable account recovery**.

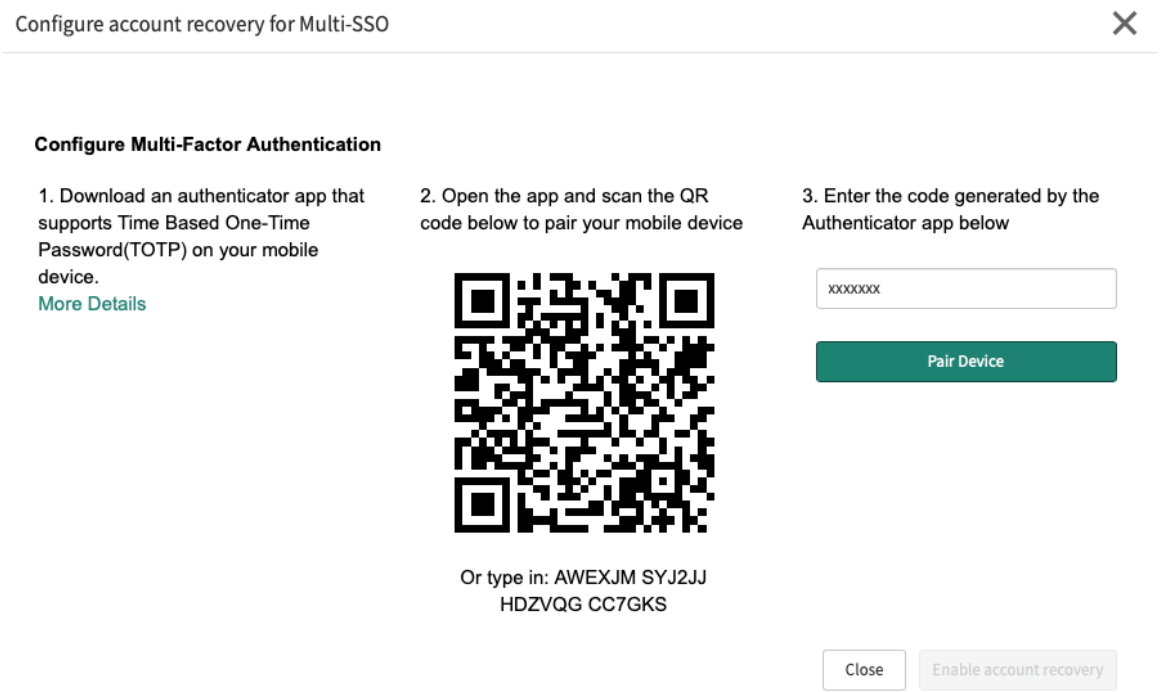
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
You need to enable account recovery when SSO is enable. Account recovery users will be limited to SSO configuration and troubleshooting-related tasks.

3. Click the **here** text in the Step 2.



4. Following the on-screen directions in the **Configure account recovery for Multi-SSO** modal.



After completing the on-screen steps, the **Enable account recovery** is enabled.

5. Click **Enable account recovery**.

Result

You have configured your user account as an account recovery user. You can verify this account, and see any other configured account recovery users by navigating to **Multi-Provider SSO** > **Account Recovery** > **Users**.

Configure an account recovery user from an admin user profile

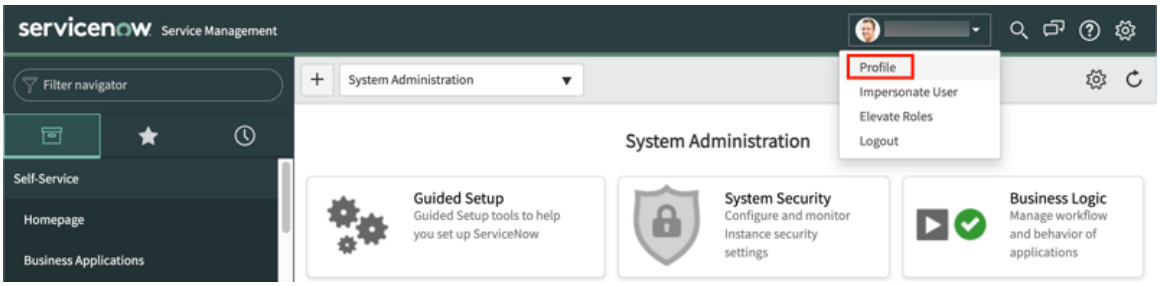
Configure an administrator as an account recovery user from the admin user profile.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

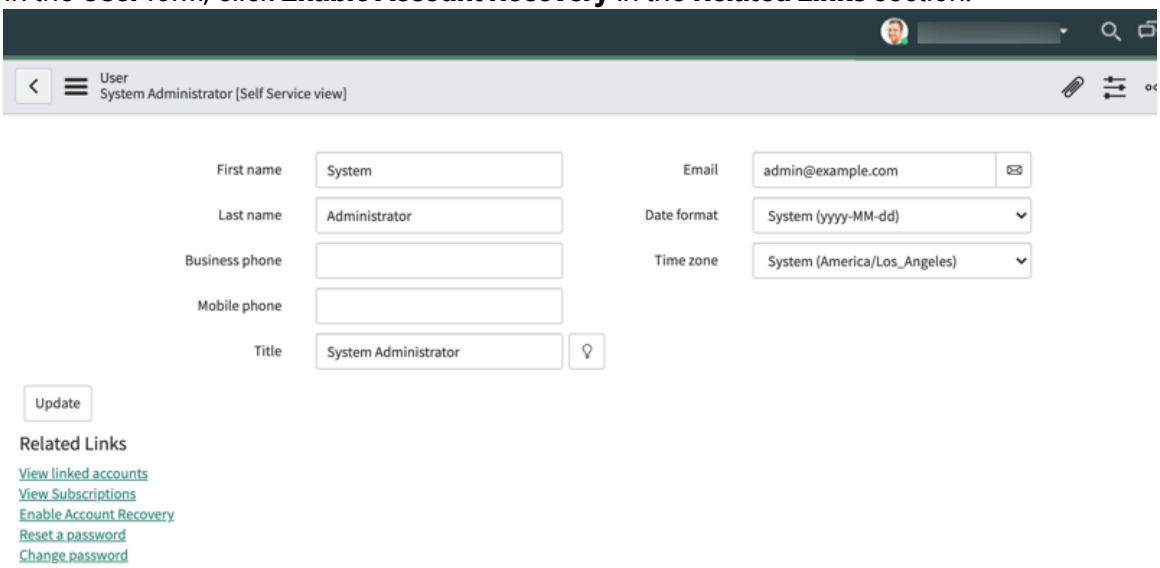
Before you begin
Role required: admin

Procedure

1. Log into your instance using an administrator account.
2. Click on the user name in the instance header, and select **Profile**.



3. In the **User** form, click **Enable Account Recovery** in the **Related Links** section.

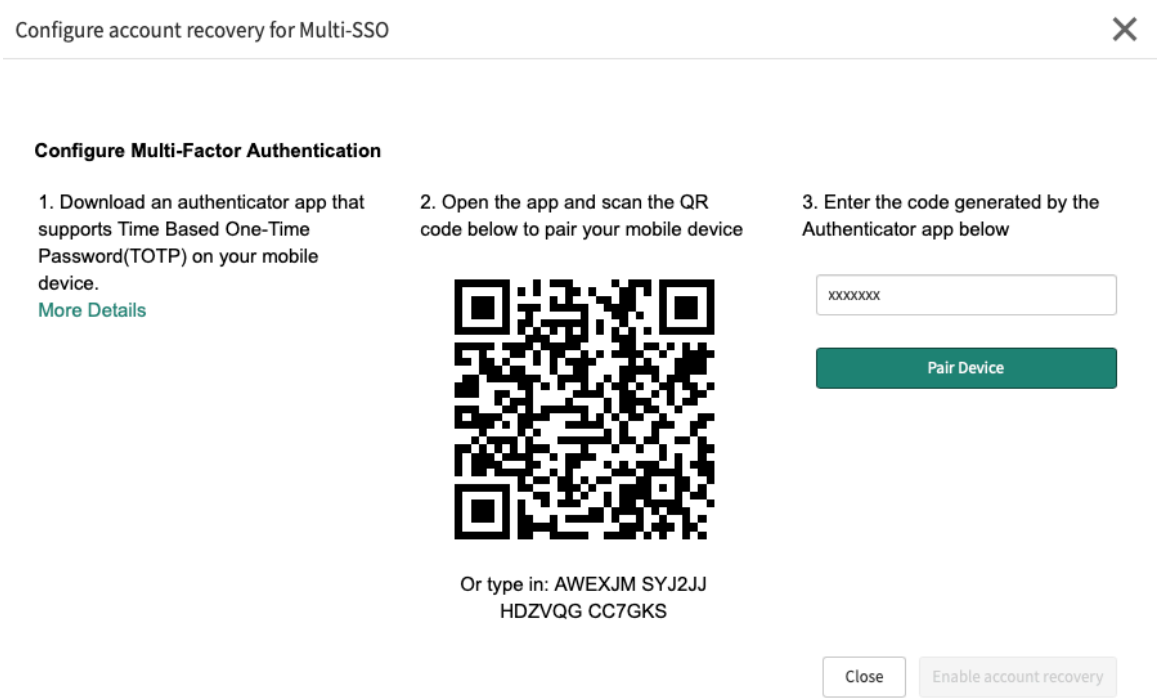


Note:

If the selected user already has account recovery enabled, **Enable Account Recovery** does not appear in the related links. There will be a **Disable Account Recovery** option instead.

4. Following the on-screen directions in the **Configure account recovery for Multi-SSO** modal.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



After completing the on-screen steps, the **Enable account recovery** is enabled.

5. Click **Enable account recovery**.

Result

You have configured your user account as an account recovery user. You can verify this account, and see any other configured account recovery users by navigating to **Multi-Provider SSO** > **Account Recovery** > **Users**.

Account recovery properties

Use system properties to configure Account Recovery (ACR) on your instance.

Access the account recovery properties on your instance by navigating to **Multi-Provider SSO** > **Account Recovery** > **Properties**.

Account recovery system properties

Property	Description
Enable account recovery feature [glide.sso.acr.enabled]	Whether the account recovery feature is enabled on your instance. This property is enabled by default.
Enable debug logging for account recovery [glide.sso.acr.debug.log.enabled]	Whether your instance includes account recovery information in debug logging. This property is disabled by default.
ACR user session timeout (in minutes) [glide.sso.acr.ui.session.timeout]	Minutes of inactivity before your instance terminates an account recovery user session. This property has a default value of 30.

E-signature for Multi-Provider SSO

E-signature with Multi-Provider SSO enables you to use the e-signature properties instead the SAML or OIDC properties for authentication.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

For single sign-on (SSO) verification during authentication and to require users to provide credentials before submitting their electronic signature, you can configure the authentication to prompt for user credentials before submitting a signature.

You can install the Approvals with e-signature (`com.glide.e_signature_approvals`) plugin to have the E-signature configuration for SSO logins.

Note:
You must install the Code Signing Signatures (`com.glide.code_signing.signatures`) to install the E-signature plugin.

Activate Approval with e-Signature plugin

The Approval with e-Signature plugin (com.glide.e_signature_approvals) allows users to approve requests by re-entering their login credentials.

Before you begin

Role required: admin

Note:
You must install the Code Signing Signatures (`com.glide.code_signing.signatures`) to install the E-signature plugin.

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

   Note:
   When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

   You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Use Multi-Provider SSO to set up an SSO approval for a SAML 2.0 authentication

An SSO approval with e-signature requires configuration on the SAML IdP and the ServiceNow instance.

Before you begin

Role required: admin

About this task

The SAML IdP must support and honor the forceAuthn attribute in SAML assertion requests. E-signature doesn't function without this IdP setting. Set up an approval with e-signature using credentials from a SAML 2.0 authentication.

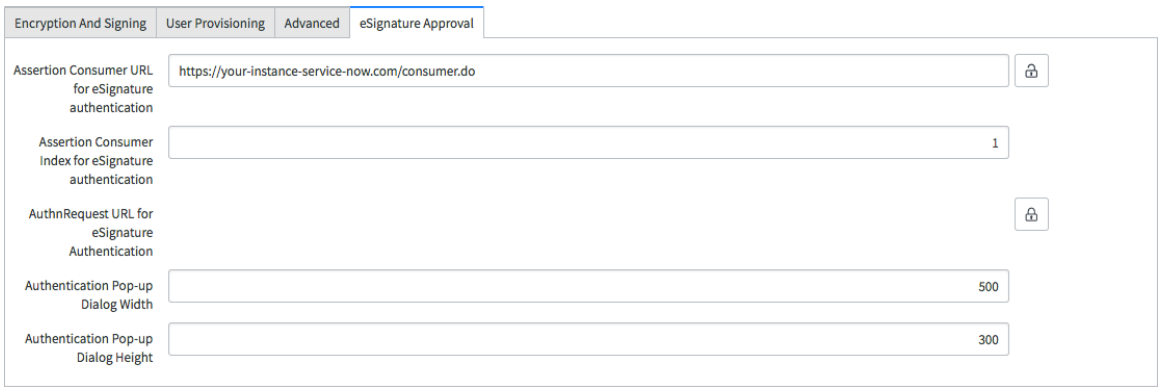
Procedure

1. Activate or upgrade to SAML 2.0 with the Activate Multi-Provider SSO plugin.
2. Activate the Approval with E-Signature plugin.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. Navigate to **Multi-Provider SSO** > **Identity Providers** and verify your 2.0 SAML IdP configuration Advanced tab shows the **Force AuthnRequest** attribute checked.
   Your SAML 2.0 IdP must support the **Force AuthnRequest** attribute, or e-signature isn't supported.
4. On the eSignature Approval tab, enter the following e-signature SAML properties.

Option	Description
Assertion Consumer URL for eSignature authentication	This property defaults to the appropriate URL. To configure this property, select the lock icon to make this field editable. After edits, select the icon to lock the field.
Assertion Consumer Index for eSignature authentication	If your Service Provider has more than one URL set for the AssertionConsumerURL, you can set the index to use for eSignature, starting with index 1 or more.
AuthnRequest URL for eSignature Authentication	You can enter the URL that points to the SAML 2.0 IdP AuthnRequest URL for eSignature authentication. If the URL is the same as the Assertion Consumer URL, you can leave this setting empty.
Authentication pop-up Dialog Width	When a user approves a request using eSignature, a dialog opens and a user can enter credentials. This setting controls the width of that dialog box. The default is 500.
Authentication pop-up Dialog Height	When a user approves a request using eSignature, a dialog opens and a user can enter credentials. This setting controls the height of that dialog box. The default is 300.



5. Select the **Generate Metadata** button underneath the tabs to regenerate the service provider metadata.
6. Copy the service provider metadata, and update it on the SAML IdP.

Use Multi-Provider SSO to set up an SSO approval for an OIDC authentication

An SSO approval with e-signature requires configuration on the SAML IdP and the ServiceNow instance.

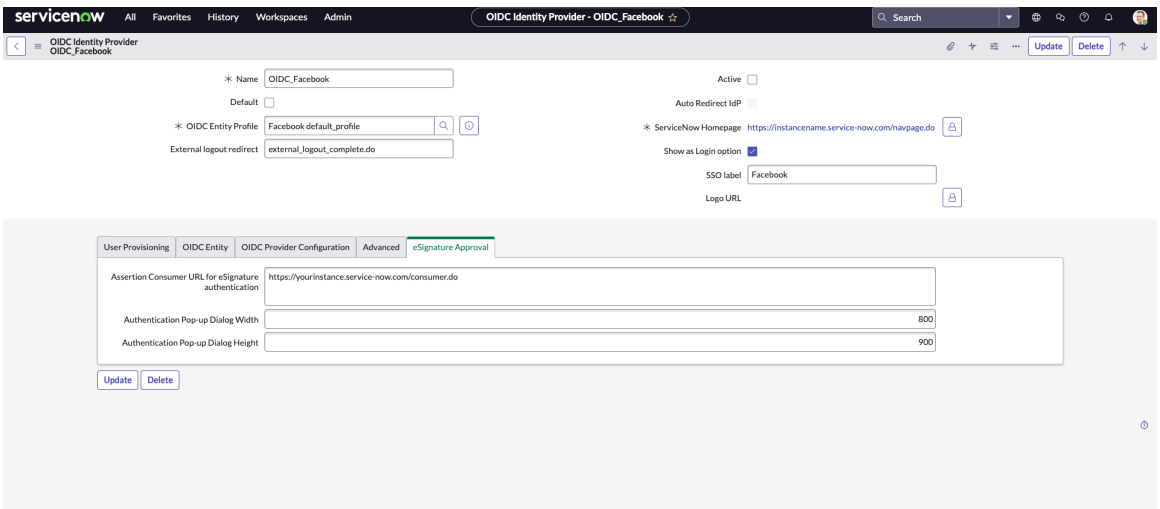
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin
Role required: admin

About this task
The SAML IdP must support and honor the forceAuthn attribute in SAML assertion requests. E-signature doesn't function without this IdP setting. Set up an approval with e-signature using credentials from a SAML 2.0 authentication.

Procedure
1. Activate the Approval with E-Signature plugin.
2. Navigate to **Multi-Provider SSO** > **Identity Providers** and verify your OIDC provider configurations
3. On the eSignature Approval tab, enter the following e-signature SAML properties.

Option	Description
Assertion Consumer URL for eSignature authentication	This property defaults to the appropriate URL. To configure this property, select the lock icon to make this field editable. After edits, select the icon to lock the field.
Authentication pop-up Dialog Width	When a user approves a request using eSignature, a dialog opens and a user can enter credentials. This setting controls the width of that dialog box. The default is 800.
Authentication pop-up Dialog Height	When a user approves a request using eSignature, a dialog opens and a user can enter credentials. This setting controls the height of that dialog box. The default is 900.



4. Select **Submit** if you are configuring the E-signature during the initial OIDC setup or **Update** if you want to update the details in the E-signature.

OpenID Connect (OIDC) as a Single Sign-On (SSO) identity provider (IdP)

OpenID Connect (OIDC) is an identity layer built on top of the OAuth protocol, which provides a modern and intuitive Single Sign-on (SSO) experience to you and your end users.

OIDC improves the log in experience for mobile applications by enabling users to log in to ServiceNow applications using their social identity provider. For example, administrators can

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

configure Single Sign-on with a third-party identity provider that supports OpenID Connect. Users then have the option to log in to your custom ServiceNow application using their identity provider credentials.

Note:
ServiceNow support the JSON Web Encryption (JWE) as part of the OIDC SSO flow. To know more, see the KB Article.

You can choose to use social identity providers like Google for your business-to-customer (B2C) users and enterprise identity providers like Okta, Microsoft Entra ID for your business-to-business users.

Create an OpenID Connect (OIDC) configuration for Single Sign-On (SSO)

Create or update an OpenID Connect (OIDC) configuration by using the Multi-Provider SSO plugin.

OpenID Connect (OIDC) configuration for Single Sign-On (SSO)

Before you begin

- Register an OIDC application with your Identity Provider (IdP) and note the Client ID, Client Secret, and Well-known configuration URL.
- Activate Multi-Provider SSO plugin. Multi-Provider SSO feature supports domain separation, you can specify different IdP's to different domains.
- Configure Multi-provider SSO properties
- Activate Approval with e-Signature plugin to enable eSignature for the OIDC IdP.
- Role required: admin

If you have a client ID, client secret, and well-known configuration URL of the identity provider, you can directly import the OIDC configuration for SSO.

Note:

- The **Login with OIDC** button is not shown on the login page for OIDC based IDPs if the domain separation plugin is installed.
- Admin can use OIDC based IdP to enable SSO for a user of specific company or domain.
- ServiceNow support the JSON Web Encryption (JWE) as part of the OIDC SSO flow. To know more, see the KB Article.

If you do not have the required information about the identity provider, you can manually configure OIDC for SSO. After completing the configuration, users can log in to ServiceNow applications using third-party social identity providers like Google Okta.

Procedure

1. Navigate to **All** > **Multi-Provider SSO** > **Identity Providers**.
2. Choose one of the following options.
   - To update an existing configuration, click an OIDC Identity Provider record.
   - To create a new configuration, click **New** and select **OpenID Connect**.
3. For a new configuration, enter the OIDC configuration information in one of the following methods.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Option	Description
Import OpenID Connect Well-Known Configuration	If you have the well-known configuration URL along with your associated client credentials, you can directly import an OIDC configuration. **Note:** If you import the OIDC well-known configuration, all related fields are auto-populated.
Manually configure the OIDC Identity Provider form	If you do not have an existing OAuth OIDC Entity, close the Import OpenID Connect Well-Known Configuration pop-up and manually fill the fields in the OIDC Identity Provider form.

Import OpenID Connect Well-Known Configuration fields

Property	Description
Name	Unique name for the OIDC identity provider configuration.
Client ID	Client ID of the application registered in the third-party OIDC identity provider.
Client Secret	Client secret of the application registered in the third-party OIDC identity provider.
Well-known Configuration URL	URL that contains metadata about the third-party OIDC identity provider.

All required fields must be filled in on the OIDC Identity Provider form.

Before you manually fill the OIDC Identity Provider form, ensure that you already have an OAuth Entity Profile for the OIDC IdP.

If you do not have a OAuth Entity Profile, you can create it using the default External OIDC Provider templates, like Okta, Azure and others.

The grant type of the OAuth Entity Profile must be with an authorization code. For more information, see Configure an OAuth OIDC provider on the ServiceNow AI Platform.

Note:
You can use the templates of third-party identity providers, Auth0, Azure AD, Google, and Okta are available in the demo data of the Multiple Provider Single Sign-On Installer plugin.

OIDC Identity Provider fields

Property	Description
Name	Name of the OIDC identity provider record.
Active	Option to make the OIDC IdP configuration active.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property	Description
	Note: This option can only be set to active after a successful test connection.
Default	Option to set the OIDC IdP configuration as default when there are more than one OIDC configurations.
Auto Redirect IdP	Option to enable auto redirection of the users to the login page of the identity provider. This field shows when the **Set as Auto Redirect IdP** option is set under the Related Links section. **Note:** If you make a new Auto Redirect IdP configuration active, the *glide_sso_id* cookie automatically updates with the new Auto Redirect IdP. The *glide.authenticate.sso.update.idp.cookie* system property controls this feature.
OIDC Entity Profile	OAuth Entity Profile for the OIDC configuration.
ServiceNow Homepage	The URL of the login page used for authentication. This field is automatically set to your instance URL. The format of the URL is: `https://yourinstance.service-now.com/navpage.do`
External logout redirect	The URL where the integration redirects users after they log out. Typically, the portal, which is used for SSO. This field is automatically set to `external_logout_complete.do` For example, `https://yourinstance.service-now.com/external_logout_complete.do`
Show as login option	Option to display the OIDC IdP as a login option on the login page. The login option appears as the **login with Identity provider** button.
SSO label	Label of the OIDC IdP displayed on the login page. This field appears only when **Show as login option** is enabled.
Logo URL	Publicly available URL that contains logo of the OIDC IdP provider. This field appears only when **Show as login option** is enabled.

4. **Optional:** Enable automatic user provisioning in the User Provisioning tab>User Provisioning tab.

   (Optional) You can choose to enable automatic user provisioning during user login. When automatic user provisioning is enabled, a user record is automatically created in the ServiceNow instance if that user record does not exist.

   User Provisioning fields

Property	Description
Automatically provision users	Option to enable automatic user provisioning. This property creates a user in the instance User (sys_user) table when the user exits on IdP but does not exist in the User table.
Provision using	Data source to use to transform, an `ID Token`, `User Info` endpoint, or `Both ID Token and User Info` to a ServiceNow user. Use the Lookup

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property	Description
	list to select the pre-defined data source template, then open the record to configure the Transforms table mapping.
Provision data source	ID token data source used for user provisioning.
User Info Datasource	The user info endpoint datasource used for user provisioning. This field is displayed when `User Info` or `Both ID Token and User Info` are selected for the **Provision using** field.
Update User on next login	Option to enable user update during the next login.
Update User Interval Time (Seconds)	Minimum time interval in seconds to update a user record between subsequent logins. This field is automatically set to 3,600 seconds. For example, after a user logs in, the user record will be updated after 3,600 seconds until the next login. This field is available only when the **Update User on next login** field is enabled.
User roles applied to provisioned users	List of roles applied to the newly provisioned users.

5. OIDC Entity tab
   You can view and modify the OIDC client configuration and OIDC connect flow using the entity record.
6. OIDC Provider Configuration tab
   You can view and modify the well-know configuration URL of the OIDC IdP or ID token claim validation.
7. **Optional:** Advanced tab

   (Optional) Scripts that are run during single sign-on and logout.

   Advanced fields

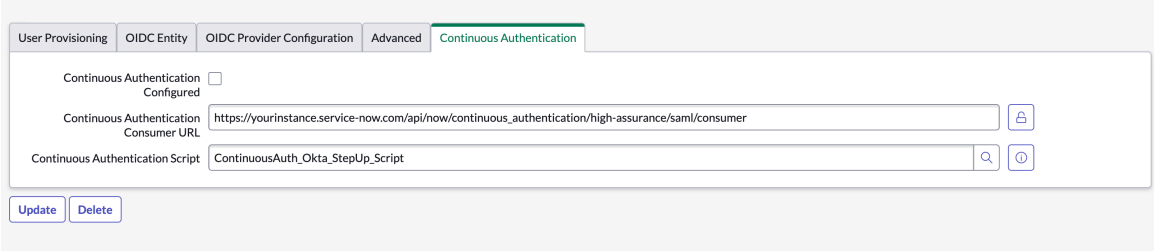
Property	Description
Single Sign-On Script	Script that executes during Single Sign-On. This field is automatically set to `MultiSSO_OIDC_custom`.
Logout Script	Script that executes after the user logs out. This field is automatically set to `MultiSSO_OIDC_logout_custom`.

8. **Optional:** On the Continuous Authentication tab, configure the following fields:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:

- The Continuous Authentication tab appears only when you install the **Zero Trust - Continuous Authentication** (`com.snc.zero_trust_continuous_authentication`) plugin that requires license.
- If you're using continuous authentication policy to protect access to table or data class, see Continuous Authentication (CA).



Continuous Authentication

Field	Description
Continuous Authentication Configured	Select the check-box to set the configuration active.
Continuous Authentication Consumer URL	Provide the Consumer URL from the Identity Provider.
Continuous Authentication Script	(Optional) Select the look-up icon to choose the script provided from the platform. In this configuration, for OIDC Okta: **ContinuousAuth_Okta_StepUp_Script**

9. **Optional:** On the eSignature Approval tab, configure the eSignature for the OIDC Idp.

Note:
The eSignature Approval tab appears only when you install the **Approval with e-Signature** plugin (com.glide.e_signature_approvals).

eSignature Approval fields

Property	Description
Assertion Consumer URL for eSignature authentication	If you employ a customized method of handling the OIDC authentication for eSignature, you can set up your own consumer URL. For example, if you are using Multi-Provider SSO, you do not need to use this property. This format of the URL is `https://yourinstance.service-now.com/consumer.do`
Authentication pop-up Dialog Width	Width of the authentication pop-up dialog. This field is automatically set to `800`.
Authentication pop-up Dialog Height	Height of the authentication pop-up dialog. This field is automatically set to `900`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

10. **Optional:** Navigate to the login page of the instance to verify that IdP appears as a login option.
    The URL should be in the following format: `https://yourinstance/login_with_sso.do?glide_sso_id=sysId_IdP`

> **Note:**
> If you have enabled **Selected as login Option**, you can go to the login URL of the instance.

Use Facebook-based Single Sign-On (SSO)

Log in to your ServiceNow instance by using your Facebook credentials on the Facebook-based SSO.

Before you begin

The Facebook-based SSO is shipped along with your ServiceNow instance.

You can define the Identity Provider (Idp) configurations to the **OIDC_Facebook** IdP as your **Identity Providers**. For more information about Idp configurations, see Configure a Facebook-based Single Sign-On (SSO).

Role required: admin

Procedure

1. Navigate to **All** > **Multi-Provider SSO** > **Identity Providers**.
2. Select **OIDC_Facebook**.
3. On the OIDC_Facebook page, specify the following fields:

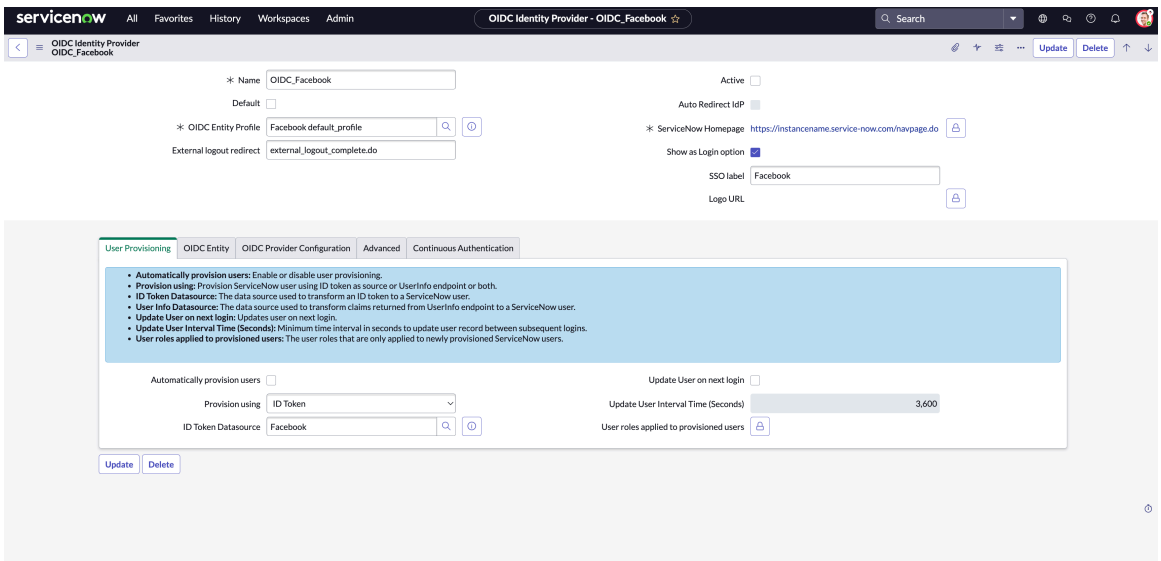
> **Note:**
> - Most of the fields are auto-populated when using the default IdP.
> - Details of the ServiceNow Homepage must be provided.
> - User-related details such as Client ID and Client Secret from Facebook must be provided within the IdP.

OIDC_Facebook Identity Provider Details

Field	Description
Name	Name of the OIDC IdP record. Enter `OIDC_Facebook`.
Default	Option to set the OIDC IdP configuration as default.
OIDC Entity Profile	OAuth Entity Profile for the OIDC configuration. Enter `Facebook default_profile`.
External logout redirect	The URL where the integration redirects users after they log out. Typically, this URL is the portal that is used for SSO. This field is automatically set to **external_logout_complete.do**. For example, `https://<yourinstance>.service-now.com/external_logout_complete.do`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Active	Option to make the OIDC IdP configuration active. **Note:** This option can only be set to active after a successful test connection.
Auto Redirect IdP	Option to enable automatic redirection of the users to the login page of the identity provider.
ServiceNow Homepage	The URL of the login page that is used for authentication. This field is automatically set to your instance URL. The format of the URL is `https://<yourinstance>.service-now.com/navpage.do`
Show as Login option	Option to display the OIDC IdP as a login option on the login page. In this case, the login option appears as the **Login with Facebook** button.
SSO Label	Label of the OIDC IdP displayed on the login page. This field appears only when **Show as Login option** is enabled.
Logo URL	Publicly available URL that contains the logo of the OIDC IdP provider. This field appears only when **Show as Login option** is enabled.



4. **Optional:** Open the **User Provisioning** tab, and fill in the fields.

Note:
You must configure the OIDC-related information such as Client ID and Client Secret of your users from Facebook.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

User Provisioning tab

Field	Description
Automatically provision users	Option to enable automatic user provisioning. This property creates a user in the instance User [sys_user] table when the user exists on the IdP but doesn't exist in the User table. **Note:** You can choose to enable automatic user provisioning during user login. When automatic user provisioning is enabled, a user record is automatically created in the ServiceNow instance if that user record doesn't exist.
Provision using	The data source to use to transform to a ServiceNow user. Choices are as follows: ○ **An ID Token** ○ **User Info endpoint** ○ **Both ID Token and User Info** Use the Lookup list to select the pre-defined data source template, then open the record to configure the Transforms table mapping.
Provision data source	The ID token data source that is used for user provisioning.
User Info Datasource	The user info endpoint data source used for user provisioning. This field appears only when **User Info** or **Both ID Token and User Info** is selected from the **Provision using** field.
Update User on next login	Option to enable user updates during the next login.
Update User Interval Time (Seconds)	Minimum time interval (in seconds) to update a user record between subsequent logins. This field is automatically set to 3600 seconds. For example, after a user logs in, the user record will be updated after 3,600 seconds until the next login. This field is available only when the **Update User on next login** field is enabled.
User roles applied to provisioned users	List of roles applied to the newly provisioned users.

5. In the **OIDC Entity** tab, view and modify the OIDC client configuration and OIDC connect flow using the entity record.
   For more information related to OIDC-based configuration, see Configure an OAuth OIDC provider for accepting third-party token
6. In the **OIDC Provider Configuration** tab, view and modify the well-know configuration URL of the OIDC IdP.
7. **Optional:** Open the **Advanced** tab, and fill in the fields.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Advanced tab

Property	Description
Single Sign-On Script	The script that executes during Single Sign-On.
Logout Script	The script that executes after the user logs out.

Note:
Scripts are run during single sign-on and logout.

8. To enable and test the configuration, click **Active**.
9. To update the record, click **Update**.
   The Facebook-based login option is displayed on the login form.
10. When logging in on the login form, do the following:
    a. Select the Facebook option.
    b. To log in to the ServiceNow instance, specify your Facebook credentials.

Configure a Facebook-based Single Sign-On (SSO)

Configure a Facebook-based SSO to your ServiceNow instance.

Before you begin

Have a valid Client ID that is configured as an IdP from Facebook.

Enable the following properties:

- Enable multiple provider SSO.
- Enable debug logging for the multiple provider SSO integrations.

Role required: admin

Procedure

1. Navigate to **All** > **Multi-Provider SSO** > **Identity Providers**.
2. To create a new Facebook identity provider, click **New**.
3. Click **OpenID Connect**.
4. On the form, fill in the fields.

Import OpenID Connect Well Known Configuration form

Fields	Description
Name	Unique name for the OIDC identity provider configuration.
Client ID	The client ID of the application registered in the third-party OIDC identity provider.
Client Secret	The client secret of the application registered in the third-party OIDC identity provider.
Well known Configuration URL	The URL that contains metadata about the third-party OIDC identity provider.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

5. Click **Import**.
   The Facebook-based IdP is created.
6. Select the Facebook IdP.
7. In the Facebook idP, do the following:
   a. Validate all the fields such as **Name**, **OIDC Entity Profile**, **External logout redirect**, and **ServiceNow Homepage**.
   b. Provide your **SSO label**.
8. In the **User Provisioning** tab, specify the fields that you need to configure users to specific user provisioning and roles.

   Only the mandatory fields are required. You can specify the remaining fields depending on what you need.
9. In the **OIDC Entity** tab, do the following:
   a. Click the entity.
   b. Set the **Redirect URL** field to your Facebook redirect URL.
10. In the **OAuth Entity Profiles** tab, do the following:
    a. In the profile details, click a profile.
    b. Select a scope and verify the details.
       For example, select **scope-1**
11. In the **OAuth Entity Scopes** tab, click the **scope-1** link and add the scope as `email`.
12. To save the configuration, right-click the header and click **Save**.
13. To set the configuration as active, select **Active**.

Result
Users are displayed with the Facebook SSO option on the login form.

SAML

The Security Assertion Markup Language (SAML) is an XML-based standard for exchanging authentication and authorization data between security domains.

SAML exchanges security information between an identity provider (a producer of assertions) and a service provider (a consumer of assertions). SAML is a product of the OASIS Security Services Technical Committee. When implemented correctly, SAML is one of the most secure methods of single sign-on (SSO) available.

The SAML 2.0 integration enables SSO by exchanging XML tokens with an external Identity Provider (IdP). The IdP authenticates the user and passes a NameID token to the system. If the system finds a user with a matching NameID token (for example, the email address), the instance logs that user in.

If you are using the SAML 2.0 plugin for SSO authentication, you must set the glide.ui.rotate_sessions property to false. Otherwise, it interferes with the session information sharing that takes place between the instance and the Identity Provider. Users with the security_admin elevated privilege can access this property.

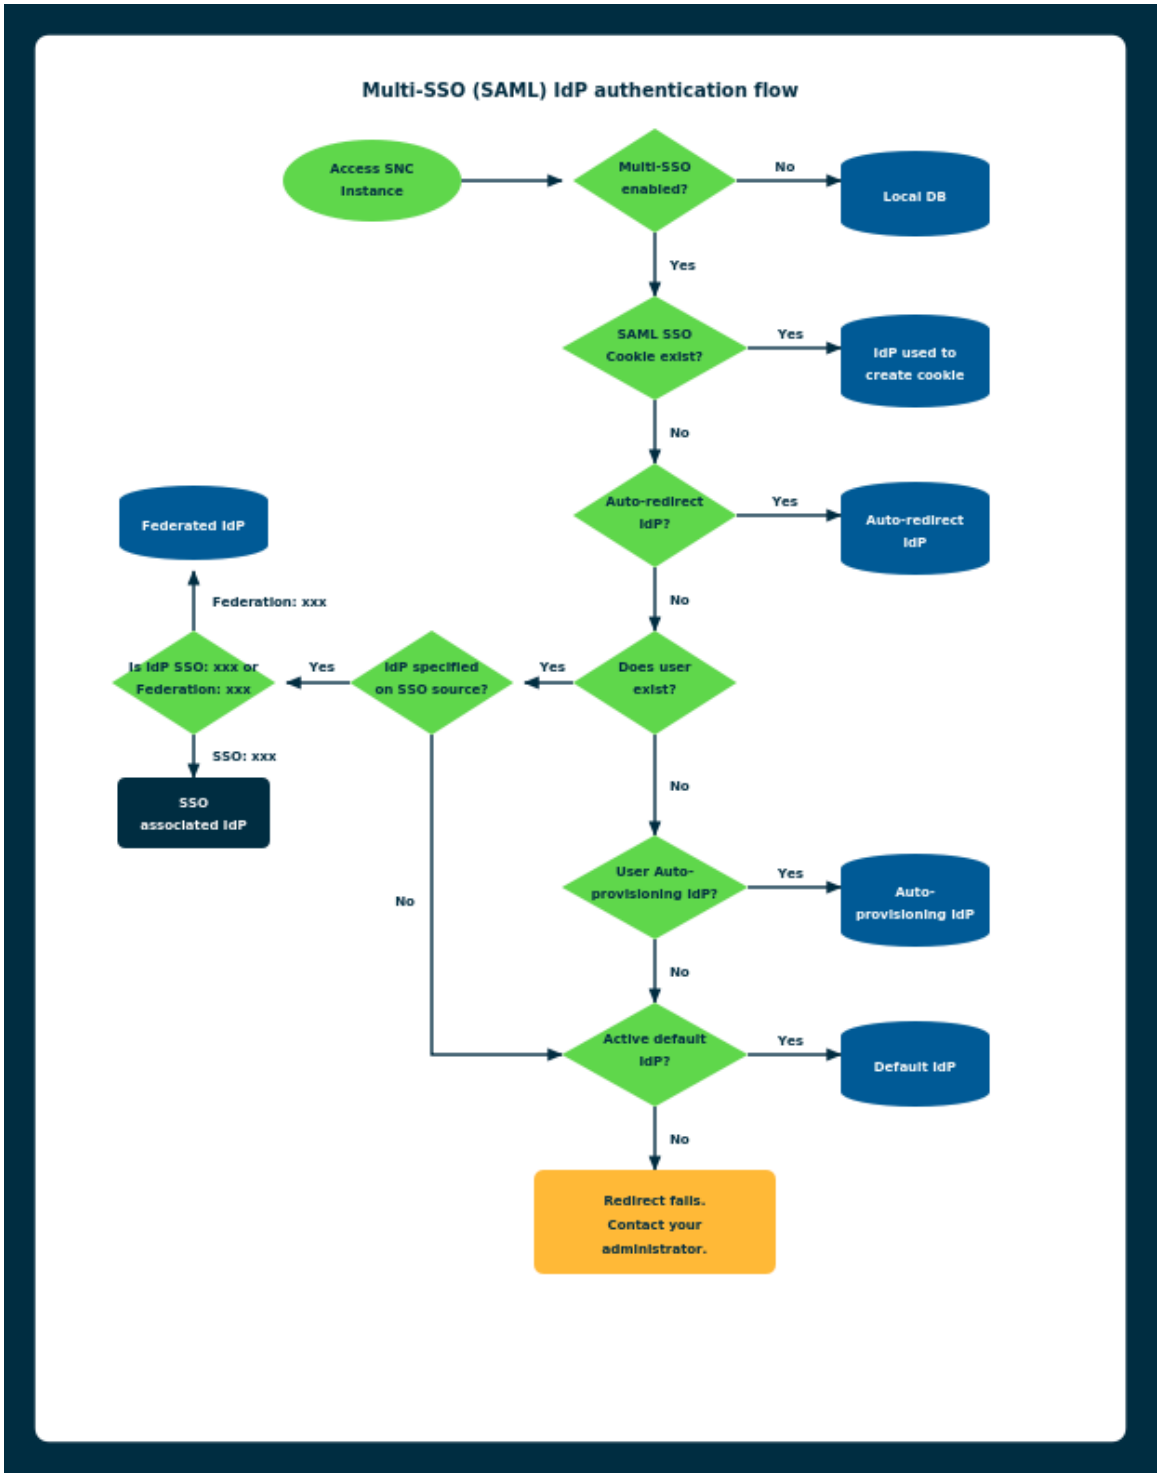
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
It is recommended that customers using an existing SAML 2.0 integration upgrade to the Multi-Provider SSO plugin.

Multi-Provider SSO (SAML) IdP authentication flow

Describes the different entities that can authenticate a user through the SAML multi-SSO.

You can follow the authentication flow to understand when an entity authenticates a user using Multi-SSO.



Local DB

If Multi-SSO is not enabled, authentication directs to a local DB.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

SAML SSO Cookie IdP

If a SAML SSO cookie exists, the IdP which is specified with this cookie authenticates the user.

Auto-redirect IdP

If the auto-redirect IdP is enabled, this IdP authenticates the user.

Federated IdP

If the user browser is redirected to the external authorization (login_locate_sso.do) login screen, and the user exists in the user table with the IdP set in the **SSO Source** field as federation: xxx, then the federated IdP authenticates the user.

Associated IdP

If the user browser is redirected to the external authorization (login_locate_sso.do) login screen, and the user exists in the user table with the IdP set in the **SSO Source** field as sso: xxx, then the associated IdP authenticates the user.

Auto-provisioning IdP

If the user browser is redirected to the external authorization (login_locate_sso.do) login screen, and the user does not exist in the user table, but auto-provisioning is enabled, then the auto-provisioning IdP authenticates the user.

Note:
If there is more than one auto-provisioning IdP enabled, the user can choose the auto-provisioning IdP they can use.

Default IdP

If the user browser is redirected to the external authorization (login_locate_sso.do) login screen, and the user either:

- Does not exist in the user table, auto-provisioning is not enabled, and there is an active default IdP
- Exists in the user table, an IdP is not specified on the SSO source user or company record, and there is an active default IdP

then the default IdP authenticates the user.

Identity Provider (IdP) system properties

An IdP generally offers an XML document containing their authentication and logout metadata.

For example, SSOCircle publishes their metadata online.

Browse the IdP metadata to find these entries:

- The `SingleSignOnService` element with a `Binding` attribute that contains a value of `HTTP-Redirect`. The `Location` attribute lists the URL the integration requires for the AuthnRequest service.
- The `SingleLogoutService` element with a `Binding` attribute that contains a value of `HTTP-Redirect`.The `Location` attribute lists the URL the integration requires for the SingleLogoutRequest service.

Note:
The SAML 2.0 integration only supports binding to IdP services by HTTP-Redirect.

For example:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
<SingleSignOnServiceBinding="urn:oasis:names:tc:SAML:2.0:binding
s:HTTP-Redirect"Location="https://
idp.ssocircle.com:443/sso/SSORedirect/metaAlias/ssocircle"/>
```

```
<SingleLogoutServiceBinding="urn:oasis:names:tc:SAML:2.0:binding
s:HTTP-Redirect"Location="https://
idp.ssocircle.com:443/sso/IDPSloRedirect/metaAlias/ssocircle"Res
ponseLocation="https://
idp.ssocircle.com:443/sso/IDPSloRedirect/metaAlias/ssocircle"/>
```

Set the IdP issuer URL

Provide the URL to the IdPs who will issue the security token.

Before you begin

Role required: admin

About this task

The integration verifies that each SAML response contains the same URL listed in this system property as the URL listed in the *Issuer* element. For example:

```
<samlp:Responsexmlns:samlp="urn:oasis:names:tc:SAML:2.0:protoc
ol"  Destination="https://demoi2.service-now.com/navpage.do"
  ID="s28da6774c88ae1eab292bf25fe625db81919d8e1e"
 InResponseTo="SNC841720c227c81948cfd68cadcad235c6"
 IssueInstant="2012-01-30T20:07:10Z"  Version="2.0"><saml:Issuer
 xmlns:saml="urn:oasis:names:tc:SAML:2.0:assertion">http://
idp.ssocircle.com</saml:Issuer>
   ...
   <saml:Assertion
 xmlns:saml="urn:oasis:names:tc:SAML:2.0:assertion"
     ID="s2f347f973c063836cf70ea38302d94976f9c5b851"
     IssueInstant="2012-01-30T20:07:10Z"
 Version="2.0"><saml:Issuer>http://
idp.ssocircle.com</saml:Issuer>
      ...
   </saml:Assertion></samlp:Response>
```

Procedure

1. Navigate to **All** > **SAML 2 Single Sign-on** > **Properties**.
2. In the property *The Identity Provider URL which will issue the SAML2 security token with user info.*, enter the URL to your IdP.

   Each IdP URL must be unique. By default, the integration contains the URL to SSOCircle. For more information, see http://idp.ssocircle.com.

Set the AuthnRequest service URL

Using the IdP's metadata, set the request service URLs for the integration's IdP.

Before you begin

Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. In the property *The base URL to the Identity Provider's AuthnRequest service. The AuthnRequest will be posted to this URL as the SAMLRequest parameter*, enter the URL to the HTTP-Redirect binding obtained from the `SingleSignOnService` element.
2. Select the check box next to *Sign AuthnRequest* to enable the Identity Provider's single-sign on service to receive a signed AuthnRequest.
3. In the property *When SAML 2.0 single sign-on fails because the session is not authenticated, or this is the first login, redirect to this URL. This is the base URL where the initial SAML 2.0 AuthnRequest is sent using the SAMLRequest parameter*, enter the URL to the HTTP-Redirect binding obtained from the `SingleSignOnService` element.

   By default, the integration contains the URL to the SSOCircle service.

Set the SingleLogoutRequest service URL

Set the request service URLs for the integration's IdP by using the IdP's metadata.

Before you begin
Role required: admin

Procedure

1. In the *The base URL to the Identity Provider's SingleLogoutRequest service. The LogoutRequest will be posted to this URL as the SAMLRequest parameter* property, enter the URL obtained from the `SingleLogoutService` element.
   The LogoutRequest is posted to this URL as the SAMLRequest parameter. By default, the integration contains the URL to the SSOCircle service.
2. In the *URL to redirect users after logout, typically back to the portal that enabled the SSO (e.g. http://portal.companya.com/logout)* property, enter the URL where you want to redirect users after they successfully logout.

   If your IdP uses form-based authentication, enter the URL to your IdP's login form. If your IdP uses a non-form-based authentication method such as Kerberos, you should set the URL to a static logout page. This way, users who log out do not get immediately get redirected to the IdP and login again. By default, the integration contains the URL to the static UI page `external_logout_complete.do`.

(Optional) Enable signed logout requests

Some IdPs require the Service Provider to sign logout requests with a certificate.

Before you begin
Role required: admin

About this task
If your IdP requires signed logout requests, use the IdP's metdata to set the following system properties.

Procedure

1. In the **Advanced** tab, from the property *Sign LogoutRequest. Set this property to true if the Identity Provider's SingleLogoutRequest service requires signed LogoutRequest*, select **Yes** to specify that your IdP requires a signed logout request, or select **No** to use unsigned logout requests.
2. If you selected **Yes** to *Sign LogoutRequest*, then in *The protocol binding for the Identity Provider's SingleLogoutRequest service. (Value can*

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

be either "urn:oasis:names:tc:SAML:2.0:bindings:HTTP-Redirect" or "urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST".) property, enter the one of the supported values listed in `Binding` attribute from the `SingleLogoutService` element.

By default, the integration uses an HTTP-Redirect binding.

3. Click **Update**.
4. Install a Service Provider (SP) key store.

Service Provider (SP) system properties

These system properties define how the instance interacts with the IdP as a Service Provider.

Follow the sequential process to define IdP as Service Provider.

- Set the instance URL for SAML
- Set the audience URL for SAML
- Set up a NameID policy for SAML
- (Optional) Enable providing an authentication context class for SAML
- (Optional) Set keystore properties for signing logout requests for SAML

Set the instance URL for SAML

Set the instance-specific URLs so that the IdP can authenticate users.

Before you begin
Role required: admin

Procedure

1. In the property *The URL to the Service-now instance (usually this instance)*, enter the URL (including login page) of the instance for which the IdP authenticates.
   For example: https://yourinstance.service-now.com/navpage.do
2. In the property *The entity identification, or the issuer*, enter the base URL (excluding login page) of the instance for which the IdP authenticates.
   For example: https://yourinstance.service-now.com/

Set the audience URL for SAML

Enable your instance to verify that it is the intended recipient of a SAML response by using the Audience property.

Before you begin
Role required: admin

About this task
The integration verifies that each SAML response contains the same URL listed in this system property as the URL listed in the *Audience* element. For example:

```
<samlp:Responsexmlns:samlp="urn:oasis:names:tc:SAML:2.0:protoc
ol"  ID="s2cdc74f37f923e26fe1aeec42b70a93d24230334f"
  InResponseTo="90AA6073F01567BFB0DF194F596314E2"
 Version="2.0"  IssueInstant="2010-04-29T23:21:51Z"
 Destination="https://dloomac.service-now.com/navpage.do">
...
<saml:Conditions NotBefore="2012-01-30T19:57:10Z"
 NotOnOrAfter="2012-01-30T20:17:10Z"><saml:AudienceRestriction><
```

```
saml:Audience>https://
demoi2.service-now.com</saml:Audience></saml:AudienceRestriction
></saml:Conditions>
...
</samlp:Response>
```

Procedure

1. Navigate to **All** > **SAML 2 Single Sign-on** > **Properties**.
2. In the property *The audience uri that accepts SAML2 token. (Normally, it is your instance URI. For example: https://<instance name>.service-now.com.)*, enter the URL of your instance. For example, https://demoi2.service-now.com. This URL must match the value of the *Audience* element in the SAML Response.
3. Click **Update**.

Set up a NameID policy for SAML

Set up a NameID policy for SAML. SAML 2.0 requires the IdP to exchange a NameID token with the service provider.

Before you begin
Role required: admin

About this task
For the SAML 2.0 integration the NameID token must map to a particular field in the User table. The integration uses the NameID token's value to determine what user the IdP authenticates.

Procedure

1. Browse the IdP metadata to find the `NameIDFormat` element that contains a value of `emailAddress`.
   The value of this element is the default format that the integration uses.
2. Review other `NameIDFormat` elements to determine if there are formats that match other fields in the User table.

Determine what User table field matches the NameID token

Identity providers specify what format the `NameID` token has.

Before you begin
Role required: admin

About this task
Setting up SAML 2.0 requires selecting a field from the User table that matches the format of the `NameID` token. Typically, IdPs offer the option to use an email address as the `NameID` token. Since the User table contains an email field, this field is a logical choice for use as a `NameID` token. To use another field from the User table as the `NameID` token, first verify that the IdP offers a `NameID` format that matches the value of a User table field. This may require adding the field to the User table.

Procedure

1. Compare the available formats in the IdP's `NameIDFormat` element to fields in the User table.
2. Select a `NameID` format where there is a matching value in the User table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. In the *The User table field to match with the Subject's NameID element in the SAMLResponse* field, enter the name of the User table field to search for matching values in the `NameID` token.

   By default, the integration uses the email field.

Set the IdP NameID policy

Specify what format the IdP uses for the `NameID` token.

Before you begin
Role required: admin

About this task
This format is listed as part of the IdP's metadata.

Procedure

1. In the property *The NameID policy to use for returning the Subject's NameID in the SAMLResponse. Your SAML identity provider will have to support this by declaring the policy in its metadata. The NameID value is used to match with the specified field in the User table to lookup the user.*, enter the value of the `NameIDFormat` element the integration uses.

   By default, the integration uses the SSOCircle `NameIDFormat` for email addresses.

2. Click **Save**.

Values in the User table field for SAML

Ensure that the integration's User table field contains appropriate matching values.

For example, if the integration uses the email field as the `NameID` token, ensure that the instance lists the same email address as the IdP. The integration fails to authenticate any user who does not have a matching value for the `NameID` token.

(Optional) Enable providing an authentication context class for SAML

You can enable the instance to send an authentication context class request to the IdP containing your instance's preferred authentication request format.

Before you begin
Role required: admin

About this task
If you enable creating an AuthContextClass message, then you must also specify an authentication context class reference format.

> **Note:**
> Some IdP's do not allow the Service Provider to set the authentication context class. Disabling this setting allows the IdP to choose the authentication context class.

Procedure

1. From the property *Create an AuthnContextClass request in the AuthnRequest statement*, select **Yes** to specify a particular context class such as Password Protected Transport, or select **No** to have the IdP select the most appropriate context class.
2. If you selected **Yes** to *Create an AuthnContextClass request in the AuthnRequest statement*, then in *The AuthnContextClassRef method that we will request in our SAML 2.0 AuthnRequest to the Identity Provider* property, enter the URN of the context class you want to use for authentication (see table).

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

AuthnContextClass URN options

Authentication type	Authentication context class URN
Forms-based authentication	`urn:oasis:names:tc:SAML:2.0:ac:classes:PasswordProtectedTranspor`
Kerberos-based authentication	`urn:federation:authentication:windows`

By default, the integration uses a Password Protected Transport authentication method.

3. Click **Update**.

(Optional) Set keystore properties for signing logout requests for SAML

Set the keystore properties to enable the integration to sign logout requests by using your signed server and signed CA certificates.

Before you begin
Role required: admin

Procedure

1. In the property *The alias of key entry stored in SAML 2.0 SP Keystore used to sign SAML 2 requests*, enter the alias name that you created for the SAML 2.0 Keystore.
   By default, the integration looks for the alias *saml2sp*.
2. In the property *The password of key entry stored in SAML 2.0 SP Keystore used to sign SAML 2 requests*, enter the password for your SAML 2.0 Keystore.
   By default, the password is the same as the default alias name.
3. Click **Update**.
4. Regenerate your SP metadata.
   For more information, see SP metadata.

Create a service provider key store for SAML

Create a Java key store containing the following items for your instance to sign logout requests.

Before you begin
Role Required: admin.

About this task

- Signed server certificate for the instance
- Signed CA certificate
- Public and private key pair

You may create your own signed certificate with a private certificate authority or purchase one from a public certificate authority.

The following steps illustrate how to generate a new Java Keytool keystore file, create a certificate signing request (CSR), and import certificates. Any root or intermediate certificates need to be imported before importing the primary certificate for your domain. Type these commands in a command line interface.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
These instructions are not specific to the platform and require technical knowledge of security certificates to complete. Technical Support cannot assist in creating the certificates.

Procedure

1. Generate a Java keystore and key pair.

```
keytool -genkey -alias mydomain -keyalg RSA -keystore
 my.keystore
```

2. Generate a CSR for an existing Java keystore.

```
keytool -certreq -alias mydomain -keystore my.keystore -file
 mydomain.csr
```

3. Import a root or intermediate certificate authority CA certificate to an existing Java keystore.

```
keytool -import -trustcacerts -alias root -file Thawte.crt
 -keystore my.keystore
```

4. Import a signed primary certificate to an existing Java keystore.

```
keytool -import -trustcacerts -alias mydomain -file
 mydomain.crt -keystore my.keystore
```

Install a service provider keystore for signing SAML requests

Use the following steps to remove the existing example key store and install your own Service Provider key store containing your public and private key pair.

Before you begin
Role required: admin

Procedure

1. Create a Service Provider key store.
2. Navigate to **SAML 2 Single Sign-on** > **Certificate** or **Multi-provider** > **Administrator** > **x509 Certificate**.
3. Click **SAML 2.0 Keystore_Key2048_SHA256**.
4. Click the **Manage Attachments** link.
5. Select the Delete checkbox next to *saml2sp_key2048withsha256.jks*.
6. Click **Remove**.
7. Click **Choose Files** and select the Keystore containing your signed certificates.
8. Click **Attach**.
9. Close the Attachments popup.

Note:
It is recommended to provide different name for the certificate that is attached newly.

10. In *Key store password*, enter the password to access the SAML 2 alias.
11. Click **Update**.

© 2026 ServiceNow, Inc. All rights reserved.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Create self-signed BCFKS keystore for SAML

Generate a FIPS 140-2 compliant self-signed BCFKS keystore for use in SAML signing and encryption operations within the Multi-Provider SSO plugin.

Before you begin

Role required: admin

Do the following:

- Install Java on your machine and the key tool command-line tool accessible in your terminal (or "command prompt" if you are running it on a windows machine).
- Perform the following steps to create a keystore using FIPS-approved cryptographic algorithms (such as RSA 2048-bit or higher paired with SHA-256) that meets federal security requirements for identity federation and single sign-on implementations.

Procedure

1. Download the FIPS Provider Library.

   Note:

   Use the latest version `bc-fips-2.1.0.jar`. Make sure you use the most recent version.

2. Generate the FIPS-compliant keystore and certificate.

   a. Run the following key tool command to generate a self-signed certificate and keystore.

   Key tool command

   Running on Linux/macOS

   ```
   keytool -genkeypair \
     -providername BCFIPS \
     -providerclass
    org.bouncycastle.jcajce.prov
   ider.BouncyCastleFipsProvider
    \
     -providerpath
    <path_to_bc-fips-<version>>.
   jar \
     -alias <key_alias> \
     -keyalg RSA \
     -keysize <key_size> \
     -keystore
    <keystore_name>.bcfks \
     -validity <validity> \
     -storetype BCFKS \
     -storepass
    <keystore_password>
   ```

   Running on Windows:

   ```
   keytool -genkeypair ^
   -providername BCFIPS ^
   -providerclass
    org.bouncycastle.jcajce.prov
   ider.BouncyCastleFipsProvider
    ^
   -providerpath
    <path_to_bc-fips-<version>>.
   jar ^
   -alias <key_alias> ^
   -keyalg RSA ^
   -keysize <key_size> ^
   -keystore
    <keystore_name>.bcfks ^
   -validity <validity> ^
   -storetype BCFKS ^
   -storepass
    <keystore_password>
   ```

   b. Replace placeholders (`<...>`) with appropriate values:

   - `<path_to_bc-fips-<version>>.jar`: Path to `bc-fips-<version>.jar`
   - `<key_alias>`: Alias for the key pair

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- `<key_size>`: 2048 or 4096
- `<keystore_name>.bcfks`: Desired file name for the keystore
- `<validity>`: Expiry in days
- `<keystore_password>`: Password for the keystore

c. Follow the prompts to enter additional DN (Distinguished Name) details for the certificate.

> **Note:**
> When you are prompted for a password for the key (alias), press the Enter or Return key to use the same password you used for the keystore. Do not give a different password.

d. Securely store the key alias and keystore password.
Provide these credentials while:

- Creating the `sys_certificate` record for this keystore.
- Configuring the SAML Identity Provider to provide the signing key or encryption key alias and password.

> **Note:**
> The key password is same as the keystore password specified during creation. Use the same password when configuring signing or encryption for the SAML Identity Provider.

3. Extract the Certificate Chain.

Key tool command

Running on Linux/macOS	Running on Windows:
`keytool -exportcert \ -provider org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider \ -providerpath <path_to_bc-fips-<version>>.jar \ -storetype BCFKS \ -keystore <keystore_name>.bcfks \ -storepass <keystore_password> \ -alias <key_alias> \ -rfc \ -file <file_name>.cer`	`keytool -exportcert ^ -provider org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider ^ -providerpath <path_to_bc-fips-<version>>.jar ^ -storetype BCFKS ^ -keystore <keystore_name>.bcfks ^ -storepass <keystore_password> ^ -alias <key_alias> ^ -rfc ^ -file <file_name>.cer`

Replace placeholders `(<...>)` with appropriate values:

- `<path_to_bc-fips-<version>>.jar`: Path to `bc-fips-<version>.jar`
- `<keystore_name>.bcfks`: keystore file name as given in previous step
- `<keystore_password>`: keystore password as given in previous step
- `<key_alias>`: Key alias as given in previous step
- `<file_name>.cer`: Desired file name for the extracted certificate in PEM format

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Create a record on `sys_certificate` table.

   a. Log in to ServiceNow AI Platform.

   b. Navigate to **All** > **Multi-Provider SSO** > **Administration** > **x509 Certificate**.

   c. Click **New** to create a record.

   d. Select **BCFKS keystore** as Type.

   e. Attach the generated BCFKS keystore file (`<keystore_name>.bcfks`).

   > **Note:**
   > To configure certificate expiry notification, use **Notify on expiration** and **Groups to notify on expiration**, and set the notification timing using **Warn in days to expire** and **Frequency**.

   f. Fill in other required fields, including the keystore password provided during keystore creation.

   g. Click **Validate Stores/Certificates** related link to ensure the keystore is valid.

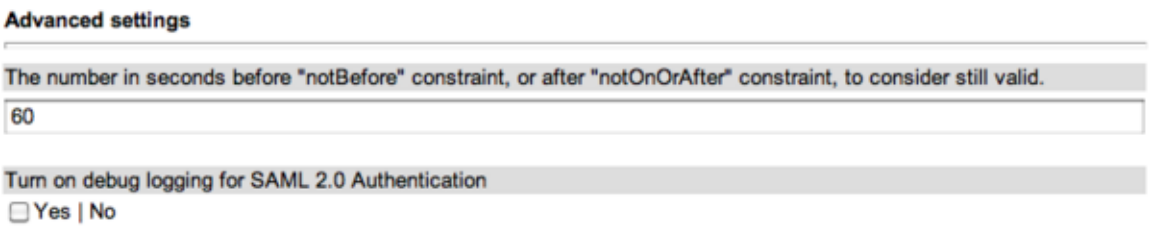
   h. Copy the `sys_id` of this record.

(Optional) Advanced SAML properties

The following advanced settings allow you to further increase security and debug the integration.

Advanced settings

Navigate to **All** > **SAML 2 Single Sign-on** > **Properties**.



Advanced system properties table

Property	Description
The number of seconds "notBefore" constraint, or after "notOnOrAfter" constraint, to consider still valid	Enter the number of seconds to add to the *NotBefore* and *NotOnOrAfter* constraints to account for time differences between the IdP clock and SP clock. These constraints prevent against replay attacks by denying requests that are not made within the specified time frame. If the IdP clock and SP clock are significantly different, network latency may result in the SAML request being unauthorized. This property adds a grace period during which SAML requests and responses are still considered valid.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Advanced system properties table (continued)

Property	Description
Turn on debug logging for SAML 2.0 Authentication	Select **Yes** to enable additional logging information for SAML 2.0 events.

Install the identity provider certificate

You can paste a PEM certificate into a X.509 Certificate form so the identify provider can verify communications with the service provider.

Before you begin

Role required: admin

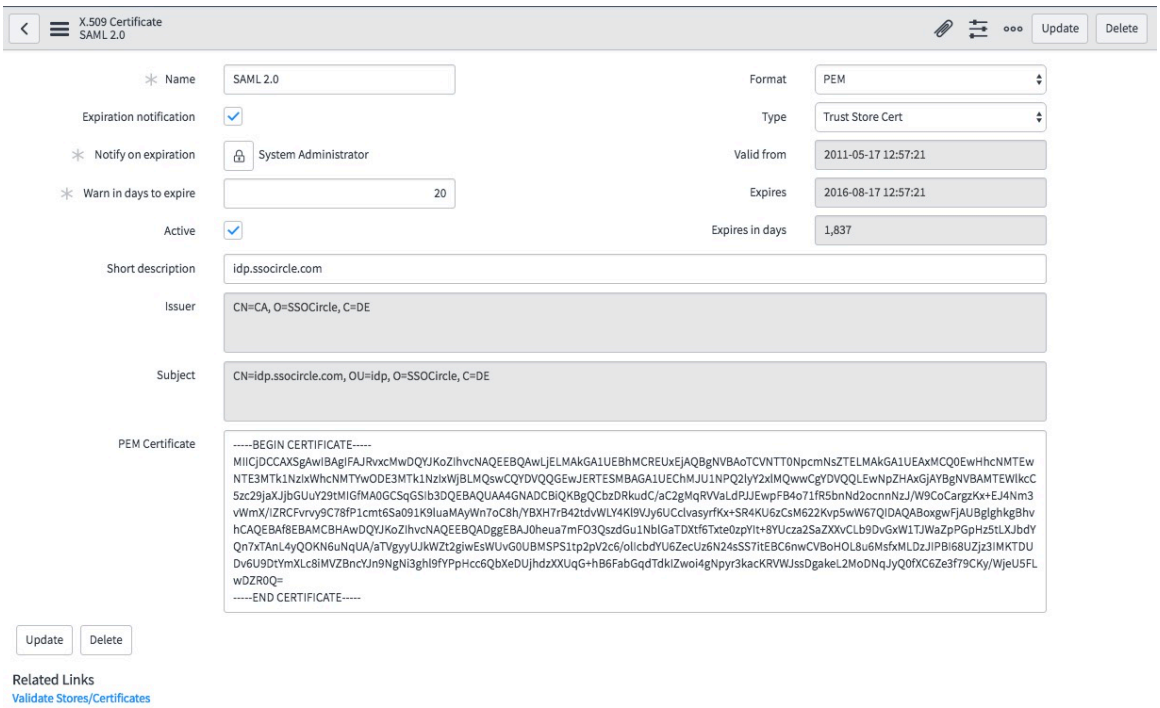
About this task

The IdP's certificate is located within the IdP's metadata. The IdP developer determines where the certificate metadata resides when creating the local IdP.

Note:
Certificates for single-sign on should always be in PEM format to work with SAML certificates.

Procedure

1. Navigate to **All** > **SAML Single Sign-on** > **Certificate**.
2. Fill in the form fields (see table).
3. Click **Save**.



Note:
The integration does not currently sign the certificate in communications between the instance and the IdP.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Name	The certificate name. Do not change the *Name* entry. The name of the X.509 certificate must be *SAML 2.0* in order for the integration to use it. This requirement is only true if you are not using Multi-Provider single sign-on (SSO).
Expiration notification	Select this option to send a notification to the users selected in the **Notify on expiration** field. By default, this is enabled.
Notify on expiration	Select the users to revive the notification regarding certificate expiration. If no users are selected, the logged in user is added by default, along with the last two logged in users with the administrator role.
Warn in days to expire	The number of days before expiration that the instance send the notification. Enter a value of at least 20. Instances upgraded to Istanbul and later releases have this value set to 20 unless a greater value is specified.
Active	A check box to indicate that this certificate is active.
Format	The format of the certificate. SAML uses the PEM format.
Type	The certificate container. The instance recognizes certificates from trust stores, Java keystore, and PKCS#12 keystores.
Valid from	The instance automatically adds the certificate valid from date to this field. Attach the certificate to the X.509 certificate record to populate this field.
Expires	The instance automatically adds the certificate expiration date to this field. Attach the certificate to the X.509 certificate record to populate this field.
Expires in days	The calculated number of days to expiration.
Short description	A description for the certificate.
Issue	The instance automatically adds the certificate issuer to this field. Attach the certificate to the X.509 certificate record to populate this field.
Subject	The instance automatically adds the certificate subject to this field. Attach the certificate to the X.509 certificate record to populate this field.
PEM Certificate	Enter the value of the X509 certificate.

What to do next
Click **Validate Stores/Certificates** to test the trust store and certificate.

Replace a missing certificate for SAML

If the **Certificate** module displays a blank page, the SAML 2.0 certificate record has been deleted. You can replace the missing certificate by manually creating a certificate record.

Before you begin
Role required: admin

Procedure

1. Navigate to **All** > **System Definition** > **Certificates**.
2. Create a new record called `SAML 2.0`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Important:
You MUST use this name. This requirement is only true if you are not using Multi-Provider single sign-on (SSO).

3. Click **SAML 2 Single Sign-on** > **Certificate**.
4. In the *PEM Certificate* field, enter the value of the `ds:X509Certificate` element from your IdP's metadata.
5. Click **Save**.

Test the SAML integration

Test the SAML integration after you complete all the other setup tasks.

Before you begin
Role required: admin

Procedure

1. Log in to the instance as a user with the admin role.
2. Navigate to **SAML 2 Single Sign-on** > **Properties**.
3. In the property *Enable external authentication*, select **Yes**.

Note:

Enabling external authentication requires all users to use SAML 2.0 single sign-on. If anyone tries to access the application in an unauthenticated state, the instance automatically sends an authentication request to the (IdP) and redirects the user to the SAML IdP Authentication page.

4. Click **Save**.
5. Log out of the instance.
6. Browse to the instance URL.
   If the integration is functioning properly, the IdP should ask for the user's credentials.

Common login and IdP errors

Error or Symptom	Diagnosis	Fix
Login requests generate an infinite loop between the system and the IdP when High Security is active.	• Typically the URL endpoint is an error page or logout page. • The logout_redirect.do might create this loop when you define *glide.security.url.whitelist* without adding the IdP host name to the property value. **Note:** To learn more about this property, see Enforce URL allowlist check [Updated in Security Center 1.3, 1.5, and 2.0] in Instance Security Hardening Settings.	Set (or create) the system property glide.authenticate.failed_redirect to redirect failed authentication requests to this URL.
The token used to authenticate the user or the request is signed with the signature algorithm http://www.w3.org/2001/04/xmldsig-more#rsa-sha256 which is not the expected signature algorithm http://www.w3.org/2000/09/xmldsig#rsa-sha1.	Check the Alert Context tab for event details.	Navigate to the Advanced tab of the Relying Party Trust configuration dialog and verify that the algorithm is set to SHA-1 and not SHA-256.
The error message `urn:oasis:names:tc:SAML:2.0:status:Requester` appears in your system log (syslog) table.	When your IdP (e.g. ADFS) responds with a status of `urn:oasis:names:tc:SAML:2.0:status:Requester`, it means the IdP rejected the login because of an issue with the request sent to it. Unfortunately, the SAML response received from the IdP in most cases does not provide further details for the error.	Review the SAML request sent to the IDP, and work with your IDP administrator, update your instance SAML settings to avoid the error. You may need to contact your IDP provider understand the reason for the login failure.

Redirect single sign-on (SSO) logins

When SSO is enabled, you can redirect users to specific pages or direct users to login locally.

For example, if a user attempts to go to `https://customerX.service-now.com`, an internal company portal can display instead of the default login page. Or, when a user logs out of an application, the browser can redirect them to a specific internal page. You can set redirection properties within the instance to ensure that users see an SSO login page rather than the default login page.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
The following properties do not force SSO. The login.do page is still accessible and users can login to the system if they have a local password set.

Redirection properties

When a user logs out, or if there is a failed attempt to sign on using SSO, you can define where the user is taken next, such as a main portal page or a knowledge base article with SSO login information. Use the following properties to specify the URLs. If one of these properties does not exist in your instance, you can create the property.

glide.authenticate.honor.sso_record.failed_requirement_redirect

URL to redirect users when they attempt to access a page that is private (for example, to view an incident) and do not provide SSO credentials. The property is typically set to a customer's login portal (for example, `http://portal.companya.com/`).

glide.authenticate.failed_redirect

URL to redirect users after a failed SSO attempt. You can redirect to a public knowledge article that describes the error and has helpful links (for example, `http://portal.companya.com/error`).

glide.authenticate.external.logout_redirect

URL to redirect users after logging out, typically back to the portal that enabled the single sign-on log in (for example, `http://portal.companya.com/logout`).

glide.authentication.external.disable_local_login

When set to true, requires SSO credentials for the main login page. Defaults to false. This property needs to be used in conjunction with the *glide.authenticate.honor.sso_record.failed_requirement_redirect* property.

The following table shows the relationship between the Installation Exit return values, the properties, and the expected behavior.

Forcing login using SSO only

Return value	Property
`failed_missing_requirement`	*glide.authenticate.honor.sso_record.failed_requir*
`failed_authentication`	*glide.authenticate.failed_redirect*
<user_id>	N/A

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Forcing login using SSO only (continued)

Return value	Property

Restricting local login

As a security precaution, you should do more than rely on redirection properties to prohibit logging in locally. If a user should never log in locally and will always be authenticated by your internal single sign-on system, then a random password should be assigned to each user that is imported into the instance. The random password is most easily set at the time of the user import. If the user data is imported into your system through an import set, you can create an onBefore transform script using the following code .

```
var r  = new Packages. java. util. Random ( ) ;

 var str1  = Packages. java. lang. Long. toString (Packages.
 java. lang.
 Math. abs (r. nextLong ( ) ) , 36 ) ; var str2  = Packages.
 java. lang.
 Long. toString (Packages. java. lang. Math. abs (r. nextLong
 ( ) ) , 36
 ) ;

 var newPass  = str1  + str2 ;

target. user_password = newPass ;

 //password now set to a random string like this:
 //qvm81zdrn7cwwylpvw94eebk
```

Clone an instance with a SAML integration

Clone an instance with a SAML integration. Before you clone an instance that uses SAML 2.0, preserve the SAML SSO-related settings on the target instance or you might make the target instance inaccessible.

Before you begin

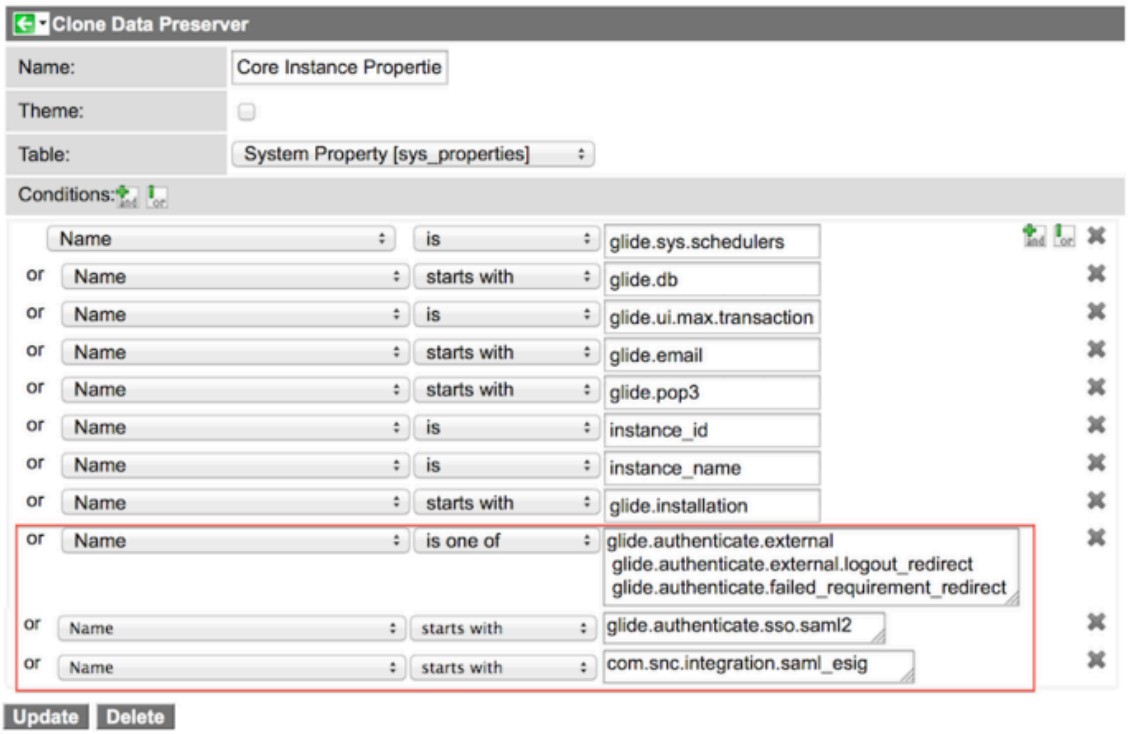
Role required: admin

Procedure

1. On the source instance, navigate to **System Clone** > **Preserve Data** > **Core Instance Properties**.
2. Make sure that the following SAML SSO-related properties are preserved using conditions.
   - glide.authenticate
   - glide.security
   - glide.entry
   - glide.script
   - glide.session
   - glide.saml2

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- com.glide.communications
- com.snc.integration.saml_esig



Note:
When you create the clone, include attachments so that certificates carry over to the target instance. Also, make sure the **Theme** check box is cleared so these properties are preserved regardless of whether you preserve the instance theme.

3. On the source instance, navigate to **System Clone** > **Preserve Data** to preserve the SAML certificates on sys_certificate and SAML users on sys_user related to SAML/SSO/Multi SSO.

   If you need them, export them into XML, then manually import them on the target.

Warning:
Do not try to clone the SAML/SSO/Multi SSO setup from one system to another. Most transfers of SAML/SSO or Multi SSO settings do NOT work because they must be configured on the identity provider. If you overwrite a working setup, the target instance will fail to authenticate so your target instance will become inaccessible. Also, do not change the sys_id of your Multi SSO provider record; doing that will force your users to flush their cookies. For more information about cloning precautions, see Checklist before cloning an instance.

4. Exclude the Multi SSO tables sso_properties, digest_properties and saml2_update1_properties.
5. Manually create the SAML/SSO/Multi SSO records on each instance independently and set up the records on your identity provider as well.
6. Make sure that you manually create a LOCAL admin account on sys_user (not in LDAP or SAML) record on the target instance and with a sys_id that does not exist on the source instance.
7. Click **Update**.

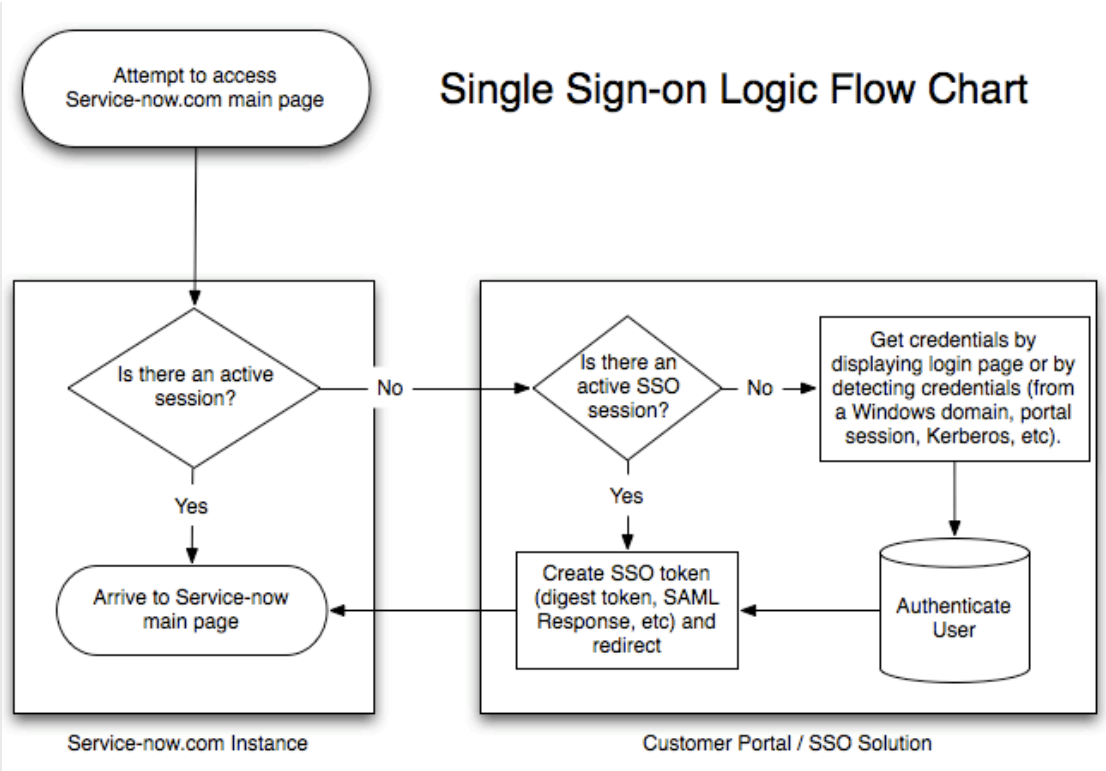
SAML 2.0 concepts

Familiarize yourself with these SAML concepts.

Typical SAML process flow (diagram)

A typical SSO logic flow involves looking for an active session, checking user credentials, and creating the necessary token.

SSO Standard



Login (AuthnRequest) process flow

SAML 2.0 specifies a Web Browser SSO Profile that involves exchanging information among an identity provider (IdP), a service provider (SP), and a principal (user) on a web browser.

The identity provider can be any SSO service offering SAML authentication services (for example SSOCircle). The service provider is always an instance. The message flow begins with a request for a secured resource at the service provider.

Request the target resource at the SP

The principal requests a target resource at the service provider:

https://instance.service-now.com/

The instance checks the request to see if the SAMLRequest and RelayState URL parameters are present. If they exist, the user has already validated with the IdP and can skip steps 2–6.

Issue AuthnRequest to Identity Provider

The instance constructs an `AuthnRequest` to be sent to the IdP using the `SAMLRequest` value. The instance also constructs and sends a `RelayState` URL parameter value.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The `RelayState` token is an opaque reference to state information maintained at the service provider. The value of the `SAMLRequest` parameter is the deflated and base64 encoded value of the `<samlp:AuthnRequest>` element:

```
<samlp:AuthnRequest
 xmlns:samlp="urn:oasis:names:tc:SAML:2.0:protocol"
   xmlns:saml="urn:oasis:names:tc:SAML:2.0:assertion"
    ID="identifier_1"    Version="2.0"
  IssueInstant="2004-12-05T09:21:59Z"
 AssertionConsumerServiceIndex="0"><saml:Issuer>https://
sp.example.com/SAML2</saml:Issuer><samlp:NameIDPolicy
 AllowCreate="true"
 Format="urn:oasis:names:tc:SAML:2.0:nameid-format:transient"/><
/samlp:AuthnRequest>
```

The integration then URL-encodes the `<samlp:AuthnRequest>` element and sends it as the `SAMLRequest` URL parameter.

The SSO service processes the `<samlp:AuthnRequest>` element by URL-decoding, base64-decoding and inflating the request, in that order. It then performs a security check. If the user does not have a valid security context, the IdP identifies the user by prompting for login credentials. If the user is already logged in, the IdP simply responds with the `SAMLResponse<tt> and <tt>RelayState` URL parameters (see step 3).

Respond with an SAMLResponse and RelayState

After collecting the required login credentials, the SSO service validates the request and responds with a document containing an XHTML form:

```
<formmethod="post"action="https://
instance.service-now.com/navpage.do" ...><input type="hidden"
 name="SAMLResponse" value="response ..." /><input type="hidden"
 name="RelayState" value="token ..." />
    ...
    <input type="submit" value="Submit" /></form>
```

The value of the `RelayState` parameter comes from this step. The value of the `SAMLResponse` parameter is the base64 encoding of the following `<samlp:Response>` element:

```
<samlp:Responsexmlns:samlp="urn:oasis:names:tc:SAML:2.0:protoc

></samlp:Response>
```

Validate SAMLResponse

The `SAMLResponse` value is base64 decoded and inflated to reveal the XML document in step 3. The login script extracts the XML value from the `//Subject/NameID` element and uses it to look up an existing user in the User table.

The login script also extracts the session ID from the `//AuthnStatement/@SessionIndex` element and stores it for the `LogoutRequest`.

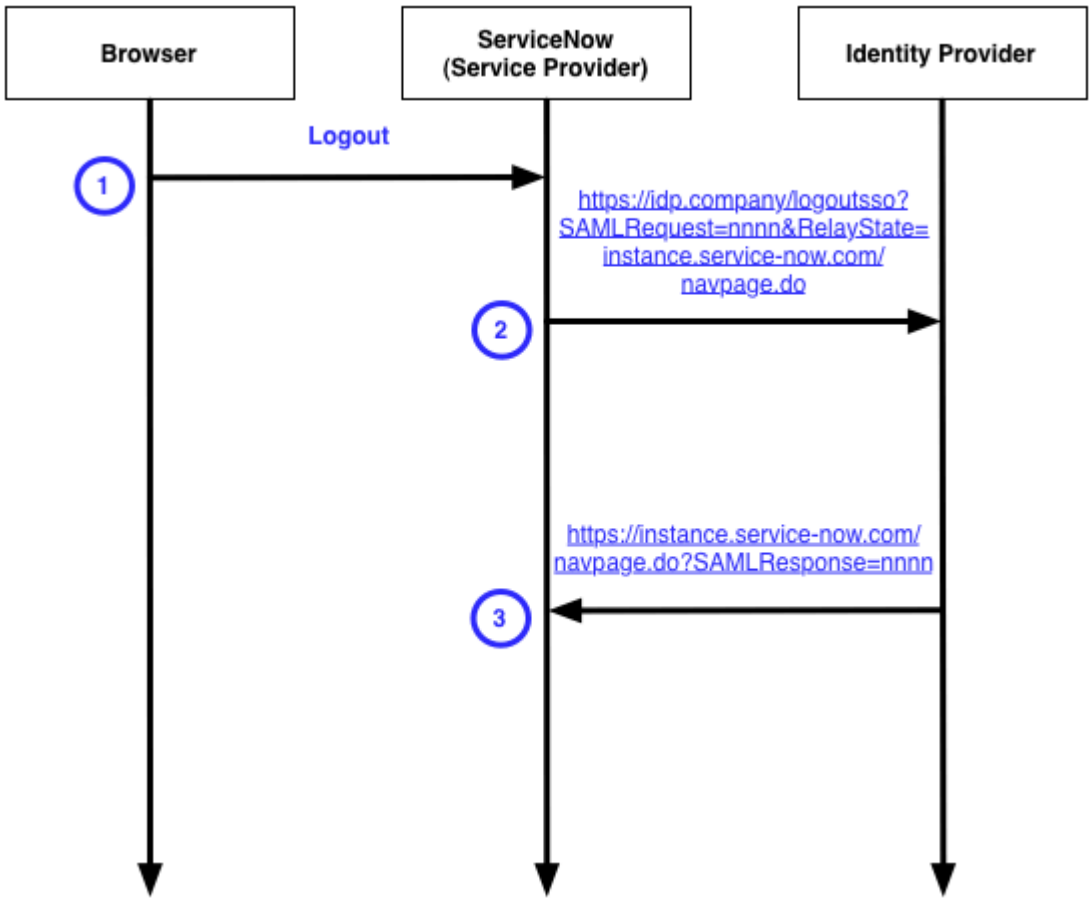
Logout (LogoutRequest) process flow

During logout, the instance issues the SAML 2.0 *LogoutRequest* service call to the IdP.

This service logs the user out and then redirects back to the specified logout URL.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

SAML 2 Logout



User Clicks the Logout Button

The user clicks the **Logout** button and the instance executes the logout script.

LogoutRequest issued

The logout script constructs a SAML 2.0 `LogoutRequest` and posts it to the preconfigured SingleLogoutRequest SAML 2.0 service at the IdP. The IdP deflates the request and then base64 encodes it. An example `LogoutRequest` looks like this:

```
<saml2p:LogoutRequestxmlns:saml2p="urn:oasis:names:tc:SAML:2.0:p
rotocol"  ID="21B78E9C6C8ECF16F01E4A0F15AB2D46"
  IssueInstant="2010-04-28T21:36:11.230Z"
 Version="2.0"><saml2:Issuer
 xmlns:saml2="urn:oasis:names:tc:SAML:2.0:assertion">https://
dloomac.service-now.com
 </saml2:Issuer><saml2:NameID
 xmlns:saml2="urn:oasis:names:tc:SAML:2.0:assertion"
 Format="urn:oasis:names:tc:SAML:1.1:nameid-format:emailAddress"
          NameQualifier="http://idp.ssocircle.com"
 SPNameQualifier="https://
dloomac.service-now.com/navpage.do">david.loo@service-now.com</s
aml2:NameID><saml2p:SessionIndex>s211b2f811485b2a1d2cc4db2b27193
3c286771104
 </saml2p:SessionIndex></saml2p:LogoutRequest>
```

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

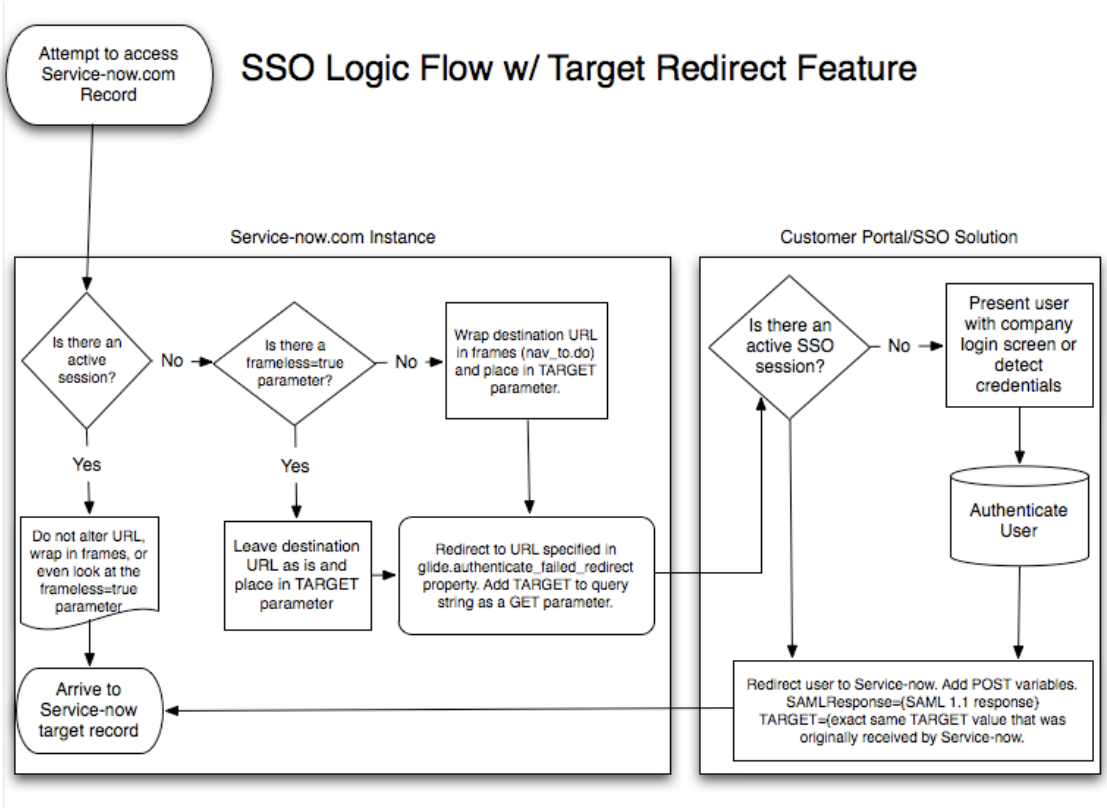
User Logs Out

The user logs out of the IdP. The IdP redirects back to the instance, which in turns redirects back to the IdP since the user is not logged in.

URL information for an SSO provider

During a login challenge resulting from a URL link into the instance that requires an SSO session, the referring URL might need to be supplied to the SSO provider so that after authentication, the URL can be passed back to the instance and linked to the correct resource.

SSO Target Redirect



Installation exit return values have been enhanced to pass a URL instead of, or in addition to the URL defined by the properties. Usually, you would return a username or a predefined string value to control authorize or challenge the SSO session. The following examples show the extended behavior of passing a URL.

```
return
 "failed_missing_requirement:%26amp;TARGET=https://
instance.service-now.com/nav_to.do?uri=incident.do?sys_id=1234
5";
```

The example above passes the URL `https://instance.service-now.com/nav_to.do?uri=incident.do?sys_id=12345` to the SSO provider in the form of a URL parameter named TARGET.

Note:
It is assumed that the SSO provider will use that information in the TARGET parameter to redirect back to the instance when the user credentials have been collected and authentication passed.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

A colon : demarcates the two return values and an encoded & (%26amp;) concatenates the URL defined in the property *glide.authenticate.failed_missing_requirement* and the TARGET parameter.

SAML 2.0 configuration using Multi-Provider SSO

You can create or update a SAML 2.0 SSO configuration from the Multi-Provider SSO feature.

Before you begin

Role required: admin

About this task

Note:
New to the Jakarta release, you must validate your configuration by using the Test Connection functionality before you can activate your IdP configuration. You can still use the Update functionality to save your configuration data, but it is not an active configuration without a successful test connection.

Procedure

1. Navigate to **All** > **Multi-Provider SSO** > **Identity Providers**.
2. Do one of the following options.
   - To update a configuration, click an SSO configuration record.
   - To create a new configuration, click **New** > **SAML**.
3. Enter the IdP information by one of the following methods.

Option	Description
Using a metadata descriptor URL	Click the URL check box and enter the URL of the IdP that you are using.
Using metadata descriptor XML file	Click the XML check box and paste in the XML data generated from the IdP you are us ing.
Entering metadata manually	Close the popup window and manually enter the data in the property fields.

Note:
All required fields must be filled-in on the Identity Provider form.

Multi-provider single sign-on fields

Property	Required	Description
Name	Yes	Enter the name for the IdP. This IdP is the auto redirect sys id.
Active	Yes	Active should be set to true for the IdP to be used for authentication. **Note:** The option to set this property only comes after a successful test connection.
Default	No	The Auto Redirect IdP, formerly known as the Primary IdP, automatically redirects users to access the base instance URL. This property sets this IdP configuration as the default.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

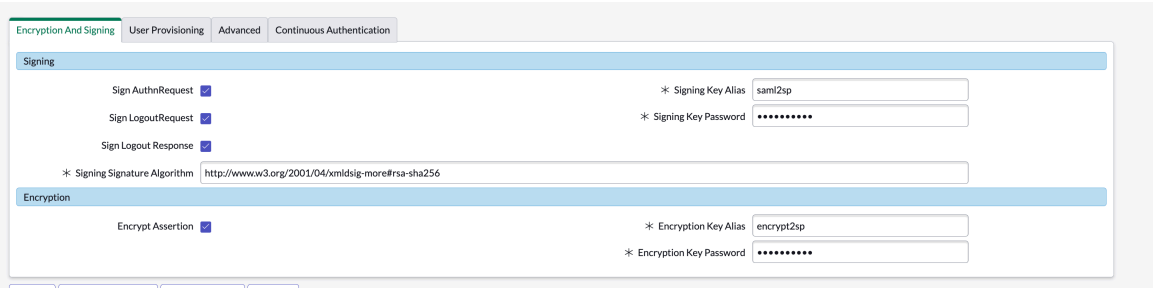
Property	Required	Description
Auto Redirect IdP	No	Sets this IdP configuration as the Auto Redirect IdP. **Note:** If you make a new Auto Redirect IdP configuration active, the *glide_sso_id* cookie updates with the new Auto Redirect IdP. The *glide.authenticate.sso.update.idp.cookie* system property, automatically enabled, controls this feature.
Identity Provider URL	Yes	Enter the URL to your IdP. Each IdP URL must be unique.
Identity Provider's AuthnRequest	Yes	Enter the URL to the HTTP-Redirect binding obtained from the SingleSignOnService element.
Identity Provider's SingleLogoutRequest	No	Enter the URL obtained from the SingleLogoutService element.
ServiceNow Homepage	Yes	Enter the URL, including login page, of the instance for which the IdP authenticates. For example: https://yourinstance.service-now.com/navpage.do
Entity ID/Issuer	Yes	Enter the base URL, excluding login page. of the instance for which the IdP authenticates. For example: https://yourinstance.service-now.com/
Audience URI	Yes	Enter the base URL, excluding login page. of the instance for which the IdP authenticates. For example: https://yourinstance.service-now.com/
NameID Policy	Yes	Enter the value of the NameIDFormat element the integration uses.
External logout redirect	No	Enter the URL where the integration redirects users after they log out.
Failed Requirement Redirect	No	Enter the URL for redirecting failed authentication requests. By default, this is the URL endpoint of an error page or logout page configured in the IdP. You can populate this value in the glide.authenticate.failed_requirement_redirect field.
Client Type	No	Choose the client type, based on the type of your client. Options:**Iframe Embedded**. **Note:** If client type field is required for your configuration, you can edit the form and add the field. To know more, see Configure client type for OAuth and SSO records.

4. **Optional:** Encryption And Signing tab

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:

- You should use your own self-signed or CA-signed certificate. The following types of certificates are supported:
  - BCFKS (FIPS-compliant) keystore (Recommended)
  - Java keystore
- The **FIPS approved mode** requires different certificates for **Encryption** and **Signing**.
- Use different certificates for **Encryption** and **Signing** for a better security posture.
- While using the certificates, make sure to update the following system properties with the sys_id of the certificates (x.509 Certificates):
  - **Signing** (`glide.authenticate.sso.saml2.keystore`)
  - **Encryption** (`glide.authenticate.sso.saml2.encryption.keystore`)
- Make sure to update the key alias and key password of the **Signing** and **Encryption** keystores in the Identity Provider record and generate the metadata (Select **Generate Metadata**).
- Upload the signing and encryption certificates present in the generated metadata (XML) to the Identity Provider.
- To configure certificate expiry notification, use **Notify on expiration** and **Groups to notify on expiration**, and set the notification timing using **Warn in days to expire** and **Frequency**.



Encryption And Signing fields

Property	Description
Signing Key Alias	Enter the Signing alias of the key entry stored in SAML 2.0 SP Keystore.
Signing Key Password	Enter the Signing password of the key entry stored in SAML 2.0 SP Keystore.
Encryption Key Alias	Enter the Encryption alias of the key entry stored in SAML 2.0 SP Keystore.
Encryption Key Password	Enter the Encryption password of the key entry stored in SAML 2.0 SP Keystore.
Encrypt Assertion	Select the check box to encrypt the assertion in the SAML response. The metadata generated for the IDP embeds the x509 certificate, which the IDP uses to encrypt the assertion in the SAML response that it generates.
Signing Signature Algorithm	Enter the URL that points to the SAML 2.0 Identity Provider AuthnRequest Consumer for eSignature Authentication.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

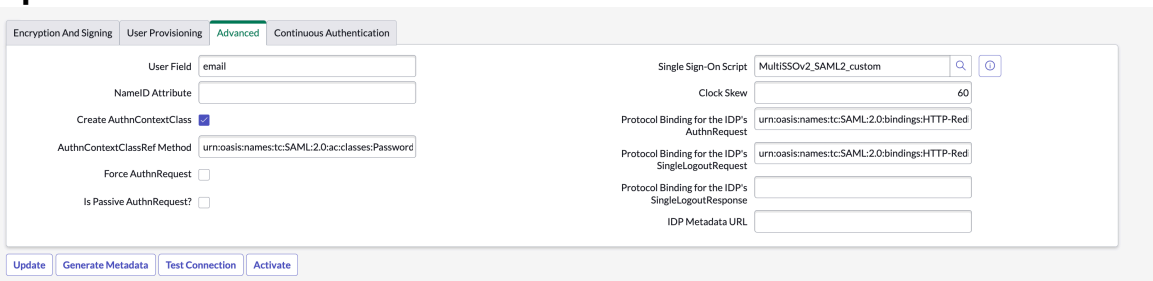
Property	Description
Sign AuthnRequest	Select the check box to enable the IdP single-sign on service to receive a signed AuthnRequest.
Sign LogoutRequest	Select the check box to enable the IdP single-sign on service to receive a signed LogoutRequest.
Sign Logout Response	Select the check box to enable the IdP single-sign on service to receive a signed Logout Response.

5. **Optional:** User Provisioning tab

User Provisioning fields

Property	Description
Auto Provisioning User	Enable automatic user provisioning, creates the users when user doesn't exists in the instance User Table based on the information provided by the IdP.
Update User Record Upon Each Login	Updates user information in the instance User table with the information in the IdP each time the user logs in using SAML.

6. **Optional:** Advanced tab



Advanced fields

Property	Description
User Field	Enter the field on the User table that contains the value the IdP requires to identify the user. This is a unique id as part of the response. For example, user name, employee id, and so on. In the sys user table, this unique id is matched with the user details.
NameID Attribute	Leave this field blank unless you configure a new NameID policy. If you configure a new policy, the system requires the User table it must use to identify the user logging in. The system matches the NameID token to the name of that User table field here.
Create AuthnContextClass	Select the check box to specify a particular context class such as Password Protected Transport. If the check box is cleared, the IdP selects the most appropriate context class.
AuthnContextClassRef Method	Enter the URN of the login mechanism you want the IdP to use to authenticate users.
Force AuthnRequest	Select the check box to force AuthnRequests to occur.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

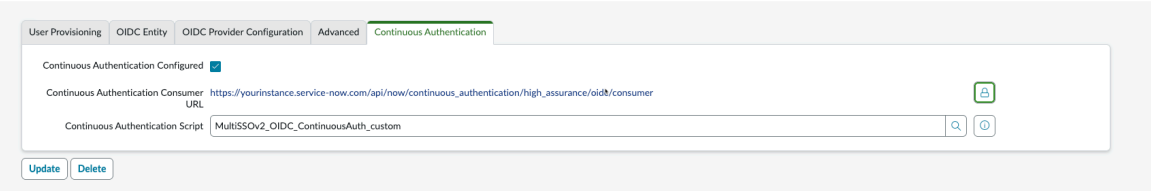
Property	Description
Is Passive AuthnRequest	Select the check box if the AuthnRequest is passive.
Single Sign-On Script	Select the Single Sign-On script. The default is *MultiSSOV2_SAML2_custom*.
Sign Logout Response	Enter the logout response details in this field.
Clock Skew	Enter the number of seconds between the two attributes that make up the SAMLResponse nonce. The default is 60. A valid SAMLResponse must fall between the *notBefore* and *notOnOrAfter* date-time values. See Sample SAML 2 Response with the SubjectConfirmation and SubjectConfirmationData Elements and Sample SAML 2 Response with the AudienceRestrictions and Audience Elements for a sample SAMLResponse message.
Protocol Binding for the IDP's SingleLogoutReuqest	Enter one of the supported values listed in the Binding attribute from the SingleLogoutService element.
Metadata URL from which IDP properties are imported	The IdP properties import from this URL. If set, it enables the automatic import of SAML certificate from the IdP if the previous certificate has expired. **Note:** If you upgrade from SAML2 Update 1 to Multi-Provider SSO or if you manually set up your SSO connection, the IdP Metadata URL does not automatically populate.
Request	An unique id as part of request, the id can be user name, employee id, and so on. **Note:** Both redirect and post binding is supported for request. The option to set this field only appears after a successful test connection. For more information see, Test IdP connections.
Response	An unique id as part of response, the id can be user name, employee id, and so on. **Note:** Both redirect and post binding is supported for response. The option to set this field only appears after a successful test connection. For more information see, Test IdP connections.

7. **Optional:** On the Continuous Authentication tab, configure the following fields:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:

- The Continuous Authentication tab appears only when you install the **Zero Trust - Continuous Authentication** (`com.snc.zero_trust_continuous_authentication`) plugin that requires license.
- If you're using continuous authentication policy to protect access to table or data class, see Continuous Authentication (CA).



Continuous Authentication

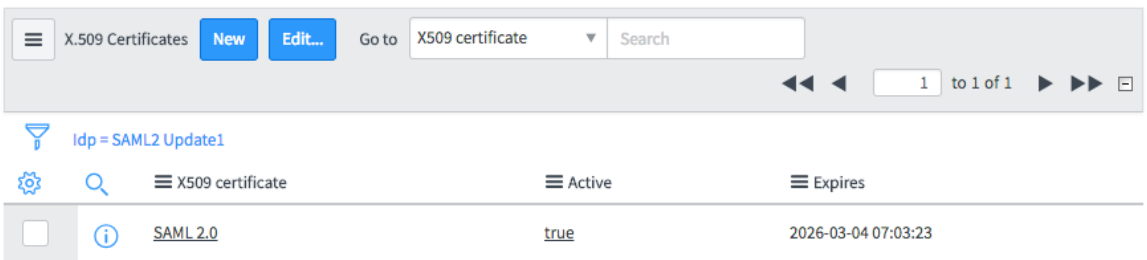
Field	Description
Continuous Authentication Configured	Select the check-box to set the configuration active.
Continuous Authentication Consumer URL	Provide the Consumer URL from the Identity Provider.
Continuous Authentication Script	(Optional) Select the look-up icon to choose the script provided from the platform. In this configuration, for SAML: **MultiSSOv2_SAML2_ContinuousAuth_custom**

X.509 certificates for SAML

Store and activate the necessary IdP certificates for your SAML configuration.

The X.509 certificates are the IdP certificates that a SAML configuration uses. After you install a certificate, you can add as many certificates as necessary. When there are multiple certificates, the system uses the first active certificate that is found. If you set the URL for the **Metadata URL from which IDP properties are imported field**, the system automatically polls the IdP for a current, valid certificate when your certificate is no longer valid. It appends this certificate to your instance, and uses it for your active SAML configuration.

Note:
Polling occurs if the IdP is accessible outside of your network.



SAML Guided Tour

Use the SAML Guided Tour to configure SAML for single sign-on.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

SAML Guided tour helps you to get trained and configure the SSO for your ServiceNow® instance. Admins can select the guided tour to quickly know the required actions when configuring SSO for the instances.

Before using the guided tour, you must configure a SAML application in your preferred Identity Provider, such as Okta, Microsoft Azure, ADFS, and so on. To learn how to configure a SAML application, refer the following documentation:

- Okta: For Okta, you must perform the following:
  - Add an Okta SAML application
  - Configure SAML 2.0 for ServiceNow®
- Microsoft Azure: Single sign-on (SSO) integration with ServiceNow®
- Ping: Configuring SAML SSO with ServiceNow®
- ADFS: Integration with SAML 2.0

To use the SAML Guided tour, activate the Integration - Multiple Provider Single Sign-On Installer plugin. For more information see, Activate Multi-Provider SSO plugin.

To use the SAML Guided Tour, follow these steps:

1. Navigate to **All** > **Multi-Provider SSO** > **Identity Provider**.
2. Click **New**.
3. Select **SAML**.
4. Click the **Help** icon.
5. Click **Take a Tour**.

SAML Guided tour use a series of steps that span across multiple pages to complete the configuration, following the steps and instructions provided as part of the tour and complete the tour. To know more about SAML configuration, see SAML 2.0 configuration using Multi-Provider SSO.

Integrating SAML 2.0 with other features

You can integration your SAML 2.0 solution with other features like E-Signature, deep linking, and ADFS.

Add deep linking support for SAML

Deep linking allows instances to support direct email links to a particular record in the system.

With the SAML 2.0 integration enabled, deep-linking URLs must pass an authentication check before the IdP redirects the user to the originally requested URL. For example, consider an email that contains this URL: `https://<instance name>.service-now.com/nav_to.do?uri=incident.do?sys_id=46c88ac1a9fe1981014de1c831fbcf6d`

The instance sends an authentication request to the IdP and uses the `RelayState` URL parameter to preserve the originally requested resource (in this case, `uri=incident.do?sys_id=46c88ac1a9fe1981014de1c831fbcf6d`). After the IdP authenticates the user, the instance reads the value of the RelayState URL parameter and redirects the user to the requested resource (if it exists in the instance).

To add support for deep linking verify that the identity provider supports the `RelayState` URL parameter.

ADFS integration with SAML 2.0

The ServiceNow Multi-Provider SSO plugin supports a SAML 2. single sign-on (SSO) integration with Microsoft ADFS.

For information about installing and configuring ADFS, see Active Directory Federation Services Overview. The Multi-Provider SSO plugin ha configured and tested with a SAML 2.0 SSO integration with ADFS 2.0, 3.0, Azure AD.ributes are not support SAML Response in

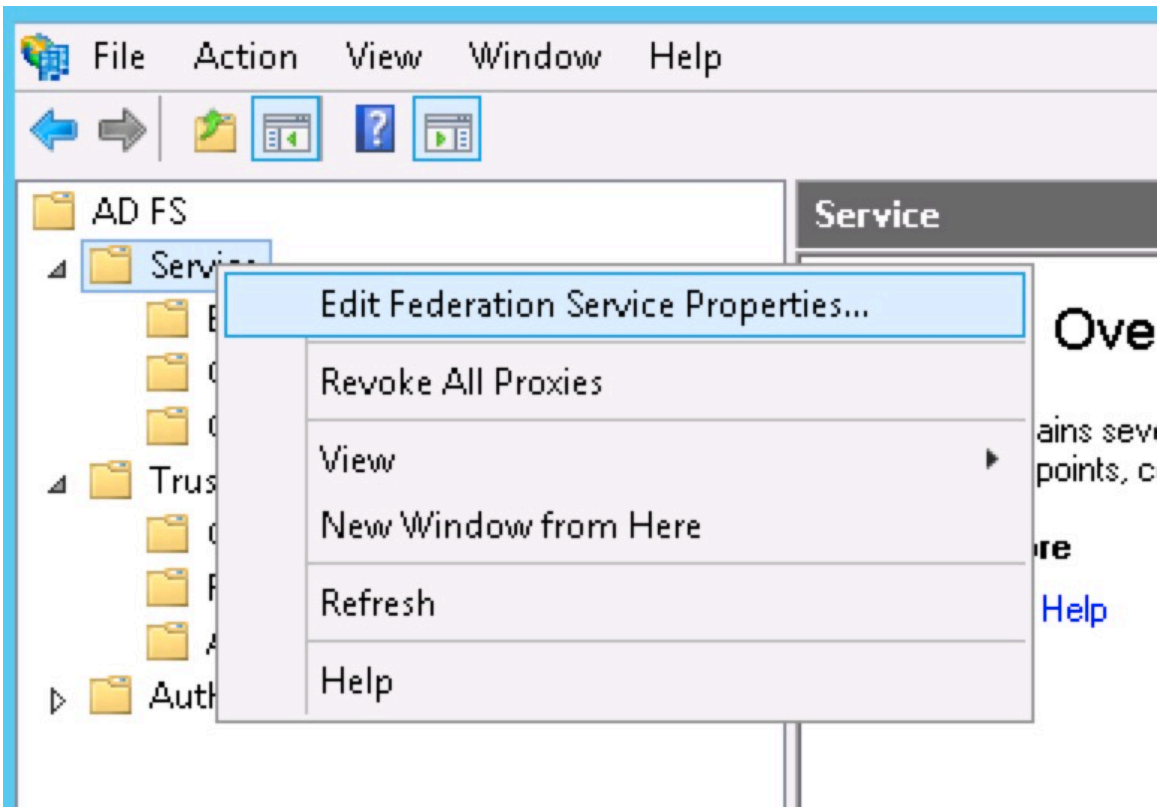
Set up ADFS for SAML

Set up ADFS for SAML. This procedure uses ADFS 2.0 and shows samportal.example.com as the ADFS website. Replace this with your ADFS website address.

Before you begin
Role required: admin

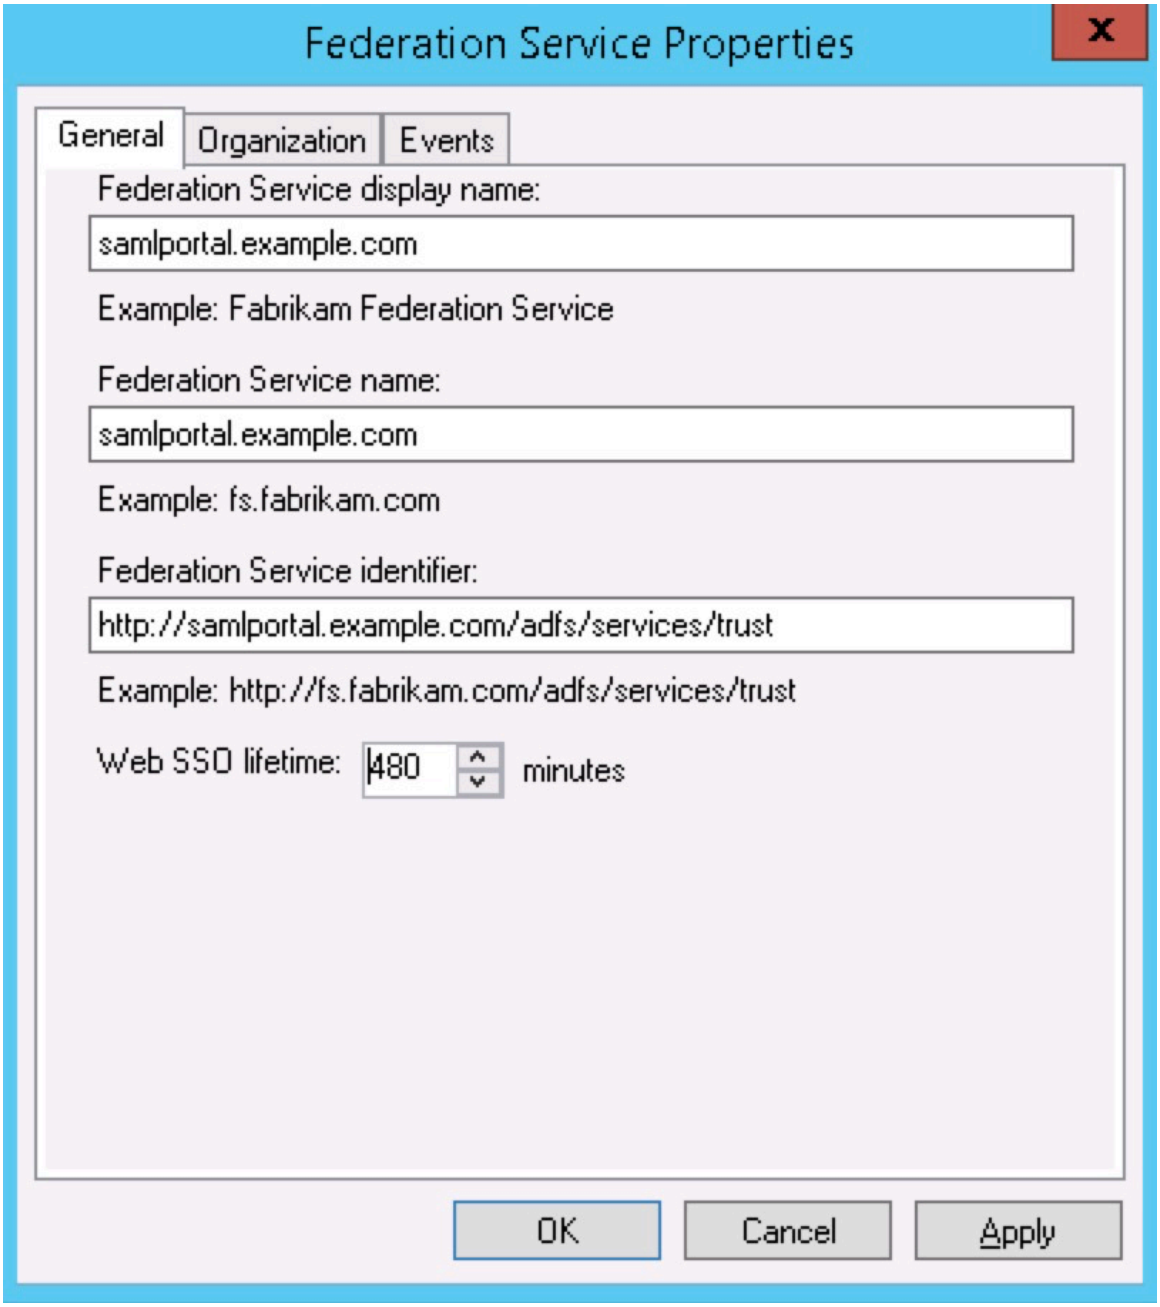
Procedure

1. Log into the ADFS 3.0 server and open the management console.
2. Right-click **Service** and select **Edit Federation Service Properties**.



3. Confirm that the General settings match your DNS entries and certificate names.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



4. Browse to the certificates and export the Token-Signing certificate.

   a. Right-click the certificate and select **View Certificate**.

   b. Select the **Details** tab.

   c. Click **Copy to File**.
   The Certificate Export Wizard opens.

   d. Select **Next**.

   e. Ensure that the **No, do not export the private key** option is selected, and then click **Next**.

   f. Select **DER encoded binary X.509 (.cer)**, and then click **Next**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

g. Select where you want to save the file and give it a name and click **Next**.

h. Select **Finish**.
The instance requires that this certificate be in PEM format. You can convert this certificate using client tools or online tools such as SSL Shopper.

5. Use the DER/Binary certificate that you just created, and export it in Standard PEM format.

Set up the instance for ADFS

Configure your instance and SAML 2.0 settings to work with ADFS.

Before you begin

Perform these steps only after you have set up ADFS for SAML. For details on that process, see set up ADFS for SAML.

Role required: admin

Procedure

1. If not already active, Activate Multi-Provider SSO plugin.
2. Configure SAML, but when you install the IdP certificate, attach the PEM certificate you created when you Set up ADFS for SAML.
3. Click **Save**.
4. Verify that the **Issue** and **Subject** fields have values and that there are no errors.
If an error occurs, open the saved PEM formatted certificate in Notepad and copy and paste the certificate into the PEM Certificate field.
5. Verify that the SAML2SingleSignon_update1 installation exit is active.
6. Continue the SAML 2.0 configuration.

> **Note:**
> When a certificate is updated on the ADFS server, you also need to upload an updated certificate to the instance.

Configure an ADFS relying party

Take the instance metadata and import it into your ADFS server. However, manual configuration of the relying party appears to be easier to implement.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **Multi-Provider SSO** > **Identity Providers** > **SAML2 Update1** > **Encryption And Signing** and verify that the SAML property Sign AuthnRequest (*glide.authenticate.sso.saml2.require_signed_authnrequest*) is not active.
Only keep this property active if your ADFS administrator can verify that you require signed requests.
2. Copy the metadata that you generated through the SAML 2 metadata link and save it to a file.
3. Log into the ADFS server and open the management console.
4. Select **Relying Party Trusts**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

5. Select **Add Relying Party Trust** from the top right corner of the window.

   The add wizard appears.

6. Click **Start** to begin.
7. Use the **Import File** option to import the metadata file.
8. Give it a display name such as `ServiceNow` and enter any notes you want.
9. Select **ADFS 3.0 Profile**.
10. Do not select a token encryption certificate.
    It will use the certificate that is defined on the service that has already been exported. Defining a certificate prevents proper communication with the instance.
11. Do not enable any settings on the **Configure URL**.
12. Enter the instance site to which you connected as the Relying Party trust identifier.
    In this case, use `https://company.service-now.com` and click **Add**.
13. Permit all users to access this relying party.
14. Click **Next** and clear the **Open the Claims when this finishes** check box.
15. Close this page.
    The new relying party trust appears in the window.
16. Right-click on the relying party trust and select **Properties**.
17. Browse to the **Advanced** tab and set the **Secure hash algorithm** as either SHA-256 or SHA-1.
18. Browse to the Endpoints tab and add a **SAML Assertion Consumer** with a **Post** binding and a URL of `https://company.service-now.com/navpage.do`.

Configure the ADFS relying party claim rules

Edit the claim rules to enable proper communication with the instance.

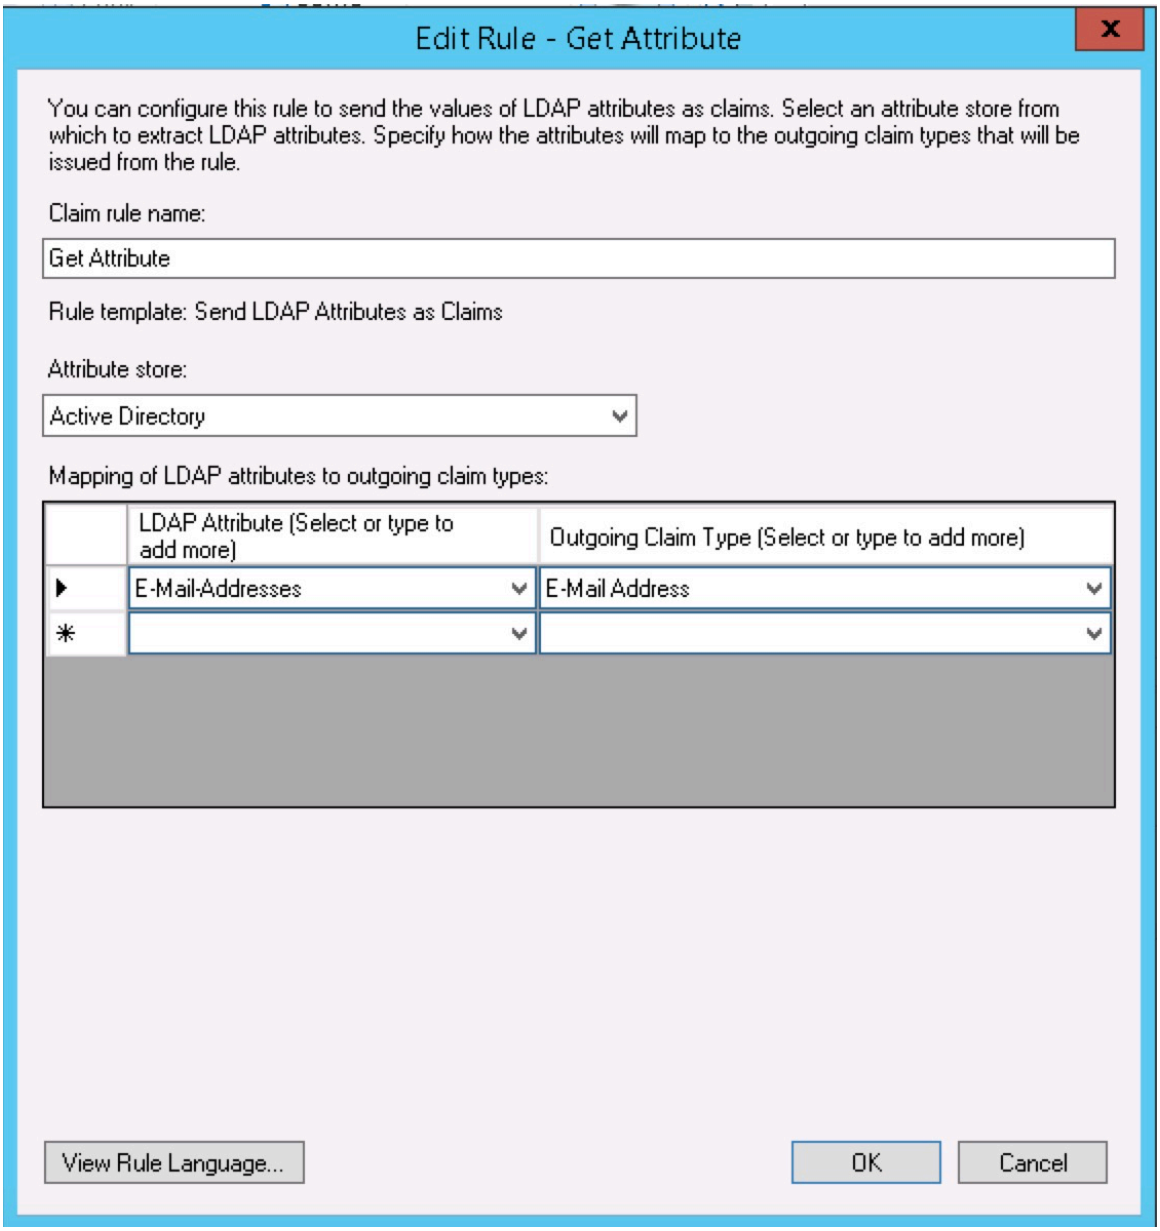
Before you begin

Role required: admin

Procedure

1. Log into the ADFS server and open the management console.
2. Right-click the relying party trust and select **Edit Claim Rules**.
3. Click the **Issuance Transform Rules** tab.
4. Select **Add Rules**.
5. Select **Send LDAP Attribute as Claims** as the claim rule template to use.
6. Give the claim a name such as `Get LDAP Attributes`.
7. Set the **Attribute store** to `Active Directory`, the **LDAP Attribute** to `E-Mail-Addresses`, and the **Outgoing Claim Type** to `E-mail Address`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



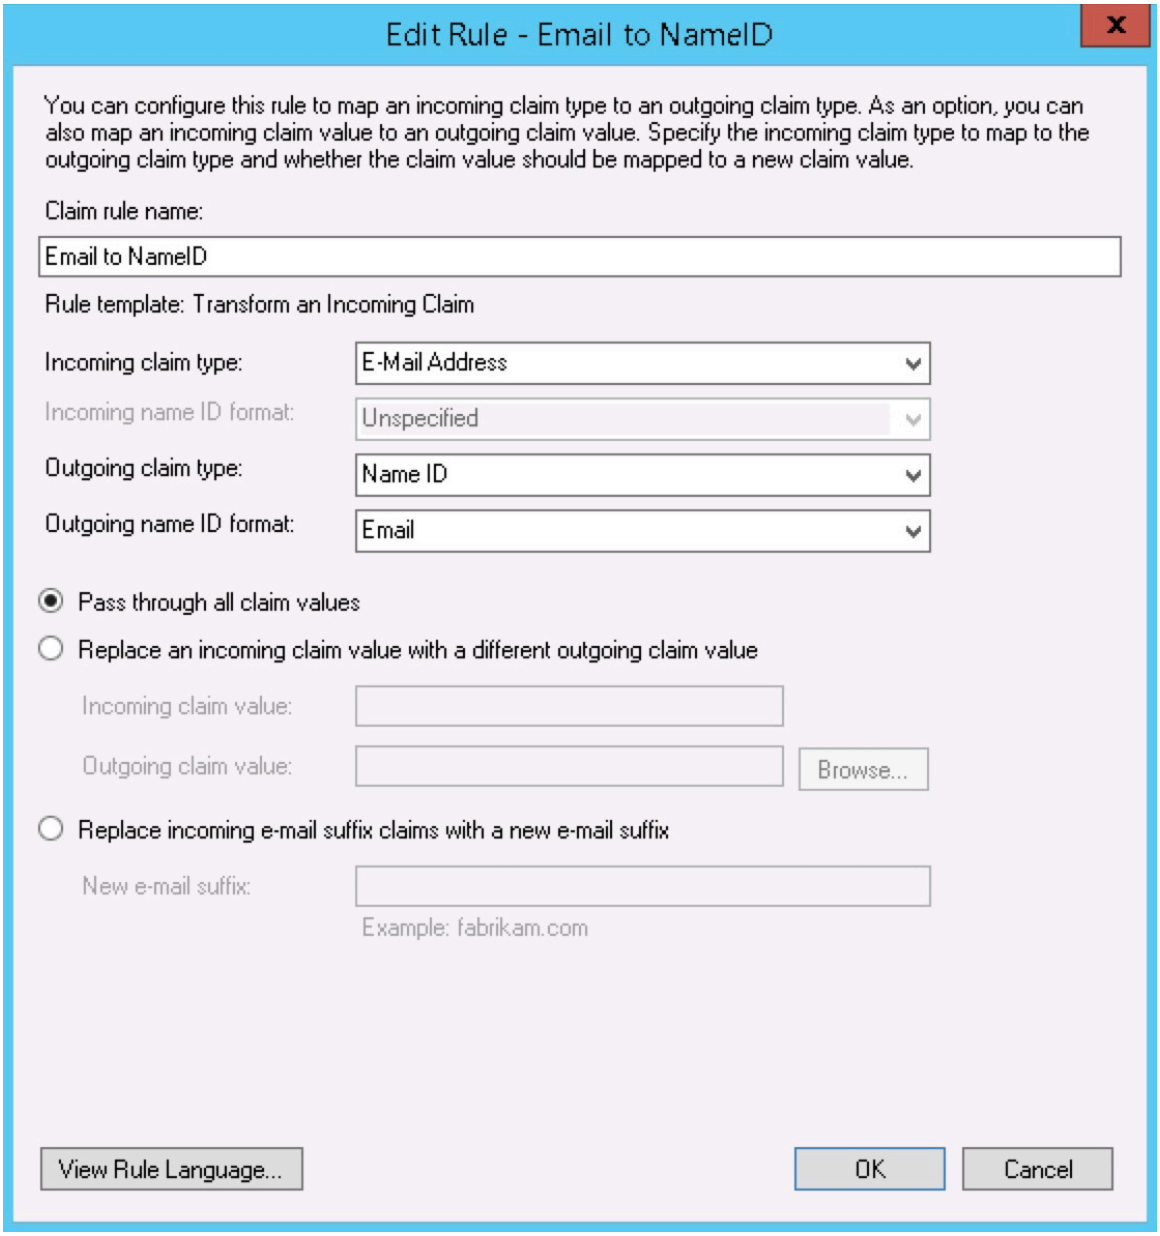
```
c:[Type ==
 "http://schemas.microsoft.com/ws/2008/06/identity/claims/windo
wsaccountname", Issuer == "AD AUTHORITY"]
=> issue(store = "Active Directory",
types =
 ("http://schemas.xmlsoap.org/ws/2005/05/identity/claims/emaila
ddress"),
query = ";mail;{0}", param = c.Value);
```

8. Select **Finish**.
9. Select **Add Rules**.
10. Select **Transform an Incoming Claim** as the claim rule template to use.
11. Give the Claim a name such as `Email to Name ID`.
12. Set the **Incoming claim type** to the **Outgoing Claim Type** in the previous rule.
    For example, `E-Mail Address`.
13. Set the **Outgoing claim type** to `Name ID` and the **Outgoing name ID format** to `Email`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
These values must match the Name ID policy you define during SAML 2.0 configuration.

14. Select **Pass through all claim values**.



This claim rule should look similar to the following rule language.

```
c:[Type ==
 "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/emailad
dress"]
 => issue(Type =
 "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/nameide
ntifier",
Issuer = c.Issuer, OriginalIssuer = c.OriginalIssuer, Value =
 c.Value, ValueType = c.ValueType,
Properties["http://
schemas.xmlsoap.org/ws/2005/05/identity/claimproperties/forma
t"]
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
= "urn:oasis:names:tc:SAML:1.1:nameid-format:emailAddress");
```

15. Click **Finish**.

Create a SAML logout endpoint

Create a SAML logout endpoint to allow single logout.

Before you begin
Role required: admin

About this task
See this article on ADFS signout for more information.

Procedure

1. Go to **ADFS manager** > **Trust Relationships** > **Relying Party Trusts** > **properties**.
2. Under the Endpoints tab, click **Add SAML**.
3. Configure the settings:
   - **Endpoint Type**: SAML Logout
   - **Binding**: POST
   - **Trusted URL**: The URL of your ADFS server. For example,

     ```
     https://myadfsserver.domain.net/adfs/ls/?wa=wsignout1.0
     ```

   - **Response URL**: The application logout URL. For example,

     ```
     https://{instancename}.service-now.com/external_logout_complete.do
     ```

Test the ADFS configuration

Test your ADFS configuration to verify that it is properly functioning as an identity provider.

Before you begin
Role required: admin

Procedure

1. Open an Internet Explorer browser.
2. Navigate to your ADFS portal.

   For example, `https://samportal.example.com/adfs/ls/idpinitiatedsignon.aspx`. This page contains a drop-down list of all configured Relying Party Trusts.

3. Select the relying party that is associated with your instance.
4. Click **Continue to Sign In**.

   If you have configured the SAML 2.0 external authentication properly, you should be automatically logged into the instance.

5. Test a direct login URL by navigating to `https://samportal.example.com/adfs/ls/idpinitiatedsignon.aspx?logintoRP=https://company.service-now.com`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

(Workaround) Enable service provider-initiated authentication

Use this workaround if authentication fails because you do not have SAML 2.0 Update 1. This issue can happen if users attempt to skip IdP authentication and navigate directly to the instance.

Before you begin
Role required: admin

About this task
This error occurs when the instance doesn't provide ADFS with the needed definition and semantics for the SPNameQualifier attribute in the SAMLResponse.

Enable service provider-initiated authentication by doing one of the following actions:

Procedure

- Upgrade to SAML 2.0 Update 1 and clear the option to create an AuthnContextClass request.
- Modify the **SAML2** script include to comment out the definitions of the `SPNameQualifier` attribute when you have SAML 2.0 active (not SAML 2.0 Update 1).

  Comment out these lines in the createNameID and createNameIDPolicy functions:

```
//nid.setSPNameQualifier (serviceURL ) ;

 //nameIdPolicy. setSPNameQualifier (serviceURLStr ) ;
```

What to do next
If you do not want the login prompt from your ADFS server to appear when you access the instance, set the following SAML 2.0 Update 1 property to false: **Create an AuthnContextClass request in the AuthnRequest** statement (*`glide.authenticate.sso.saml2.createrequestedauthncontext`*).

(Workaround) Support Kerberos authentication

A workaround is available for the SAML 2.0 integration that changes the authentication context from forms-based authentication to Windows-based authentication.

Before you begin
Role required: admin

About this task
Currently, the SAML 2 integration uses a PasswordProtectedTransport or "forms-based authentication" authentication context. This authentication context requires the IdP to present users with a form for authentication credentials. With Kerberos, a SAML session is already active through an established Windows login, so the user does not need to authenticate with the IdP.

Procedure

1. Navigate to **All** > **Multi-Provider SSO** > **Identity Providers**.
2. Open the **SAML2 Update1** IdP record.
3. Set the **The AuthnContextClassRef method that we will be included in our SAML 2.0 AuthnRequest to the Identity Provider** to one of the following:

AuthnContextClassRef method values
`urn:oasis:names:tc:SAML:2.0:ac:classes:PasswordProtectedTransport` (Default)

```
urn:federation:authentication:windows
```

4. Click **Update**.

Azure AD Integration with SAML 2.0

Integrate ServiceNow with Azure Active Directory (Azure AD).

Integrating ServiceNow with Azure AD enables you to:

- Control in Azure AD who has access to ServiceNow.
- Enable users to automatically sign-in to ServiceNow with their Azure AD accounts.
- Manage your accounts in the Azure portal.

Prerequisities

To get started, you need the perform the following:

- An Azure AD subscription. If you don't have a subscription, you can get a free account.
- A ServiceNow single sign-on (SSO) enabled.
- A ServiceNow instance or tenant of ServiceNow that supports San Diego versions or later.
- A ServiceNow tenant must have the Multiple Provider Single Sign On Plugin enabled.
- For automatic configuration, enable the multi-provider plugin for ServiceNow.

Set of Actions for Configuration

Following are the set of actions that needs to performed to configure Azure AD:

- Add ServiceNow from the gallery to Azure AD.
- Configure Azure AD SSO
- Create an Azure AD test user
- Assign the Azure AD test user
- Configure ServiceNow

Add ServiceNow from the gallery

Add ServiceNow from the gallery to your list of managed SaaS apps on Azure AD.

Before you begin

Role required: Azure admin

Procedure

1. Sign in to the Azure portal by using a Microsoft account.
2. Select the **Azure Active Directory** service from the left pane.
3. Navigate to **Enterprise Applications** > **All Applications**.
4. To add new application, select **New** application.
5. In the Add from the gallery section, enter ServiceNow in the search box.
6. Select ServiceNow from results panel, and then add the app.
7. Wait a few seconds while the app is added to your tenant.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Configure Azure AD SSO

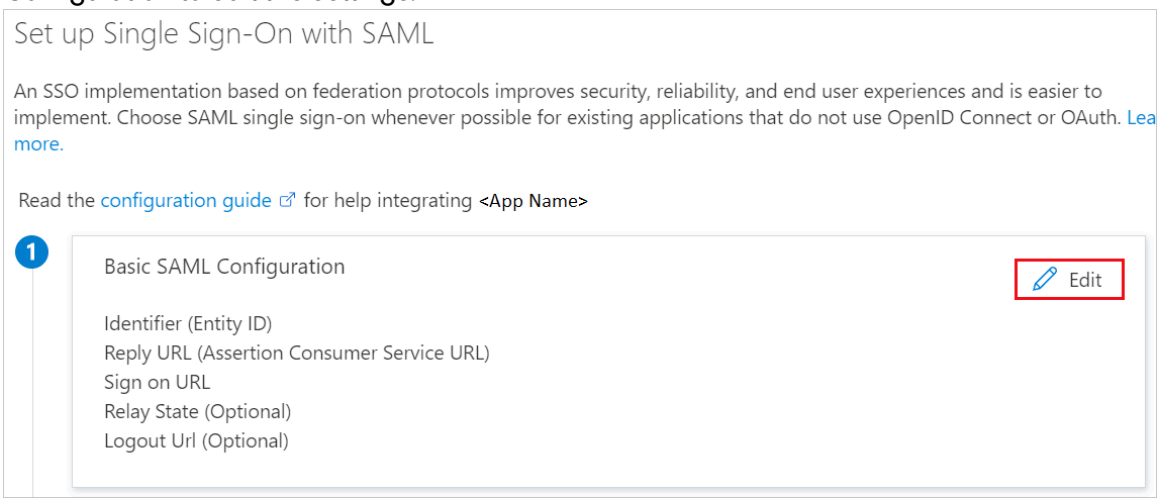
Configure Azure AD SSO in the Azure portal.

Before you begin

Role required: Azure admin

Procedure

1. In the Azure portal, on the ServiceNow application integration page, find the Manage section.
2. Select single sign-on.
   On the Select a single sign-on method page, select SAML.
3. On the Set up single sign-on with SAML page, select the pen icon for Basic SAML Configuration to edit the settings.



4. In the Basic SAML Configuration section, perform the following:

   a. In **Sign on URL**, enter one of the following URL patterns:

   ```
   https://<instancename>.service-now.com/navpage.do
   https://<instance-name>.service-now.com/login_with_sso.do?glide_sso_id=<sys_id of the sso configuration>
   ```

   Note:
   You need to provide the sys_id within this URL.

   b. In Identifier (Entity ID), enter a URL with the pattern: `https://<instance-name>.service-now.com`.

   c. For **Reply URL**, enter one of the following URL patterns:

   ```
   https://<instancename>.service-now.com/navpage.do
   https://<instancename>.service-now.com/customer.do
   ```

   d. In Logout URL, enter a URL with the pattern: `https://<instancename>.service-now.com/navpage.do`

   Note:
   You must update the actual sign-on URL, Reply URL, Logout URL and identifier. the values shown in these URLs are for demo purpose.

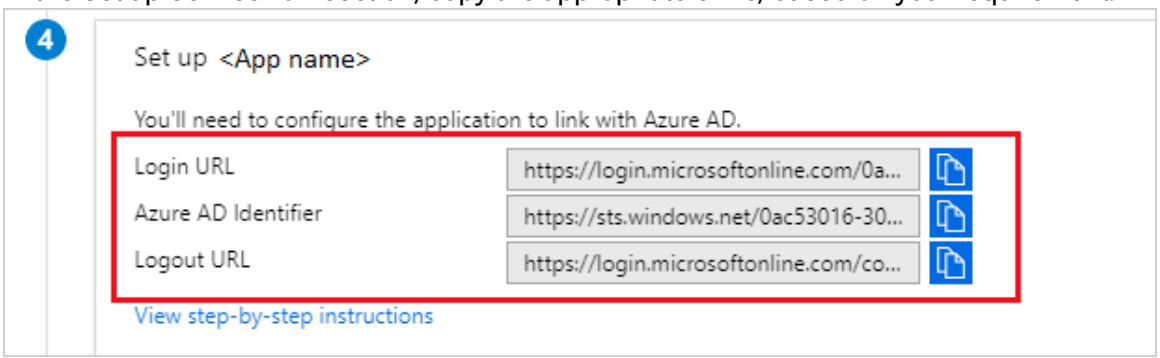
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

5. On the Set up single sign-on with SAML page, in the SAML Signing Certificate section, find **Certificate (Base64)**.

   a. Select the copy button to copy **App Federation Metadata Url**, and paste it into Notepad. This URL is required for further configuration.

   b. Select **Download** to download Certificate(Base64).

6. In the Set up ServiceNow section, copy the appropriate URLs, based on your requirement.



Create an Azure AD test user

Create a test user on Azure AD.

Before you begin

Role required: Azure admin

Procedure

1. On the Azure portal, navigate to **All** > **Azure Active Directory** > **Users** > **All users**.
2. Select **New user**.
3. In the User properties, provide the following information:
   - Name
   - User name
   - Password
4. Click **Create**.

Assign the Azure AD test user

Assign the Azure AD test user that is created to use Azure single sign-on by granting access to ServiceNow.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin
Role required: Azure admin

Procedure
1. On the Azure portal, navigate to **All** > **Enterprise Applications** > **All applications**.
2. From the applications list, select ServiceNow.
3. On the app's page,in the Manage section, select **Users and groups**.
4. Select **Add user**.
5. In the **Add Assignment** window, select **Users and groups**.
6. In the **Users and groups** window, select the `test user` that was created from the users list.
7. Choose the role for the assigned user from the **Select a role** drop-down if required.
8. In the **Add Assignment** window, select **Assign**.

Configure ServiceNow

Configure ServiceNow with Azure AD details to use SSO.

Before you begin
Plugin: `Integration - Multiple Provider single sign-on Installer`

Enable the Multi Provider SSO properties:

- Select **Enable multiple provider SSO**.
- Select **Enable Auto Importing of users from all identity providers into the user table**.
- Select **Enable debug logging for the multiple provider SSO integration**.
- Enter **email**, The field on the user table that.....

Role required: admin

Procedure
1. Navigate to **All** > **Multi-Provider SSO** > **Identity Providers**.
2. On the Identity Providers page, select **New**.
3. On the Identity Providers windows, select **SAML**.
4. On the Import Identity Provider Metadata, you can either:
   - **URL**: App Federation Metadata URL to auto-populate the details on the Identity Provider configuration page.
   - **Import**: Import the XML to import the details on the Identity Provider configuration page.
5. Right click on the top of the screen, click **Copy sys_id**, and use this value to the **Sign on URL** in **Basic SAML Configuration** section.
6. On the form, fill in the fields.

Multi-provider single sign-on fields

Property	Required	Description
Name	Yes	Name for the IdP. This IdP is the auto redirect sys id.
Active	Yes	Active should be set to true for the IdP to be used for authentication.

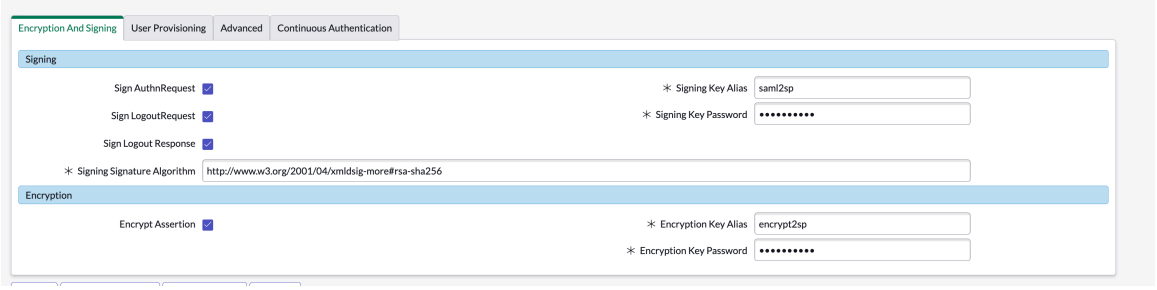
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property	Required	Description
		Note: The option to set this property only comes after a successful test connection.
Default	No	Auto Redirect IdP, formerly known as the Primary IdP, automatically redirects users to access the base instance URL. This property sets this IdP configuration as the default.
Auto Redirect IdP	No	IdP configuration that you can set as the Auto Redirect IdP. **Note:** If you make a new Auto Redirect IdP configuration active, the `glide_sso_id` cookie updates with the new Auto Redirect IdP. The `glide.authenticate.sso.update.idp.cookie` system property, automatically enabled, controls this feature.
Identity Provider URL	Yes	URL to your IdP. Each IdP URL must be unique.
Identity Provider's AuthnRequest	Yes	URL to the HTTP-Redirect binding obtained from the SingleSignOnService element.
Identity Provider's SingleLogoutRequest	No	URL obtained from the SingleLogoutService element.
ServiceNow Homepage	Yes	URL, including the login page, of the instance for which the IdP authenticates. For example: https://yourinstance.service-now.com/navpage.do
Entity ID/Issuer	Yes	Base URL, excluding the login page of the instance for which the IdP authenticates. For example: https://yourinstance.service-now.com/
Audience URI	Yes	Base URL, excluding the login page of the instance for which the IdP authenticates. For example: https://yourinstance.service-now.com/
NameID Policy	Yes	Value of the NameIDFormat element the integration uses.
External logout redirect	No	URL where the integration redirects users after they log out.
Failed Requirement Redirect	No	URL for redirecting failed authentication requests. By default, this is the URL endpoint of an error page or logout page configured in the IdP. You can populate this value in the glide.authenticate.failed_requirement_redirect field.

7. **Optional:** Encryption And Signing tab

Note:
Use your own certificates for the encryption and signing.

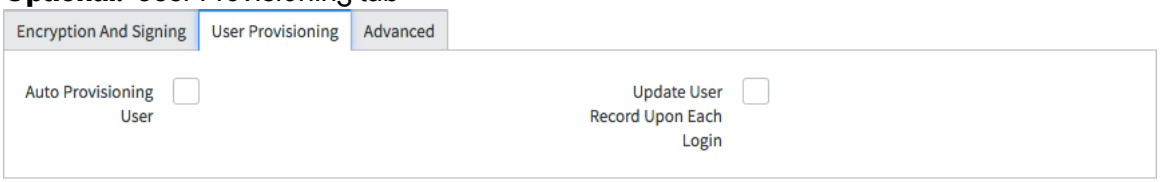
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Encryption and Signing fields

Property	Description
Signing/ Encryption Key Alias	Alias of the key entry stored in SAML 2.0 SP Keystore.
Signing Key Password	Password of the key entry stored in SAML 2.0 SP Keystore.
Encrypt Assertion	Check box to encrypt the assertion in the SAML response. The metadata generated for the IDP embeds the x509 certificate, which the IDP uses to encrypt the assertion in the SAML response that it generates.
Signing Signature Algorithm	URL that points to the SAML 2.0 Identity Provider AuthnRequest Consumer for eSignature Authentication.
Sign AuthnRequest	Check box to enable the IdP single-sign on service to receive a signed AuthnRequest.
Sign LogoutRequest	Check box to enable the IdP single-sign on service to receive a signed LogoutRequest.

8. **Optional:** User Provisioning tab

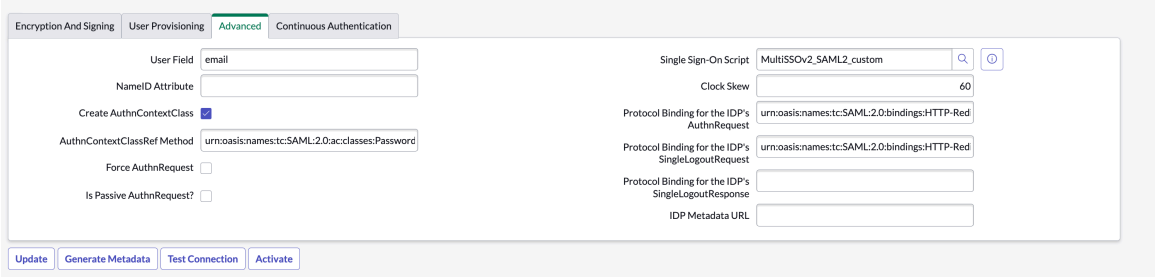


User Provisioning fields

Property	Description
Auto Provisioning User	Automatic user provisioning, creates the users when user doesn't exists in the instance User Table based on the information provided by the IdP.
Update User Record Upon Each Login	Update to user information in the instance User table with the information in the IdP each time that the user logs in using SAML.

9. **Optional:** Advanced tab

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Advanced fields

Property	Description
User Field	Field on the User table that contains the value that the IdP requires to identify the user. This unique id is part of the response. For example, a user name, employee id, and so on. In the sys user table, this unique id is matched with the user details.
NameID Attribute	Field that you leave empty unless you configure a new NameID policy. If you configure a new policy, the system requires the User table it must use to identify the user logging in. The system matches the NameID token to the name of that User table field.
Create AuthnContextClass	Check box to specify a particular context class such as Password Protected Transport. If the check box is cleared, the IdP selects the most appropriate context class.
AuthnContextClassRef Method	URN of the login mechanism that you want the IdP to use to authenticate users.
Force AuthnRequest	Check box to force AuthnRequests to occur.
Is Passive AuthnRequest	Check box if the AuthnRequest is passive.
Single Sign-On Script	Single Sign-On script. The default is *MultiSSOV2_SAML2_custom*.
Sign Logout Response	Logout response details in this field.
Clock Skew	Nnumber of seconds between the two attributes that make up the SAMLResponse nonce. The default is 60. A valid SAMLResponse must fall between the *notBefore* and *notOnOrAfter* date-time values. See Sample SAML 2 Response with the SubjectConfirmation and SubjectConfirmationData Elements and Sample SAML 2 Response with the AudienceRestrictions and Audience Elements for a sample SAMLResponse message.
Protocol Binding for the IDP's SingleLogoutReuqest	One of the supported values listed in the Binding attribute from the SingleLogoutService element.
Metadata URL from which IDP properties are imported	IdP properties import from this URL. If set, it enables the automatic import of SAML certificate from the IdP if the previous certificate has expired. **Note:** If you upgrade from SAML2 Update 1 to Multi-Provider SSO or if you manually set up your SSO connection, the IdP Metadata URL does not automatically populate.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property	Description
Request	Unique id as part of request. The id can be a user name, employee id, and so on. **Note:** Both redirect and post binding is supported for request. The option to set this field only appears after a successful test connection. For more information, see Test IdP connections.
Response	Unique id as part of response. The id can be a user name, employee id, and so on. **Note:** Both redirect and post binding is supported for response. The option to set this field only appears after a successful test connection. For more information, see Test IdP connections.

10. Select **Test Connection** at the upper-right corner of the page.
11. Enter your credentials.
    The SSO Logout Test Results are displayed.
12. Select **Activate** to activate the configuration.

Email links with external authentication

You can use email links when using the digestive token external authentication, however, you must establish how to handle links in email notifications.

The default links contain a URL that directs you to a specific location in the instance, like an Incident or Change Request, without incorporating SSO credentials. Below are examples for directing the user to the location in the instance without logging in on the instance login page.

- Unencrypted HTTP technique to connect to the /demo instance (it does not navigate to specific record):

```
https://<instance
 name>.service-now.com/?
SM_USER=user_name&DE_USER=lQjIVp7aRJtyPx5+2O/vgU24tbE=
```

- Link (in an email notification) to a specific record, so that the user first goes to the company's own login portal:

```
https://login.company_portal_page.com/nav_to.do?uri=incident.
do?sys_id=009f8eda0a0a0b2b01ab4eb094223466%26sysparm_stack=inci
dent_list.do%3Fsysparm_query=active=true
```

  You must set the *glide.email.override.url* property in your instance to contain the URL of the company portal page. If this property does not exist, you can create it.

- The company portal must then take that URL and construct the redirect URL to the instance preserving the segment necessary to access the specific record, and adding the SSO credentials to the end of the URL:

```
https://<instance
 name>.service-now.com/nav_to.do?uri=incident.do?sys_id=009f8ed
```

```

Add E-Signature support for SAML

Configure the following properties for E-Signature with Security Assertion Markup Language (SAML) 2.0 update 1.

When E-signature is active with Multi-SSO, SAML properties aren't used. The system adds E-signature properties to the SAML2 Update1 Properties [saml2_update1_properties] table:

Property	Description	Default
Assertion Consumer Index for eSignature authentication	An index number that identifies the endpoint.	1
Assertion Consumer URL for eSignature authentication	The URL that identifies the consumer.	`https://yourinstance.service-now.com/consumer.do`
AuthnRequest URL for eSignature Authentication	The URL for authentication	none

If you're using E-Signature with SAML 1.0 or SAML 2.0 (not including update 1), see the special configuration instructions: E-signature for Multi-Provider SSO.

Note:
If you're a Life Science Customer using E-Signature, deactivate the User self-lockout prevention business rule.

Migrating an existing SAML 1.1 integration to SAML 2.0

To migrate from a SAML 1.1 integration to a SAML 2.0 integration, contact customer support.

Update your existing SAML 2.0 integration

Update your existing SAML 2.0 integration.

Before you begin
Role required: admin

About this task
Request the SAML 2.0 Update 1 plugin. Contact Customer Service and Support to request the *SAML 2.0 Single Sign-On - Update 1: security enhancements* plugin. The plugin applies updated versions of the *SAML2SingleSignon* installation exit (login script), *SAML2Logout* installation exit (logout script), and *SAML2* script include (script object).

Merge customizations from existing installation exit scripts into new scripts. The update saves an inactive copy of the integration's original installation exit scripts. You can use these copies to merge any customizations that you made to the login and logout scripts to the new versions of these installation exits.

Merge Customizations from Existing Installation Exit Scripts into New Scripts

Original Installation Exit Script Name	Original Script Status	New Installation Exit Script Name	New Script Status
SAML2SingleSignon	Inactive	SAML2SingleSignon_update1	Active

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Merge Customizations from Existing Installation Exit Scripts into New Scripts (continued)

Original Installation Exit Script Name	Original Script Status	New Installation Exit Script Name	New Script Status
SAML2	Inactive	SAML2_update1	Active
SAML2Logout	Inactive	SAML2Logout_update1	Active

You can navigate to the SAML 2.0 login and logout installation exit scripts using these paths:

- **SAML 2 Single Sign-on** > **Login script**.
- **SAML 2 Single Sign-on** > **Logout script**.
- **System Definition** > **Installation Exits**.

You can navigate to the SAML 2.0 update 1 script include using these paths:

- **SAML 2 Single Sign-on** > **Script object**.
- **System Definition** > **Script Includes**.

Test the Update.

Procedure

1. Add a system property called `glide.authenticate.sso.saml2.debug` with a value of *true*.
2. Attempt SAML 2.0 login.
3. Review the system log.
   SAML2 validation errors begin with the text *SAML2ValidationError*.
4. Identify and fix typical login errors.
   For more information, see Multi-SSO (SAML 2.0) errors and fixes.

Sample SAML 2 responses after the update

The following sections illustrate the new required elements and attributes that the IdP should provide in the SAML Response.

Sample SAML 2 Response with Issuer Element

The following SAML 2 response uses the *Issuer* element.

```

saml:Audience>https://
demoi2.service-now.com</saml:Audience></saml:AudienceRestriction
></saml:Conditions>
```

SAML user provisioning

If users exist in your IdP but are not in your instance, SAML user provisioning can automatically create the users in your instance's User [sys_user] table.

SAML user provisioning is supported for SAML 2.0 Update 1 when Multi-SSO is enabled.

How SAML user provisioning works

When SAML user provisioning is enabled and the system encounters a new user that is not in the instance, the instance automatically creates a record in a temporary table with the name `u_imp_saml_user_<suffix>`, where `<suffix>` is an automatically generated text identifier. The system also creates transform map that specifies the data relationships between the import table and the User table. Each IdP in identified in the system has its own transform map. The transform map is created once for each IdP. Administrators can update it as necessary.

When the user logs in, they access an IdP to log in.

- The system presents a list of all IdPs that are able to use SAML user provisioning. If there is only one IdP that can use SAML user provisioning, that one is used automatically.
- If none of the above conditions are true, the system uses the Auto Redirect IdP.

Administer SAML user provisioning

Update the User table with the users in your IdP by first setting up field mapping and then enabling user provisioning through Multi-SSO IdP settings.

Before you begin

Set up your IdP mapping to identify which fields in the IdP are mapped to the correct fields in the User table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Role required: admin

Procedure

1. Navigate to **All** > **Multi-Provider SSO** > **Properties**.
2. Select **Enable Auto Importing of users from all identity providers into the user table** (*glide.authenticate.multisso.user.autoprovision*) to activate this feature.
3. Click **Save**.
4. Navigate to **Multi-Provider SSO** > **Identity Providers**.
5. Open the Identity Provider record that you want to use.
6. Create a record in the User table when the user does not already exist by selecting **Auto-provision Users**.
   If you upgraded to this release, you need to configure the form and add this field.
7. Enable user records to be updated when users log in to the IdP and the information on the IdP is out of date with the information on the User table by selecting **Update User Record Upon Each Login**.
   If you upgraded to this release, you need to configure the form and add this field.
8. Click **User Provisioning Transform Map** to see the map that the system automatically creates.
9. Make changes to the map as needed.

Result

When the first unknown users try to log in, the system creates the fields in the import set table from the metadata.xml file.

Note:
You cannot map the fields from the IdP table until this first user logs in.

SAML 2.0 troubleshooting

Before contacting support, try the troubleshooting solutions available in the knowledge base on Hi.

Note:
The instance does not support solutions provided by external sites.

See the following knowledge base article: KB0540617 "'SAML Error Matrix'".

Other Common Issues

Error or Symptom	Solution
Error message: "is not a function." This issue might occur in a multi-node environment. If the plugin does not get activated on all nodes, an error like the following appears: org.mozilla.javascript.EcmaError: *[JavaPackage org.opensaml.saml2.core.impl.AuthnRequestBuilder]* is not a function.	This error occurs because the plugin was not active and did not load the .jar file. Therefore, the code appears to be missing. Contact Technical Support to restart nodes that are missing the plugin.
SAML does not authenticate users accessing CMS pages.	By default, CMS pages are public and therefore

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Other Common Issues (continued)

Error or Symptom	Solution
	do not require authentication. If you want SAML to authenticate CMS pages, change the *view_content.do* public page from *active=true* to *active=false*.
Cannot redirect a user back to a CMS page after SAML authentication.	By default, the SSO integration uses a URL parameter called *URI* to control where the user is directed after authentication at the IdP. SSO ignores relative URLs. For example, SSO cannot redirect users to a */ess* relative URL. Instead, the user has to navigate to a URL such as */nav_to.do?uri=/ess*, which uses deep linking syntax. However, this puts the ESS portal inside the main navigation content IFrame. In other words, the site does not take up the full page, but rather loads as a page in your instance. For more information, see CMS Sites and Single Sign-On. If you change the CMS entry page to make it private by setting *view_content.do* to *active=false*, deep linking behavior then requires a customization to the Installation Exit login script. Create a script that looks for the *URI* portion of the

© 2026 ServiceNow, Inc. All rights reserved.

Other Common Issues (continued)

Error or Symptom	Solution
	URL and constructs a *RelayState* URL parameter containing the relative URL path to redirect users after authenticating at the IdP.
SAML does not redirect users to the appropriate page after authentication.	Determine if the relay state is passed out to the IdP and then passed back during authentication. You can do this with a browser capable of saving HTTP request headers and POST info, such as Chrome with its built-in developer tools, or Firefox with the add-on called HTTPfox. For Internet Explorer, use a third-party application such as Fiddler. The goal is to watch the requests pass from the client (browser) to the instance, and from the client to the IdP.

Monitor the event queue for login activities

Every single sign-on integration creates events for login activities.

You can use these events to monitor for login failures and determine if there are any security concerns to address.

Monitoring the event queue for login failures

Event Name	Description	Record	Parameter 1	Parameter 2
`external.authentication.succeeded`	External authentication succeeded and the user accessed the instance URL.	Session ID	User ID of user who successfully logged in	The URL the user accessed (which may be a deep link)
`external.authentication.failed`	The single sign-on requirements		Session ID	The missing authentication requirements

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Monitoring the event queue for login failures (continued)

Event Name	Description	Record	Parameter 1	Parameter 2
	are not present or are missing.			
external.authentication.failed	The user does not exist in the User [sys_user] table		User ID	The string, "User does not exist"
external.authentication.failed	The user is locked out.		User ID	The string, "User locked out."

Event queue login events

The SAML 2.0 integration creates events for login activities.

You can use these events to monitor for login failures and determine if there are any security concerns to address.

Login activities events

Event name	Description	ID used with event	Event string
saml2.logout.validation.failed	The logout response from the IdP failed validation against your logout request. The event validates the <inResponseTo> element against the session ID (ID attribute of the <saml2p:LogoutRequest> element). For example, see the workflow for logout request issued.	Session ID	The string, "SAML2 LogoutResponse validation failed.'
external.authentication.succeeded	External authentication successed.		The string, 'Authentication Successed'
external.authentication.succeeded	External authentication succeeded and the user accessed the instance URL.	Session ID & User ID of user who successfully logged in	The URL the user accessed (which may be a deep link)
external.authentication.failed	The single sign-on requirements are not present or are missing.	Session ID	The missing authentication requirements
external.authentication.failed	The user does not exist in the User [sys_user] table.	User ID	The string, 'User does not exist'

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Login activities events (continued)

Event name	Description	ID used with event	Event string
external.authentication.failed	The user is locked out.	User ID	The string, 'User locked out'

OAuth Inbound and Outbound authentication

OAuth based authentication validates the identity of the client that attempts to establish a trust on the system by using an authentication protocol.

OAuth 2.0 - Open Authorization is the industry-standard protocol for authorization, that ocuses on client developer simplicity while providing specific authorization flows for web applications, desktop applications, and mobile devices.

It is a standard that is designed to allow a website or application to access resources hosted by other web apps on behalf of a user.

Instead of using the resource user's credentials to access protected resources, the client obtains an access token. Access tokens are issued to third-party clients with the user's approval, the client then uses the access token to access the protected resources.

From Zurich, you can configure OAuth integration with the following enhancements:

- Increase client secret length to 2048 characters to meet security requirements of third-party systems like Azure DevOps (ADO).
- Provide a JSON Web Key Set (JWKS) URL to automatically manage and update the public key for JSON Web Tokens (JWT) signature validation.
- Request OAuth tokens using the JWT grant type signed with Enhanced Security (ES) algorithms.
- Configure a unique identifier for JWT tokens.

Inbound

Create an endpoint for external clients that want to access your instance. This creates an OAuth client application record and generates a client ID and client secret that the client needs to access the restricted resources on the instance. For more information see, OAuth inbound.

Outbound

Use a third-party OAuth provider that provides the authorization for access to your instance. Specify an OAuth profile and OAuth scope when you are connecting to another OAuth provider. For more information see, OAuth outbound.

OAuth 2.0

OAuth 2.0 lets users access instance resources through external clients by obtaining a token rather than by entering login credentials with each resource request.

You must have the security_admin role to manage the OAuth integration. Configure OAuth 2.0 for the following scenarios:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **OAuth external client scenario** (Inbound): Your instance provides an endpoint for third-party clients to pull data from the instance.
- **OAuth provider scenario** (Outbound): Your instance pulls data from a third-party provider.

Note:
You must user authenticate for the first time to fetch the token post which, you don't need to authenticate using a user account before the token expiry.

Both, simple security and high security frameworks support OAuth 2.0. High Security is recommended. See for information about which versions have high security already active and how to activate high security.

Key concepts of the OAuth 2.0 implementation

Concept	Description
Resource Owner	An entity capable of granting access to a protected resource. A resource owner who is a person is called an end user. The resource owner is always a user account.
Client	An application that, with the authorization of the resource owner, makes requests for protected resources on behalf of the resource owner.
Resource Server	The server that hosts the protected resources, capable of accepting and responding to requests for protected resources.
Authorization Server	The server that issues access tokens to the client after successfully authenticating the resource owner and obtaining authorization.
Authorization Request	The permission that a client requires to access a protected resource. The authorization request is always an HTTP POST message that contains the ID of the client that is acting on behalf of the resource owner and credentials that authorize the request.
Authorization Grant	A credential that represents the authorization from the resource owner to access a resource. The authorization grant is either user login credentials or a refresh token.
Access Token	A secure string that a client uses to access protected resources. An instance issues access tokens to clients that have a valid authorization grant. Each access token has a specific scope, lifespan, and other attributes. By default, an instance issues access tokens with a 30-minute lifespan in the scenario where the instance is the OAuth provider. For third-party tokens, 30 days.
Refresh Token	A credential that a client uses to obtain new access tokens without requiring additional user authorization. An instance issues a refresh token to a client when it is first authorized to have an access token. By default, an instance issues refresh tokens with a 100-day lifespan in the scenario where the instance is the OAuth provider. For third-party tokens, 365 days.
Self-signed certificates	The ServiceNow AI Platform does not support self-signed certificates. The OAuth client does not utilize the certificate trust store or allow connection to OAuth endpoints that incorporate a self-signed certificate.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Concept	Description
User agent	The user who delegates access rights to a client application, which is often a website. The access rights permit the client application or website to access data in the instance that the user has access rights to. The user agent is used in the scenario.

OAuth grant types

A grant type is the way that the client obtains the access token. The following grant types are supported:

- **Authorization code**: The consumer first gets an authorization code and then uses it to get an access token. You can Specify an OAuth profile and specify this grant type. The process that uses the authorization code is also referred to as auth code flow or authorization code flow.
- **Resource owner password credentials**: The consumer of the resource already has the user credentials to get the access token. This process is also referred to as password flow.
- **Client credentials**: The consumer of the resource uses the client ID and client secret that is already configured in the application registry.

Storage of authentication credentials

The OAuth client secret is stored as a *password2* type field, which is encrypted with KMF. User passwords, which are used to check incoming endpoint requests, are stored as a hash value in the User table in a *password* type field (SHA 256). For details on this encryption, see Password2 encryption with KMF

Set up OAuth

Set up and activate OAuth, enable the OAuth system property, create an OAuth application endpoint for external client applications to access the instance, and set OAuth parameters.

Before you begin

Role required: admin

Procedure

1. Make sure the OAuth plugin is active and the OAuth activation property is set to true.
2. Create an OAuth application registry using one of the following methods:
   - Create an endpoint for external clients that want to access your instance. This creates an **OAuth client application** record and generates a client ID and client secret that the client needs to access the restricted resources on the instance.
   - Use a third-party OAuth provider that provides the authorization for access to your instance.

     Specify an OAuth profile and Specify an OAuth scope when you are connecting to another OAuth provider.
3. Configure your client applications to create an HTTP POST that requests an OAuth token. The application must also be able to parse the JSON response to use the returned access token and refresh token.

Activate OAuth

By default, the **OAuth 2.0 (com.snc.platform.security.oauth)** plugin is active on new and upgraded instances. If the plugin is not active on your instance, you can activate it.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin
Role required: admin

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

   Note:
   When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

   You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Set the OAuth property

To generate OAuth 2.0 tokens to registered applications, the `com.snc.platform.security.oauth.is.active` property must be active for the instance.

Before you begin
Role required: admin

Procedure

1. To use OAuth 2.0, enter **sys_properties.list** in the navigator and select **New**.
   You can also open the system properties list by navigating to **All** > **System Properties** > **All Properties** > .
2. Fill out the form with the following settings:

   - **Name**: com.snc.platform.security.oauth.is.active
   - **Type**: true | false
   - **Value**: true

Change OAuth password parameter

Use this property to ensure only POST body parameters are accepted as input for all supported grant types.

Sending sensitive information over URI query parameters might lead to sensitive information disclosure by clients, the server, or any host between the requests. Starting with the Madrid release, this new property ensures only the POST body parameters are accepted as input for all supported grant types. Supported grant types include:

- authorization code
- password
- client credential
- refresh token

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

OAuth password parameter property

Property	Description
`glide.oauth.allow.parameters.in.post.body.only`	This property is set to true for zBoots only, as part of the OAuth 2.0 plugin. If you need this setting for your instance, create and set the property to true.

OAuth inbound

OAuth Inbound authentication allows trusted external applications to securely access ServiceNow APIs, ensuring controlled and authorized connections.

You must have one of the following roles to configure or manage OAuth integrations in the system:

- `oauth_admin`
- `mi_admin`
- `admin`

Inbound authentication enables external applications such as third-party systems or other ServiceNow® instances to connect securely to ServiceNow APIs. Inbound authentication confirms that only trusted clients can access your ServiceNow instance in a controlled and secure manner. ServiceNow supports several OAuth 2.0 grant types, each designed for specific integration scenarios. Use the following information to choose the grant type that best fits your use case:

Authorization Code Grant

Ideal usage scenario	Functionality
Applications that must access user data on behalf of user with the user's consent. Example: Web, mobile, or desktop applications acting on behalf of a user.	The user initiates the login process from the client application, which redirects them to a ServiceNow login page. After the user logs in and grants consent, the client application receives an authorization code. The client application exchanges the authorization code with the ServiceNow instance for an access token. Authorization code grant is the most secure and widely used workflow for user-facing integrations. It supports both confidential clients (with a client secret) and public clients using Proof Key for Code Exchange (PKCE).

For more information about Authorization code grant workflow and configuration, see

Client Credentials Grant

Ideal Usage Scenario	Functionality
Client applications such as back-end services or automated system integrations that must	The client application authenticates directly with the ServiceNow instance using its own credentials (client ID and

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Ideal Usage Scenario	Functionality
access ServiceNow APIs without user involvement.	secret). Once authenticated, the application receives an access token to access the ServiceNow APIs.

For more information about Client credentials grant workflow and configuration, see .

Third party ID Token Flow

Ideal Usage Scenario	Functionality
Federated authentication scenarios where ServiceNow trusts identity or access tokens issued by external identity providers such as Azure AD or Okta.	The client application obtains an ID or access token from a trusted third-party identity provider, and includes it in the authorization header when making API requests to the ServiceNow instance. ServiceNow validates the token and, if trusted, grants access based on the identity it asserts. This enables seamless single sign-on (SSO) and federated authentication across systems.

For more information about Third party token flow and configuration, see.

JWT Bearer Grant

Ideal Usage Scenario	Functionality
Client applications that need secure access to ServiceNow resources, either on behalf of a user or as themselves, without requiring user interaction or storing a shared secret. The client application creates a signed JSON Web Token (JWT) that includes identity-related claims, such as the user or system it represents. It then presents it to the ServiceNow instance to request for access token.	**When acting on behalf of a user:** The token represents a previously authenticated user. This enables secure, seamless access without prompting the user for credentials or consent again. The signed token asserts the user's identity, enabling ServiceNow to trust the request without requiring real-time user interaction. **When acting as itself:** The token identifies and authenticates the client application directly. Instead of using a shared secret, the client signs the token with a private key, making it a more secure alternative to the client credentials grant.

For more information about JWT bearer grant workflow and configuration, see .

Resource Owner Password Credentials Grant

Ideal Usage Scenario	Functionality
Highly trusted internal client applications in controlled environments where the app collects the user's credentials directly.	The client application collects the user's user name and password, and redirects them to the ServiceNow instance to obtain an access token. The workflow bypasses redirection and consent screens, but exposes user credentials to the client application. ServiceNow recommends that you implement the Resource owner password credentials grant only in legacy or controlled environments.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

For more information about Resource owner password credentials grant workflow and configuration, see .

Implicit Grants

Ideal Usage Scenario	Functionality
Legacy Single-page applications (SPAs) or browser-based apps that can't securely store a client secret, and require a lightweight, client-side authentication flow.	The user logs in through a browser. The client application receives the access token directly in the URL after login, bypassing the intermediate authorization code step. This flow was originally designed for public clients that run entirely in the browser, where securely storing secrets isn't possible. While it simplifies implementation, it exposes tokens in the browser, increasing the risk of interception. For stronger security, ServiceNow recommends implementing an authorization code grant with PKCE.

For more information about Implicit grant workflow and configuration, see OAuth implicit grants.

OAuth Scopes

You can scope the OAuth authentication scope support for REST API. OAuth Scope provides access to only the particular REST APIs. For more information, see REST API Auth Scope.

New Inbound integrations experience

The new inbound integration workflow in the ServiceNow Machine Identity Console provides enhanced experience for managing inbound integrations.

Inbound integrations methods

Inbound Integrations allow you to configure and manage external applications to access ServiceNow APIs. To view detailed usage statistics for each OAuth client, see View Inbound API Integration Usage dashboard .

On the instance, navigate to **All** > **Machine Identity Console** > **Inbound integrations** > **New integration**. Choose the application connection type (grant type).

- Authorization code grant
- Client credentials grant
- Third party token grant
- JSON Web token bearer grant
- Resource owner password credential grant

Authorization code grant

The OAuth authorization code grant is a secure and widely used flow for web, mobile, or desktop apps that access user data with user consent. It supports both private clients (using a client secret), and public clients (using PKCE).

In the Authorization code grant flow, ServiceNow functions as both the authorization server (handling user authentication and token issuance) and the resource server (hosting the APIs). If SSO is enabled, ServiceNow redirects the user to the configured Identity Provider (IdP) for authentication. After the IdP successfully authenticates the user, control returns to ServiceNow, which then issues the authorization code. This process ensures that even with external authentication, ServiceNow remains the authority for issuing tokens and managing API access.

Note:
If you want to use your own identity provider (such as Azure AD or Okta) as the authorization server, consider using the flow.

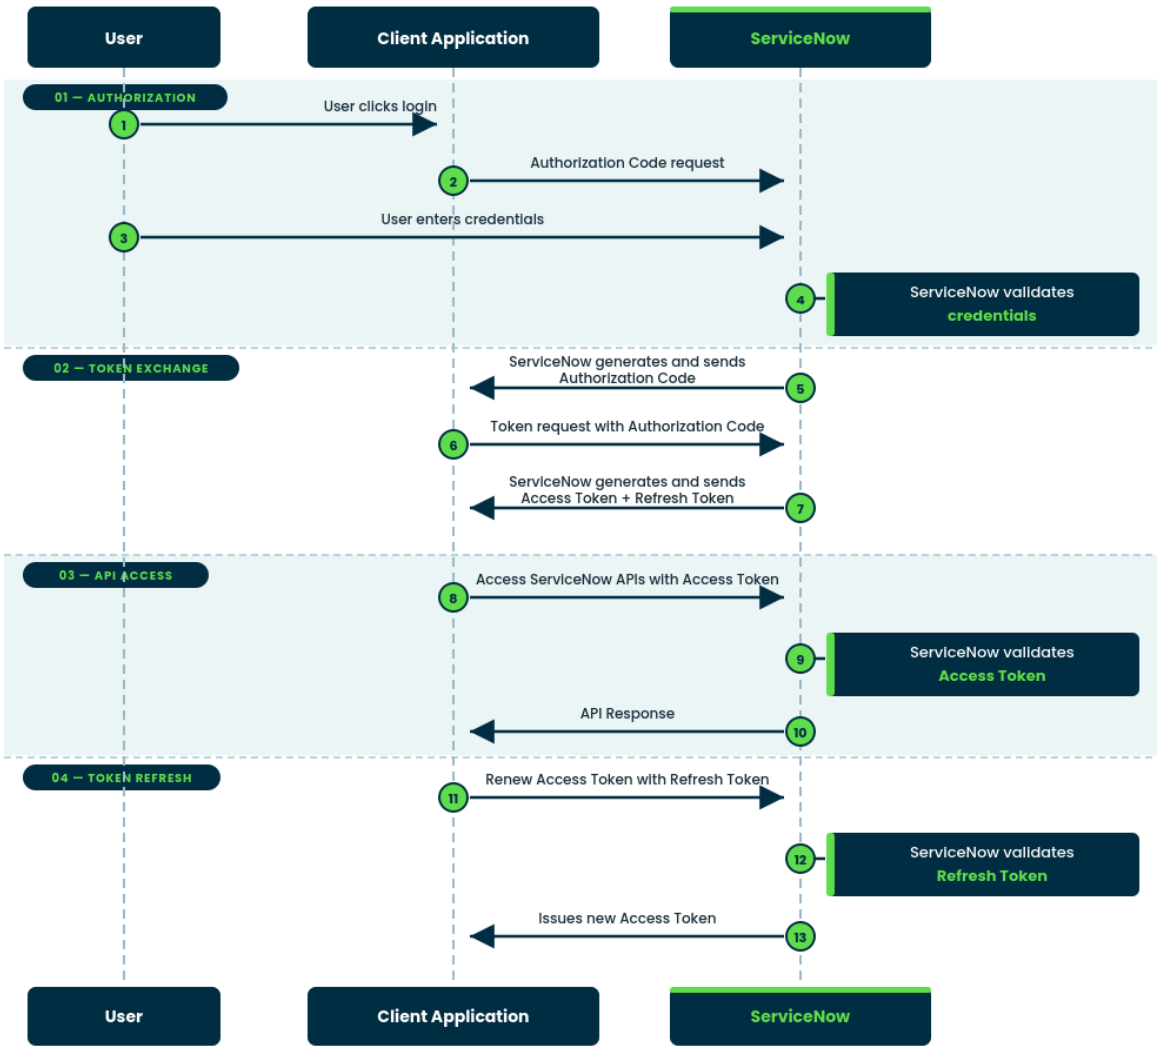
Before you begin

Role required: `oauth_admin, mi_admin, admin`

About this task

This topic collection provides information on how a client application can use the Authorization code grant flow to obtain a token from ServiceNow and make API calls with that token. Private clients use client secret, while public clients use PKCE code challenge.

Authorization workflow



Procedure

1. Log in from the client application.

   The user begins the login process from the client application interface.

2. Initiate the authorization request.

   The client redirects the user to the ServiceNow authorization endpoint. The method of initiating the authorization request depends on the type of client: Public or Private.

   ### Public Clients

   Public clients (Example: Mobile or Single-page applications) cannot securely store a client secret. Therefore, they must use **Proof Key for Code Exchange (PKCE)** to enhance security.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- In the authorization request, include the **PKCE code challenge** and specify the **code challenge method**.
- During the token request, the client must send the **code verifier** to validate the authorization code.

Perform a GET request to the authorization endpoint with the following parameters:

```
Method: GET
Endpoint: https://<servicenow_base_url>/oauth_auth.do
```

Authorization Request Parameters (Public Client - PKCE)

Parameter	Required	Description
`response_type`	Yes	Set the value to `code` to initiate the authorization code flow.
`client_id`	Yes	The unique identifier for your client application. Format: YOUR_CLIENT_ID
`redirect_uri`	Yes	The URI to which ServiceNow sends the authorization code. Example: https://yourapp.com/callback
`code_challenge`	Yes	A base64url-encoded SHA-256 hash of the code verifier. This is used as part of the PKCE flow.
`code_challenge_method`	Yes	Specifies the transformation method used for the code challenge. Set to `S256`.
`scope`	Optional	A space-delimited list of requested scopes. Example: `incident_read incident_write`.
`state`	Yes	A client-generated value used to avoid CSRF attacks. The value is returned unchanged in the redirect URI, enabling the client to validate it.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
Starting with the Madrid release, the system property `glide.oauth.state.parameter.required` mandates the use of the `state` parameter in the OAuth requests. The `state` property is set to `true` by default in the new instances, and `optional` in upgraded instances. In case of missing `state` parameter, the authorization request fails and the following error is displayed: `Missing State parameter in request`.

Private Clients

Private clients (Example: Server-side applications) can securely store a client secret and do not require PKCE.

- The authorization request is initiated by redirecting the user to the authorization endpoint. **No client secret or PKCE code challenge is required** in this step.
- During the token request, the client includes the **client secret** along with the **authorization code** to obtain the access token.

Perform a GET request to the authorization endpoint with the following parameters:

```
Method: GET
Endpoint: https://<servicenow_base_url>/oauth_auth.do
```

Authorization Request Parameters (Private Client-Client Secret)

Parameter	Required	Description
`response_type`	Yes	Set the value to `code` to initiate the authorization code flow.
`client_id`	Yes	The unique identifier for your client application. Format: YOUR_CLIENT_ID
`redirect_uri`	Yes	The URI to which ServiceNow sends the authorization code. Example: https://yourapp.com/callback
`scope`	Optional	A space-delimited list of requested scopes. Example: `incident_read incident_write`.
`state`	Yes	A client-generated value used to avoid Cross-Site Request Forgery (CSRF) attacks. The value is returned unchanged in

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Parameter	Required	Description
		the redirect URI, enabling the client to validate it.

3. Log in and grant access consent to the client application.
   Log in to ServiceNow (or IdP, if SSO is enabled), and grant access consent to the client application.
4. ServiceNow (or IdP, if SSO is enabled) validates the credentials and ServiceNow returns an authorization code to the client.

   After the successful authentication, the browser is redirected to the `redirect_uri`, and the authorization code is included in the query string:

   ```
   https://yourapp.com/callback?code=AUTH_CODE&state=xyz123
   ```

5. Initiate the authorization request.

   The client redirects the user to the ServiceNow authorization endpoint for an access token. The method of initiating the authorization request depends on the type of client: Public or Private.

   Public Clients

   Public clients (Example: Mobile or Single-page applications) cannot securely store a client secret. Therefore, they must use **Proof Key for Code Exchange (PKCE)** to enhance security.

   - In the authorization request, include the **PKCE code challenge** and specify the **code challenge method**.
   - During the token request, the client must send the **code verifier** to validate the authorization code.

   The client sends a POST request to token endpoint with the following parameters:

   ```
   Method: POST
   Endpoint: https://<servicenow_base_url>/oauth_token.do
   Headers: Content-Type:
    application/x-www-form-urlencoded
   ```

   Token Request Parameters (Public Client-PKCE)

Parameter	Required	Description
`grant_type`	Yes	Set the value to `authorization_code` to exchange the code for a token.
`code`	Yes	The authorization code received from the authorization endpoint.
`redirect_uri`	Yes	The URI used in the initial authorization request. Example: https://yourapp.com/callback

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Parameter	Required	Description
`client_id`	Yes	The unique identifier for your client application.
`code_verifier`	Yes	The original string used to generate the PKCE `code_challenge`.
`state`	Yes	A client-generated value used to help prevent CSRF attacks. The value is returned unchanged in the redirect URI, enabling the client to validate it.

Private Clients

Private clients (Example: Server-side applications) can securely store a client secret and do not require PKCE.

- The authorization request is initiated by redirecting the user to the authorization endpoint. **No client secret or PKCE code challenge is required** in this step.
- During the token request, the client includes the **client secret** along with the **authorization code** to obtain the access token.

Perform a POST request to the authorization endpoint with the following parameters:

```
Method: POST
Endpoint: https://<servicenow_base_url>/oauth_token.do
Headers: Content-Type:
 application/x-www-form-urlencoded
```

Token Request Parameters (Private Client-Client Secret)

Parameter	Required	Description
`grant_type`	Yes	Set the value to `authorization_code` to exchange the code for a token.
`code`	Yes	The authorization code received from the authorization endpoint.
`redirect_uri`	Yes	The URI used in the initial authorization request. Example: https://yourapp.com/callback
`client_id`	Yes	The unique identifier for your client application.
`client_secret`	Yes	The client's secret used to authenticate with the token endpoint.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Parameter	Required	Description
`state`	Yes	A client-generated value used to help prevent CSRF attacks. The value is returned unchanged in the redirect URI, enabling the client to validate it.

6. Access the ServiceNow APIs with the access token.

   Example:

   Make a GET request to the APIs using the access token. Include the access token in the `Authorization` header.

```
Method: GET
End Point: https://<servicenow_base_url>/api/now/incident
Authorization: Bearer YOUR_ACCESS_TOKEN
```

7. Renew the access token if it has expired.
   Make a POST request to refresh the access token (private clients only) with the following parameters:

```
Method: POST
Endpoint: https://<servicenow_base_url>/oauth_token.do
Headers: Content-Type: application/x-www-form-urlencoded
```

Refresh Token Request Parameters (Private Client)

Parameter	Required	Description
`grant_type`	Yes	Set the value to `refresh_token` to request a new access token.
`refresh_token`	Yes	The refresh token previously issued by the token endpoint.
`client_id`	Yes	The unique identifier for your client application.
`client_secret`	Yes	The client secret used to authenticate with the token endpoint.

Configure an OAuth authorization code grant

Configure the OAuth authorization code grant to enable secure and interactive user authentication to enable applications to access resources on behalf of users. The OAuth authorization code grant verifies that the API access is granted based on the user identity and permissions.

Before you begin

Role required: `oauth_admin, mi_admin, admin`

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **Machine Identity Console** > **Inbound integrations** > **New integration** > > **OAuth authorization code grant**.
   The New Record page appears.
2. Update the text fields in the Details form with the appropriate information.

Details form

Field	Description
Name of OAuth entity	Name of the OAuth entity.
Provider name	Enter the name of the service provider you want to integrate with. Example: Microsoft, Google, Zoom, SAP, etc
Redirect URL	URL to which the authorization code should be sent after authentication.
Client ID	Unique ID assigned to identify the application.
Client Secret	The secret key that only the application and the authorization server can identify. The application uses this key to authenticate and obtain access tokens.

Select the **This is a public client check box** if the application can't securely store credentials, and doesn't require a secret key to prove its identity during authorization. The client secret information is processed for public clients.

3. Update the text fields in the **Auth scope** form with the appropriate information. The authentication scope defines the level of access an application has to a resource. Select the authentication scope for the specific REST APIs you want to access.

Auth scope form

Field	Description
Auth scope	The level of access an application has to a resource. The authentication scope restricts the actions that an access token can perform on APIs or data.
Limit authorization	The names of the APIs for which you want to restrict authorization.
Allow access only to APIs in selected scope	Enable the option for the integration to only access APIs that are explicitly listed in the selected scopes.

4. Update the text fields in the Advanced options (optional) form with the appropriate information.

Advanced options form

Field	Description
Enforce token restriction	The Enforce token restriction option limits the client to accessing only the APIs specified in

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	the REST API Access Policies. If you unselect it, the client can access other REST APIs based on the user ACL permissions.
Token Format	Format of token to generate. Options: ○ JWT ○ Opaque **Note:** ○ The jwks url is available in the location: `api/now/oauth/jwks`. ○ The rotated (inactive keys) from jwks response after is removed after 105 days default.
Access token lifespan	Duration (in seconds) for which the OAuth access token remains valid before it expires. **Note:** The default value is 1800 seconds.
Refresh token lifespan	Duration (in seconds) for which the OAuth refresh token remains valid before it expires. **Note:** The default value is 8,640,000 seconds.
Login URL	HTTP redirection endpoint to authenticate with the authorization server.
Logo URL	Web address of an image that represents the application during the authentication and authorization process. It's displayed on the authorization server's consent screen to help you recognize the requesting application.

Enforcing token restriction applies limitations on how an OAuth access token can be used, enhancing security by verifying that tokens are valid only under specific conditions. Enable the **Enforce token restriction** check box to limit OAuth access tokens to specific APIs defined in the API access policy. If the Enforce token restriction is turned off, the token can be used across other REST APIs.

5. Select **Create new auth scope** to add a new auth scope.
6. Select **Save**.
   A new OAuth authorization code grant is created.
7. Go to **All** > **Inbound integrations** > **Application Registries** to view the newly created OAuth authorization code grant.

Client credentials grant

Use the OAuth client credentials grant type for back-end services or automated integrations that access ServiceNow® APIs without user interaction. The client application authenticates directly

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

using its client ID and secret, and receives an access token that represents the application itself, and not the user.

Related topics

Client credentials grant workflow

Configure an OAuth Client credential grant

Client credentials grant workflow

Authenticate a client application using a client credentials workflow. The client credentials grant workflow is used by back-end services or system integrations to access ServiceNow® APIs without user involvement.

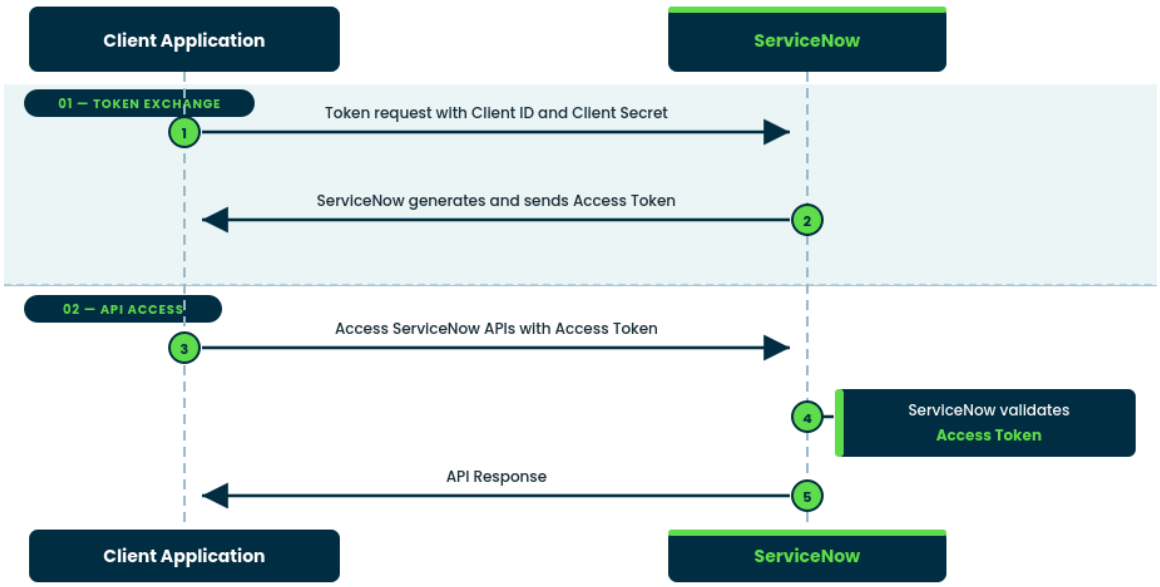
Before you begin

Role required: `oauth_admin, mi_admin, admin`

About this task

This workflow describes how a client application (back-end service or system integration) authenticates directly with ServiceNow using its client credentials without user interaction. The application requests an access token using its client ID and client secret, which ServiceNow validates before issuing the token. The client then uses this token to access ServiceNow APIs. ServiceNow validates each request before returning the appropriate response.

Client credentials grant workflow



Procedure

1. **The client application makes a token request** to the ServiceNow end point with the following parameters:

```
Method: POST
Endpoint: https://<servicenow_base_url>/oauth_token.do
```

Token Request Parameters

Parameter	Required	Description
`grant_type`	Yes	OAuth 2.0 grant type.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Parameter	Required	Description
		Example: `client_credentials`
`client_id`	Yes	Unique identifier for the client application. Example:`YOUR_CLIENT_ID`
`client_secret`	Yes	Secret associated with the client ID. Example:`YOUR_CLIENT_SECRET`
`scope`	Optional	Requested permissions for the access token. Example: `incident_read incident_write`

2. ServiceNow validates the credentials and returns the access token.
3. Make an API request with the access token.

   Include the access token in the `Authorization` header of each API request.

```
Method: POST
Endpoint: https://<servicenow_base_url>/api/now/incident
Authorization: Bearer YOUR_ACCESS_TOKEN
```

4. ServiceNow validates the token and returns the appropriate API response.

Note:
Use the client credentials grant workflow only with trusted, server-side applications. Maintain the `client_secret` securely. Ensure that you don't use the `client_secret` in client-side environments such as browsers or mobile apps.

Configure an OAuth Client credential grant

Configure the OAuth Client Credentials Grant for secure machine-to-machine authentication without user interaction. It authenticates applications using client credentials and grants-controlled API access with scoped permissions.

Before you begin

Role required: `oauth_admin, mi_admin, admin`

Procedure

1. Navigate to **Machine Identity Console** > > **Inbound integrations** > > **New integration** > **OAuth Client credential grant**.
   The OAuth Client credential configuration page appears.
2. Update the text fields in the Details form with the appropriate information.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Details form

Field	Description
Name	The name of the OAuth entity.
Provider name	Enter the name of the service provider you want to integrate with. Example: Microsoft, Google, Zoom, SAP, etc
Client ID	The unique ID assigned to identify the application.
Client Secret	The secret key that only the application and the authorization server can identify. The application uses this key to authenticate and obtain access tokens.

Select the **Active** check box.

3. Update the text fields in the Advanced options (optional) form with the appropriate information.
4. Update the text fields in the **Auth scope (optional)** form with the appropriate information. The authentication scope defines the level of access an application has to a resource. Select the authentication scope for the specific REST APIs you want to access.

Auth scope form

Field	Description
Auth scope	The level of access an application has to a resource. The authentication scope restricts the actions that an access token can perform on APIs or data.
Limit authorization	The names of the APIs for which you want to restrict authorization.
Allow access only to APIs in selected scope	Enable the option for the integration to only access APIs that are explicitly listed in the selected scopes.

   a. Select **Create new auth scope** to add a new auth scope.

5. Update the text fields in the Advanced options (optional) form with the appropriate information.

Advanced options form

Field	Description
Enforce token restriction	The Enforce token restriction option limits the client to accessing only the APIs specified in the REST API Access Policies. If you unselect it, the client can access other REST APIs based on the user ACL permissions.

Field	Description
	Note: ○ The jwks url is available in the location: `api/now/oauth/jwks`. ○ The rotated (inactive keys) from jwks response after is removed after 105 days default.
Access token lifespan	Duration (in seconds) for which the OAuth access token remains valid before it expires. **Note:** The default value is 1800 seconds.

6. Select **Save**.
   A new OAuth Client credential grant is created.
7. Go to **All** > **Inbound integrations** > **Application Registries** to view the newly created client credential grant.

Third party token grant

The third party token grant enables ServiceNow® to accept identity tokens from trusted external identity providers, such as Azure AD or Okta. Third party token grant provides secure, token-based access. This method supports secure access and single sign-on (SSO) in federated authentication scenarios.

The client application requests an ID or access token from a trusted external identity provider, such as Azure AD or Okta, and includes it in the `Authorization` header of API requests to ServiceNow®. ServiceNow® validates the token and, if trusted, grants access based on the asserted identity.

You can use accounts from a third-party identity provider (IdP) to access the ServiceNow® API for:

- Third party token workflow for user accounts
- Third party token workflow for service accounts

Third party token workflow for user accounts

This workflow is based on the token federation concept. It allows client applications to obtain tokens directly from an IdP and use them to access ServiceNow APIs.

Before you begin

Role required: `oauth_admin, mi_admin, admin`

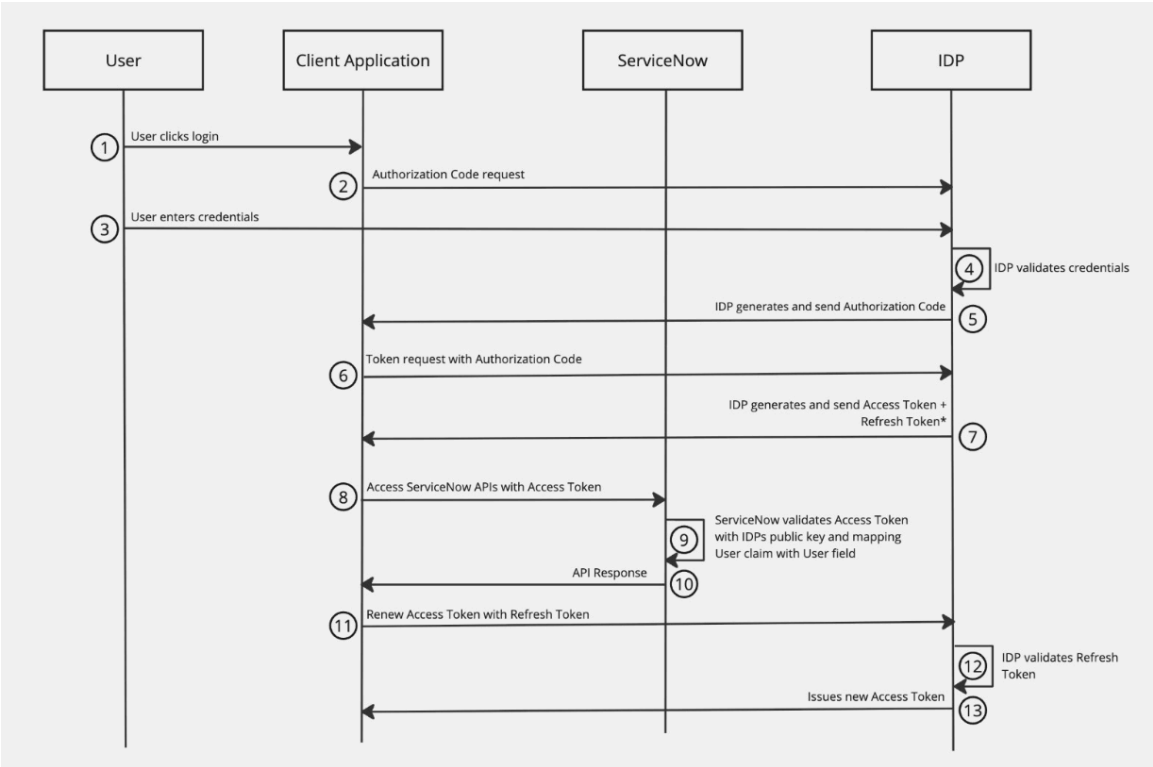
About this task

The third-party client application requests tokens directly from your identity provider (IdP). The authentication method between the client and the IdP is flexible and can be configured to meet your specific requirements. After successful authentication, the IdP issues an ID token or access token, and optionally a refresh token. These tokens are sent directly to the client application, which then uses them to access ServiceNow APIs.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
ServiceNow validates the token using the public key configured during setup and grants access to the requested APIs. Ensure that the token is in JSON Web Token (JWT) format.

User Account Workflow



Note:
This diagram is for illustrative purpose. It shows the Authorization code grant flow between your client application and the identity provider. The workflow is flexible. You can use a different flow based on your requirements.

Procedure

1. Configure your third party client application.

   Set up your third party client application to request tokens directly from your identity provider (IdP). Select an authentication method that best fits your security and integration requirements.

2. Create an OAuth client in ServiceNow.

   Provide the required details to enable validation of incoming tokens from your identity provider (IdP). For more information on how to configure, see Configure a third party ID token

Third party token workflow for service accounts

Create a service account in ServiceNow® to represent the identity of a third-party application accessing APIs through a trusted identity provider (IdP). This account maps the token claims to a user record and manages access with roles and permissions.

Before you begin

Role required: `oauth_admin, mi_admin, admin`

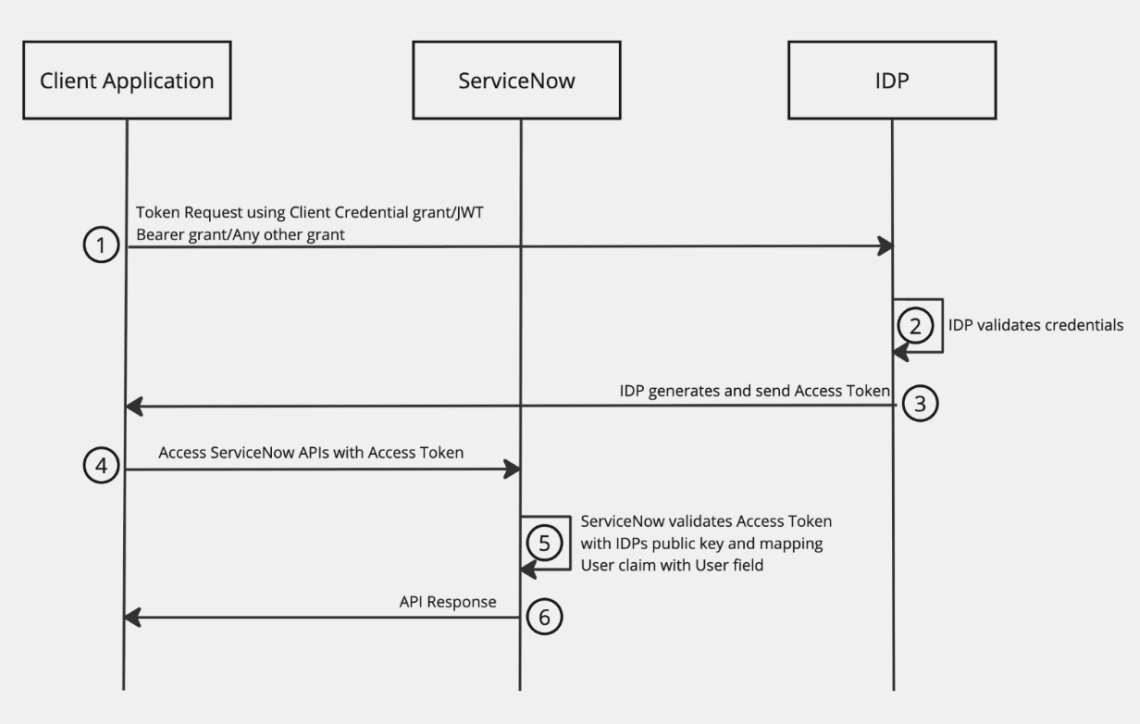
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

About this task

When a third-party application authenticates using a token from an external identity provider (IdP), ServiceNow needs a corresponding user record to map the identity and apply access controls.

Create a corresponding `sys_user` account in ServiceNow for your service account. The value of the claim configured during the initial setup in the token issued by your Idp is mapped to the user field specified. This account represents the service identity in ServiceNow. You can restrict this account to API access only, and assign the necessary permissions by adding the appropriate roles and groups.

Service Account Workflow



Procedure

1. Follow the Third party token workflow for user accounts to create a user account.
2. Create a `sys-user` account in ServiceNow to represent your service account identity. Ensure that the token claim value matches with that of the value in the mapped user field (such as user_name or email) in the user record. Example: user_name, email.
   a. Select the Web service access only option to restrict the account to API access.
   b. Assign the required roles and groups to grant the appropriate permission.

   The ServiceNow platform maps the configured claim to the specified user field in the `sys_user` record. It enforces access based on that user's assigned roles and groups.
3. Make a GET request with the authorization header to the following endpoint:

```
Method: GET
Endpoint: https:// <servicenow_base_url> /api/now/incident
Authorization: Bearer YOUR_THIRD-PARTY_TOKEN
```

Configure a third party ID token

Configure a third-party ID token to enable secure authentication by verifying user identities through an external IdP. The third-party ID token improves security by reducing stored

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

credentials, confirms seamless authentication, and supports interoperability with industry standards like OpenID Connect (OIDC).

Before you begin

Role required: `oauth_admin, mi_admin, admin`

Procedure

1. Navigate to **Machine Identity Console** > > **Inbound integrations** > **New integration** > **Third party ID token**.
2. Update the text fields in the **Details** form with the appropriate information.

Details form

Field	Description
Name	The name provided by the resource owner (user) during authentication.
Provider name	Enter the name of the service provider you want to integrate with. Example: Microsoft, Google, Zoom, SAP, etc
Client ID	The unique ID assigned to identify the application.
Client secret	The secret key that only the application and the authorization server can identify. The application uses this key to authenticate and obtain access tokens.

Enforcing token restriction applies limitations on how an OAuth access token can be used, enhancing security by verifying tokens are valid only under specific conditions. Enable the **Enforce token restriction** check box to limit OAuth access tokens to specific APIs defined in the API access policy. If **Enforce token restriction** is turned off, the token can be used across other REST APIs.

3. Update the text fields in the **Auth scope (optional)** form with the appropriate information. The authentication scope defines the level of access an application has to a resource. Select the authentication scope for the specific REST APIs you want to access.

Auth scope form

Field	Description
Auth scope	The level of access an application has to a resource. The authentication scope restricts the actions that an access token can perform on APIs or data.
Limit authorization	The names of the APIs for which you want to restrict authorization.
Allow access only to APIs in selected scope	Enable the option for the integration to only access APIs that are explicitly listed in the selected scopes.

   a. Select **Create new auth scope** to add a new auth scope.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Update the text fields in the **Advanced options (optional)** form with the appropriate information.

Advanced options form

Field	Description
Access token lifespan	The duration (in seconds) for which the OAuth access token remains valid before it expires. **Note:** The default value is 1800 seconds.
Refresh token lifespan	The duration (in seconds) for which the OAuth refresh token remains valid before it expires. **Note:** The default value is 8,640,000 seconds.

5. Select **Save**.
   A new third-party ID token is created.
6. Go to **All** > **Inbound integrations** > **Application Registries** to view the newly created third party ID token.

JSON Web token bearer grant

Use this flow when a client application needs secure, unattended access to ServiceNow resources, either as itself or on behalf of a user.

The client application generates a signed JWT that includes identity-related claims, such as the user or system it represents. It sends it to the ServiceNow instance to request an access token.

JWT Structure

The JWT must be signed using the client's private key. It must include the following standard claims:

- iss – Issuer (client ID)
- sub – Subject (user or system identity)
- aud – Audience (ServiceNow token endpoint)
- exp – Expiration time
- iat – Issued at

Note:
ServiceNow uses the public key (uploaded in the OAuth JWT profile) to validate the signature and maps the sub claim to a user record.

JSON Web token grant workflow

Use this flow when a client application needs secure, unattended access to ServiceNow resources, either as itself or on behalf of a user.

Before you begin

Role required: `oauth_admin, mi_admin, admin`

About this task

The client application generates a signed JWT with identity-related claims such as the user or system it represents. The client application sends the JWT to the ServiceNow instance to request an access token.

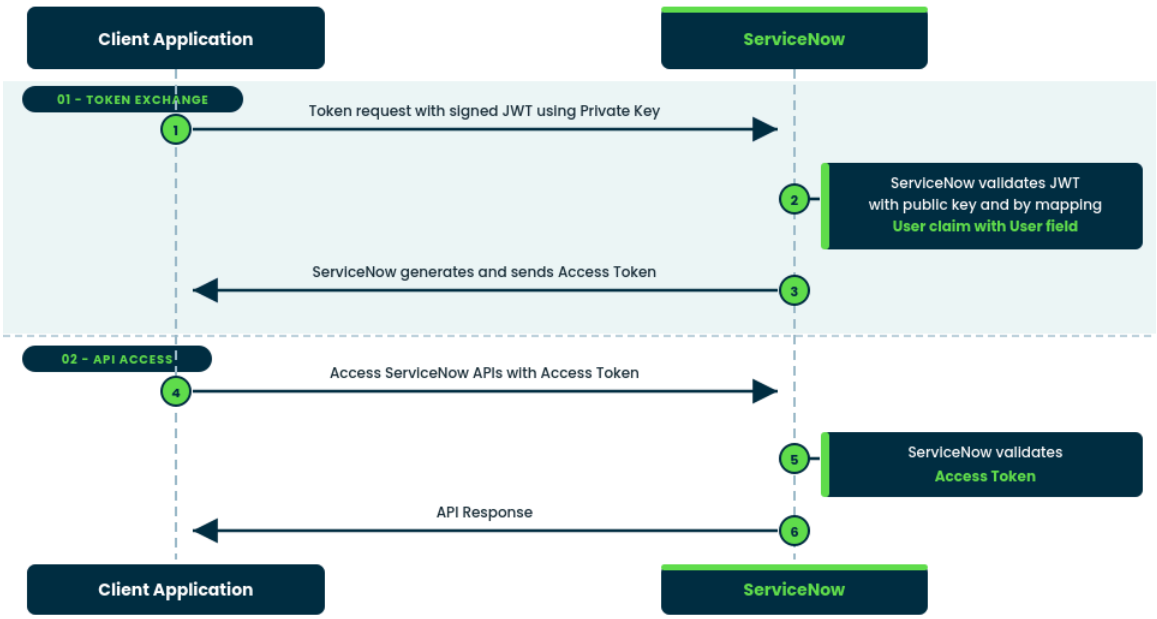
- **When acting on behalf of a user:**

  The token represents a previously authenticated user. It enables secure, seamless access without prompting the user for credentials or consent. ServiceNow trusts the request by validating the user's identity from the signed token, eliminating the need for real-time user interaction.

- **When acting as itself:**

  The token identifies and authenticates the client application. Instead of using a shared secret, the application signs the token with a private key. This offers a more secure alternative to the client credentials grant.

JWT Grant workflow



Procedure

1. The client application sends a token request to ServiceNow, with a JWT signed with its private key.
2. ServiceNow validates the JWT using the corresponding public key.
   It maps the `sub` (subject) claim in the token to a `sys_user` record.
3. ServiceNow validates the JWT, and issues the access token.
4. The client includes the access token in the API requests to ServiceNow.
5. ServiceNow validates the access token, and returns the appropriate API response.

Configure an OAuth JSON web token bearer grant

Configuring an OAuth JSON Web Token (JWT) bearer grant secures token-based authentication without user interaction. It enhances security with signed JWTs and reduces authentication overhead by eliminating repeated login attempts.

Before you begin

Role required: `oauth_admin, mi_admin, admin`

The supported algorithms for JSON Web Token (JWT): RS256, RS384, RS512, ES256, ES384, ES512, HS256, HS384, and HS512.

Procedure

1. Navigate to **Machine Identity Console** > > **Inbound integrations** > > **New integration** > **JWT bearer grant**.
2. Update the text fields in the Details form with the appropriate information.

Details form

Field	Description
Name	A unique name that identifies the application that you require JWT OAuth access for.
Provider name	Enter the name of the service provider you want to integrate with. Example: Microsoft, Google, Zoom, SAP, etc
Client ID	The auto-generated unique ID of the application. The system uses the value of this field to retrieve the public or shared key and validate the JWT. The value of this field should match the value of the issuer and audience claims in the JWT.
Client secret	The shared secret string that both the instance and the client application or website use to authorize communications with one another. Leave this field empty to have the instance auto-generate a client secret. To display existing client secrets, select the lock icon.
User field	Field in the User (sys_user) table that the system uses to match the value of the subject claim in the JWT. Example: If you add a token that has a subject claim value of user.name@example.com, then you would set the **User Field** to **Email**. This field tells the system to search the email field for the user.name@example.com value and use the matching user record in the inbound request.
Enable JTI Verification	Select to require a new token every token exchange.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Default: Selected.
JWKS URL	The JSON Web key set URL. Its is a collection of public keys in JSON format. Identity providers publish a JWKS at a well-known URL so that client applications and services can retrieve the keys and validate the signatures of JSON Web Tokens (JWTs).
JTI claim	Unique identifier for each token. ServiceNow uses this claim to detect and prevent token replay by verifying that a token is not reused.
Comments	Add relevant comments.
JWT verifier map	Specify the identity provider, the verification method (such as a JWKS URL or certificate), and the mapping of JWT claims to ServiceNow user fields. Click on the Plus icon to add or edit the maps. Provide the following details in the **JWT verifier map** page: ○ Name- The unique name of the JWT verifier map configuration. ○ Application - The application where the verifier map is used. ○ Kid (Key ID)- The identifier of the key used to validate the JWT signature. ○ Sys certificate - The ServiceNow certificate record used for token verification ○ Shared key - A symmetric key used to validate tokens.
Active	Select the check box to make the OAuth application active.

3. Update the text fields in the Advanced options (optional) form with the appropriate information.

Advanced options (Optional) form

Field	Description
Enforce token restriction	Select to only enable tokens to be used with APIs set to enable the authentication profile. You can set grant access using an API access policy. Default: Unselected.
JWKS cache lifespan	The duration (in minutes) for which ServiceNow caches the JSON Web Key Set (JWKS) from the identity provider.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Access token lifespan	The duration (in seconds) for which the access token remains valid before it expires.
Clock skew	Small differences in the system clocks of servers or devices involved in generating and validating a token can lead to issues when validating time-sensitive claims. Adjust the time above. Default value is: 0 seconds.

4. Update the text fields in the Auth scope (optional) form with the appropriate information.

Note:
When you select an **Auth scope**, all the associated APIs are automatically populated in the **Limit authorization** text box.

Auth scope form

Field	Description
Auth scope	Access level of an application. The authentication scope restricts the actions that an access token can perform on APIs or data.
Limit authorization	Names of the APIs for which you want to restrict authorization.
Allow access only to APIs in selected scope	Enable the option for the integration to only access APIs that are explicitly listed in the selected scopes.

a. Select **Add another row** to add auth scopes.

b. Select **Create new auth scope** to add a new auth scope.
Enter the name of the Auth scope in the **Scope field** text box to select the newly created Auth scope. You can manually add and edit the APIs that needs to be associated with the new Auth scope.

Note:
Adding or editing APIs from the **Auth scope** menu affects all OAuth entities that are associated with the same authorization scope.

5. Update the text fields in the Advanced options (optional) form with the appropriate information.

Advanced options (Optional) form

Field	Description
Enforce token restriction	Select to only enable tokens to be used with APIs set to enable the authentication profile. You can set grant access using an API access policy. Default: Unselected.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
JWKS cache lifespan	The duration (in minutes) for which ServiceNow caches the JSON Web Key Set (JWKS) from the identity provider.
Access token lifespan	The duration (in seconds) for which the access token remains valid before it expires.
Clock skew	Small differences in the system clocks of servers or devices involved in generating and validating a token can lead to issues when validating time-sensitive claims. Adjust the time above. Default value is: 0 seconds.
Token Format	Format of token to generate. Options: ○ JWT ○ Opaque **Note:** ○ The jwks url is available in the location: `api/now/oauth/jwks`. ○ The rotated (inactive keys) from jwks response after is removed after 105 days default.

6. Select **Save**.
   A new OAuth JSON Web Token bearer grant is created.
7. Go to **All** > **Inbound integrations** > **Application Registries** to view the newly created JWT bearer grant.

Resource owner password credential grant

Configuring an OAuth Resource Owner Password Credential (ROPC) grant enables applications to authenticate users by directly using their credentials to obtain an access token.

Security Considerations

The ROPC flow exposes user credentials directly to the client application, making it inherently less secure than modern alternatives. It should only be used in scenarios where the client is fully trusted, tightly controlled, and securely managed.

Avoid using this grant in modern applications unless absolutely necessary. For secure user-based access, it is strongly recommended to use the Authorization Code Flow with PKCE, which keeps credentials out of the client and leverages secure redirection and token handling practices.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Resource owner password credential grant workflow

This flow is used in legacy or highly controlled environments where secure alternatives aren't feasible. The client app directly collects and sends user credentials to ServiceNow to obtain an access token, making it suitable only for trusted internal use.

Before you begin

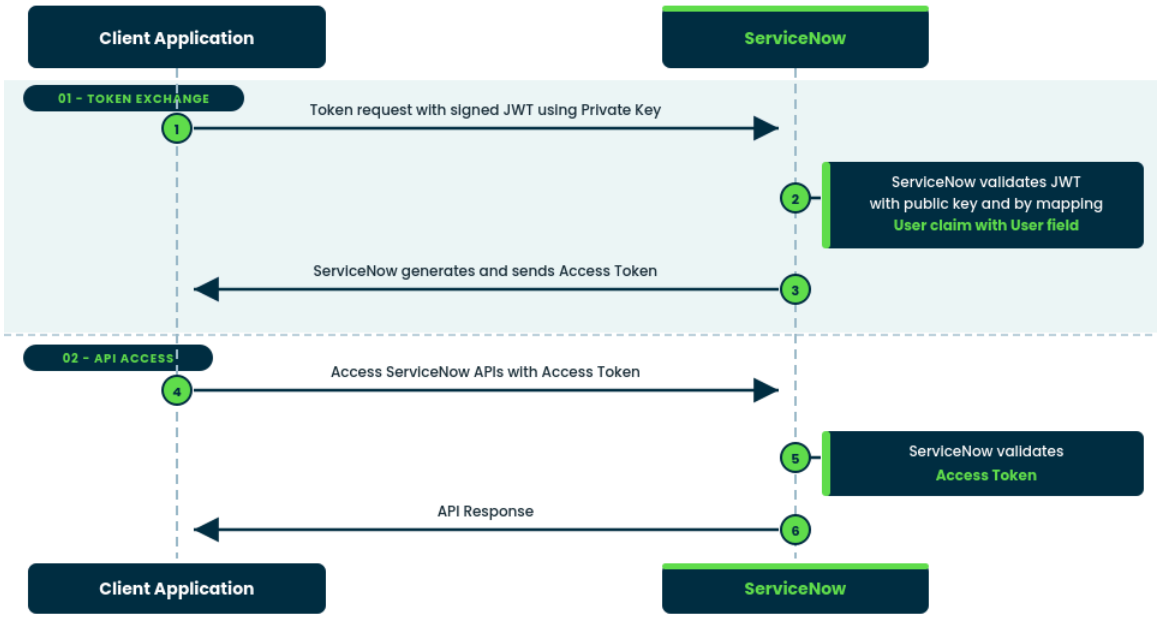
Role required: `oauth_admin, mi_admin, admin`

About this task

This procedure outlines how a trusted client application obtains an access token by directly handling user credentials and uses it to access ServiceNow APIs.

The user logs in through the app, which sends both its own credentials and the user's to ServiceNow. ServiceNow validates the credentials and issues an access token that the app uses to call APIs.

Resource owner password credential grant workflow



Procedure

1. The user logs in to the client application.
2. The client application sends a token request to with the following parameters:
   - Client ID and client secret.
   - Username and password of the user.

Example

```
Method: POST
Endpoint: https://<servicenow_base_url>/oauth_token.do
Headers: Content-Type: application/x-www-form-urlencoded
```

Token Request Parameters

Parameter	Required	Description
`grant_type`	Yes	Specifies the OAuth grant type.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Parameter	Required	Description
`client_id`	Yes	The unique identifier for your client application. Format: YOUR_CLIENT_ID
`client_secret`	Yes	The client application's secret key. Format: YOUR_CLIENT_SECRET
`username`	Yes	The user's ServiceNow username.
`password`	Yes	The user's ServiceNow password.
`scope`	Optional	Defines the level of access requested. Example: ○ incident_read ○ incident_write

3. ServiceNow validates both the client and user credentials, and returns the access token.
4. The client uses the access token to call ServiceNow APIs.

Example

```
Method: GET
Endpoint: https://<servicenow_base_url/api/now/incident
Authorization: Bearer YOUR_ACCESS_TOKEN
```

5. ServiceNow validates the access token, and returns the API response.

Configure an OAuth resource owner password credential grant

Configuring an OAuth resource owner password credential (ROPC) grant enables applications to authenticate users by directly using their credentials to obtain an access token. This method is ideal for trusted applications and legacy systems that require authentication without browser-based flows, enabling secure token validation and controlled API access.

Before you begin

Role required: `oauth_admin, mi_admin, admin`

Procedure

1. Navigate to **Machine Identity Console** > > **Inbound integrations** > > **New integration** > **OAuth Resource owner password credential grant**.
2. Update the text fields in the **Details** form with the appropriate information.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Details form

Field	Description
Name	The name provided by the resource owner (user) during authentication.
Provider name	Enter the name of the service provider that you want to integrate with. Example: Microsoft, Google, Zoom, SAP, and so on
Client ID	The unique ID assigned to identify the application.
Client secret	The secret key that only the application and the authorization server can identify. The application uses this key to authenticate and obtain access tokens.
Active	Select the check box to make the OAuth application active.

3. Update the text fields in the **Advanced options (optional)** form with the appropriate information.

   Enforcing token restriction applies limitations on how an OAuth access token can be used, enhancing security by verifying that tokens are valid only under specific conditions. Enable the Enforce token restriction check box to limit OAuth access tokens to specific APIs defined in the API access policy. If the Enforce token restriction is turned off, the token can be used across other REST API.

   Details form

Field	Description
Access token lifespan	The duration (in seconds) for which the access token remains valid before it expires.
Refresh token lifespan	The duration (in seconds) that a refresh token remains valid after it's issued is specified in the Lifespan field.

4. Update the text fields in the Auth scope (optional) form with the appropriate information. The authentication scope defines the level of access an application has to a resource. Select the authentication scope for the specific REST APIs you want to access.

   Note:
   When you select an **Auth scope**, all the associated APIs are automatically populated in the **Limit authorization** text box.

   Auth scope form

Field	Description
Auth scope	Access level of an application. The authentication scope restricts the actions that an access token can perform on APIs or data.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Limit authorization	Names of the APIs for which you want to restrict authorization.
Allow access only to APIs in selected scope	Enable the option for the integration to only access APIs that are explicitly listed in the selected scopes.

Note:
Adding or editing APIs from the **Auth scope** menu affects all OAuth entities that are associated with the same authorization scope.

a. Select **Create new auth scope** to add a new auth scope.

5. Update the text fields in the **Advanced options (optional)** form with the appropriate information.

   Enforcing token restriction applies limitations on how an OAuth access token can be used, enhancing security by verifying tokens are valid only under specific conditions. Enable the Enforce token restriction check box to limit OAuth access tokens to specific APIs defined in the API access policy. If Enforce token restriction is turned off, the token can be used across other REST API.

   Advanced options form

Field	Description
Enforce token restriction	The Enforce token restriction option limits the client to accessing only the APIs specified in the REST API Access Policies. If you unselect it, the client can access other REST APIs based on the user ACL permissions.
Token Format	Format of token to generate. Options: ○ JWT ○ Opaque **Note:** ○ The jwks url is available in the location: `api/now/oauth/jwks`. ○ The rotated (inactive keys) from jwks response after is removed after 105 days default.
Access token lifespan	Duration (in seconds) for which the OAuth access token remains valid before it expires. **Note:** The default value is 1800 seconds.
Refresh token lifespan	Duration (in seconds) for which the OAuth refresh token remains valid before it expires.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Note: The default value is 8,640,000 seconds.

6. Select **Add another row** to create another Auth scope with the associated APIs.
7. Select **Save**.
   A new OAuth resource owner password credential grant is created.
8. Go to **All** > **Inbound integrations** > **Application Registries** to view the newly created OAuth Resource owner password credential grant.

Old inbound integrations experience

Old experience - Inbound integrations.

Note:

You can perform the OAuth inbound configuration, depending on the following type of grant type:

- OAuth authorization code grant flow

  Note:
  For authorization code flow, user needs to complete the Authentication by local login, SSO or MFA and then provide consent.

- Password grant
- JWT bearer grant flow
- ID token flow
- OAuth implicit grants
- Client Credentials

Configure OAuth integration that includes the following enhancements from Zurich release:

- Increase client secret length up-to 4096 characters to meet security requirements of third-party systems.
- Provide a JSON Web Key Set (JWKS) URL to automatically manage and update the public key for JSON Web Tokens (JWT) signature validation.
- Request OAuth tokens using the JWT grant type signed with Elliptic Curve Digital Signature Algorithm (ES) signing algorithms, including ES256, ES384, and ES512, for inbound JSON Web Tokens (JWT).
- Customize the JWT ID (JTI) claim name in both inbound OpenID Connect (OIDC) and JWT Bearer flows.

OAuth authorization code grant flow

Authorization code grant flow allows a user to access a resource by authenticating directly with an OAuth server that trusts the resource, in contrast with authenticating with username/password credentials.

This implementation of OAuth authorization code flow allows access to a resource via REST. The authorization code framework gets the access token through the authorized URL that the

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

user configures rather than requiring the user to enter a username/password. The username/password are never exposed to the client that is requesting access to the resource.

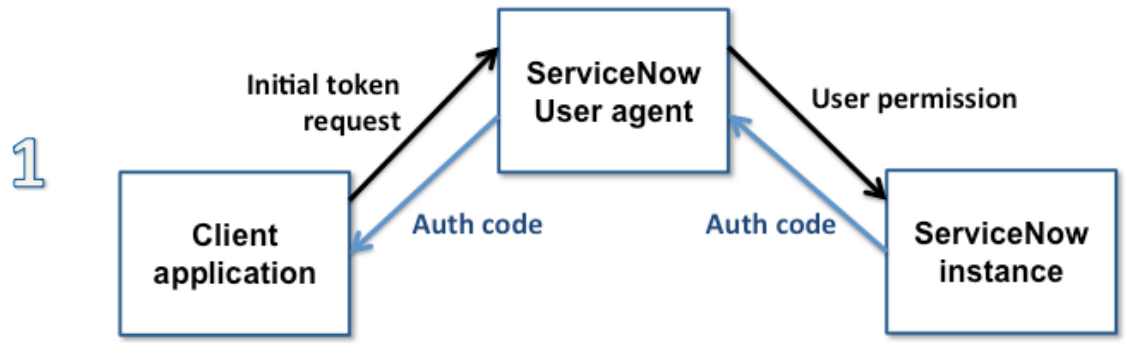
A ServiceNow instance as the authorization server

The OAuth server is typically a third-party authorization server. You can also specify a ServiceNow instance as the authorization server that issues the tokens for authorization code flow.

The user who owns the restricted resource must authorize access. The user can also revoke the issued access token at any time to terminate access.

Authorization code grant flow process

The Authorization code grant flow process consists of these three steps:



In step one, the client application or website initiates a REST API call in the form of a GET request to the instance via the user agent. Typically, the REST call is initiated when the end user clicks a button or a link on the client application or website to request an access token. In the client application, the end user also has to specify the authorization URL, token URL, client ID, and client secret. For an explanation of these items, see the field descriptions in this topic: Use a third-party OAuth provider. If the client asks for a grant type, the end user must select **Authorization Code**.

Example GET request from the client application to the instance:

```
https://myinstance.service-now.com/oauth_auth.do?response_type=code&redirect_uri={the_redirect_url}&client_id={the_client_identifier}
```

Note:
The **response_type** must be **code** to use the standard OAuth code grant flow.

The end user must manually allow access to the restricted resource on the instance. In the ServiceNow implementation, the end user must be logged into the instance. The instance prompts the end user with a UI page that has **Allow** and **Deny** buttons.

The item that the client application is actually requesting the token from is the OAuth provider application registry record that you created, also known as the authorization endpoint (see Use a third-party OAuth provider). The auth code is sent from the authorization endpoint to the client. It does not go to the client directly but to the **Redirect URL** that you specify on the authorization endpoint form. This URL is also known as a callback URL. You can obtain this URL from the client application or website.

Example response from the instance to the client application, providing an authorization code:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
https/http://{callbackURL}?code={the actual auth code}
```

Now that the client application has the authorization code, the client uses the code to request the access token. The authorization code proves that the user has consented in step 1.

Example POST request from the client application to the ServiceNow instance that provides the auth code and requests the access token:

```
https://myinstance.service-now.com/oauth_token.do?grant_type=aut
horization_code&code={the auth
 code}&redirect_uri={the_same_redirect_url}&client_id={the_same_
client_identifier}&client_secret={client_secret_value}
```

The endpoint on the instance returns an access token and a refresh token. The refresh token can be used to request additional access tokens.

You can manage the tokens, including revoking the token, in the instance. See Manage OAuth tokens.

The client application uses the access token to authenticate to the REST API. After authenticating the client application, the REST API returns the requested data in a JSON payload.

Example GET request for the JSON payload of data for the Incident [incident] table:

```
https://myinstance.service-now.com/api/now/table/incident?access
_token={the_token}
```

Note:
The system also supports OAuth implicit grants, also known as implicit grant code flow.

Integration support

Authorization code flow supports the following integrations on the instance:

- Multi-SSO
- SAML 2.0 Update 1
- Multifactor authentication

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The mobile interface is also supported.

Authorize access to an OAuth endpoint using auth code flow

End users who own a protected resource on the ServiceNow instance must authorize access to the resource before the instance can provide the access token.

Before you begin

Role required: none. You must already be logged in to the instance that holds the protected resource. Alternatively, you can log in using the authentication method (such as multi-factor authentication or SAML) that your ServiceNow administrator already set up.

Procedure

1. Click the link or button on the client application where you are requesting access to the protected resource on the instance.
   This kicks off the token request. If you are making a REST call from one instance to another, this link is **Get OAuth Token** on the REST Message form.
2. If you are not logged in, log in now.
   If you are not the same user as the user specified in the upper-right corner, click **Not You?** and log in.
3. Click account permissions to open the list of access tokens that you have already issued.
   This is the same as the **Self-Service** > **My connected** apps token list.
4. Click **Allow** to allow access and have the instance issue the authorization code (if using auth code flow) or the access token (if using implicit grant type).

   If you click **Deny**, the authorization is not allowed, but you are not logged out of the instance.

   A message that confirms access should appear. If you are requesting access from the REST Message form on an instance, the following message appears at the top of the form: OAuth Refresh token is available and will expire at {date}.

Authorization code flow state parameter requirement

The glide.oauth.state.paramater.required system property enables the State parameter to be required in an OAuth request for authorization code flow.

State parameter

Role required: none.

Beginning in the Madrid release, the system property *`glide.oauth.state.parameter.required`* adds a State parameter for an OAuth request. For zbooted instances, the property is true. For upgraded instances, the property is not present, so the State parameter is not enabled. The State parameter is a string value, and should not contain special characters. The State parameter cannot be empty or " ".

Validating the state parameter

Create an endpoint for clients to access the instance. Initiate an authorization code flow for an oauth_auth.do. For example:

```
http://myinstance.service-now.com/oauth_auth.do?grant_type=authorization_code&client_id=e9dba45b380d1300e676ccc91cef468f&response_type=code
```

If you do not specify the state parameter in the request, you get an error and the authorization code is not returned.`Missing State parameter in request.`

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Adding the State parameter to the request:

```
http://myinstance.service-now.com/oauth_auth.do?grant_type=authorization_code&client_id=e9dba45b380d1300e676ccc91cef468f&response_type=code&state=123
```

Adding the State parameter redirects you to the login screen and the regular authorization code flow returns the authorization code.

Note:
The response URL contains the state parameter passed in the request. In the example, the added parameter is `state=123`.

If the authorization code flow starts from oauth_initiator.do:

```
http://myinstance.service-now.com/oauth_initiator.do?oauth_requestor_context=sys_rest_message&amp;oauth_requestor=eab8341fec0d1300964f214a2c2fcf67&amp;oauth_provider_profile=dfa8f01fec0d1300964f214a2c2fcf51&amp;response_type=code
```

The State parameter is automatically added when redirected by oauth_auth.do.

```
http://myinstance.service-now.com/oauth_auth.do?response_type=code&amp;state=-790938844&amp;redirect_uri=http://10.11.95.5:16001/oauth_redirect.do&amp;client_id=e9dba45b380d1300e676ccc91cef468f
```

Authorization code flow example: ServiceNow instance as authorization server

You can use an instance as an authorization server to issue tokens to a client using authorization code flow.

Before you begin

Role required: none.

This example uses two instances: one as the authorization server and the other as the client. One instance uses a REST call to request tokens from another instance.

You must Activate OAuth on both instances.

Procedure

1. On the authorization server instance (running the Istanbul or later release), navigate to **System OAuth** > **Application Registry** and then click **New**.
2. Click **Create an OAuth API endpoint for external clients**.
3. Fill out the form fields for the OAuth application record as described in Create an endpoint for clients to access the instance.
   Completing these steps sets up an authorization server. Follow the next steps to set up the client server.
4. On the client instance, navigate to **System OAuth** > **Application Registry** and then click **New**.
5. Click **Connect to a third party OAuth Provider**.
6. Fill out the form fields for the OAuth application record as described in .
   Note the following field values:
   - **Name**: A unique name that identifies the application that you require OAuth access for.
   - **Client ID**: Client ID of the application registry record that you created for the authorization server.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **Client Secret**: [Read-Only] The auto-generated unique ID of the application. The instance uses the client ID when requesting an access token.
- **Default Grant type**: Select **Authorization code**.
- **Authorization URL**: URL of the instance that is the authorization server. Remember to append `oauth_auth.do` at the end of the URL.
- **Logo URL**: The URL that contains an image to use as the application logo. The logo appears on the approval page when the user receives a request to grant a client application access to a restricted resource on the instance.
- **Token URL**: URL of the instance that is the authorization server. Remember to append `oauth_token.do` at the end of the URL.
- **Redirect URL**: URL of the instance: the client server instance. Remember to append `oauth_redirect.do` at the end of the URL.

7. Create a profile for the record with the **Authorization code** grant type.
   The client server is setup. You can now create an outbound REST message and get an OAuth token.

Create an endpoint for clients to access the instance

Create an OAuth application endpoint for external client applications to access the ServiceNow instance.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System OAuth** > **Application Registry** and then click **New**.
2. On the interceptor page, click **Create an OAuth API endpoint for external clients** and then fill in the form.

Field	Description
Name	A unique name that identifies the application that you require OAuth access for.
Client ID	[Read-Only] The auto-generated unique ID of the application. The instance uses the client ID when requesting an access token.
Client Secret	[Required] The shared secret string that both the instance and the client application or website use to authorize communications with one another. The instance uses the client secret when requesting an access token. Leave this field blank to have the instance auto-generate a client secret. To display existing client secrets, click the lock icon.
Redirect URL	The callback URL that the authorization server redirects to. Enter the full URLs of the clients requesting access to the resource, appended by `/oauth_redirect.do`. For example, `http://token_consumer:port/oauth_redirect.do`. Enter as many URLs as needed for all possible token consumers. The instance matches the URL of the incoming request to one of the redirect URLs. If no match is made, the instance uses the first redirect URL.
Logo URL	The URL that contains an image to use as the application logo. The logo appears on the approval page when the user receives a request to grant a client application access to a restricted resource on the instance.
Active	Select the check box to make the application registry active.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Refresh Token Lifespan	The number of seconds that a refresh token is valid. The instance uses the lifespan value when requesting a refresh token. By default, refresh tokens expire in 100 days (8640000 seconds).
Enforce Token Restrictions	Select to only allow tokens to be used with APIs set to allow the authentication profile. You can set grant access using an API access policy. For more information, see Create REST API access policy. Default: Unselected.
Mobile Client	Represents the entity for mobile app or web. This information is used to analyze the login information with mobile or web.
Access Token Lifespan	The number of seconds that an access token is valid. The instance uses the lifespan value when requesting an access token. By default, access tokens expire in 30 minutes (1800 seconds).
Token Format	Format of the token to generate. The format determines the structure of a token and the information it includes.
Subject Claim	Field in the User (sys_user) table that's used to populate the value of the subject (sub) claim of a JWT token. The sub claim is a piece of information that identifies the subject, or user, of the JWT token. This field only applies if the **Token Format** is JWT.
Comments	Additional information to associate with the application.
Client Type	Choose the client type, based on the type of your client. Options: ○ **Iframe Embedded** ○ **Integration as a User** ○ **Integration as a Service** To know more, see Configure client type for OAuth and SSO records.

3. Click **Submit**.

Result

The system creates a record in the Application Registries [oauth_entity] table with of type OAuth Client. When the instance actually issues tokens and authorization codes, they are stored in the table. See Manage OAuth tokens for more information.

OAuth API response parameters

The OAuth 2.0 API produces a JSON response containing the following parameters as name:value pairs.

Access token response parameters

Response parameter	Description
scope	Amount of access granted by the access token. The scope is always **useraccount**, meaning that the access token has the same rights as the user account that authorized the token. For example, if Abel Tuter authorizes an application by providing login credentials, then the resulting access token grants the token bearer the same access privileges as Abel Tuter.

Access token response parameters (continued)

Response parameter	Description
token_type	Type of token issued by the request as defined in the OAuth RFC. The token type is always **Bearer**, meaning that anyone in possession of the access token can access a protected resource without providing a cryptographic key. See RFC6750 for more information about how OAuth 2.0 uses bearer tokens.
expires_in	Lifespan of the access token in seconds.
refresh_token	String value of the refresh token.
access_token	String value of the access token. Access requests made within the access token expiration time always return the current access token.
format	[Optional] Output format of the response. This value is always JSON.

Note:
If any OAuth provider sends the response body as "content-type" instead of "Content-Type", the OAuth HTTP client may not parse the response correctly. To correct this issue, create a system property using these parameters.

Field	Value
Name	glide.oauth.inhouse.httpclient.enabled
Type	true|false
Value	false

For details on creating system properties, see Add a system property

The following example illustrates the JSON string returned by an access token request. (Spaces have been added to improve readability).

```
{"scope":"useraccount","token_type":"Bearer","expires_in":1800,
"refresh_token":"w599voG89897rGVDmdp12WA681r9E5948c1CJTPi8g4HGc4
NWaz62k6k1KOFMxHW4OH8yOO3Hoe",
"access_token":"FOjh9korTyzd9kaZqZOSzjKZuS3utOi4P46Lc52m2JYHiLIc
qzFAumpyxshU9mMQ13gJHtxD2fy"}
```

OAuth API request parameters

Learn about the OAuth API request parameters that access token requests use.

Note:
The content-type of the OAuth API should be *application/x-www-form-urlencoded*. A content-type of *application/json* results in an unspecified error.

Access token request parameters

Request parameter	Description
grant_type	[Required] The type of credentials authorizing the request for an access token. This parameter must have one of the following values:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Access token request parameters (continued)

Request parameter	Description
	• **password**: A set of user credentials to authorize the access token request. Specify the user credentials in the username and password parameters. • **refresh_token**: An existing refresh token authorizes the access token request. Specify the refresh token in the refresh_token parameter.
client_id	[Required] Auto-generated unique ID of the client application requesting the access token.
client_secret	[Required] Shared secret string that the instance and the OAuth application use to authorize communications with one another.
username	User account name that authorizes the access token request. This parameter is required for access token requests with a **grant_type** of **password**.
password	Password for the user account that authorizes the access token request. This parameter is required for access token requests with a **grant_type** of **password**.
refresh_token	Existing refresh token that authorizes the access token request. This parameter is required for access token requests with a **grant_type** of **refresh_token**.

Requests Using User Credentials

The instance requires clients to provide user login credentials when first authorizing the client or when authorizing the creation of a new refresh token. This type of request always returns two tokens:

- An access token
- A refresh token

The instance verifies that the user is active, not currently locked out, and has an interactive session. If any of these conditions are false, the instance does not produce an access token. Access requests made within the expiration time of the access token always return the current access token.

Note:
This type of authorization grant relies on TLS encryption to protect the user credentials during transmission.

The following example illustrates requesting an access token with a set of user credentials (Spaces have been added to improve readability).

```
$ curl
 -d"grant_type=password&client_id=be3aeb583ace210011c15b24a43e2
5d8
&client_secret=client_password
&username=admin&password=admin"
https://instancename.service-now.com/oauth_token.do
```

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Requests Using a Refresh Token

The instance can use an existing refresh token to create a new access token. This type of request returns only an access token. The instance confirms that the refresh token has not expired before generating a new access token. Access requests made within the refresh token expiration time always return the current refresh token. Transmitting refresh tokens is generally more secure than transmitting user credentials. The following example illustrates requesting an access token with an existing refresh token (Spaces have been added to improve readability).

```
$ curl
 -d"grant_type=refresh_token&client_id=be3aeb583ace210011c15b24a
43e25d8
&client_secret=client_password
&refresh_token=w599voG89897rGVDmdp12WA681r9E5948c1CJTPi8g4HGc4NW
az62k6k1K0FMxHW40H8yOO3Hoe"
https://instancename.service-now.com/oauth_token.do
```

Create an OAuth JWT API endpoint for external clients (machine to machine integration)

OAuth JWT bearer token enables the client web applications to authenticate with your instance seamlessly using the inbound JWT grant type instead of requiring the end user to manually log in or share the password.

Before you begin

The supported algorithms for JSON Web Token (JWT): RS256, RS384, RS512, ES256, ES384, ES512.

Generate a JWT with the following claims at the client side:

- `aud`: Must match the value of the Client ID.
- `sub`: Must be a user identifier, such as the user's mail that you want to associate the token with.
- `iss`: Recommended matching the value of the Client ID. If the `aud` and `iss` isn't matching, then add the `iss` value in the claim validation.
- `exp`: Any desired expiration.

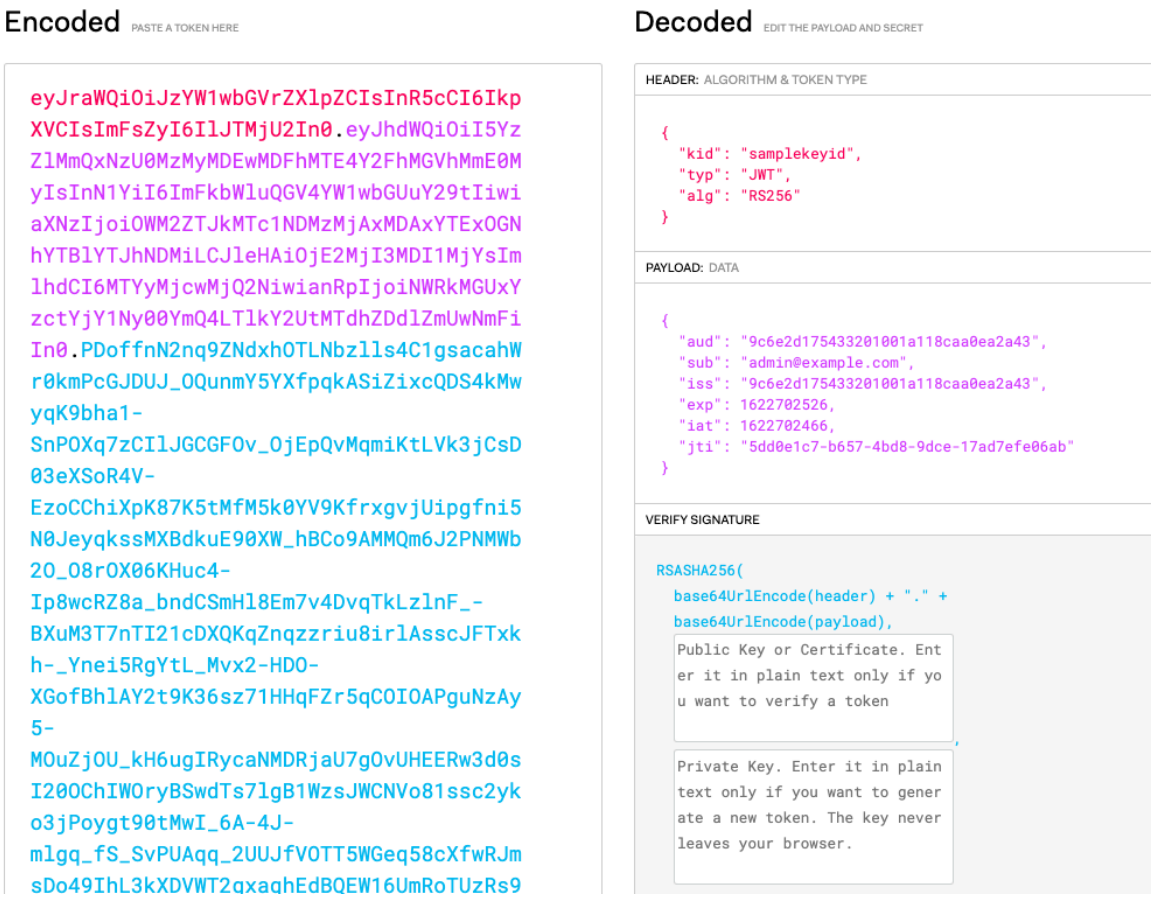
Example decoded JSON Web Token



Configuration in ServiceNow

About this task

Since using the JWT grant type doesn't include the password in the request, it enables a greater security between web services. For example, you can develop an external application and use tokens to authenticate inbound requests to your ServiceNow instance.

Role required: admin

For more information about JSON Web Tokens, see https://jwt.io/ .

Procedure

1. Add the public key of the client app to the **sys_certificate** table.
2. Set up the configuration in your ServiceNow instance to verify the incoming JWT.
   a. Navigate to **System OAuth** > **Application Registry**.
   b. Select **Create an OAuth JWT API endpoint for external clients**.
   c. Complete the form with information about your token.

© 2026 ServiceNow, Inc. All rights reserved.

OAuth JWT table

Field	Description
Name	A unique name that identifies the application that you require JWT OAuth access for.
Client ID	The auto-generated unique ID of the application. The system uses the value of this field to retrieve the public or shared key and validate the JWT. The value of this field should match the value of the issuer and audience claims in the JWT.
Client Secret	The shared secret string that both the instance and the client application or website use to authorize communications with one another. Leave this field empty to have the instance auto-generate a client secret. To display existing client secrets, select the lock icon. **Note:** If **Public Client** is selected, you can omit the **Client Secret**.
User Field	Field in the User (sys_user) table that the system uses to match the value of the subject claim in the JWT. For example, if you add a token that has a subject claim value of user.name@example.com, then you would set the **User Field** to **Email**. This field tells the system to search the email field for the user.name@example.com value and use the matching user record in the inbound request.
Enable JTI Verification	Select to require a new token every token exchange. Default: Selected.
Application	Read-only application scope. This field is auto-populated.
Accessible from	Cross-scope access policy. For more information, see Application access settings.
Access Token Lifespan	Amount of time that the token is valid. Unit: Seconds
Token Format	Format of the token to generate. The format determines the structure of a token and the information it includes.
Subject Claim	Field in the User (sys_user) table that's used to populate the value of the subject (sub) claim of a JWT token. The sub claim is a piece of information that identifies the subject, or user, of the JWT token. This field only applies if the **Token Format** is JWT.
Clock Skew	Allowed time difference between the server and client clocks when validating the `exp` and `nbf` claims in the JWT. Unit: Seconds Default: 300
Enforce Token Restrictions	Select to only enable tokens to be used with APIs set to enable the authentication profile. You can set grant access using an API access policy. For more information, see Create REST API access policy.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Default: Unselected.
Comments	Additional information to associate with the application.
Public Client	Add this field to the form if the JWT client is public. When selected, you don't need to include a **Client Secret**. Default: Unselected.
Client Type	Choose the client type, based on the type of your client. Options: ▪ **iframe Embedded** ▪ **Integration as a User** ▪ **Integration as a Service** To know more, see Configure client type for OAuth and SSO records.

d. Save the form.

e. Add records to the JWT Verifier Maps related list to verify the JWT signature.

JWT Verifier Maps table

Field	Description
Name	Name of the JWT-mapping record.
Kid	Key ID from the JWT.
Shared Key	The shared key for the specified key ID.
Application	Read-only application scope.
Sys certificate	Certificate record in the X.509 Certificates (sys_certificate) table. The certificate that was uploaded in step 1.

f. Add any custom claims associated with your JWT to the OAuth JWT Claim Validations related list.

You don't need to add records for the following required claims:

- iss
- aud
- sub
- exp

Note:

- If the `aud` and `iss` isn't matching, then add the `iss` value in the claim validation.
- For certificates, you can add multiple verifier maps associated with multiple keys.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

OAuth JWT Claim Validations table

Field	Description
My external client	Auto-populated with the OAuth JWT record.
Claim Value Type	Data type of the claim value.
Claim Name	Name of the claim you want to add.
Claim Value	Value of the claim.
Application	Read-only application scope.

3. Send a cURL request containing the JWT token to obtain an access token from your instance.

Example

The following is a sample cURL command requesting an access token:

```
$ curl -d"grant_type=
 urn:ietf:params:oauth:grant-type:jwt-bearer
&client_id=be3aeb583ace210011c15b24a43e25d8
&client_secret=client_password
&assertion=
 eyJraWQiOiJzYW1wbGVrZXlpZCIsInR5cCI6IkpXVCIsImFsZyI6IlJTMjU2In
0.eyJhdWQiOiI5YzZlMmQxNzU0MzMyMDEwMDFhMTE4Y2FhMGVhMmE0MyIsInN1Y
iI6ImFkbWluQGV4YW1wbGUuY29tIiwiaXNzIjoiOWM2ZTJkMTc1NDMzMjAxMDAx
YTExOGNhYTBlYTJhNDMiLCJleHAiOjE2MjI3MDI1MjYsImlhdCI6MTYyMjcwMjQ
2NiwianRpIjoiNWRkMGUxYzctYjY1NyOOYmQ4LTlkY2UtMTdhZDdlZmUwNmFiIn
0.PDoffnN2nq9ZNdxhOTLNbzlls4C1gsacahWr0kmPcGJDUJ_OQunmY5YXfpqkA

k1SvzyQXjuFqPdS2vzg2m1eKGUwr3m6uNs_HflcDystwVdMZ7nLlBG4"
https://instancename.service-now.com/oauth_token.do
```

If the JWT client is a public client, such as the Mobile SDK, then you can omit the client_id and client_secret parameters from the request. The following is a sample cURL command requesting an access token that omits the client_id and client_secret:

```
$ curl -d"grant_type=
 urn:ietf:params:oauth:grant-type:jwt-bearer
&assertion=
 eyJraWQiOiJzYW1wbGVrZXlpZCIsInR5cCI6IkpXVCIsImFsZyI6IlJTMjU2In
0.eyJhdWQiOiI5YzZlMmQxNzU0MzMyMDEwMDFhMTE4Y2FhMGVhMmE0MyIsInN1Y
iI6ImFkbWluQGV4YW1wbGUuY29tIiwiaXNzIjoiOWM2ZTJkMTc1NDMzMjAxMDAx
YTExOGNhYTBlYTJhNDMiLCJleHAiOjE2MjI3MDI1MjYsImlhdCI6MTYyMjcwMjQ
2NiwianRpIjoiNWRkMGUxYzctYjY1NyOOYmQ4LTlkY2UtMTdhZDdlZmUwNmFiIn
0.PDoffnN2nq9ZNdxhOTLNbzlls4C1gsacahWr0kmPcGJDUJ_OQunmY5YXfpqkA
SiZixcQDS4kMwyqK9bha1-SnPOXq7zCIlJGCGFOv_OjEpQvMqmiKtLVk3jCsDO3
eXSoR4V-EzoCChiXpK87K5tMfM5k0YV9KfrxgvjUipgfni5NOJeyqkssMXBdkuE
90XW_hBCo9AMMQm6J2PNMWb2O_O8rOXO6KHuc4-Ip8wcRZ8a_bndCSmHl8Em7v4
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
DvqTkLzlnF_-BXuM3T7nTI21cDXQKqZnqzzriu8irlAsscJFTxkh-_Ynei5RgYt
L_Mvx2-HDO-XGofBhlAY2t9K36sz71HHqFZr5qCOIOAPguNzAy5-MOuZjOU_kH6
ugIRycaNMDRjaU7gOvUHEERw3dOsI2OOChIWOryBSwdTs7lgB1WzsJWCNVo81ss
c2yko3jPoygt90tMwI_6A-4J-mlgq_fS_SvPUAqq_2UUJfVOTT5WGeq58cXfwRJ
msDo49IhL3kXDVWT2gxaqhEdBQEW16UmRoTUzRs9A9sOm18y3skmOVtnEOm-MlJ
MFQZ754UMzbiHOZsMmk1ivCGIjex5JO_lDjKElWF5RHGz3YShCoa4JKDZsqYMvI
k1SvzyQXjuFqPdS2vzg2m1eKGUwr3m6uNs_HflcDystwVdMZ7nLlBG4"
https://instancename.service-now.com/oauth_token.do
```

The instance returns the access token in its response:

```
{
    "access_token":
 "KynMY2HOuwWkRc8g8YLXjnQxWbH5_wbnSiLsnaOoKw61GZkkV0ytZP74uF7hJ
yjfsWfaaFijqQzq2kcABNJxNA",
    "scope": "useraccount",
    "token_type": "Bearer",
    "expires_in": 1799
}
```

Note:
The inbound JWT grant type doesn't include refresh tokens.

4. Make a REST API call to access a resource using the access token.

Example

The following is a cURL command to access the incident table using the token.

```
$ curl -H "Authorization: Bearer
 KynMY2HOuwWkRc8g8YLXjnQxWbH5_wbnSiLsnaOoKw61GZkkV0ytZP74uF7hJy
jfsWfaaFijqQzq2kcABNJxN"
https://instancename.service-now.com/api/now/v1/table/incident
```

Result
The system retrieves the access token in the REST call and enables access to the requested resource.

Configure an OAuth OIDC provider for accepting third-party token

Configure an OAuth OpenID Connect (OIDC) provider to accept identity tokens generated by a third-party OIDC provider using inbound API calls using Single Sign-On option (Multi-Provider SSO).

Before you begin
Role required: admin

About this task
The ServiceNow AI Platform supports OpenID Connect (OIDC) through the external Single Sign-On (SSO) implementation in addition to inbound API calls.

For an example of an OIDC provider configuration, see Set up Microsoft Entra ID spoke. For an SSO-specific example of an OIDC provider configuration, see Create an OpenID Connect (OIDC) configuration for Single Sign-On (SSO).

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **System OAuth** > **Application Registry**.
2. Select **Submit**.
   The record is saved in the Application Registries [oauth_entity] table.
   When your instance issues tokens and authorization codes it creates a record in the Application Registries [oauth_entity] table with type **External OIDC Provider**. See for more information.
3. **Optional:** Go to the related list on the record OAuth Entity Profiles to validate a system-generated default profile for the new OAuth provider without any scope.
   You can change or add an OAuth provider profile including the name, grant type, and OAuth Scope.
4. **Optional:** Go to the related list on the record OAuth Entity Scopes to define all available OAuth scopes for this OAuth provider.
   The scopes defined can be selected when you create or update a profile. Each OAuth scope defined contains a name and a scope that you must get from the provider specification, such as a read-scope or a write-scope. Each scope must be defined separately.
5. **Optional:** Go to the related list on the record User Provisioning to enable automatic user provisioning.

Option	Description
Automatically provision users	Option to enable force authentication for users.
Provision data source	The data source to use to transform an OIDC token to a ServiceNow user. Use the **Lookup list** to select the predefined data source tem plate, then open the record to configure the Transformed table mapping. When configur ing the Transform mapping, the source fields are from the *JWT token*, the target fields are from the *sys_user* table.
User roles applied to provisioned users	The user roles applied to the newly provi sioned ServiceNow users.

Example: The following is an example of a cURL request to invoke a REST API call

Invoke a REST API call.

Perform the following steps:

- Register the app in the OpenID Connect Provider.
- Configure the OAuth OIDC Entity.
- Configure the OIDC Provider:

OIDC Provider

OIDC Provider	Name of the OIDC provider.
OIDC Metadata URL	Specify the OIDC Metadata URL (well-known configuration URL). This information is used

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

	to fetch the public keys to validate the token through the `jwks` endpoint.
User Claim	The the claim which is validated against user table.
User Field	User claim which identifies user record.
Enable JTI claim verification	When enabled, the ServiceNow JWT token validation will also validate the JTI sent by the provider. **Note:** If validation isn't checked, the `jti` can't be validated, regardless if it's present in the JWT token. The claim name in the token must be `jti`. This information is used to help prevent replay attacks.

- Get a JWT token.
- Invoke a REST API call.
  - The ID token in the Authorization header to access Table API or scripted web service.

```
curl -X GET --header "Accept:application/json"
 https://<instance_name>.service-now.com/api/now/table/incide
nt/897b04f2dbd4a300a135364e9d961952 -k

```
User Not Authenticated
{"error":{"message":"User Not
 Authenticated","detail":"Required to provide Auth
 information"},"status":"failure"}
```

Configure client type for OAuth and SSO records

Configure the **Client Type** field for OAuth and SSO record related configurations.

When establishing sessions for various login types such as Web UI (interactive login), Iframe Embedded, Embedded or Integration, you can configure the client type for the OIDC (OAuth Entity), SAML, and Digest records that are used for various login.

The client type choices are as follows:

- **Iframe Embedded**: Can be used for interactive ServiceNow instance that resides in an Iframe in the third party websites. For example, if there is a sensitive table (sys_user table - phone number of the user), as admin you can configure the ACL with the sec attribute (Iframe Embedded) set to false, to avoid the user accessing the data (table information) on the Iframe Embedded session in the third-party.
- **Integration as a User**: Can be used for Virtual Agent chat bot that are installed in desktop apps such as Slack, Teams etc.
- **Integration as a Service**: Can be used for machine to machine integration (communication between services).

Note:

- For OIDC (OAuth Entity): All the choices are available.
- For SAML and Digest: Only Iframe embedded. You must edit the form and add the **Client Type** field to the record and select the **Iframe Embedded** client type.
- If the **Client Type** selected is none, then there is no classification of the session.

It is recommended to use client type field to every records created for OIDC (OAuth Entity), SAML, and Digest. This enables you to have a better control over each login methods that has the same configurations but distinguished with the client type.

After configuring the field, whenever a user logs in from the corresponding configuration (OAuth or SSO), once the authentication is successful, the session is considered based on the configured client type and accordingly the session timeout is leveraged.

For the current session, the corresponding security attribute are included or can be leveraged to prevent users from accessing table specific information within the selected client type. For more information, see OOB (Out-of-Box) Security Attributes.

Session time out for the Client Types

Following are the system properties related to session time out for the various client types:

- `glide.session_timeout.iframe_embedded`
- `glide.session_timeout.integration_as_a_user`
- `glide.session_timeout.integration_as_a_service`

OAuth implicit grants

ServiceNow instances support the implicit grant of an access token.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The implicit grant type, also known as *`implicit grant code flow`*, allows the access token to be given directly to the client application via the user agent, which is typically the web browser or mobile device. No refresh tokens are granted. The end user must still grant access to the protected resource on the instance, just as with standard.

OAuth implicit grant flow process

Just as with the standard authorization code flow process, the client application makes a request to use the restricted resource on the instance and the end user approves it. The request is in the form of a URL sent to the instance. The URL must include the following parameters:

- `client_id=<the necessary client ID>`. This is mandatory to identify which protected resource the client application wants access to.
- `response_type=token`. This is mandatory to request the access token directly (as opposed to asking for an authorization code). The value must be `token` for implicit grants. In the standard authorization code flow example, the response type is `code`.
- `redirect_uri=<a URL>`: The location where the token is sent.

The authorization server sends the access token, rather than an authorization code, to client application via the user agent.

Here is an example GET request to receive the JSON payload of data for the Incident [incident] table:

```
https://myinstance.servicenow.com/oauth_auth.do?response_type=token&redirect_uri={the_redirect_url}&client_id={the_client_identifier}
```

If the user grants access, the token is included in the redirect (callback) URL:

```
https/http://{callbackURL}?access_token={the_token}
```

Client Credentials

Use the OAuth client credentials grant type for Inbound Integrations from a third party OAuth client to the ServiceNow® platform.

The administrators can use the client credential (CC) grant type to enable integration from a third party OAuth client to the ServiceNow platform.

Inbound client credentials grant type is a capability that can be controlled through a system property. By default the system property is false.

To use the client credentials grant type, you must perform the following steps:

- Create the `glide.oauth.inbound.client.credential.grant_type.enabled` system property.
- Add the **OAuth Application User** field to the OAuth Entity form.

Create the Client Credentials system property

Create the `glide.oauth.inbound.client.credential.grant_type.enabled` system property to use Client Credentials grant type for OAuth inbound integrations.

Before you begin
Role required: admin

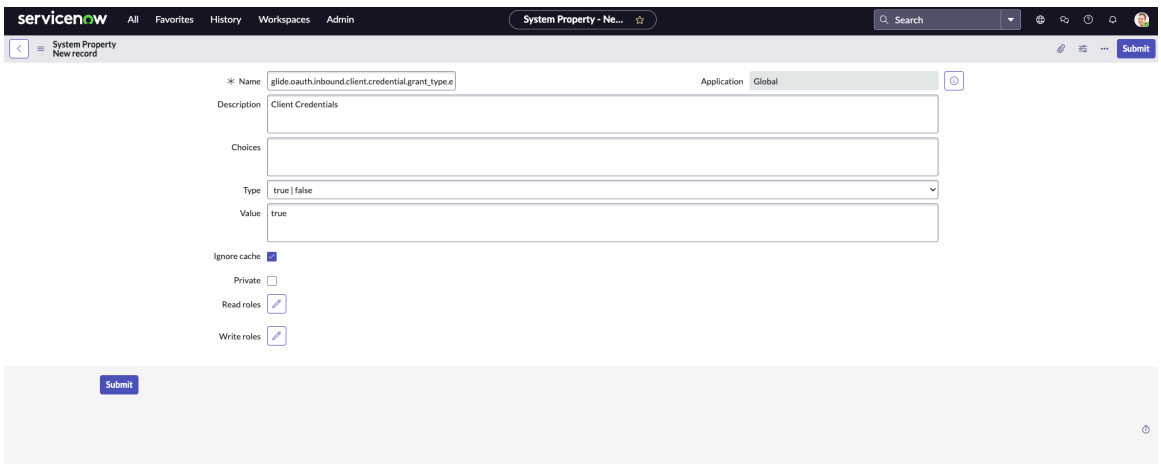
Plugin required: OAuth 2.0.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. In the navigation filter, enter `sys_properties.list`.
   The entire list of properties in the System Properties [sys_properties] table appears.
2. Select **New**.
3. On the form, fill the following fields.

Field	Description
Name	Name of the property you're creating. In this case, `glide.oauth.inbound.client.credential.gran`
Description	Type a brief, descriptive phrase describing the function of the property.
Type	Select the appropriate data type from the list. In this case, `true| false`.
Value	Set the desired value for the property. In this case, `true` to enable the client credentials grant type for OAuth inbound integrations.



Note:
Other fields in the form such as Choices, Ignore cache, Private, Read roles, and Write roles can be configured according to your requirements.

4. Select **Submit**.

Note:
If the **Ignore cache** check box is selected, the system flushes the server cache when the parameter is changed.

Next, you must create an OAuth client (OAuth API endpoint for external client) and add OAuth Application User field to the OAuth client record.

Add the OAuth Application User

Add the OAuth Application User field on the OAuth Entity form to use the Client Credentials grant type for OAuth inbound integrations.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

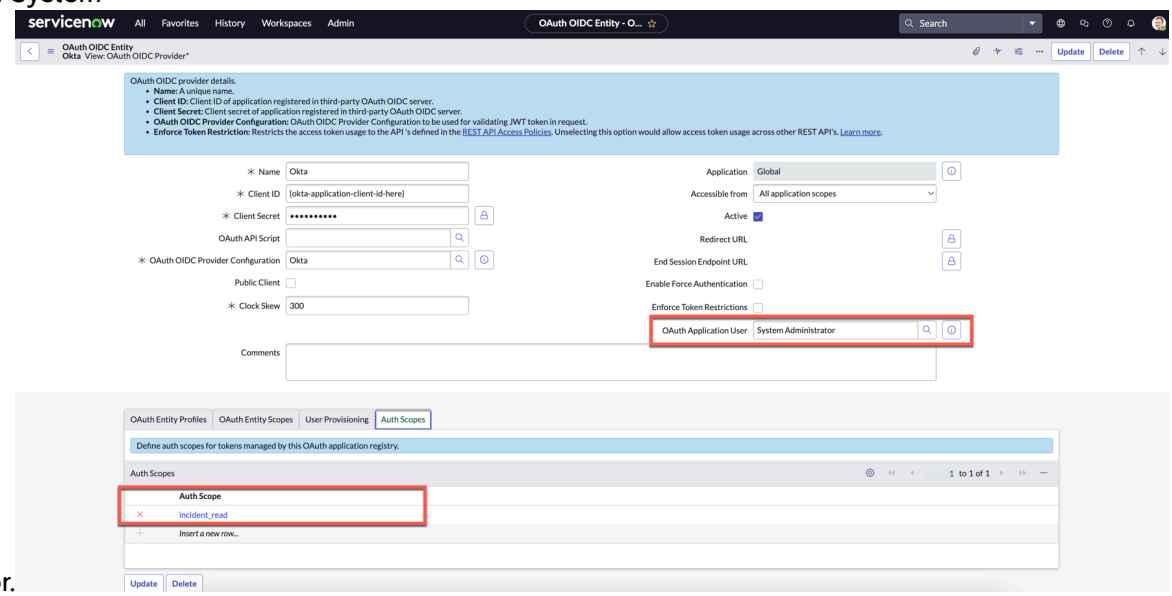
Before you begin
Role required: admin

Plugin required: OAuth 2.0.

You must create an OAuth client. For more information, see Create an endpoint for clients to access the instance.

Procedure

1. Open the OAuth client record that was created.
2. Select more options icon on the page header.
3. Select **Configure** > **Form Design**.
4. On the Form Design page, add **OAuth Application User** from the list of fields.
5. Save or Update the form.
6. Select the user for the **OAuth Application User**.
   For example, System Administrator.



> **Note:**
> You must use the REST API Auth Scope with client credentials grant type to control the access provided to the 3rd party client.

7. Save or Update the form.

   Any authorization request with the **Grant Type** as **Client Credentials**, **Client ID**, and **Secret** is passed for the associated OAuth Application User in ServiceNow®.

> **Note:**
> If the OAuth Application User isn't selected on the OAuth client record or the Client Credentials property is set to `false`, then the authorization request isn't passed.

Manage OAuth tokens

Open OAuth tokens to provide access to restricted resources.

Before you begin
Role required: any user or admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

About this task
OAuth tokens issued by the instance and third party OAuth provider are stored in oauth_credential table.

Some of the important columns in this table:

- Token: Value of the token issued by ServiceNow instance.
- Type: Determines if the token is Access Token or Refresh Token.
- Expires: Data/Time when the Access or Refresh Token expire.
- Token Received: Value of the token issued by a 3rd party OAuth Provider. This value is in encrypted format.

Token Expiration and Validity is as follows:

- Access Token: By default, an instance issues access tokens with a 30-minute lifespan in the scenario where the instance is the OAuth provider.
- Refresh Token: By default, an instance issues refresh tokens with a 100-day lifespan in the scenario where the instance is the OAuth provider.

Procedure
1. Navigate to one of the following menu options:
   - **Self-Service** > **My Connected Apps** to see the tokens that the instance created when you granted access to a resource on the instance.
   - **System OAuth** > **Manage Tokens** to see all tokens. Only administrators can access this module.
2. Click the **Name** to open the token.
3. Click **Revoke Access** to prevent access to the restricted resource.

   You can also view other information about the token, including the scope it allows access to and the expiration date.

   You can select the **Clean Expired OAuth Credentials** record from the Schedule page (`sys.trigger.list`) and configure the following:

   - **com.snc.platform.security.oauth.is.active**: By default, the value is set true.
   - **com.snc.platform.security.oauth.hours.expired.credential.is.kept**: Set the value based on your requirement to determine the number of hours you want the keep the expired `oauth` credential in the system.
   - **com.snc.platform.security.oauth.day.old.credential.is.kept**: Set the value based on your requirement to determine the number of days you want the keep the expired `oauth` credential in the system.

Revoke an OAuth token

You might want to revoke an OAuth access or refresh token for security reasons.

Before you begin
Role required: admin

About this task
Revoking the token pertains to the situation where your instance acts as the OAuth resource server. You can revoke the token through a URL.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

Access your instance using `oauth_revoke_token.do` and append the access or refresh token.

For example: `https://[Your_ServiceNow_Instance]:[port]/oauth_revoke_token.do?token=[access or refresh token]` without the brackets `[ ]`.

Result

This endpoint access does not require authentication. The token in this request is marked as expired.

OAuth outbound

OAuth outbound enables you to pull data from a third-party provider to your instance.

You must have the security_admin role to manage the OAuth integration.

You can configure outbound OAuth 2.0 for the following grant types:

- **Connect to third-party provider**: Use the client ID and secret to send it to the OAuth provider. For more information, see Connect to a third-party OAuth provider.
- **JWT Bearer**: An authorization server validates a JWT token which enables identity and security information to be shared across security domains. For more information, see Set up OAuth provider with JWT Bearer grant type.
- **SAML2 Bearer**: Generates the SAML2 assertion and then exchanges the assertion for the access tokens wit the provider.

  Note:
  For outbound request to SuccessFactors use the **SAML2 Bearer** as the Default Grant Type. To know more about how to configure **SAML2 Bearer**, refer the example in Set up the v4.x.x.

- **Authorization code**: The code that is granted to the client to obtain an access token, which is then used to obtain access to the resource. If you select this option, then you need an authorization URL (the URL of the authorization server).
- **Resource owner password credentials**: The user name and password of the user that is trying to obtain access to the resource.
- **Client Credentials**: The client ID and client secret, which are both used to get the access token. This method does not provide refresh tokens.
- **MID Server**: The MID Servers facilitate communication and data movement between a single ServiceNow® instance and external applications, data sources, and services. Use the Authorization code, resource owner password credential, SAML bearer, and JWT bearer OAuth grant types of OAuth for outbound integration requests through the MID Server. Personal Auth is also supported through the MID server.

You can configure **OAuth provider scenario** (Outbound): Your instance pulls data from a third-party provider.

Note:
You must user authenticate for the first time to fetch the token post which, you don't need to authenticate using a user account before the token expiry.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Connect to a third-party OAuth provider

Configure how the client ID and secret are sent to your OAuth provider.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System OAuth** > **Application Registry** and then click **New**.
2. On the interceptor page, click **Connect to a third-party OAuth provider** and then fill in the form.

Field	Description
Name	Unique name for the third-party OAuth connection.
Client ID	The client ID of application registered in the third-party OAuth server.
Client Secret	The client secret of the application registered in the third-party OAuth server.
OAuth API Script	The script used to customize request and response to the external OAuth provider.
Logo URL	The OAuth application logo URL.
Default Grant type	The default grant type used to establish the token. Choices include: ○ **Authorization code**: The code that is granted to the client to obtain an access token, which is then used to obtain access to the resource. If you select this option, then you need an authorization URL (the URL of the authorization server). ○ **Resource owner password credentials**: The user name and password of the user that is trying to obtain access to the resource. ○ **Client Credentials**: The client ID and client secret, which are both used to get the access token. This method does not provide refresh tokens. ○ **JWT Bearer**: An authorization server validates a JWT token which enables identity and security information to be shared across security domains. ○ **SAML2 Bearer**: Generates the SAML2 assertion and then exchanges the assertion for the access tokens wit the provider. **Note:** For outbound request to SuccessFactors use the **SAML2 Bearer** as the Default Grant Type.
Refresh Token Lifespan	Time, in seconds, that the refresh token is valid. The default time is 8,640,0000 seconds.
Public Client	Enables public clients to require PKCE for an authorization. **Note:** You can use only Authorization Code as the *`Default Grant type`* when PKCE is enabled.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Code challenge method	The code challenge method used in OAuth PCKE workflow. Choices include: ○ S256 [Default] ○ Plain ○ None
Comments	Add any comments regarding the OAuth app.
Application	Application and scope that contain this record.
Accessible from	Make this app accessible from all application scopes or from this scope only.
Active	Select the check box to make the app active.
Authorization URL	The OAuth authorization code endpoint.
Token URL	The OAuth server token endpoint.
Token Revocation URL	The OAuth server token revocation endpoint.
Redirect URL	The OAuth callback endpoint. If blank, the instance auto-generates an entry.
Use mutual authentication	Check the box to use mutual authentication for token request and revocation. This feature requires a mutual authentication profile to be specified.
Send Credentials	The OAuth client populates the client credentials in the request: ○ In Request Body (Form URL-Encoded) ○ Basic Authorization header ○ As Private Key JWT
Client Type	Choose the client type, based on the type of your client. Options: ○ **Iframe Embedded** ○ **Integration as a User** ○ **Integration as a Service** To know more, see Configure client type for OAuth and SSO records.

The system creates a record in the Application Registries [oauth_entity] table with type OAuth Provider.

3. **Optional:** Select OAuth Entity Profiles to validate a system-generated default profile for the new OAuth provider without any scope.
   You can change or add an OAuth provider profile including the name, grant type, and OAuth Scope.
4. **Optional:** Select OAuth Entity Scopes to define all available OAuth scopes for this OAuth provider.
   You can select the scopes when you create or update a profile. Each OAuth scope contains a name and a scope that you must get from the provider's specification, such as a read scope or a write scope. Each scope must be defined separately.
5. **Optional:** Select OAuth Entity Resources to define all OAuth resources this OAuth provider.
6. Select **Submit**.

JWT Bearer

JSON Web Tokens (JWTs) enable the capability to configure server-to-server API interactions between ServiceNow and external API providers without requiring any user intervention.

The JSON Web Token(JWT) bearer grant is a JSON string contains claim values which are evaluated and validated by the JWT Grant Handlers at the Authorization Server end, before issuing an access token.

Using the JWT Bearer grant type, you can configure OAuth 2.0 JWT bearer grant flow for outbound rest message.

Set up OAuth provider with JWT Bearer grant type

JSON Web Tokens (JWTs) enable the capability to configure server-to-server API interactions between ServiceNow and external API providers without requiring any user intervention. This support enables Integration Hub or other automated tasks using JWTs to configure API and Service integrations with different providers.

Before you begin

Role required: admin

About this task

The following tasks show how ServiceNow can be set up to use JWTs for OAuth 2.0 client authentication and authorization grants. ServiceNow is the OAuth client, and you can configure an OAuth provider, such as Box or Docusign.

Procedure

1. Upload Java Key Store certificate
   Attach a JKS certificate to your instance to use to enable the JWT client authentication.
2. Configure a JWT signing key
   Create a JWT signing key to assign to your Java KeyStore (JKS) certificate.
3. Create a JWT provider with a JWT signing key
   Add a JWT provider to your ServiceNow instance.
4. Connect to a third-party OAuth provider
   Create a third-party OAuth provider with a JWT Bearer as the default grant type in the ServiceNow Application Registry.
5. Specify an OAuth profile
   Open the OAuth entity profile of the OAuth provider and assign a JWT provider.

Upload Java Key Store certificate

You can attach a Java KeyStore (JKS) certificate to your instance to use to enable the JWT client authentication.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **Multi-Provider SSO** > **x509 Certificate**.
2. Fill in the form as needed.

Option	Description
Name	A unique name for your certificate.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Option	Description
Notify on expiration	Designate whom to notify when the certificate expires.
Warn in days to expire	Send an email notification to your certificate manager before your certificate expires.
Active	Enables the certificate to use for token re quests.
Type	The type of certificate you are uploading.
Expires in days	The amount of days until the certificate ex pires.
Key store password	The password associated with the certificate.
Short description	

3. Click **Submit**.

Configure a JWT signing key

Create a JSON Web Token (JWT) signing key to assign to your Java KeyStore (JKS) certificate,

Before you begin

Role required: admin

Note:
If you want to add **X.509 Certificate SHA-1 Thumbprint int (x5t)** to the header as part of the JWT Key, you must configure the form and add the **X.509 Certificate SHA-1 Thumbprint int (x5t)** field.

Procedure

1. Navigate to **All** > **System OAuth** > **JWT Keys**.
2. Fill in the form as needed.

Option	Description
Name	A unique name for your JWT Key signing con figuration.
Signing Keystore	The keystore designated when signing the JWT.
Key ID	The Key ID (kid) helps identify which key is used when multiple keys are used to sign to kens. **Note:** If you configure this field, the Key ID claim is included in the JWT. If you do not configure this field, your JWT will not have a Key ID claim.
Signing Algorithm	The algorithm to use to sign with the JWT key. RSA 256 is the only algorithm available.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Option	Description
Signing Key Password	The password associated with the signing key.
Active	Designate that the JWT key alias is actively referenced from a JWT provider.

3. Click **Submit**.

Create a JWT provider with a JWT signing key

Add a JSON Web Token (JWT) provider to your ServiceNow instance.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System OAuth** > **JWT Provider**.
2. Fill in the form and click **Submit**.

Option	Description
Name	A unique name for your JWT provider configu ration.
Expiry Interval (sec)	The lifespan of the tokens, in seconds, gener ated by the JWT provider.
Signing Configuration	The ServiceNow JWT signing key configura tion to apply.

Generate a JSON Web Token (JWT)

Create a JSON Web Token (JWT) for representing claims securely between two parties on the ServiceNow AI Platform.

The GlideJWT API is a scoped, scriptable API which generates a JWT. There are three arguments necessary before generating the JWT:

- Sys_id of JWT Provider
- JSON serialized header
- JSON serialized payload

There are two JWT API scripts, JWTTokenInternal and JWTTokenRestricted, that you can use when configuring a JWT Provider. The JWTTokenRestricted script enables administrators to configure who can generate a JWT. The JWTTokenInternal script is read-only and enables only logged in users to generate a JWT.

To generate a JWT:

- Create a JWT Key with a shared key (HMAC) or a signing keystore (RSA)
- Associate a JWT provider with the signing configuration referring a JWT key

You can use the API to create your token.

You can use standard and custom claims when configuring a JWT provider. You can pass dynamic header and payload claims as part of the generateJWT API signature.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Sample script to test API:

```
var jwtAPI = new sn_auth.GlideJWTAPI();
var headerJSON = {  "kid": "a1234"  };
var header = JSON.stringify(headerJSON);

var payloadJSON = { "jti": "testjti", "iss": "testiss", "sub":
 "testsub" };
var payload = JSON.stringify(payloadJSON);

var jwtProviderSysId = "7a40dde2d5303300964fb7c8f3c14ab5";
var jwt = jwtAPI.generateJWT(jwtProviderSysId, header, payload);

gs.info("JWT:" + jwt);
```

OAuth client APIs

The OAuth client API provides methods to request and revoke OAuth tokens.

The OAuth client provides these classes:

- GlideOAuthClient: Methods for requesting and revoking the refresh and access tokens.
- GlideOAuthClientRequest: Methods for handling client requests.
- GlideOAuthClientResponse: Methods for handling client responses.
- GlideOAuthToken: Methods for retrieving the access token and information about the access token.

You can also customize the OAuthUtil script include to intercept the request parameters and also parse the responses from external OAuth providers.

When using OAuth classes in a scoped script, use the `sn_auth` namespace identifier.

OAuth parameters for default profile support

The default profile feature requires a set of parameters that you can use with the *`setParameter()`* API to specify the OAuth requestor, a context for the request, and the provider profile.

In the OAuth provider scenario, you must set three parameters that tell the OAuth provider which OAuth profile to use by default. When these three parameters are set, the access token is saved in the instance database. Use the parameters with *`GlideOAuthClientRequest`*.

OAuth parameters for default profile support

Parameter	Description
`oauth_requestor`	The sys_id of the object, which can be a user record or an email account.
`oauth_requestor_context`	Descriptor that provides context for the OAuth requestor. As a good practice, use the name of the table where the `oauth_requestor` object is saved.
`oauth_provider_profile`	The sys_id of the OAuth profile record that is the default (see Specify an OAuth profile).

You do not need to use parameters to set the grant type and scope because the values are configured in the OAuth profile record. If you do not use the parameters, you can use the

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

GlideOAuthClientRequest API methods `setScope` and `setGrantType`. For additional information, see setScope and setGrantType.

Private Key JWT Support for OAuth 2.0 Client Authentication

Support JWT Support for OAuth 2.0 Client Authentication.

Private Key JWT Client Authentication is an authentication method that can be used by clients to authenticate to the authorization server when using the token endpoint.

In this authentication mechanism, only the clients that have registered a public key and signed a JWT using that key can authenticate.

The JWT must contain REQUIRED claim values and may contain OPTIONAL claim values. To know more about the claim values needed for the JWT for `private_key_jwt` authentication, refer the Client Authentication section in the OpenID Connect core documentation.

Note:
The authentication token must be sent as the value of the client_assertion parameter. The value of the#**client_assertion_type** parameter must be `#urn:ietf:params:oauth:client-assertion-type:jwt-bearer`.

Plugins required for OAuth 2.0 Client Authentication using JWT token:

- **OAuth 2.0 (com.snc.platform.security.oauth)**: This plugin is active on new and upgraded instances. If the plugin is not active on your instance, you can activate it.
- **Integration - Multiple Provider Single Sign-On Installer (com.snc.integration.sso.multi.installer)**: For OIDC based single sign-on use case.

You can use the OAuth 2.0 Client Authentication using Private Key JWT for the following:

- OIDC based single sign-on
- Outbound OAuth integrations

Configure Private Key JWT for OIDC based SSO

Configure Private Key JWT for OIDC based SSO integrations.

Before you begin

Role required: admin

You must perform the following tasks before choosing Private Key JWT for OIDC based SSO.

- Upload Java Key Store certificate: Attach a JKS certificate to your instance to use to enable the JWT client authentication.
- Configure a JWT signing key: Create a JWT signing key to assign to your Java KeyStore (JKS) certificate.

  Note:
  If you want to add **X.509 Certificate SHA-1 Thumbprint int (x5t)** to the header as part of the JWT Key, you must configure the form and add the **X.509 Certificate SHA-1 Thumbprint int (x5t)** field.

- Create a JWT provider with a JWT signing key: Add a JWT provider to your ServiceNow instance.

To include a JWT Key for OIDC based Identity Provider, you must:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

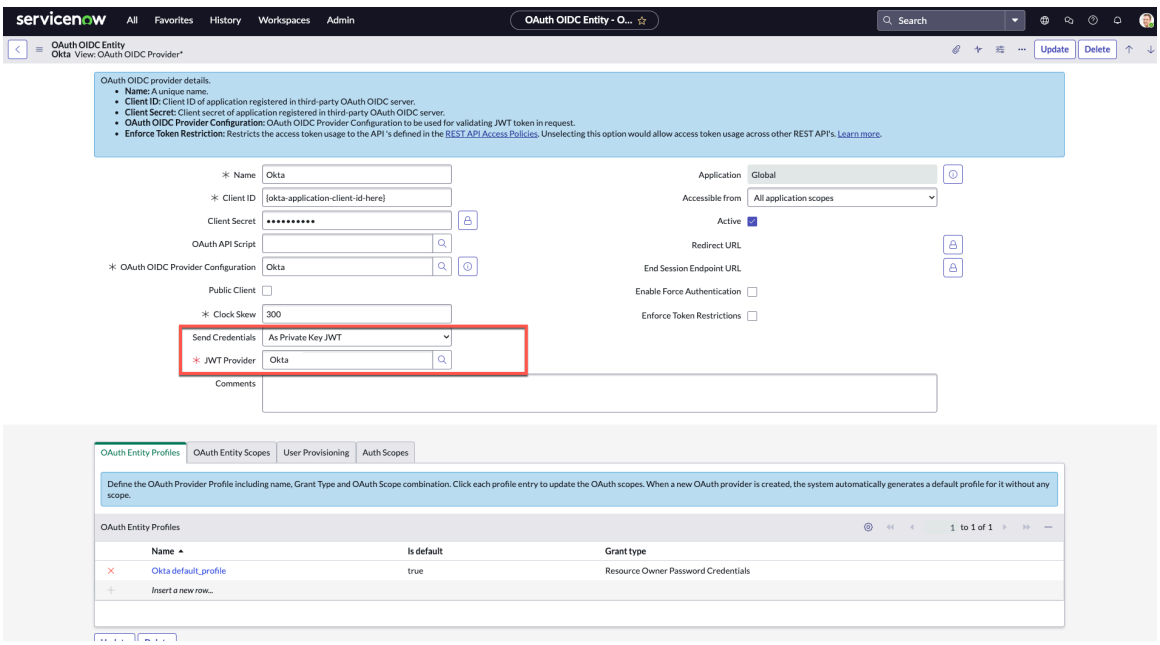
- Install the **Integration - Multiple Provider Single Sign-On Installer** (`com.snc.integration.sso.multi.installer`) plugin.
- Enable the properties for **Multiple Provider SSO Properties**. For more information, see Multi-Provider SSO properties, tables, and scripts.
- Create an OIDC Identity Provider. For more information, see Create an OpenID Connect (OIDC) configuration for Single Sign-On (SSO).

Procedure

1. Navigate to **All** > **System OAuth** > **Application Registry**.
2. Select the OIDC Identity Provider that you had created.
3. On top of the form, select **Configure** > **Form Design**.

> **Note:**
> You must add **Send Credentials** and **JWT Provider** fields to the form to use the Private Key JWT for OIDC based Identity Provider authentication requests.

4. Choose the **As Private Key JWT** for Send Credentials.
5. Select the **JWT Provider**.



When the user authenticates, the authentication page has options to login through Okta.

Configure Private Key JWT for Outbound OAuth

Configure Private Key JWT for outbound OAuth integrations.

Before you begin

Role required: admin

Before configuring Private Key JWT for outbound OAuth integrations, you must perform the following tasks:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Upload Java Key Store certificate: Attach a JKS certificate to your instance to use to enable the JWT client authentication.
- Configure a JWT signing key: Create a JWT signing key to assign to your Java KeyStore (JKS) certificate.

> **Note:**
> If you want to add **X.509 Certificate SHA-1 Thumbprint int (x5t)** to the header as part of the JWT Key, you must configure the form and add the **X.509 Certificate SHA-1 Thumbprint int (x5t)** field.

- Create a JWT provider with a JWT signing key: Add a JWT provider to your ServiceNow instance.

Procedure

1. Navigate to **All** > **System OAuth** > **Application Registry** and then click **New**.
2. On the interceptor page, click **Connect to a third-party OAuth provider** and then fill in the form.

> **Note:**
> You must add **Send Credentials** and **JWT Provider** fields to the form to use the Private Key JWT for Outbound OAuth authentication requests.

Field	Description
Name	Unique name for the third-party OAuth connection.
Client ID	The client ID of the application registered in the third-party OAuth server.
Client Secret	The client secret of the application registered in the third-party OAuth server.
OAuth API Script	The script used to customize requests and responses to the external OAuth provider.
Logo URL	The OAuth application logo URL.
Default Grant type	Choose: **Client Credentials**: The client ID and client secret, which are both used to get the access token. This method does not provide refresh tokens.
Refresh Token Lifespan	Time, in seconds, that the refresh token is valid. The default time is 8,640,000 seconds.
Public Client	Enables public clients to require PKCE for an authorization. **Note:** You can use only Authorization Code as the *`Default Grant type`* when PKCE is enabled.
Comments	Add any comments regarding the OAuth app.
Application	Application and scope that contain this record.
Accessible from	Make this app accessible from all application scopes or from this scope only.
Active	Select the check box to make the app active.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Authorization URL	The OAuth authorization code endpoint.
Token URL	The OAuth server token endpoint.
Token Revocation URL	The OAuth server token revocation endpoint.
Redirect URL	The OAuth callback endpoint. If blank, the instance auto-generates an entry.
Use mutual authentication	Check the box to use mutual authentication for token request and revocation. This feature requires a mutual authentication profile to be specified.
Send Credentials	Choose: **As Private Key JWT**
JWT Provider	JWT Provider details. You can use the lookup to select the JWT provider.

The system creates a record in the Application Registries [oauth_entity] table with type OAuth Provider that can be used for Private JWT Key authentication.

Create an outbound REST message

Create outbound rest message to authorize instance as authorization server.

Before you begin

Role required: admin

Procedure

1. Navigate to **System Web Services** > **Outbound** > **REST Message** and then click **New**.
2. Fill out the form fields for the OAuth application record as described in .
   Note the following field values:
   - **Endpoint**: URL of the instance that is the authorization server.
   - **Authentication type**: **OAuth 2.0**.
   - **OAuth profile**: OAuth profile that you created for the client server.
3. On the REST message record, click **Get OAuth Token**.
4. Authenticate with the instance that provides the token—the method depends on the single-sign on integration.
   You might use:
   - Your username and password that you use to authenticate to the instance.
   - The username and password for the IdP if is enabled. Click **Use External Login** to access the IdP login screen.

     Note:
     In order to automatically get redirected to the IdP login page, you must set the glide.authenticate.external system property.

   - Your code, if MFA is enabled.
5. Click **Allow** or **Deny** to complete the authorization and issue the tokens.
   The process that follows is outlined in OAuth authorization code grant flow.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Personal authentication

Personal authentication enables you to securely connect and manage your OAuth-based integrations like Microsoft OneDrive or Google Drive.

OAuth 2.0 Credentials

The OAuth 2.0 Credentials module in ServiceNow `(oauth_2_0_credentials)` enables you to configure and manage access tokens used to connect with external OAuth 2.0-compliant systems. Use the Personal integration type when each user must authenticate with their own identity to an external system.

Use the Credential form to configure OAuth 2.0 credentials with `integration_type = Personal`. For more information, see OAuth 2.0 credentials.

Personal authentication is supported only for the following OAuth 2.0 grant types:

- Authorization Code
- Resource Owner Password Credentials (ROPC)

Grant types such as Client Credentials, and JWT Bearer Grant aren't supported with `integration_type = Personal`.

Note:
Personal authentication is also supported via a MID Server for the Authorization Code and ROPC grant types. For more information, see OAuth token fetching via MID.

Personal authentication dashboard

Use your personal credentials to connect to third-party integrations. View, authenticate, revoke, and renew your personal authentications through a simplified, consolidated interface. For more information, see Using the Personal Authentication dashboard.

Note:
The personal authentication dashboard can only be accessed by users who are assigned to the role: `sn_personal_auth.personal_auth_user`

Configure Personal Authentication

You can configure personal OAuth authentication with the REST step in Flow Designer.

Before you begin

Role required: admin

Ensure that you install the IntegrationHub Starter Pack Installer (com.glide.hub.integrations) or a higher version.

About this task

This task guides you through configuring personal OAuth authentication for REST steps in ServiceNow® Flow Designer. It enables REST calls to run using the session user's credentials, ensuring secure and personalized API access.

For information on how to check if a personal OAuth token exists for a user, see Get Personal OAuth Token (using GlideOAuthClient).

For information to generate the initial token for a user, who doesn't have access to the credentials page, see Generate Personal Auth Initiator URL.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **Application Registries**, and create an OAuth application registry to connect to an external endpoint.
2. Navigate to **Connection & Credentials Aliases**, and create a connection alias.
   This alias is used in the REST steps. For more information, see Create a Connection & Credential alias.
3. Navigate to **HTTP(s) Connection**, and update the external end-point details for the connection record created in the previous step.
4. Create an **OAuth Credential**.
   a. Navigate to **OAuth 2.0 Credentials**.
   b. Create a new OAuth credential record and link it to the OAuth profile created in Step 1.
5. Add the **IntegrationType** field to the credential form.
6. Update the **IntegrationType** field of the credential created in Step 4 to **Personal**.
7. Generate a personal access token.
   a. As a logged-in user, open the credential record.
   b. Select **Get OAuth Token** to create a personal token.
   c. Select **Manage Tokens** to view and manage the tokens.

   Note:
   Add a UI action to your application so that the end users can generate tokens. Only administrators can open the credential form directly.

8. Navigate to **Action** to create an action for your use case.
9. Add a REST step to the action.
   Select the connection alias created in Step 2.

   Note:
   Test the action with the REST outbound call. The credential is marked to be used for personal integration. The REST step might display an error since the action runs with the System integration role.

10. Create a new subflow, and add the action created in Step 8.
    a. In the **Subflow properties** window, select **User who initiates session** in the **Run As** text field. Don't select **System User** instead from the **Run As** text field.
11. Test the subflow.
    The REST step uses the token created for the session user. The subflow can also be invoked using FlowAPIs.

    Sample script to invoke a subflow:

```
try {
    // Execute synchronously in the foreground. Allows
 access to subflow outputs.
    var result = sn_fd.FlowAPI.getRunner()
        .subflow('global.getpersonalincidentssubflow')
        .inForeground()
        .run();
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
    var outputs = result.getOutputs();
} catch (ex) {
    var message = ex.getMessage();
    gs.error(message);
}
```

12. Manage missing or expired tokens.

    If the session user has no access token, the REST request returns a **HTTP 401 Unauthorized status code** response. Ensure that the token is created before you initiate the flow.

    If the access token is expired but a valid refresh token exists, the system automatically renews the access token.

Get Personal OAuth Token (using GlideOAuthClient)

Check whether the user has a personal OAuth token. Use it to confirm valid access before running REST steps or integrations that require personal OAuth credentials.

Before you begin

Role required: admin

About this task

Use the `GlideOAuthClient` API to check if a personal OAuth token exists for the currently logged-in user. You can also use `ScopedPersonalAuthAPI` to get the personal OAuth token. For more information, see PersonalAuthAPI - Scoped.

Procedure

1. Use the following sample script to check for a personal access token associated with the current session user:

```
function dumpToken(token) {
  if (token) {
    gs.info("Access token: " + token.getAccessToken());
    gs.info("Expires in: " + token.getExpiresIn());
    gs.info("Refresh token: " + token.getRefreshToken());
  }
}

var oAuthClient = new sn_auth.GlideOAuthClient();
oAuthClient.setPersonal(true); // Returns the token for the
 logged-in user

var token = oAuthClient.getToken('<credential_sys_id>',
 '<oauth_profile_sys_id>');
dumpToken(token);
```

2. Replace `<credential_sys_id>` and `<oauth_profile_sys_id>` with the appropriate record values.
   The `setPersonal(true)` method confirms that the token returned belongs to the currently logged-in user.

> **Note:**
> For more information on the methods for requesting and revoking OAuth refresh and access tokens, see: Glide OAuth Client API Documentation.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Generate Personal Auth Initiator URL

Generate the initial token for a user who doesn't have access to the credentials page to configure personal authentication.

Before you begin

Role required: connection_admin

About this task

Users without the **connection_admin** role can't access the Credentials page to generate OAuth tokens. These users must generate a personal token using the `oauth_initiator` URL with additional parameter indicating that the token is personal and requested for session user.

You can also use the scoped `PersonalAuthAPI` with the `sn_personal_auth` plugin to generate the initiator URL. For more information, see PersonalAuthAPI - getInitiatorURL(String aliasId)

Note:
If the personal authentication plugin (`com.snc.sn_ihub_personal_auth`) is activated, use the scoped API to generate the initiator URL. This. API is available only if the plugin is installed.

Procedure

1. Use the following format to construct the token generation URL for Password Grant Type:

```
https://<instance-name>.service-now.com/oauth_password_input.
do?
sysparm_oauth_requestor_context=oauth_2_0_credential&sysparm_oa
uth_requestor=
<credential#sys_id>&sysparm_oauth_provider_profile=<OAUTH#profil
e#sys_id>&sysparm_oauth_personal=true
```

2. Use the following format to construct the token generation URL for Authorization Code Grant Type:

```
https:// ://<instance-name>.service-now.com /
oauth_initiator.do?
oauth_requestor_context=oauth_2_0_credentials&oauth_requestor=
<credential#sys_id>&oauth_provider_profile=<OAUTH#profile#sys_id
>&response_type=code&personal=true
```

Activate Personal Authentication Dashboard

You can activate the Personal Authentication plugin (com.snc.sn_ihub_personal_auth) for Integration Hub if you have the admin role. The application includes demo data and installs related ServiceNow® Store applications and plugins if they are not already installed.

Before you begin

Integration Hub requires a separate subscription from the rest of the ServiceNow AI Platform.

To purchase a subscription, contact your ServiceNow account manager. When you purchase a subscription, certain plugins are activated automatically. If a paid plugin isn't activated automatically, you can manually activate it from the All Applications list in your instance.

Note:

Before purchasing a subscription, you can evaluate this feature on a non-production instance without charge by requesting it from the Now Support Service Catalog.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Role required: admin

About this task

The following items are installed with Integration Hub:

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the Personal Authentication plugin (com.snc.sn_ihub_personal_auth) using the filter criteria and search bar.

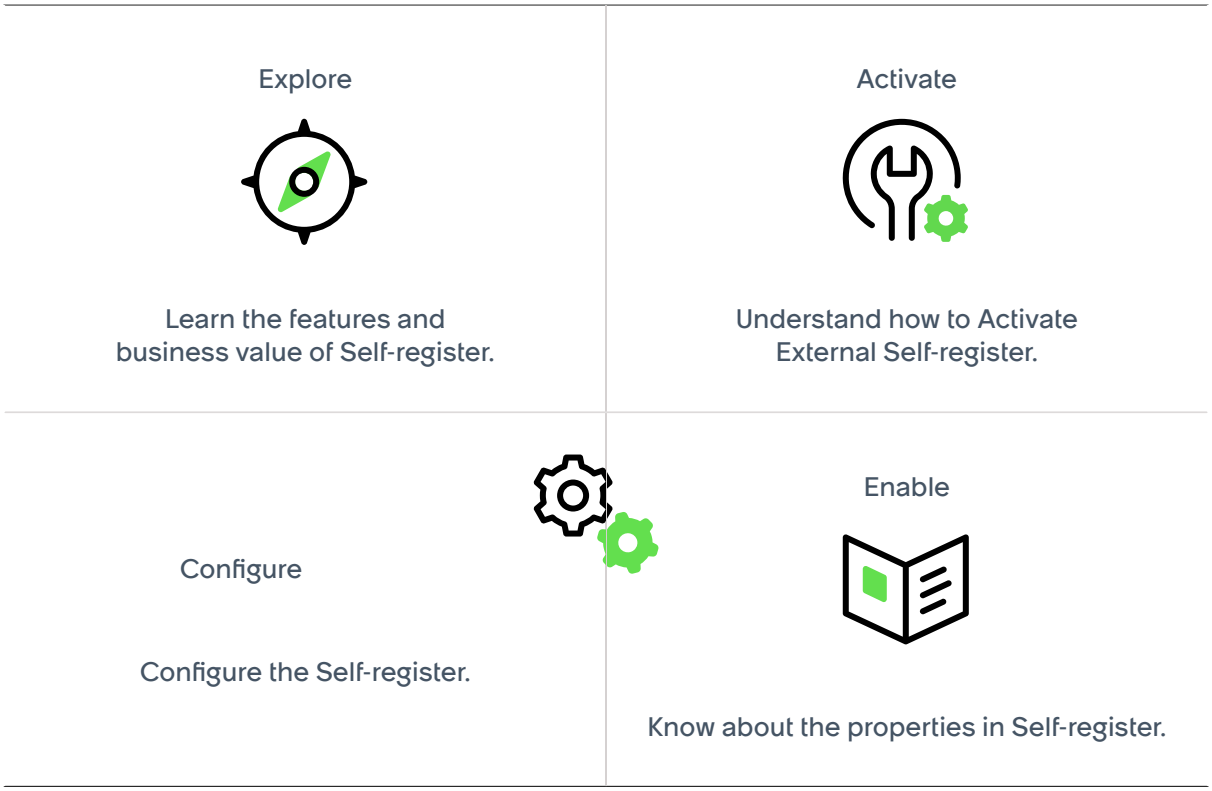
   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

Note:
When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Self-register to ServiceNow instance

Use external user self-registration to on-board a large volume of external users to your instance. This feature enhances identity verification to improve customer experiences and supports commonly used registration flows.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Explore Self-register

Use external user self-registration to on-board a large volume of external users to your instance. This feature enhances identity verification to improve customer experiences and supports commonly used registration flows.

External user self-registration enables a large group of users to register to a ServiceNow app without the help of an administrator. For example, a university with a large group of students needing on-campus parking could register themselves to the campus parking app. Each student would be given a limited set of privileges specific to parking, and would complete an automated registration process. This system could generate a parking number, unique to each student, and insure they had a parking space.

A self-registration flow consists of a custom ServiceNow app, in this case, a campus parking app. After configuring an app with necessary tables, an administrator would configure the registration, including a pre-registration flow, field mapping, post registration mapping, captcha, role mapping and post registration flow.

Activate External User Self-Registration

You can activate the External User Self-Registration plugin (com.snc.external_user_self_registration) if you have the admin role.

Before you begin

Role required: admin

About this task

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

   Note:
   When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

   You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

External roles in self-registration

To prevent inadvertently providing access to external users, you can assign the snc_external role to all external users.

External users that self-register must be assigned the snc_external role, which has the least privileges. The snc_external role indicates that the user is external to your organization and should not have any access to resources unless explicitly allowed through ACLs for the snc_external role or additional roles that inherit the snc_external role.

By default, users with the snc_external role cannot access:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Tables without the role that inherits the snc_external role or the public role.
- Non-record type resources, such as processors and UI pages without the snc_external role or a role that inherits the snc_external role.
- Platform Analytics dashboards.

Beginning with the Paris release, you must enable an exclude-list property to enforce the explicit assignment of snc_external roles. For information about enabling the property, see Prevent future internal role assignments for external users.

Configure a user registration configuration for external users

Create a user registration configuration record to bootstrap the onboarding process of external users to custom ServiceNow applications. This form guides the external users through the self-registration process.

Before you begin

- Role required: admin
- Activate External User Self-Registration

Procedure

1. Navigate to **All** > **External User Self-Registration** > **User Registration Configurations** and click **New**.
2. On the form, fill in the fields.

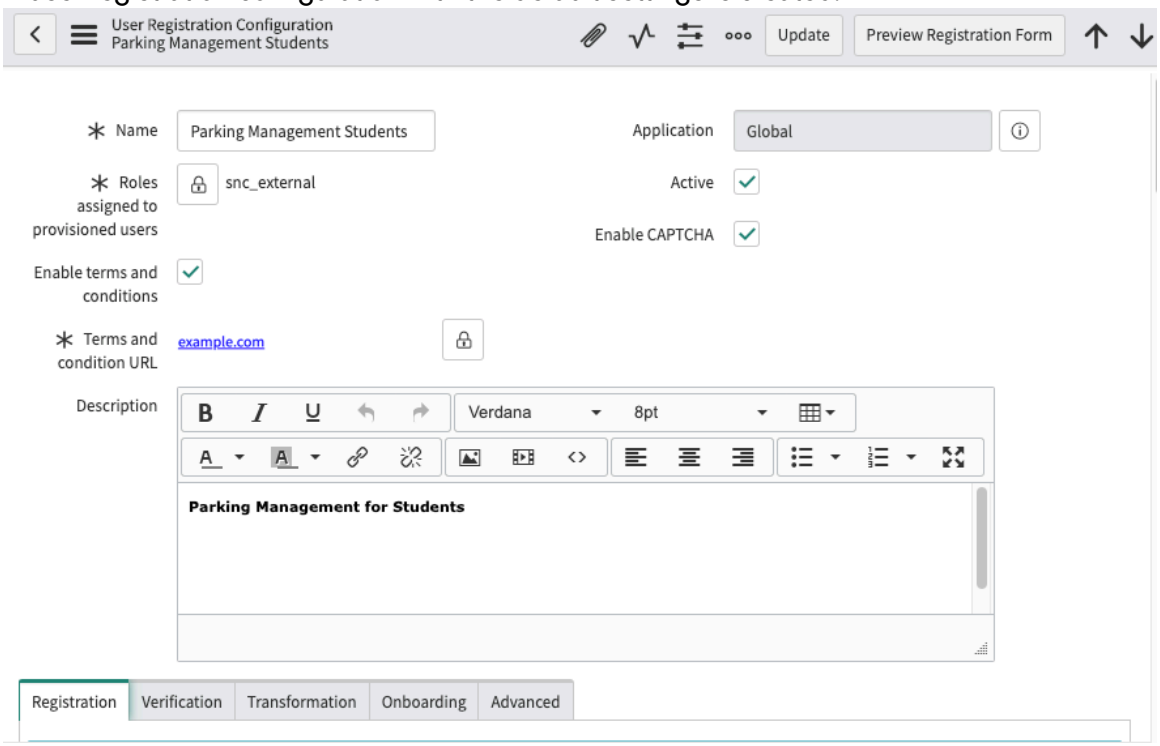
User registration configuration form

Field	Description
Name	Name of the registration form. For example, a student parking registration might be Parking Management Students.
Roles assigned to provisioned users	Roles assigned to the provisioned users. The specified roles have to extend or contains the `snc_external` role. The specified role can also be `snc_external` role. For external users, each role must have an `snc_external` to notate an external user. If you have pre-configured roles, the roles should be accessible when you unlock the roles and search for users.
Enable terms and conditions	Option to add a terms and conditions URL to the registration page.
Terms and conditions URL	The publicly accessible URL which contains the terms and conditions of the registration form. This field appears only when **Enable terms and conditions** is selected.
Description	The description of the registration form. This field appears only when you save or submit the configuration. You can add more information about the registration form in this field. **Note:** You can only add a description after you save or update a user registration configuration.
Application	Application containing this record. The application is automatically set to `Global`.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Active	Option which makes the user registration configuration active. This option is selected by default.
Enable CAPTCHA	Option to add a CAPTCHA to the registration form. The default CAPTCHA provider is Google reCAPTCHA. **Note:** To enable CAPTCHA for user registration, follow the steps in Configure Google reCAPTCHA for external user self-registration.

3. Click **Submit**.
   A user registration configuration with the default settings is created.



4. **Optional:** Configure the **Registration** tab to show fields and the order that they appear:

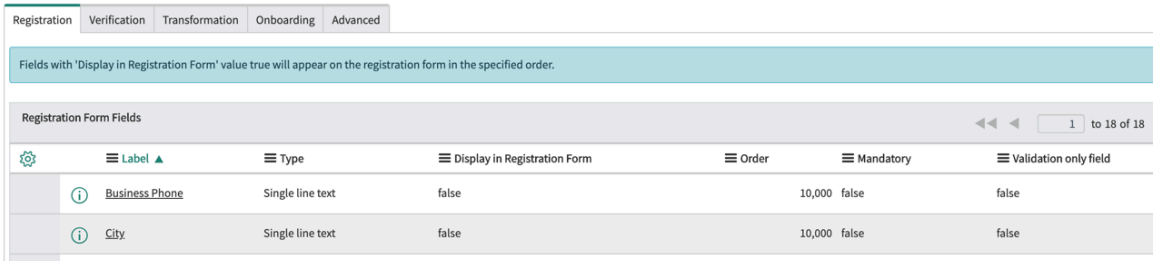
Registration Form Fields

Column	Description
Display in Registration Form	Set any field you want to display as `True`.
Order	Set an order number to display fields on your form.
Mandatory	Set any field you want to make it mandatory as `True`.
Validation only field	Set any field you want to use only for validation. For example, registration code.

You can choose to display the default form fields or you can add custom form fields to the Registration Form. For more information, see Default registration form fields.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Registration tab



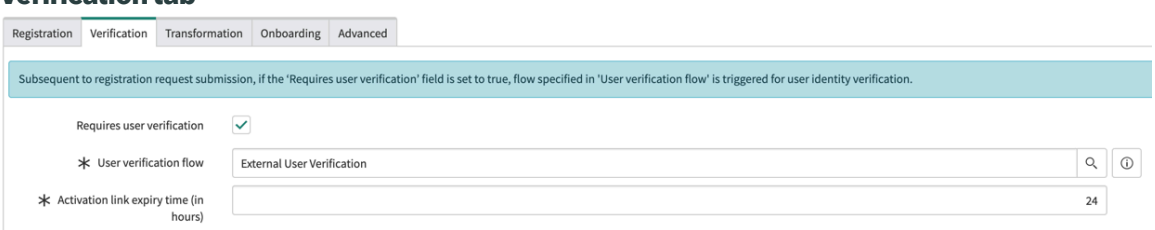
You can also add custom registration form fields. For more information, see Add a custom registration form field.

5. **Optional:** Configure the **Verification** tab to verify the identity of the registered users. When the user verification flow triggers, an activation link is sent to the user's registered email address.

Verification tab fields

Field	Description
Requires user verification	Option to trigger a user verification subflow which runs after user registration. The subflow is for user identity verification.
User verification flow	The subflow used to verify the identity of the user. The subflow triggers only when you enable user verification. (Optional) The **External User Verification** subflow is available by default. You can create a copy of the default subflow in Workflow Studio and modify it according to your requirements. For more information, seeFlow Designer . **Note:** To preview the **External User Verification** subflow in a new tab use the following shortcuts: ○ Macintosh: Command + Click ○ Windows: Control + Click
Activation link expiry time (in hours)	The number of hours after which an activation link expires. The default value is 24.

Verification tab

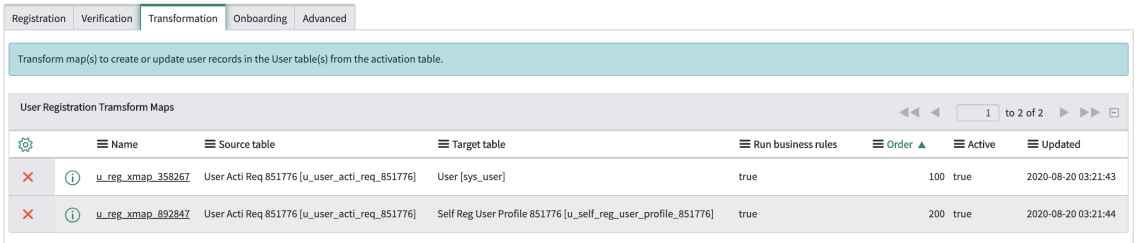


6. **Optional:** Configure the **Transformation** tab to map self-registered users and activated users.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

There are two transformation maps (u_reg_xmap_[number]) which automatically map the registered users from the User Acti Req [number] table to the Self Registered User [number] table. You can create a copy of these default transformation maps and modify the map according to your requirements. For more information, see Transform maps.

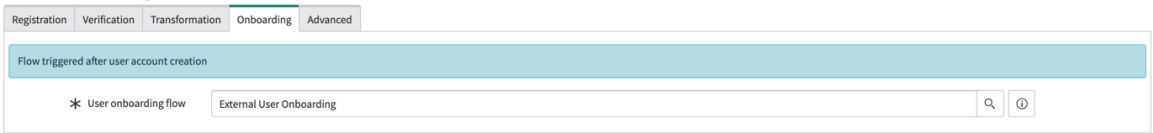
Transformation tab



7. Configure the **Onboarding** tab to trigger subflows for onboarding activated users.
   The default **External User Onboarding** subflow sends an email to the user that contains a link to reset their password. You can create a copy of the default subflow and modify it according to your requirements.

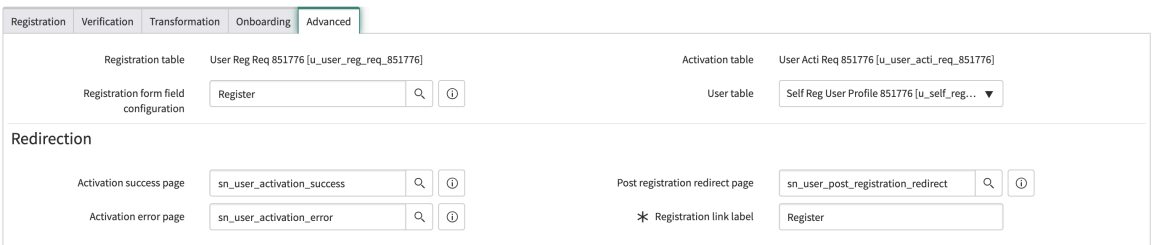
   Note:
   When the **External User Onboarding** subflow triggers, the subflow sends an email to the user that contains a link to reset the password.

Onboarding tab



8. **Optional:** Configure the **Advanced** tab to map user tables and redirection pages of the registration form.

Advanced tab



Advanced tab

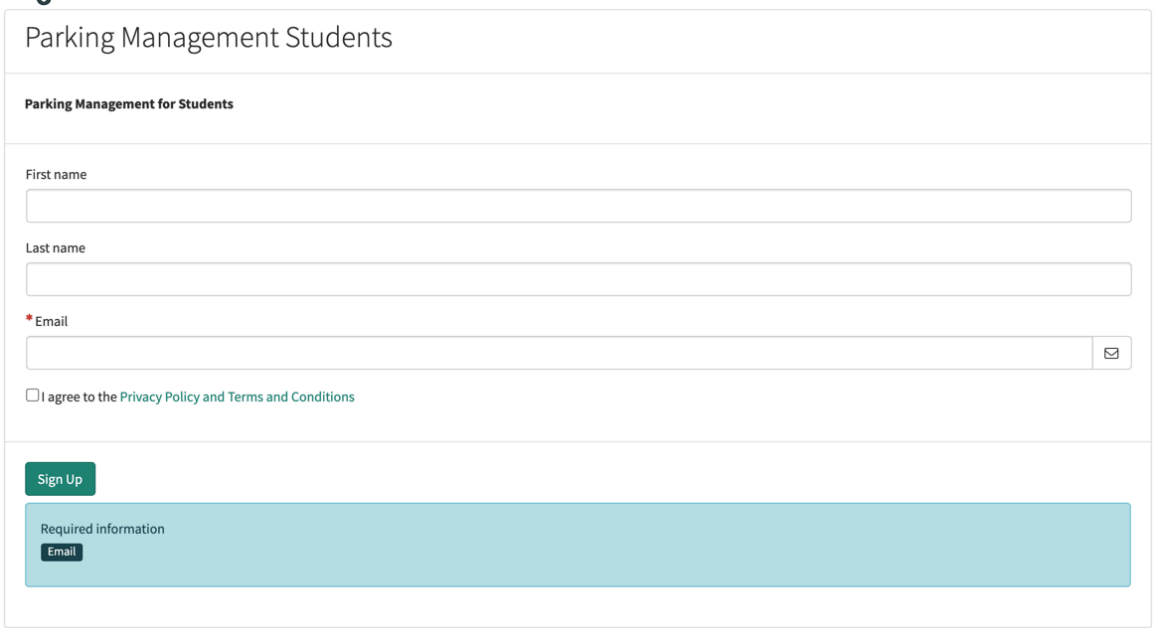
Field	Description
Registration table	Name of the table where registration form information is saved.
Registration form field configuration	The record associated to the registration form in the Record Producer.
Activation table	Label and name of the table used for user activation. The activation table contains records of the users who have completed verification.
User table	Label and name of the user profile table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Activation success page	The page to which a user redirects after the activation is successful.
Activation error page	The page to which a user redirects when the activation fails.
Post registration redirect page	The page to which user is redirected after registration.
Registration link label	The button name used for registration from the service portal. The default value is Register.

While making changes or after completing all changes in the user registration configuration, you can use the **Preview Registration Form** button to preview changes in the registration form.

Registration Form Preview



Configure Google reCAPTCHA for external user self-registration

To use the Google reCAPTCHA service, you must request an API key pair from Google and then configure the related system properties.

Before you begin

- Request an API key pair (a site key and a secret) from Google at https://www.google.com/recaptcha.
- Role required: admin

About this task

Procedure

1. Navigate to **All** > **System Properties** > **All Properties**.
2. Search for the following properties and set the values:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property	Value
glide.user.registration.google.recaptcha.secret	The secret authorizes communication between the application and the reCAPTCHA server. Type: password2
glide.user.registration.google.recaptcha.site_key	The site key used to invoke the reCAPTCHA service on your registration page. Type: string
glide.user.registration.captcha.widget	The Sys_ID of the Captcha Widget. Type: String

Default registration form fields

You can use the default registration form fields or create custom registration form fields.

Registration form fields

The following form fields are added in the Registration form by default.

Field Label	Type
Business Phone	Single line text
City	Single line text
Country	Select Box
EDU Status Used to differentiate staff, students, and visitors. **Note:** This field is useful when the registration form is for an educational institution.	Select Box
Email	Email
First name	Single line text
Gender	Single line text
Home phone	Single line text
Language	Select Box
Last name	Single line text
Middle name	Single line text
Mobile phone	Single line text

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field Label	Type
Name	Single line text
Prefix Title of the user. For example, Mr. , Dr. , and so on.	Select Box
State / Province	Single line text
Street	Wide Single Line Text
Title - Job title	Select Box
Zip / Postal code	Single line text

Note:
You cannot delete the default registration form fields.

Add a custom registration form field

You can add custom fields in the user self-registration form.

Before you begin
Role required: admin

Procedure

1. Navigate to **All** > **External User Self-Registration** > **User Registration Configurations**.
2. Open the record for the required user registration configuration.
3. Navigate to the end of the Registration Form Fields section and click **Insert a new row...**.
4. Enter the field name under the **Label** column and click check mark.
   A new row is added with the default values. You can configure the custom registration form field based on your requirements.

Registration Form Field Columns

Column	Description
Label	The field name which appears on the registration form.
Type	The type of the user interface element. Following are the supported types: ○ Single line text ○ Email ○ Date ○ Date/time ○ Yes/No ○ Wide Single Line Text ○ Multiple Choice ○ Select Box
Display in Registration Form	Option to display the field in the registration form.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Column	Description
Order	The sequence in which the form fields appear on the registration form. The field with the lowest order value appears first and the field with the highest order value is appears last. The default value is 10,000.
Mandatory	Option to make a field mandatory on the registration form.
Validation only field	Option to use a field only for validation purposes. For example, registration code. When set to true, this field is not saved in the User Table (sys_user).

5. Save or Update the changes.

Enable external user self-registration for Service Portal

Enable external users to register to a ServiceNow app through Service Portal.

Before you begin
Role required: admin

Procedure

1. Navigate to **All** > **Service Portal** > **Portals**.
2. Open a portal record.
3. On the form, fill in the **External user registration configuration** field.

   Select a user registration configuration.
4. Click **Update**.

Result
The login widget includes a link to the registration form that you previously configured.

Verify user self-registration requests

After a user registers from the Service Portal , a user record is added to the Registration Requests module. You can view the list of registered users who have successfully registered in the Service Portal .

Before you begin
Role required: admin

Procedure

1. Navigate to **All** > **External User Self-Registration** > **Registration Requests**.
   The list of user records are displayed.
2. (Optional) Review the individual user records and modify according to your requirements. For example, you can change the status of a user record form **Pending** to **Processed**.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Token based authentication (User logins)

Enhance the security mechanism for users to access a network using token based authentication.

Time limited authentication

Token based authentication is a protocol which allows users to verify their identity, and in return receive a unique access token.

It helps to enhance the security mechanism for users to access a network.

Digest Token Authentication

The digest token authentication passes user credentials and a digest token within an unencrypted HTTP header.

Time limited authentication

Support time limited authentication for your ServiceNow instance.

Explore

Learn the features and business value of Time limited authentication.

Activate

Understand how to Activate Time limited authentication.

Tutorial: Time limited authentication

Know about the properties in Zero Trust Access.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Explore Time limited authentication

Support time limited authentication for your ServiceNow instance.

> **Note:**
> Time limited authentication is very specific to ServiceNow instance, the customized links for users can only be created within ServiceNow.

Admins can configure link based authentication on the ServiceNow instance. The configured link can be shared with the user through Email or SMS and user can use those links to log in to the instance.

Login to instance with this authentication scheme is controlled through Adaptive Authentication policies configured on the ServiceNow instance.

Time based authentication enables you to perform the following:

- Admin can configure link based auth to use it within an expiry time.
- Application team can fetch nonce to be used with link for the specific configuration item using exposed scriptable API. Link generation will be taken care by Application team.
- Application team can generate the link and send to the user through an existing channel.
- User with the link can log in to instance one time and within expiry time specified as part of configuration.
- Admins can configure the low privileged roles for the authentication scheme.
- Admins can enforce MFA for the authentication scheme as a second factor for authentication with the TLA link.

Activate time limited authentication

Time limited authenication activates through the Integration - Multiple Provider Single Sign-On Installer plugin.

Before you begin

Role required: admin

> **Note:**
> Time limited authentication is very specific to ServiceNow instance, the customized links for users can only be created within ServiceNow.

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the Time Limited Authentication (*com.snc.authenticate.time_limited_authentication*) plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Time limited authentication with SMS - Twilio Tutorial

Set up time limited authentication with MFA factors such as SMS using Twilio.

Before you begin

Role required: admin

Plugins required:

- *com.snc.authenticate.time_limited_authentication* (Time Limited Authentication)
- *com.snc.authentication.sms_mfa* (Multi-factor authentication with SMS)

Note:
Time limited authentication (TLA) is very specific to ServiceNow instance, the customized links for users can only be created within ServiceNow.

The tutorial instructions provided enable the admin to provide a link-based login with SMS as second factor (MFA) for users with a specific role.

After a successful configuration, the system generates a link, and then shares the link with the user through notification (Email/SMS) channel. Clicking the link, the user is prompted to specify the OTP sent to Email or SMS factor based on user role (configuration).

Note:

- TLA should always be followed by MFA and MFA should be enabled by admin using Adaptive Authentication for TLA login. To know more about how to configure MFA with Adaptive Authentication, see Multi-factor Authentication context.
- TLA should be used for the users who have limited privileges.

Procedure

1. Creating a Twilio configuration.
   a. Create a Twilio test account. For more information, see Twilio.
   b. Navigate to **All** > **Notify** > **Administration** > **Twilio Direct Configuration**.
   c. Provide the **Account SID** and **Auth token** (created from Twilio) and save the record.

   Note:
   You can create your own provider configuration and use that for TLA. In this example, it is Twilio. To know more about how to create a MFA provider configuration, see Configure MFA Provider.

2. Configuring and enabling Time limited authentication(TLA) record.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

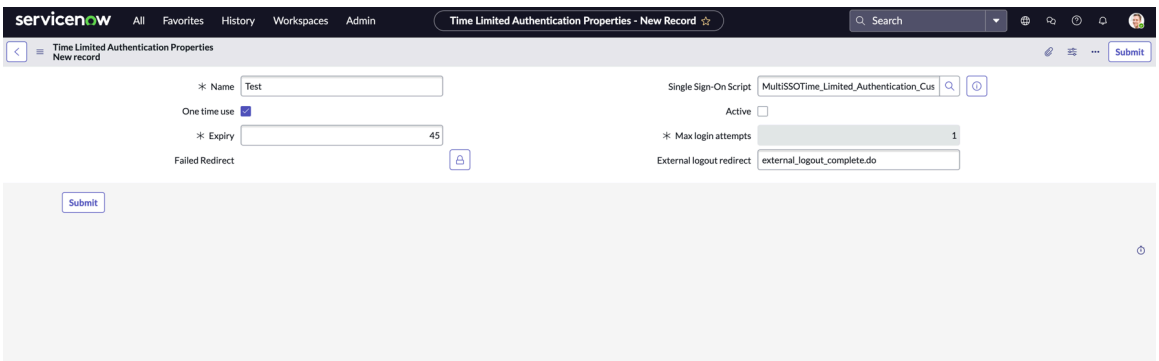
a. Navigate to **All** > **Time Limited Authentication Config records** and click **New**.

b. On the form, fill the fields.

Time Limited Authentication Properties

Field	Description
Name	Name of the record.
One time use	Enable to use the TLA link once.
Expiry	Specify the seconds for the link expiry. The default is 45 minutes.
Failed Redirect	Enter the URL to redirect users after a failed authentication.
Single Sign-On Script	Details of the SSO script that you want to use.
Active	Option to make the configuration active.
Max login attempts	Specify the number of attempts allowed with the generated TLA link for login. Un-check the **One time use** checkbox to provide the max number of attempts.
External logout redirect	Enter the URL to redirect users after logout.

c. Click **Submit**.



d. Navigate to **All** > **Multi-Provider SSO** > **Administration** > **Properties** and enable the **Enable multiple provider SSO** property and **Save**.

3. Allowing TLA to only a specific user persona using the post-authentication context policy.

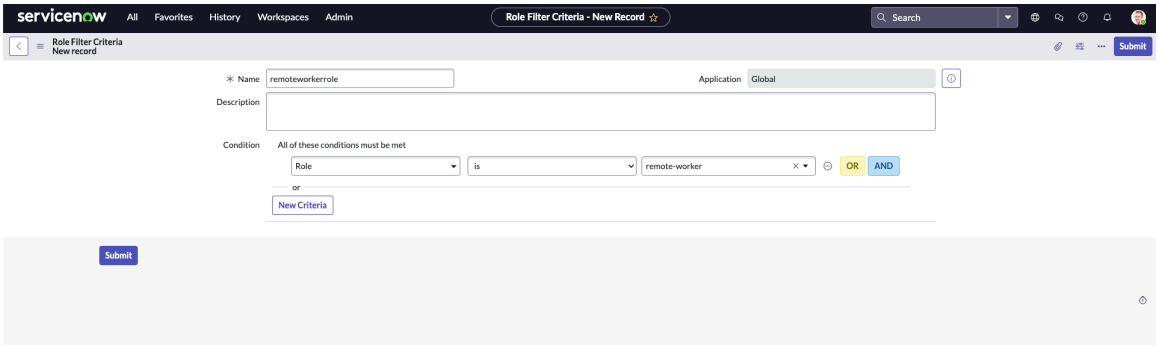
a. Navigate to **Roles** and create a role. For example: remote_worker.

b. Create a user with a valid email id and mobile number. To know how to create a user see, Create a user.

c. Assign the role to the user. To know how to assign the role to the user, see Assign a role to a user.

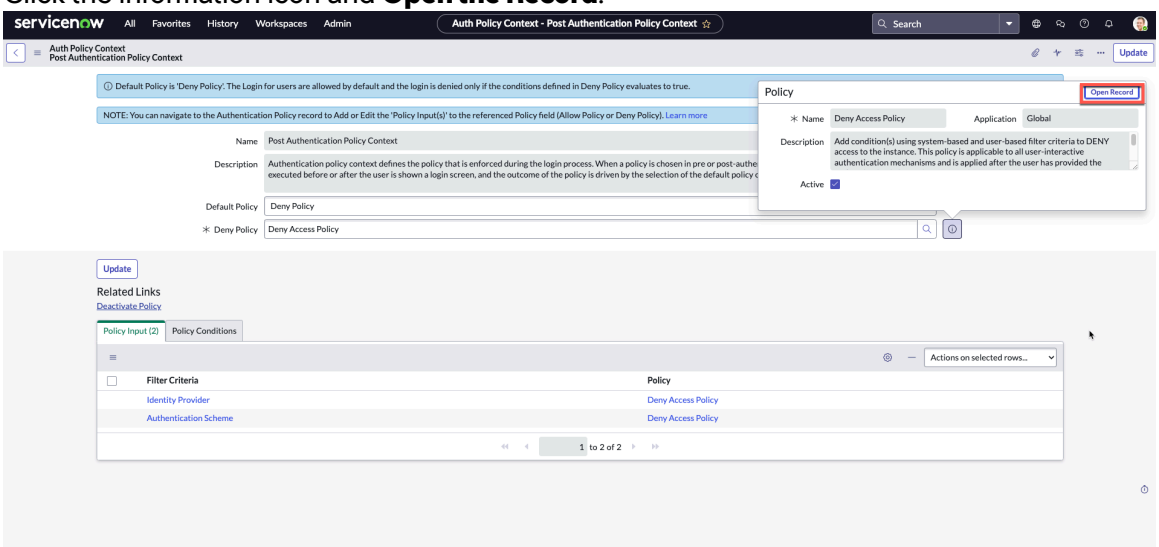
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

d. To create a role filter criteria, navigate to **All** > **Adaptive Authentication** > **Role Filter Criteria**, create a new filter **remoteworkerrole** and condition **Role is remote_worker**.

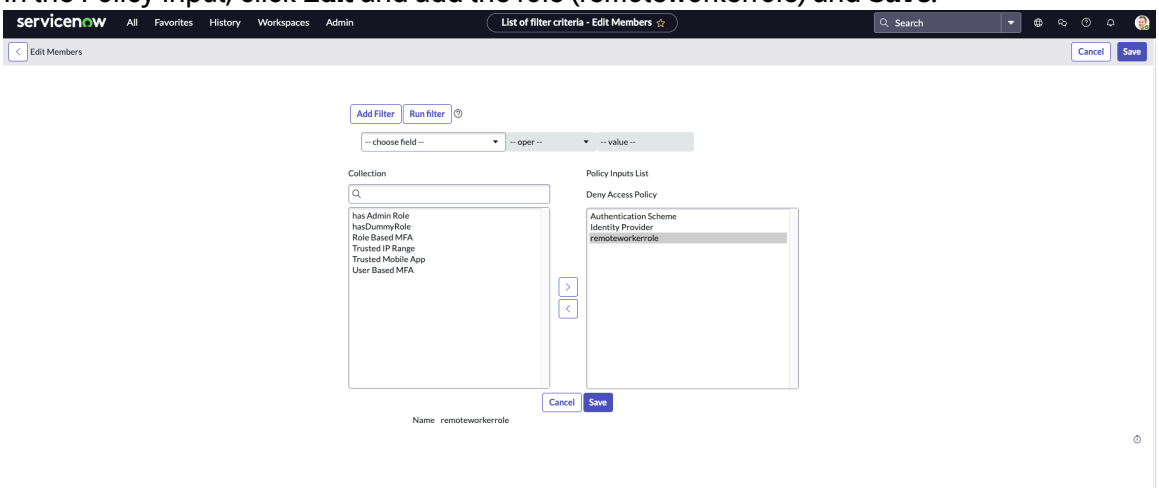


e. To add policy condition based on the deny policy context based on the IdP and role filter criteria, navigate to **All** > **Adaptive Authentication** > **Post Authentication Context**.

f. Click the information icon and **Open the Record**.



g. In the Policy Input, click **Edit** and add the role (remoteworkerrole) and **Save**.



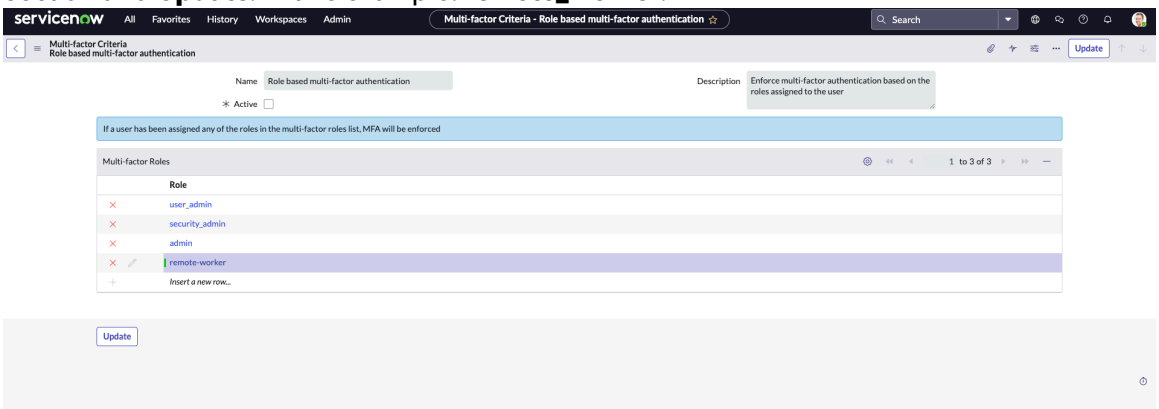
h. In the Policy Condition, add the condition for the policy input and **Submit** the record.

4. Configuring the step-up authentication policy - MFA context.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

a. Navigate to **All** > **Multi-factor Criteria**.

b. Select the **Role based multi-factor authentication** and add the role under Multi-factor Roles section and **Update**. In this example: **remote_worker**.

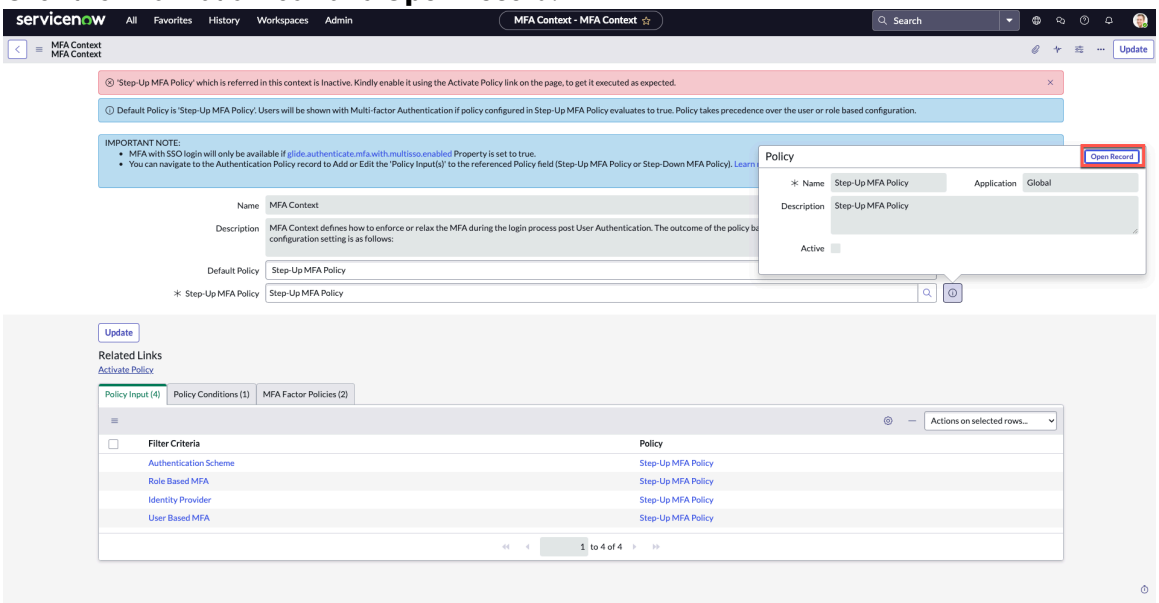


c. Navigate to **All** > **Adaptive Authentication** > **MFA Context**.

d. Make sure the following:

- Default Policy field is **Step-up MFA Policy**
- Step-Up MFA Policy is **Step-up MFA Policy**

e. Click the Information icon and **Open Record**.



f. On the Step-Up MFA Policy form, in the Policy Inputs, click **Edit**.

g. Add the **Role based multi-factor authentication** to the list and **Save**. In this example, **remoteworkerrole**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

h. In the Policy Condition, click **Enforce MFA if Role based or User based MFA settings are true**.

i. In the Enforce MFA if Role based or User based MFA settings are true page, make sure **Role Based MFA** is **true**.

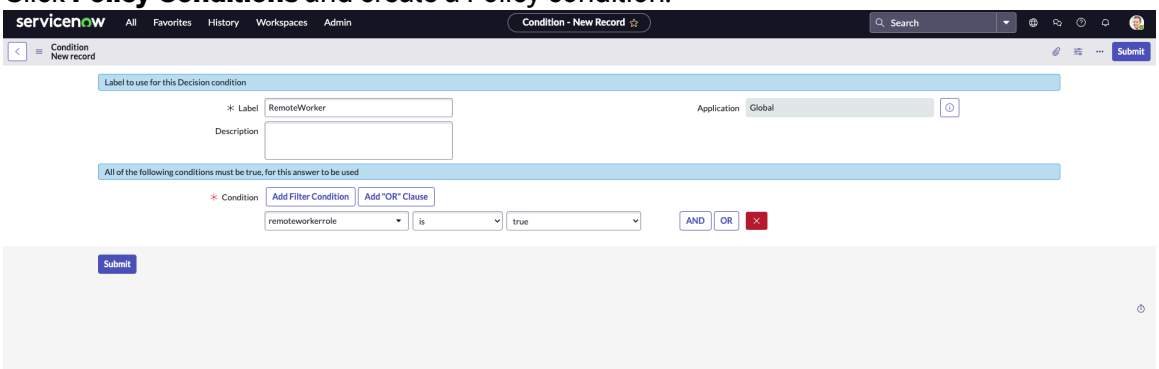
5. Enforcing MFA to use SMS as a MFA factor policy.

a. Navigate to **All** > **Adaptive Authentication** > **MFA Context**.

b. On MFA Context page, click **MFA Factor Policies** and click on policy **Display SMS OTP as an MFA Factor Policy**.

c. Click **Edit** and add **remoteworkerrole** in the **Policy Inputs**.

d. Click **Policy Conditions** and create a Policy condition.



e. Click **Submit**.

The TLA link generated and shared to the users assigned with **remoteworkerrole** as role will be promoted to use the SMS code as a second factor to login the instance.

6. Enabling the other required properties.

a. Navigate to **All** > **Multi-factor Authentication** > **Properties**.

b. Enable the following check-boxes.

- **Enable Multi-factor authentication**
- **Enable Multi-factor Authentication with SSO**

c. Save the record.

d. Navigate to **All** > **Adaptive Authentication** > **Authentication Policies** > **Properties**.

e. Enable the **Enable Authentication Policy** checkbox.

f. Save the record.

7. Generating a TLA link – Example.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

a. Navigate to **All** > **System Definition** > **Scripts – Background**.

b. Use the following API by providing user sysid and config id.

```
var tla=new global.TimeLimitedAuthentication();
gs.info(tla.generateNonce("user_sysid",
"config1_sys_id","IAR2"));
```

Note:
The source (IAR2) is not a mandatory parameter.

c. Query Parameter is returned as shown:

```
nonce=VCeinfboDtOM&glide_sso_id=b3277f1b44351110f8779b5a2d9909f3&user=3b02
```

d. Create a URL in the below format:

```
https://<instance-url> /login_with_sso.do?uri=<encoded url>&
nonce=2olIQSxdgkjs&glide_sso_id=0c15bf09c3711110c5ec4e483c40dd7a&user=6282
```

8. Click the URL, the following MFA screen is displayed for login.

Digest token authentication

The digest token authentication passes user credentials and a digest token within an unencrypted HTTP header.

Explore	Configure
Learn the features and business value of Digest token authentication.	Understand how to configure Digest token authentication.

Explore Digest token authentication

The instance reads the HTTP header value and compares its computed hash value of the digest token. If the computed hash value matches the digest token value, then the instance searches for a matching value in the User table. If there is a matching value in the User table, the instance considers the user pre-authenticated and logs the user in.

Digest token authentication is more secure than simple unencrypted HTTP headers because any accidental or intentional change to the unencrypted HTTP header produces a different hash value. If the hash value fails to match, the instance denies the user access to the requested instance. This prevents users from attempting to login with another user's credentials.

To know more about digest link expiry, see this KB article.

Note:
Use Time Limited Authentication (TLA) to configure time based expiry links. To know more, see Time limited authentication.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Integration requirements

A Digest Token Authentication integration requires:

- A web server
- SiteMinder or another single sign-on application to pre-authenticate the user on the local network
- A web page or portal that passes user credentials to the target instance in one of these formats
  - HTTP Header
  - URL parameter
  - Cookie
- A web page or portal that creates and passes a digest token to the target instance using one of these encoding techniques
  - SHA1
  - MD5
  - SHA 256 (recommended)

Configure the digest properties for multi-provider single sign-on (SSO)

After enabling a digest installation exist script, configure properties for multi-provider SSO.

Before you begin

Role required: admin

About this task

If you are not using multi-provider single sign-on, configure standard single sign-on properties.

Procedure

1. Navigate to **All** > **Multi-Provider SSO** > **Identity Providers**.
2. Fill in the fields of Digest Properties form.

Option	Description
Name	Enter the name of the digest token.
User	Enter the sys_user field that contains the matching data for the incoming header.
HTTP Digest header name	Enter the HTTP header you generated. For ex ample, DE_USER.
HTTP header name	Enter the HTTP header you generated for your created digested token. For example, SM_USER.
Secret Passphrase	Enter the secret key to use for encoding digest keys. For example, `32 or more characters`.
Failed SSO Redirect field	Enter the URL to redirect users after a failed authentication.
External logout redirect	Enter the URL to redirect users after a logout.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Option	Description
Single Sign-on Script	Select **MultiSSO_DigestedToken**.
Client Type	Choose the client type, based on the type of your client. Options:**Iframe Embedded**. **Note:** If client type field is required for your configuration, you can edit the form and add the field. To know more, see Con figure client type for OAuth and SSO records.

3. Click **Update**.
4. Set your Digested Token default to true.
   When you set the default to true, this overwrites the system default digest token record associated to SSO. Once the first multi-provider SSO related IdP record activates, only records associated to multi-provider SSO will be used.

   Digest token records which exist in digest properties table can be individually called by appending the Sys_ID of the IdP. For example, a digest token record in the following authentication URL: `https://<instance_name>.service-now.com/login_with_sso.do?glide_sso_id=<sys_id_of_Digest_token_record>&SM_USER=<user_name>&DE_USER=<d`

Sample digest token implementations

Here are several samples of creating a digest token.

Sample digest authentication implementations

Digest built with	Secret key value	Hash method	Example
Java	32 and more characters	SHA256	Sample Java Digest Algorithm for Encryption
C	Value of sharedKey parameter	Value of strEncryptionMethod parameter (SHA256 or MD5)	Sample C

Sample Java digest algorithm for encryption

This Java algorithm illustrates creating a digest token from an HTTP header.

This sample assumes:

- The web server supports Java
- The hash computation method is SHA1
- The secret key value is abc123
- The unencrypted HTTP header name is user_name

Change the Java code to use another hash computation mechanism (such as MD5), change the secret key value, or HTTP header name.

© 2026 ServiceNow, Inc. All rights reserved.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
public class DigestTest
{
    private static final String MAC_ALG = "HmacSHA256";
       fKey  = {32 or more characters};
    public byte[] getDigest(String acct) {
        try {
            byte[] bkey = fKey.getBytes();
            byte[] data = acct.getBytes();
            Mac mac = null;
            try {
                mac = Mac.getInstance(MAC_ALG);
                mac.init(new SecretKeySpec(bkey, MAC_ALG));
            } catch (Exception e) {
                e.printStackTrace();
            }
            byte[] sig = mac.doFinal(data);
            String signature = new String(sig);
            System.out.println("value:" + acct);
            System.out.println("digested value:  " + signature);
            return sig;
        } catch (IllegalStateException e) {
            e.printStackTrace();
        }
        return null;
    }
    public static void main(String[] args) {
        BASE64Encoder encoder = new BASE64Encoder();
        DigestTest test = new DigestTest();
        String userName = "user_name";
        System.out.println("base 64 digest username: " +
 encoder.encode(test.getDigest(userName)));
    }
}
```

Sample C

This C class illustrates creating a digest token from three input parameters.

- strEncryptionMethod – lists the hash computation method (SHA1, SHA256 or MD5)
- message – lists the value to be converted into a digest token
- sharedKey – lists the secret key

Note:
Use stronger secure hash algorithm like SHA256 for digest token generation.

This sample assumes:

- The web server supports C
- Other code calls this class and passes the expected parameters

Sample Code

```
  private stringdigestData(string strEncryptionMethod , string
 message , string sharedKey ) {
            UnicodeEncoding myUnicodeEncoding  = new
 UnicodeEncoding ( ) ;
```

Explore web security	Configure mutual authentication
Learn the features and business values of web service security.	Use mutual authentication to establish trust by exchanging secure sockets layer (SSL) certificates.

Explore Web service security

Enforce security using basic authentication, mutual authentication, or WS-Security.

Basic Authentication

To enforce basic authentication on each request for a WSDL document or posting of SOAP messages, you may set the property *glide.basicauth.required* to `true`. If you do so, each WSDL or SOAP request would have to contain the "Authorization" header as specified in the Basic Authentication protocol. Because the request is non-interactive, the **Authorization** header is always required during a request.

Supplying basic authentication information whether or not it is required has the added advantage that the data created or updated as a result of the Web Service invocation is done on behalf of the user supplied in the basic authentication credentials. As an example, when creating an Incident record, the journal fields have the user id of the basic authenticated user, instead of the default **Guest** user.

To make the authorization header ignore the capitalization rules, use the *glide.security.script.include.name.case.insensitive.list* property. You can modify this property in the System Properties [sys_properties] table and add the script includes that are necessary to process the authentication. By default, this property has these values:

- BasicAuth
- CustomAuth

Add other script includes as needed.

To supply basic authentication when using Perl and the SOAP::Lite libraries, you can implement the following function:

```
sub SOAP :: Transport :: HTTP :: Client :: get_basic_credentials
 { return 'user_name' => 'password' ; }
```

- When using C# .NET VS 2005 or older, you can take advantage of the Credentials object, for example:

```
System.Net . ICredentials cred  = new System.Net .
 NetworkCredential ( "user_name",  "password" ) ;

service . ServiceNow proxy  = new service . ServiceNow ( ) ;
service . get getService  = newservice . get ( ) ;
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
service . getResponse getServiceResponse  = new service .
 getResponse ( ) ;

 try {
  proxy . Credentials = cred ;
  getService . sys_id = "bf522c350a0a140701972dbf876f1610" ;
  getServiceResponse  = proxy . get (getService ) ; catch
 (Exception ex ) { }
```

- When using C# .NET VS 2008, you can take advantage of the ClientCredentials object, for example:

```
Demo_Incident. ServiceNowSoapClient client  = new
 Test08WebService . Demo_Incident . ServiceNowSoapClient ( ) ;
client . ClientCredentials . UserName . UserName = "admin" ;
client . ClientCredentials . UserName . Password = "admin" ;
```

Then in your app.config file look for the following and change `None` to `Basic`:

```
<transport clientCredentialType= "None" proxyCredentialType=
 "None" realm= "" />
```

- When using VB .NET taking advantage of the Credentials object would look like the following:

```
Sub Main()
         Dim cred  As New
 System.Net.NetworkCredential( "user_name",  "password")

         Dim proxy  As New VB_Democm.incident.ServiceNow
         Dim getIncident  As New VB_Democm.incident. get Dim
 getResponse  As New VB_Democm.incident.getResponse

        proxy.Credentials = cred

        getIncident.sys_id =  "[your sysID here]"

        getResponse = proxy. get(getIncident)

     End Sub
```

The resulting response when Basic Authentication is turned on and no credentials are supplied looks like this:

```
<html> <head > <title >Apache Tomcat/5.0.28
 - Error report </ title > <style > <!--H1
 {font-family:Tahoma,Arial,sans-serif;color:white;background-co
lor:#525D76;font-size:22px;}    H2

html >
```

Configure mutual authentication

Mutual authentication establishes trust by exchanging secure sockets layer (SSL) certificates.

During the SSL handshake, the server presents its certificate to the client. Subsequently, depending on the server's configuration, it may request a certificate from the client. Both server and client perform certificate validation procedures to ensure the authenticity and integrity of the presented certificates.

Following a successful validation, acknowledgments are exchanged before the initiating the HTTPS connection.

Note:
For information about using a custom HTTPS protocol profile to enable mutual authentication, see Create a protocol profile.

Administrators do the preliminary work of setting up the client Key Store and generating certificates before certification requests are fulfilled.

Warning:
This feature only enables mutual authentication on outbound https connections.

Creating the Key Store

The instance currently supports uploading a Java Key Store file, which contain a private key and a public certificate pair, the public certificate includes complete chain including the root certificate.

To set up your client Key Store:

- You require a certificate signed by a trusted certificate authority (CA).
- Your API endpoint provider may assist you in generating the Key Store.

If you need to generate the Key Store, the process involves several steps using command-line interface commands to generate a new Key Store file, create a certificate signing request (CSR), and import signed certificates. Before importing your domain's primary certificate, any root or intermediate certificates should be imported first. Here's a step-by-step instruction:

1. Generate a Java keystore and key pair.

```
keytool -genkey -alias mydomain -keyalg RSA -keystore
 my.keystore
```

2. Generate a CSR for an existing Java keystore.

```
keytool -certreq -alias mydomain -keystore my.keystore -file
 mydomain.csr
```

3. Send the CSR to your CA signing authority to sign and return the certificate files, which includes intermediate and root certificates along with signed certificate.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Import a root or intermediate certificate authority CA certificate to an existing Java keystore.

```
keytool -import -trustcacerts -alias root -file Thawte.crt
 -keystore my.keystore
```

Note:
You can bundle all the certificates in one file and import. This is preferable option. If you do this way you can skip 5

```
keytool -import -alias mydomain -file merged.crt -keystore
 my.keystore
```

5. Import a signed primary certificate to an existing Java keystore.

```
keytool -import -trustcacerts -alias mydomain -file
 mydomain.crt -keystore my.keystore
```

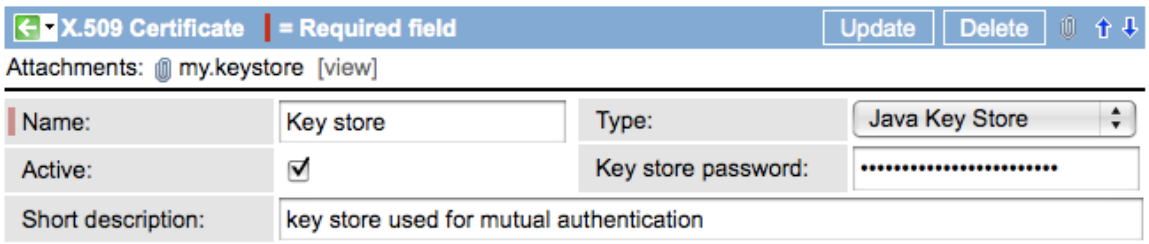
Setting up the Key Store

Now that the key store has been created, it can be uploaded to the Certificates table. On the **System Definition** > **Certificates** page, click **New** and set the following fields:

- Enter a certificate **Name**.
- Store the key store as **Active**.
- Set **Type = Java Key Store**.
- Provide a **Key store password**. This is the password that was used to create the keystore.

Click **Submit** to create the Java Key Store entry.

Key Store



Specifying a Trusted Server Certificate

During an outbound SSL connection, which is an HTTPS Web Service call, it is possible to specify a certificate provided by the service provider that ensures the validity of the service provider during the SSL connection. For example, a browser attempting to connect to a secure service which identifies itself by a certificate.

By uploading the trusted server certificate, ServiceNow ensures that the service it is connecting to is valid and secure.

Create a new Certificate entry with the type of "Trust Store Cert" and attach a DER formatted certificate, or copy and paste its PEM format into the **PEM Certificate** field.

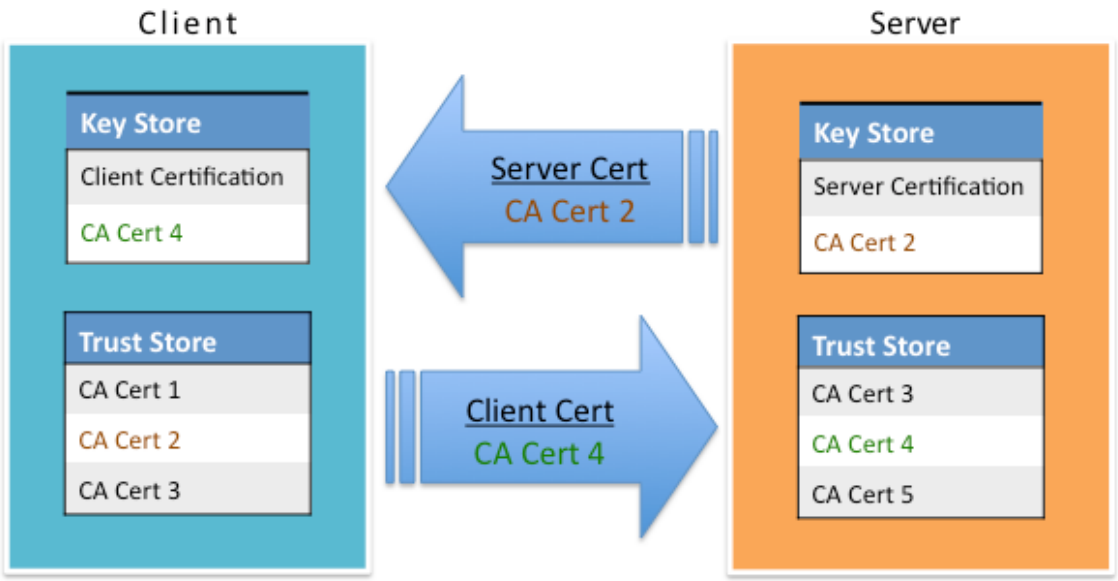
Protocol Profile

Certificate Exchange



- When a client requests the server certificate for authentication, a certificate signing request (CSR) is generated.
- To respond to a CSR, the server generates two unique cryptographic keys: A public key, which is used to encrypt messages to the server and a private key, which is used to decrypt messages. Both keys are kept in the Key Store.
- Keys are used to decrypt the client secure messages so they can be read by the server. Any outgoing connection that is going to be HTTPS verifies the certification by checking the Key Store, offering its public certification, and uses the trust store certificates to verify mutual trust back.
- To complete the secure link between the client and the server, the server matches the certificate to the corresponding private key. Because only the server has access to the private key, the server can decrypt the data from the client.

Note:
For information about using a custom HTTPS protocol profile to enable mutual authentication, see Create a protocol profile.

The server responds by sending a certificate. Is this a certificate that the client accepts? If yes, a message is sent to the server accepting the certificate and a secure channel is initiated. If the certificate is not accepted, it may mean that the root authority is needed for certification.

Access Control List Rules

Rules for access control lists (ACLs) restrict access to data by requiring users to pass a set of requirements before they can interact with it.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Explore ACLs Learn about Access Control Lists(ACLs).	Configure ACLs Configure ACLs.
Contextual Security Manager Learn about the about Contextual Security Manager.	Advanced ACL Configuration Learn about Advanced ACL configurations and tools.

Explore Access Control Lists

Explore Access Control Lists (ACLs).

All access control list rules specify:

- The decision type, rule type and operation which defines the ACL
- The object being secured
- The conditions required to access the object

Components of ACL

The decision type defines whether users are allowed to access the object if conditions are met or denies access the object unless conditions are met.

Decision type	Description
Deny-Unless	Restrict access to resource by explicitly denying access unless conditions are passed. See #unique_1496_Connect_42_section_qnd_snl_zbc for more information.
Allow-If	Allow access to resource if conditions are passed.

The object is the target to which access needs to be controlled. Each object consists of a type and name that uniquely identifies a particular table, field, or record. With the Applies-to field users have granular control over which specific records this ACL will apply to.

For example, all these entries specify an object:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Type	Name	Object secured
record	[incident].[--None--]	The Incident table.
record	[incident].[active]	The Active field in the Incident table.
record	[incident] Applies-To: Priority = P1	Only Priority 1 incidents in the incident table.
REST_Endpoint	user_role_inheritance	The record for the user_role_inheritance Scripted REST API.

Each operation describes a valid action the system can take on the specified object. Some objects, such as records, support multiple operations, while other objects, such as a REST_Endpoint, only support one operation.

For example, all these entries specify an operation:

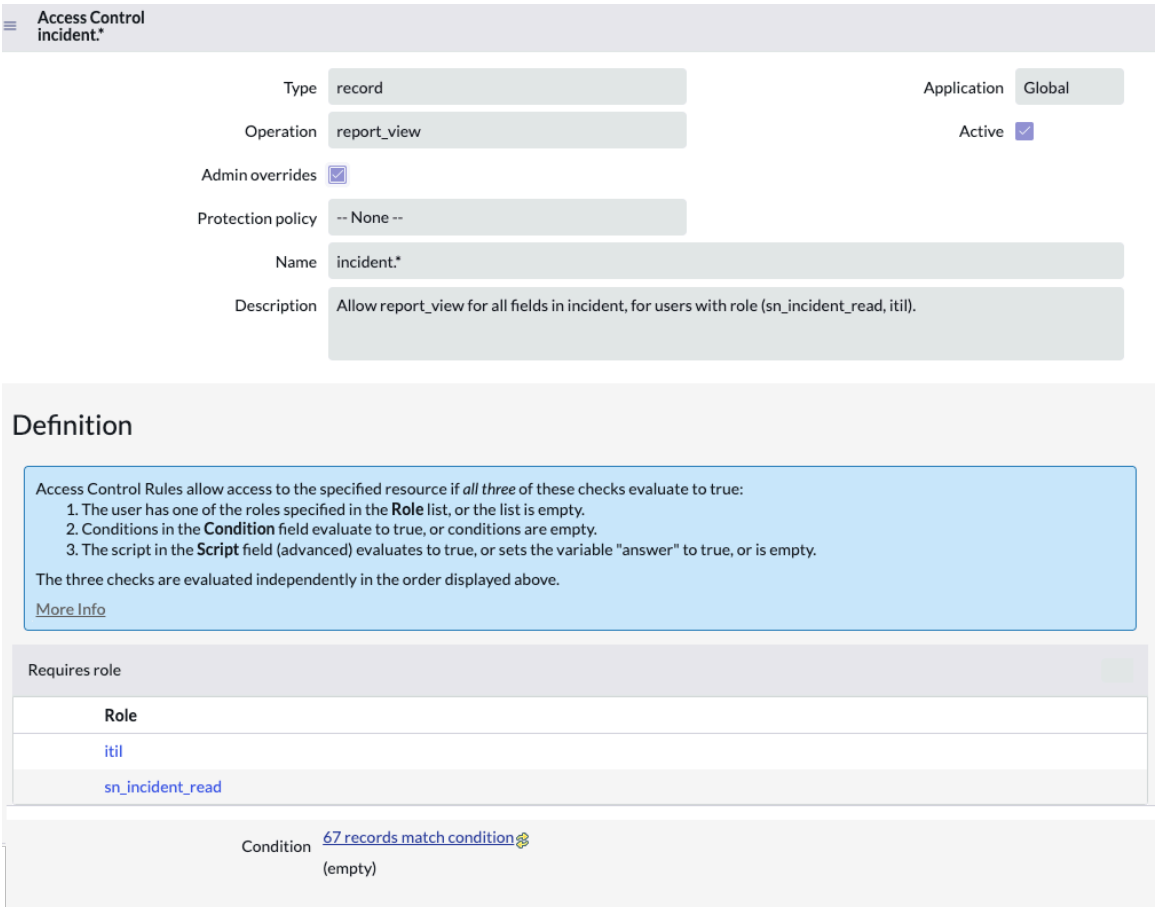
Type	Name	Operation	Operation secured
record	[incident].[-- None --]	create	Creating records in the Incident table.
record	[incident].[active]	write	Updating the Active field in the Incident table.
REST_Endpoint	user_role_inheritance	execute	Running the user_role_inheritance scripted REST API.

The conditions specify when someone can access the named object and operation. Security administrators can specify condition requirements by adding:

- One or more user roles to the **Requires role** list.
- One or more security attributes need to be evaluated to be true.
- One or more data conditions.
- A script that evaluates to true or false or sets the `answer` variable to true or false.

To gain access to an object and operation, a user must pass all conditions listed in an access control. For example, this access control restricts access to view operations on the incident table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



To update a record in the incident table, a user must have the listed roles and the record must meet the condition.

Condition type	Requirement	Description
Requires role	**Requires role**:itil	Only allow users with the itil role to update incidents.
Security Attributes	UserIsAuthenticated	Only authenticated users to update incidents.
Data Condition	[Incident state] [is not] [Closed]	Only allow updates to active incident records.

Applies-to behavior

The Applies-to field determines whether an ACL applies to records, whereas data condition evaluates an ACL that's already applied. Applies-to specifies whether the ACL affects a specific record; if it's empty, the ACL applies to all records. Applies-to can be used for granular ACL enforcement whereas "Data Condition" is an evaluation criteria.

Note:
Applies-to is case sensitive.

Deny by default behavior

By default the ACL engine completely denies access if an ACL is empty or invalid. Empty ACLs are defined as ACLs without one or more of these components:

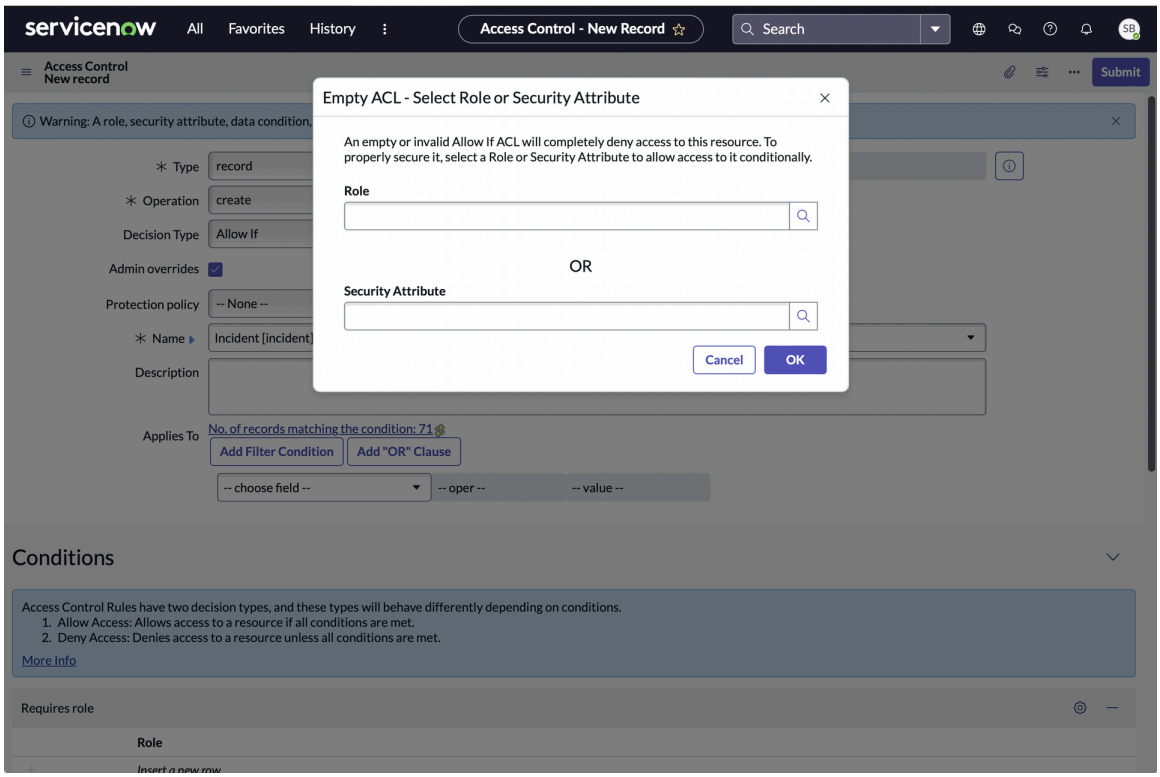
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Defined role
- Security attribute
- Data condition
- Script

Invalid ACLs are defined as:

- ACLs with roles that do not exist (e.g. have no row in the database)
- ACLs with Security Attributes that do not exist (e.g. have no row in the database)
- ACLs with a script that contains "answer=true" or "true"

If the system detects the user creating an ACL it will prompt the user to select a role or an existing security attribute.



ACL evaluation process

An ACL rule only grants a user access to an object if the user meets all conditions required by the matching ACL rule.

- The condition must evaluate to *true*.
- The script must evaluate to *true* or return an answer variable with the value of *true*.
- The user must have one of the roles in the required roles list. If the list is empty, this condition evaluates to *true*.
- [Record ACL rules only] The matching table-level and field-level ACL rules must both evaluate to *true*.

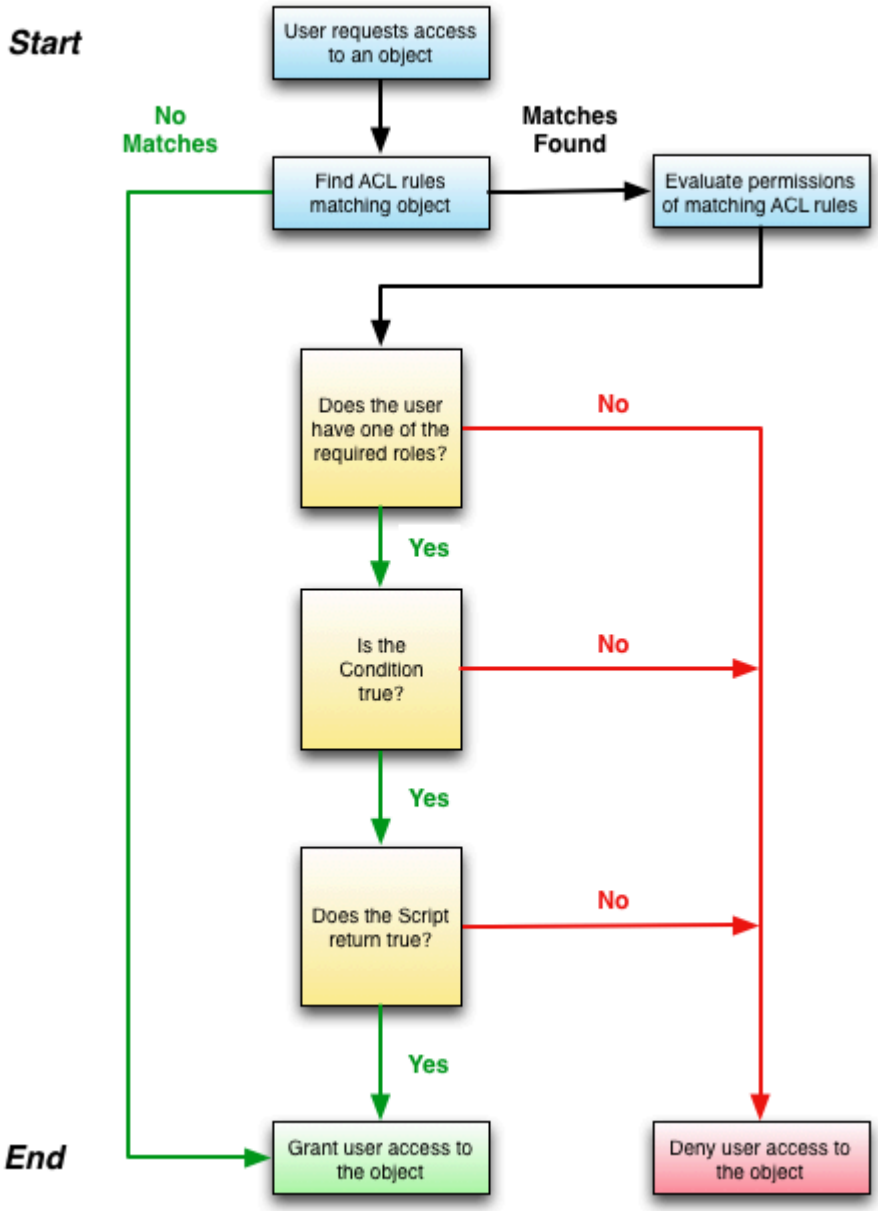
ACL evaluate conditions



Whenever a session requests data, the system searches for access control rules that match the requested object and operation. If there's a matching access control rule, then the system evaluates if the user has the conditions required to access the object and operation. If an access control rule specifies more than one condition, then the user must meet all conditions to gain access to the object and operation. Failing any one condition check prevents the user from accessing the matching object and operation.

If a user does not meet the conditions of the first matching rule, the system evaluates the conditions of the next matching access control rule as specified by the access control processing order. If the user fails to meet the conditions of any matching access control rule, the system denies access to the requested object and operation.

Note:
If there are no matching access control rules for the requested object and operation, then the system grants the user access to it. In practice, it is rare for the system to find no matching rules because the system has a set of default access control rules that protect all record operations.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The effects of being denied access to an object depend on the ACL rule that the user failed. For example, failing a read operation ACL rule prevents the user from seeing the object. Depending on the object secured, the ACL rule hides a field on a form, hides rows from a list, or prevents a user from accessing a UI page. The following table contains a complete list of results of failing an ACL rule for a given operation and object type.

Pre and post query ACL checks

Your instance checks ACL rules both before and after a user makes a query. Because different information is available before and after a query, results can be different.

Pre-query ACL check

Before your instance runs a database query, it checks the ACL rules for each field in the queried table to determine which fields a user may access. This check only looks at the user's roles, and checks to see if these roles allow access to fields. Because this check runs before the query, the ACL doesn't have access to the records on the table, so it can't take that data into account. Scripts and conditions that rely on knowing the contents of a record aren't evaluated.

If the user doesn't have read access at this point, the value for the field isn't shown to the user.

Post-query ACL check

After the query, your instance checks each record returned by the query. During this check, there's context for the ACL, so the role, condition, and script portions of the ACL are evaluated. If the user doesn't have read access at this point, the value for the field isn't shown to the user, however the user sees the field label if their roles allow access to the field.

Operation	Results of failing an ACL rule on object
execute	User can't execute scripts on a record or UI page.
create	User can't see the **New** UI action from forms. The user also cannot insert records into a table using API protocols such as web services. A **create** ACL with a condition requiring that a field contain a specific value may evaluate as false. Fields on new records are considered empty until the record is saved.
read	User can't see the object in forms or lists. The user also can't retrieve records using API protocols such as web services.
write	User sees a read-only field in forms and lists, and the user can't update records using API protocols such as web services.
delete	User cannot see the **Delete** UI action from forms. The user also can't remove records from a table using API protocols such as web services.
edit_task_relations	User cannot define relationships between task tables.
edit_ci_relations	User cannot define relationships between Configuration Item [cmdb_ci] tables.
save_as_template	Used to control the fields that should be saved when a template is created.
add_to_list	User can't view or personalize specific columns in the list mechanic.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Operation	Results of failing an ACL rule on object
list_edit	User can't update records (rows) from a list.
report_on	User can't create a report on the ACL table. For more information, see Restrict report creation with an ACL rule.
report_view	User can't view the content of a report on the ACL table or on the ACL field. For more information, see Reporting.
personalize_choices	User can't right-click a list field and select **Configure Choices**.

ACL matching requirements for objects

Object Type	Matching ACL Rules Required to Access Object	Existing wild-card ACL Rules
Client-callable script includes Processors	Users must meet the conditions of two ACL rules: **1.** All wild-card ACL rules for the object (if any ACL rule exists for the operation). **2.** The first ACL rule that matches the object's name (if any ACL rule exists for the operation).	By default, there are no wild-card (*) rules for these object types. If you create a wild-card ACL rule for one of these objects, then the ACL rule applies to all objects of this type.
UI pages Record	Users must meet the conditions of two ACL rules: **1.** The first ACL rule that matches the record's field (if any ACL rule exists for the operation). **2.** The first ACL rule that matches the record's table (if any ACL rule exists for the operation).	By default, there are wild-card table rules (*) for the create, read, write, and delete operations and wild-card field rules (**) for the personalize_choices, create, and save_as_template operations. When you create a table, create ACL rules for the table unless you want to use the provided wild-card ACL rules.

Note:
The Security manager default behavior (`glide.sm.default_mode`) property determines whether users can access objects that only match against wild-card table ACL rules. When this property is set to *Deny access*, only administrators can access objects that match the wild-card table ACL rules.

Note:
The wild-card field ACL rule (**) for the create operation reuses the same conditions as the write operation. This means that the create conditions are the same as the write conditions unless you define an explicit create operation ACL rule.

Multiple ACL rules at the same point in the processing order

If two or more rules match at the same point in the processing order, the user must pass any one of the ACL rules conditions to access the object. For example, if you create two field ACL

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

rules for *incident.number*, then a user who passes one rule has access to the number field regardless of whether the user failed any other field ACL rule at the same point in the processing order.

Required role

Normal admin users can view and debug access control rules. However, to create or update existing access control rules, administrators must elevate privileges to the security_admin role. See Elevate to a privileged role for instructions.

ACL rules in scoped applications

You can create ACL rules for objects in the same scope as the ACL rule. You can also create ACL rules for tables with at least one field that is in the same scope as the ACL rule.

For tables that are in a different scope than the ACL rule record, the types of rules are limited.

- You can create an ACL rule for any table, UI page, or other object that is in the same scope as the ACL rule.
- You can create an ACL for a field that is in the same scope as the ACL rule.
  - If the table is in the same scope, you can use a script to evaluate conditions.
  - If the table is in a different scope, you can't use a script to evaluate conditions.
- You can't create or modify ACL rules for objects that are in a different scope than the application you've selected in the application picker, including adding a role to an ACL in a different scope.
- You can create wild-card table rules (*) only in the global scope.
- You can create wild-card field rules (*) only for tables in the same scope as the ACL rule.

ACL rule types

Create ACL rules on different components of the system.

Record ACL rules

Record ACL rules consist of table and field names.

- The table name is the table that you want to secure. If other tables extend from this table, then the table is considered a parent table. ACL rules for parent tables apply to any table that extends the parent table.
- The field name is the field that you want to secure. Some fields are part of multiple tables because of table extension. ACL rules for fields in a parent table apply to any table that extends the parent table.

ACL rules can secure the following record operations:

Operation	Description
execute	Enables users to execute client callable script includes and REST endpoint execution.
query_match	Enables users to submit match queries("is", "is not", "is empty", etc).
conditional_table_query_range	Enables users to give partial ACL-access based on read ACLs.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Operation	Description
	Created for the tables that have the read ACLs without Data condition and script.
query_range	Enables users to submit range queries("starts with", "ends with", "contains", etc) and sorting is unrestricted.
create	Enables users to insert new records (rows) into a table.
read	Enables users to display records from a table.
write	Enables users to update records in a table.
delete	Enables users to remove records from a table or drop a table.
edit_task_relations	Enables users to extend the Task [task] table.
edit_ci_relations	Enables users to extend the Configuration Item [cmdb_ci] table.
save_as_template	Enables users to save a record as a template.
add_to_list	Prevents users from viewing or personalizing specific columns in the list mechanic. **Note:** Conditions and scripts are not supported.
list_edit	Enables users to update records (rows) from a list.
report_on	Enables users to report on tables.
report_view	Enables users to report on field ACLs.
personalize_choices	Enables users to configure the table or field.
data_fabric	Allows a data fabric table to reference a local table.

Record ACL rules are processed in the following order:

- Match the object against table ACL rules.
- Match the object against field ACL rules.

This processing order ensures that users gain access to more specific objects before gaining access to more general objects. A user must pass both table and field ACL rules to access a record object.

- If a user fails a table ACL rule, the user is denied access to all fields in the table, even if the user passes a field ACL rule.
- If a user passes a table ACL rule, but fails a field ACL rule, the user cannot access the field described by the field ACL rule.

Processor ACL rules

Processor ACL rules specify the processor you want to secure. For a list of available processors, navigate to **System Definition** > **Processors**.

By default, an ACL rule for the EmailClientProcessor is included to restrict the email client to users with the itil role.

Processor ACL rules honor the STAR (*) rule if they cannot find a more specific ACL for those resources.

Table ACL rules

The user must first pass the table ACL rule. Since the base system includes STAR (*) table ACL rules that match every table, the user must always pass at least one table ACL rule. The base system provides additional table ACL rules to control access to specific tables.

Table ACL rules are processed in the following order:

1. Match the table name. For example, incident.
2. Match the parent table name. For example, task.
3. Match any table name (*). For example, *.

If a user fails all table ACL rules, the user cannot access any fields in the table. If a user passes a table ACL rule, the system then evaluates the field ACL rules.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field ACL rules

After a user passes a table ACL rule, field ACL rules are processed in the following order:

1. Match the table and field name. For example, incident.number.
2. Match the parent table and field name. For example, task.number.
3. Match any table (*) and field name. For example, *.number.
4. Match the table and any field (*). For example, incident.*.
5. Match the parent table and any field (*). For example, task.*.
6. Match any table (*) and any field (*). For example, *.*.

A user must pass the table ACL rule to be granted access to the table's fields. For example, the user must first pass the table ACL rule for the incident table to access the **Number** field in the incident table.

The first successful field ACL evaluation stops ACL rule processing at the field level. When a user passes a field ACL rule, the system stops searching for other matching field ACL rules. For example, if a user passes the field ACL rule for incident.number, the system stops searching for other ACL rules that secure the **Number** field in the incident table.

Access to query information of inferred data is restricted for protected fields, therefore preventing return of predictive information.

UI page ACL rules

UI page ACL rules specify the UI page to be secured. For a list of available UI pages, navigate to **System UI** > **UI Pages**. When defining an ACL rule for a UI page, use the fully scoped page name. For example, **x_myapp_mypage**.

Note:
You can use the STAR (*) character in the **Name** field on **ui_page** type ACLs to match any UI pages.

UI page ACL rules honor the STAR (*) rule if they cannot find a more specific ACL for those resources. For example, if you have a UI page named `mysecretpage` but do not define an ACL for this UI page, the STAR (*) rule for the UI page processor is used for access check.

ACL rules can secure the following UI page operation:

Operation	Description
read	Allows users to display the UI page.

Client-callable script include ACL rules

Script include ACL rules specify the client-callable script include to be secured. For a list of available script includes, navigate to **System Definition** > **Script Includes**. You can personalize the list to show the *Client callable* column.

The base system does not include any ACL rules for client-callable script includes.

Client-callable script include ACL rules honor the STAR (*) rule if they cannot find a more specific ACL for those resources.

Datatype ACL

The datatype ACL enables you to write ACL rules that apply to all fields of a specific type.

Datatype ACLs provide a targetted approach to access controls by restricting table fields based on data type. This allows for broader security constraints than wildcard(*) ACLs. The syntax for datatype ACLs follows the format *.[(`field to be restricted`)].

Conventional field ACLs are limited to specific table-field identifiers, all fields in a table, or all tables with a specific field name, in contrast the datatype ACLs enable you to apply security uniformly across fields that share certain metadata. This helps prevent creating additional ACLs to apply security uniformly across all fields.

When implementing datatype ACLs, its essential to validate all affected fields before and after adding them to avoid unexpected security issues. See Create a datatype ACL to create your own datatype ACL.

To review existing datatype ACLs navigate to **All** > **System Security** > **Access Controls** and use the **Name** field to search for ACLs that start with `*.[`.

> **Note:**
> Scripting Governance uses datatype ACLs by default for scripting restrictions, see _ for more details.

Create a datatype ACL

Learn how to create a datatype ACL.

Before you begin

Role required: admin

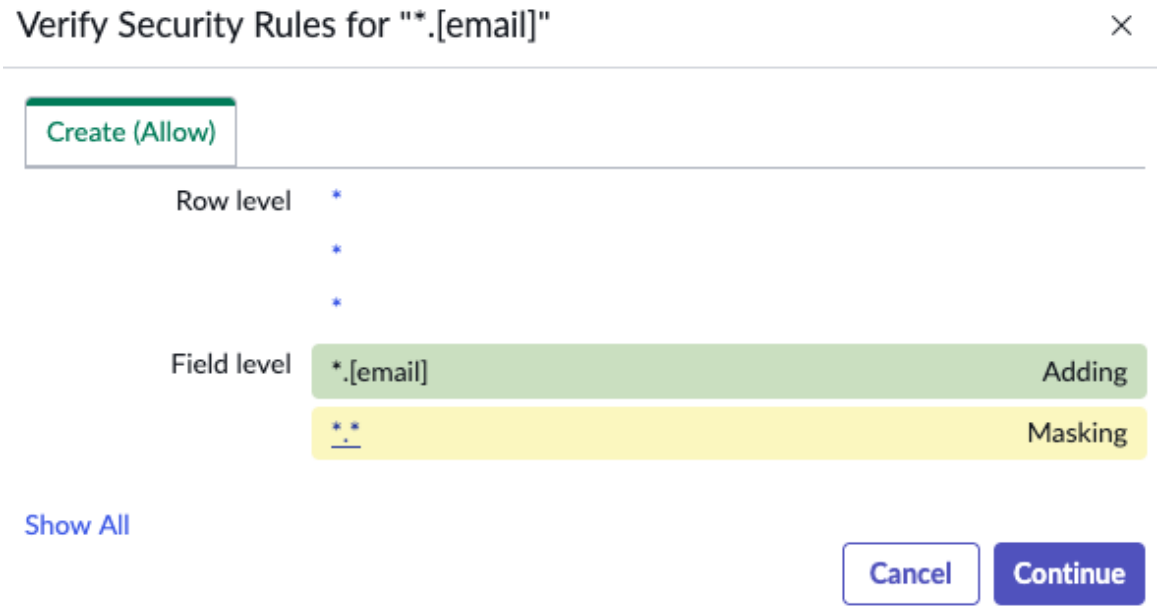
Procedure

1. Navigate to **All** > **System Security** > **Access Controls**.
2. Select the **New** button.
3. Select the **Change mode** icon near the **Name** field
4. Enter your datatype in the form of `*.[User Datatype]` in the **Name** field.
5. Select a **Role** or **Security Attribute** to associate with the ACL.
6. **Optional:** Fill in any additional details on the **Create an ACL** form.
   See Configure an ACL rule for additional information.
7. Select **Submit**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

8. Verify the security rules for the ACL in the popup **Verify Security Rules** window.

Example of Verify Security Rules



ACL control of function fields

When evaluating access to a function field, in addition to checking access to the function field itself, the system also checks access to the function's contributing fields. Contributing fields are those used as the arguments in a given function definition.

For more information about function fields, see Function field.

In Rome and earlier, the system simply checks access to the function field itself (as with any other field). If the ACLs on that field allow access, the user receives the resulting value, regardless of whether the user has access to the contributing fields.

In Zurich and later, the system also requires access to all contributing fields in order to allow access to the function field. If one or more of the contributing field ACLs refuse access, the function field also refuses access.

The only operations affected by the new requirement are read and report_view. Report_view has its own additional requirements.

Operation	Description
read operation	A user has read access to a function field only if both of the following are true: • The user has read access to the function field. • The user has read access to all of the contributing fields used in the function.
report_view operation	A user has report_view access to a function field only if all of the following are true: • The user has report_view access to the function field. • The user has report_view access to each of the contributing fields.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Operation	Description
	• There is a role-only read ACL without conditions and without a script, and the user has that role. • The user has role-only read access to the contributing fields, such that only ACLs without condition or script can allow.

Examples

Given:

- Table: salary
- Columns: base, bonus, total (all are Integers in this example)
- Function field: The total column is marked as a function field, with function definition `glidefunction:add(base, bonus)`.
- Contributing fields: base and bonus, since they're used in the function definition
- Roles: salary_admin, bonus_admin

Example 1: All fields allow access

ACLs	Result
total, base, bonus: read and report_view for role salary_admin, with no conditions or scripts	A user with the salary_admin role is granted read and report_view access to total because they have the required role.

Example 2: Contributing field refuses read access

ACLs	Result
• total, base: read and report_view for role salary_admin, with no conditions or scripts • bonus: report_view for role salary_admin , with no conditions or scripts • bonus: read for role bonus_admin, with no conditions or scripts	A user with the salary_admin role is refused read and report_view access to total, because bonus refuses read access to their role.

Example 3: Contributing field ACL has script

ACLs	Result
• total, base: read and report_view for role salary_admin, with no conditions or scripts • bonus: report_view for role bonus_admin, with no conditions or scripts	A user with the salary_admin role is granted read access to total, because they have the required role for all fields. But the same user with the salary_admin is refused report_view access, because the read ACL with the script refuses access by default for this case, even though they have the required role.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Example 3: Contributing field ACL has script (continued)

ACLs	Result
• bonus: read for role salary_admin, with a script (note that it doesn't matter what's in the script, only that it's there)	

Security jump-start - ACL rules plugin

The Security jump-start access control level (ACL Rules) plugin is installed automatically on all new instances. Use this plugin to quickly secure multiple system tables and expedite the production launch process for your organization.

This plugin isn't intended for existing instances, as it may alter security access to tables already in use in a production environment. If an admin strongly desires to install this plugin on an existing instance, you should test it thoroughly in a test instance first. Doing so helps to verify compatibility with the organization's current implementation.

If an admin is interested in the new ACL rules provided by this plugin, they can manually create one or more in an existing instance, using the list of ACLs as a guideline.

The following ACLs are included in this plugin. Select the icon in a header row to sort that column in ascending or descending order. The Operation key is as follows:

- R=read
- W=write
- D=delete
- C=create

Name	Operation	Description
`cmdb_ci`	WCD	asset or itil role required to write/create/delete Configuration Item records
`cmn_department`	WD	user_admin role required to write/delete Department records
`cmn_location`	WC	user_admin role required to write/create Location records
`core_company`	WD	user_admin role required to write/delete Company records
`kb_knowledge`	create	knowledge role required to create Knowledge records
`ldap_ou_config`	RWCD	user_admin role required to read/write/create/delete LDAP OU Definition records
`ldap_server_config`	RWCD	user_admin role required to read/write/create/delete LDAP Server records
`process_guide`	WCD	admin role required to write/create/delete Process Guide records

© 2026 ServiceNow, Inc. All rights reserved.

Name	Operation	Description
process_step	WCD	admin role required to write/create/delete Process Step records
sc_category	create	catalog_admin role required to create Service Catalog Category records
sc_category	delete	catalog_admin role required to delete Service Catalog Category records
sc_category	write	catalog_admin role required to write to Service Catalog Category records
sc_cat_item	write	catalog_admin role required to write to Catalog Item records
sc_cat_item	delete	catalog_admin role required to delete Catalog Item records
sc_cat_item	create	catalog_admin role required to create Catalog Item records
sysevent_email_action	read	all users can read Email Notification records (for subscription purposes)
sysevent_register	RWCD	admin role required to read/write/create/delete Event Registry records
sysevent_script_action	RWCD	admin role required to read/write/create/delete Script Action records
syslog	RWCD	admin required to read/write/create/delete Log Entry records
sysrule	RWCD	admin required to read/write/create/delete Rule records (Email Notifications, Inbound Email Actions, Approval Rules, and so on)
sysrule	read	all users can read Email Notification records for (subscription-based notifications)
sys_app_application	WCD	admin required to write/create/delete Application records
sys_app_category	WCD	admin role required to write/create/delete Application Category records
sys_app_module	WCD	admin required to write/create/delete Module records
sys_audit	RWCD	admin required to read/write/create/delete Audit records
sys_dictionary	RWC	personalize_dictionary role required to read/write/create Dictionary records
sys_dictionary.*	read	personalize_dictionary role can read Dictionary fields
sys_documentation	delete	personalize_dictionary role required to delete Field Label records
sys_documentation	create	personalize_dictionary role required to create Field Label records

sys_ui_action_view	delete	admin role required to delete UI View Action records
sys_ui_policy	create	admin role required to create UI Policy records
sys_ui_policy	delete	admin role required to delete UI Policy records
sys_ui_policy	write	admin role required to write to UI Policy records
sys_ui_policy_action	create	admin role required to create UI Policy Action records
sys_ui_policy_action	delete	admin role required to delete UI Policy Action records
sys_ui_policy_action	write	admin role required to write to UI Policy Action records
sys_ui_script	write	admin role required to write to UI Script records
sys_ui_script	delete	admin role required to delete UI Script records
sys_ui_script	create	admin role required to create UI Script records
sys_user	write	Users with no role can't update any user record but their own
sys_user_grmember	delete	user_admin role required to delete Group Member records
sys_user_grmember	write	user_admin role required to write to Group Member records
sys_user_group	create	Only itil and above can create group records
sys_user_group	write	Only itil and above can write to group records
sys_user_has_role	read	itil role required to see User Role records
sys_user_role	create	admin role required to create Role records
sys_user_role	delete	admin role required to delete Role records
sys_user_role	write	admin role required to write to Role records

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Name	Operation	Description
sys_user_role_contains	read	itil role required to see Contained Role records
sys_user_role_contains	write	admin role required to write to Contained Role records
sys_user_token	RWCD	admin role required to read/write/create/delete User Token records

Note:
To learn more about this plugin, see Enable security jump start plugin (ACL Rules) [Updated in Security Center 1.3] in Instance Security Hardening Settings.

Configure an ACL rule

Configure custom access control list (ACL) rules to secure access to new objects or to change the default security behavior.

Before you begin
Role required: security_admin

About this task
To create ACL rules, you must elevate privileges to the security_admin role.

For tables that are in a different scope from the ACL rule record, the types of rules are limited. For Scope Master tables to derive scope and execute scoped ACLs, set the *glide.enforce_security_scope.<scope_name>* property to **true**. This ensures ACLs in the global scope don't match when there are scope-specific ACLs created on the relevant table. Examples are when securing data within shared application tables in the Global scope, such as sys_attachment or sys_question_answer tables.

Procedure

1. Elevated privilege roles to the security_admin role.
2. Navigate to **System Security** > **Access Control (ACL)**.
3. Select **New**.

   Tip:
   When creating an ACL, it's helpful to review the Deny-Unless ACL.

4. Complete the form.

Access control fields

Field	Description
Type	Select what kind of object this ACL rule secures. The type of object determines how the object is named and what operations are available. This field becomes read only after the ACL rule is created. If you want to change the type, you must delete the ACL and create one with the correct type.
Operation	Select the operation that this ACL rule secures. Each object type has its own list of operations. An ACL rule can only secure one operation. To secure multiple operations, create a separate ACL rule for each.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	If you're creating a rule for a report_view operation, see also Report_view access control.
Decision Type	Select the decision type of the ACL. **Allow If** allows access upon successful evaluation. **Deny Unless** denies access unless there's successful evaluation.See Deny-Unless ACL for more information.
Admin overrides	Select this check box to have users with the admin role automatically pass the permissions check for this ACL rule. Admin users pass regardless of what script or role restrictions apply. However, the **nobody** role, which only ServiceNow personnel can assign, takes precedence over the admin override option. If an ACL is assigned the **nobody** role, admin users can't access the resource even when **Admin overrides** is selected. See Base system roles. Clear this check box if administrators must meet the permissions defined in this ACL rule to gain access to the secured object. Since administrators always pass role checks (see the description of the **Requires role** field), use the condition builder or **Script** field to create a permissions check that administrators must pass.
Protection Policy	Select this to set the protection policy on the ACL
Name	Enter the name of the object being secured, either the record name or the table and field names. The more specific the name, the more specific the ACL rule. You can use the wildcard character asterisk (*) in place of a record, table, or field name to select all objects that match a record type, all tables, or all fields. You can't combine a wildcard character and a text search. For example, inc* isn't a valid ACL rule name, but incident.* and *.number are valid ACL rule names. **Note:** Select the blue triangle to manually enter the record name or the table and field names of the object being secured. Use this option to secure an object that doesn't appear in the dropdown.
Description	Enter a description of the object or permissions that this ACL rule secures.
Applies To	Select **Add Filter Condition** to create a filter for the table selected in the **Name** field. The ACL applies only to the records matching this filter condition. For example, you could create an ACL for the incident table that applies only to incidents with the Critical priority. **Note:** You must select a table in the **Name** field to use this option. ACLs beginning with * cannot use the **Applies To** filter.
Active	Select this check box to enforce this ACL rule.
Advanced	Select this check box to display the **Advanced Condition** fields. See step 6.

5. **Optional:** To narrow the scope of the ACL fill in the **Conditions** fields as necessary.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Requires role	Use this list to specify the roles a user must have to access the object. If you list multiple roles, a user with any one of the listed roles can access the object. The *Requires role* list appears as a related list. **Note:** Users with the admin role always pass this permissions check because the admin role automatically grants users all other roles.
Security Attribute Condition	Use this section to define what the user can access based on user and environment criteria. For more information, see Security Attributes fundamentals. **Note:** The Condition field is case-sensitive.
Data Condition	Use this condition builder to select the fields and values that must be true for users to access the object. **Note:** The Condition field is case-sensitive.

6. **Optional:** If the **Advanced** box is checked, fill in the **Advanced Conditions** fields as necessary.

Controlled by References	Enforces the ACL on related records. See Related record access for more details.
Script	Enter a custom script describing the permissions required to access the object. The script can use the values of the *current* and *previous* Global variables in business rules as well as system properties. The script must generate a true or false response in one of two ways: ○ return an *answer* variable set to a value of true or false ○ evaluate to true or false In either case, users only gain access to the object when the script evaluates to true and the user meets any conditions the ACL rule has. Both the conditions and the script must evaluate to true for a user to access the object. If there's script in the **Script** field. This script executes even if the field isn't displayed on the form. **Note:** If the evaluated item is in a related list, **current** points to the item the related list is on, not to the current item the ACL is for. However, If the item you're evaluating the ACL for isn't in a related list, **current** points to the actual item.

7. Select and hold (or right-click) the form header and select **Save**.

© 2026 ServiceNow, Inc. All rights reserved.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Deny-Unless ACL

Learn details about Deny-Unless ACLs.

Deny-Unless ACLs are evaluated with a "deny-unless" approach. The ACL defines the users that will NOT be denied. Said another way, the user will be denied access **unless** the role, condition, and script requirements are met.

Important:

Deny-Unless ACLs will take priority against Allow-If ACLs in ACL Evaluation, as it will be evaluated first.

A Deny-Unless ACL produces two outcomes

Evaluation outcome	Result
Pass	The defined roles, data conditions, security attributes, and script requirements are met. The ACL proceeds to further evaluation **Important:** Even if a Deny-Unless ACL matches, access is only granted when an Allow-If ACL explicitly permits it. If no Allow-If ACL is matched and the Deny-Unless ACL passes, the system grants access by default.
Fail	The Deny-Unless ACL is marked as failing and access will be denied.

The following is an explained example of a Deny-Unless ACL:

- ACL has roles `sn_hr_core.manager` and `itil`
- Condition has active = `true`
- script has answer = `gs.isLoggedIn();`

The user is denied access unless all three requirements for this ACL are satisfied. In order for this Deny-Unless ACL to pass, a user needs either the `sn_hr_core.manager` or `itil` roles, be accessing a record that has active field = `true`, and be logged in. The Deny-Unless ACL will fail if any of the three requirements isn't met.

Query ACLs

Query ACLs allow you to define more granular access control by explicitly defining who can query the data.

What is a query ACL

A query ACLs have their operation set to either `query_range` or `query_match`. Query ACLs allow for more specific control of user queries, restricting or enabling access based on their setup. Query ACLs are powerful tools against blind query attacks, where an attacker blindly queries the data to extract information from results, even when they can't see the values.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

When to use a query ACL

Wherever a column contains sensitive values, and allows partial/conditional access to data a query ACL should be considered and implemented as necessary based on the sensitivity of the data. Wherever there is a partial/conditional access to rows and their columns in tables, especially where that access is not enforced by data filters, query ACLs should be implemented as necessary based on the sensitivity of the data.

Note:
Consider query ACLs when some users have access to some rows or columns and not others .

Example: Payroll query control

I can see one row in payroll table with my salary, but there is no reason for me to be able to issue range queries to query users with a salary contained within 2 boundaries. A `query_range` ACL on salary would prevent me from issuing that query.

Example: HR query control

I can see all hr_profiles, but can only see SSN for myself. I have no business querying SSN, and query ACLs should prevent me from running queries against SSN of other hr profiles to try to extract SSN mappings.

Query ACL behavior

Query ACLs use `query_match` and `query_range` operations for secure and granular table querying behavior. Their behaviors are described below:

`query_match`

`query_match` is composed of: EQUALS, NOT_EQUALS, IN, NOT_IN, SAMEAS, NSAMEAS, ANYTHING, ISEMPTYSTRING, ISEMPTY, ISNOTEMPTY, ISNULL, ISNOTNULL. `query_match` is made of the "safe operators", in a sense that they are built to fetch specific record(s), and can't be exploited to return others.

Evaluation outcome	Result
Pass	User can submit match queries
Fail	User will not be able to submit match queries: • EQUALS • NOT_EQUALS • IN • NOT_IN • SAMEAS • NSAMEAS • ANYTHING • ISEMPTYSTRING • ISEMPTY • ISNOTEMPTY

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Evaluation outcome	Result
	• ISNULL • ISNOTNULL

`query_range`

`query_range` is composed of all the others (STARTS_WITH, CONTAINS, >=, <= etc) which are more dangerous as they allow users to query for more records by adjusting the boundary values.

Evaluation outcome	Result
Pass	User can submit range queries and sorting is unrestricted
Fail	The user will not be able to submit range queries with (STARTS_WITH, CONTAINS, >=, <=, etc. Sorting by column is restricted

Important:

Query ACLs (both query_match and query_range) default to a star.star ACL that delegates to read access. This means, where ACLs are enforced on queries, if no query ACL was created then read access to the column is evaluated ; if query ACLs are defined then they override the default behavior.

Secure records in an embedded list

To apply security to the records in embedded lists, limit editing and deleting records in embedded lists to specific roles.

Before you begin

Role required: security_admin

Procedure

1. Navigate to **All** > **System Security** > **Access Control (ACL)**.
2. Open the **Write** or **Delete** record for the appropriate table.
3. In the Requires Role section of the form, add the roles that have write or delete permission for that table.
4. Save the changes.
   When records from the associated table appear in an embedded list, the edit and delete options are available only to users with the specified roles.

Related record access

Related record access enable consistent control over what records users are able to access between related tables.

Related record access details

Related record access enables you to configure access to related record, determining whether the related parent table's ACL should be enforced on data that is allowed access from the

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

ACL. Consider the following use-case, a user has access to a record via ACL, then related record access enables the users' access to all other records related to it, via either reference or bidirectional relationship.

Contextual Security Manager

Contextual Security Manager protects your data by controlling read, write, create, and delete authorization.

Key advantages

The Contextual Security Manager is aware of the system table hierarchy, enabling you to create specific security rules for a field based on where in the hierarchy it is displayed. Benefits of the Contextual Security Manager include:

- **Contextual security**: Secure a record based on the contents of the record.
- **Hierarchical security**: Apply security rules to any level in the object hierarchy.

Securing fields and tables

With the legacy Simple Security Manager, you could secure fields and tables by adding roles to the appropriate dictionary entry. With the Contextual Security Manager, these dictionary roles are no longer tested. Instead, the system looks for ACL rules on fields and tables.

> **Warning:**
> After you install the Contextual Security Manager, you must secure fields and tables via ACL rules. Even if you Configuring the form layout the dictionary form and add roles to a dictionary entry, no change in rights occurs.

Contextual security and roles

You can grant roles to users or groups. However, after installing the Contextual Security Manager, the **roles** field on the user record is no longer checked and no longer appears on your user and group forms. Instead, you must add roles to the Roles related list instead of to the user or group record.

Applications and modules contain lists of the roles required to view them. For example, to view the System Definition application, the admin role is required. Security rights for applications and modules are still defined using role arrays.

Both catalog items and catalog variables contain lists of the roles required to view them. Security rights for catalog items and catalog variables are still defined via these role arrays.

Under the Contextual Security Manager, a group still automatically inherits any role granted to the group when the inherits flag for the role is set to *true*.

Activating the Contextual Security Manager

The Contextual Security Manager is active in the base system. If there are many duplicate entries in the User Roles table, you may need to upgrade to Contextual Security: Role Management V2 to eliminate duplicate roles. Plugins include:

Contextual Security: Role Management [com.glide.role_management]

Provides contextual security functionality. This plugin is automatically installed.

Contextual Security: Role Management V2 [com.glide.role_management.inh_count]

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Prevents duplicate entries caused by inherited roles in the User Roles [sys_user_has_role] table. This plugin is automatically installed on new instances and can be activated for upgrades. The Contextual Security: Role Management Enhancements plugin is a previous version of this plugin. The Role Management Enhancements plugin does not include the RoleManagementVerify() script. This script returns a list of changes that an upgrade will perform, enabling you to monitor changes made by the plugin.

Note:
After activating Role Management V2, you must set the glide.role_management.v2.audit_roles system property to allow the Audit Roles table to create audit records related to user roles. To learn more about setting this property and about the Audit Roles table, see:

- Enable role auditing with Contextual Security: Role Management V2.
- Hardening settings in Instance Security Hardening Settings.
- Audit user roles

Prevent duplicate entries with Contextual Security: Role Management V2

Roles inherited from other roles are added as individual entries in the User Roles table [sys_user_has_role], potentially causing one role to have duplicate entries. Contextual Security: Role Management V2 eliminates these duplicate entries and prevents future duplicates.

Eliminate duplicate entries through inheritance count

Contextual Security: Role Management V2 uses the Inheritance Count (inh_count) column to track the number of times a role is inherited from another role or group. In the User Roles [sys_user_has_role] table, a user can inherit a specific role only one time, eliminating duplicate entries. The Inheritance Count (inh_count) column is read-only and calculates the number of times the user inherits a role.

Activation changes

Contextual Security: Role Management V2 is automatically installed on new instances and can be activated for upgrades. When activated, Contextual Security: Role Management V2 replaces both Contextual Security and Contextual Security: Role Management Enhancements.

When Contextual Security: Role Management V2 is activated, the following columns are deprecated, but remain in the User Roles table for backward compatibility:

- granted_by (used only by Role Delegation)
- included_in_role
- included_in_role_instance

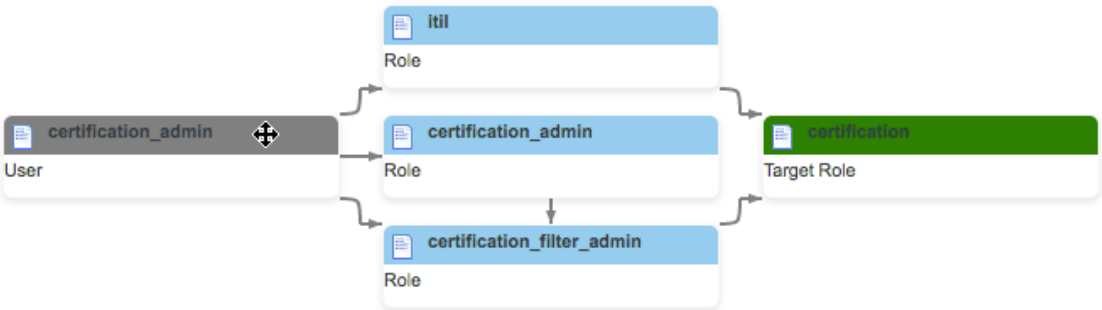
Warning:
If these columns are in use in any custom scripts on your instance, do not upgrade to Role Management V2.

Visualize role inheritance through the Role Inheritance Map

The Role Inheritance Map displays a visual representation of inherited roles. You can use this map to understand the roles represented in the Inheritance Count (inh_count) column. To view the Role Inheritance Map, configure the User Roles [sys_user_has_role] table to display the Role Inheritance Map column.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Role Inheritance Map



Note:
Concurrent update to group or role assignment may result in incorrect inheritance count. You must enable the `glide.security.inh_count_patcher.enabled` property to get the exact inheritance count.

Upgrade to Contextual Security: Role Management V2

Contextual Security: Role Management V2 is automatically installed on new instances. You can upgrade from Contextual Security: Role Management to Contextual Security: Role Management V2 to eliminate duplicate roles in the User Roles table and prevent future duplicates.

Before you begin

Role required: admin, security_admin
You must have the admin role and Elevate to a privileged role to obtain the effective security_admin role.

Note:
Before upgrading to Contextual Security: Role: Management V2, you must enable the Audit Roles table to create audit records related to user roles. To learn more about setting the required system property, see Enable role auditing with Contextual Security: Role Management V2.

About this task

This procedure describes how to upgrade your Contextual Security role and how to activate the related plugins described in the following table.

Plugins for Contextual Security: Role Management V2

Plugin	Description
Contextual Security: Role Management V2 [com.glide.role_management.inh_count]	Prevents duplicate entries in the User Roles [sys_user_has_role] table. The security_admin role or a user with elevated privileges is required to activate the plugin, or contact Customer Service and Support.
Contextual Security: Role Management V2 REST API [com.glide.role_management.inh_count.rest_api]	Enables API functionality for role management.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before upgrading from Contextual Security: Role Management to Contextual Security: Role Management V2, test the results of an upgrade by running the script. The script returns a list of changes that an upgrade will perform. If the changes are acceptable, install the Contextual Security: Role Management V2 plugin. If the changes are not acceptable, do not install the Contextual Security: Role Management V2 plugin. Alternatively, you can perform the upgrade and then manually make any necessary changes.

Procedure

1. Test the impact of an upgrade prior to upgrading by running the following script.

   a. Navigate to **System Definition** > **Scripts - Background**.

   b. Run the following script in global scope.

   ```
   new RoleManagementVerify().verifyInheritedRoles();
   ```

   For large sys_user_has_role tables, the execution may take up to several hours to complete. Do not edit or add user roles during this time.
   Example result based on test data:

   ```
   *** Script: 2016-12-01 19:58:54 Starting checking of
    inherited roles for all users...
   *** Script: User: itam, inherited roles to be ADDED:
    financial_mgmt_user
   *** Script: User: bernard.laboy, inherited roles to be
    DELETED: api_analytics_read,pa_viewer,rest_api_explorer,a123
   *** Script: User: bernard.laboy, inherited roles to be ADDED:
    dependency_views
   *** Script: Number of inherited-role records in sys_user_has
    role, current: 260, after re-calculation: 258
   *** Script: Number of users with discrepancies for inherited
    roles: 2
   *** Script: 2016-12-01 19:58:55 Finished checking of
    inherited roles for all users!
   ```

   c. Evaluate the script results to determine whether the proposed changes are acceptable.

2. Activate the Contextual Security: Role Management V2 plugin.

   Important:
   The security_admin role or a user with elevated privileges is required to activate the plugin, or contact Customer Service and Support.

   a. Navigate to **System Definition** > **Plugins**.

   b. Find and click the plugin name.

   c. On the System Plugin form, review the plugin details and then click the **Activate/Upgrade** related link.

   d. Click **Activate**.

Result

After activating Role Management V2, the changes outlined in the script result are enacted. The Inheritance Count (inh_count) column in the User Roles table is read-only and automatically reflects the number of times the user inherits a role.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Enable role auditing with Contextual Security: Role Management V2

Set a system property to enable the Audit Roles table to create audit records related to user roles.

Before you begin

Role required: admin

About this task

When enabled, the Audit Roles [sys_audit_role] table maintains changes to user records. For more information about role audits, see Audit user roles. If the Contextual Security: Role Management V2 [com.glide.role_management.inh_count] plugin is installed, you must set a system property to **true** to enable role auditing.

Procedure

1. Navigate to the System Properties [sys_properties] table.
2. Add the *glide.role_management.v2.audit_roles* system property and set it to **true**.

   If the Contextual Security: Role Management V2 [com.glide.role_management.inh_count] plugin is installed, setting this property to **true** enables the Audit Roles [sys_audit_role] table to create records when user roles change.

Double-check form submission

When the system determines that a particular field (such as task.number) should not be written to by the current user, the system renders that field in a read-only mode, which is why the number field is not writable on most incidents.

If you set the system to double-check the values of any incoming fields for writability, then the system applies the same set of security rules to the inbound leg of a transaction. When you submit an incident, for example, the system double-checks to determine if the number field can be written to before posting any changes.

If you tell the system not to double-check inbound transactions, then the system allows you to write to a nominally read-only field if that is the transaction the client sends back. In many deployments this is actually a desirable behavior if, for example, you are using client scripts to set nominally read-only fields in response to user selections in other, writable fields.

Property	Location	Default
Double check security on inbound transactions during form submission (rights are always checked on form generation)	**System Properties** > **Security**	Disabled (no double-checking)

Default deny property

The default deny property (`glide.sm.default_mode`) controls the security manager default behavior when the only matching ACL rules are the wildcard table ACL rules.

A set of wildcard table ACL rules for the most common record-based operations are available: read, write, create, and delete. A significant number of ACLs to provide role-based access to system tables are also available. For example, there are ACLs that grant sys_script access to the

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

business_rule_admin role because that role is documented as being able to manage business rules.

Use the `glide.sm.default_mode` property to deny or allow these operations on all tables:

- **Deny Access**: The wildcard table ACL rules restrict the read, write, create, and delete operations on all tables unless the user has the admin role or meets the requirements of another table ACL rule. Other operations, such as report_on and personalize_choices, are unaffected by this setting.
- **Allow Access**: The wildcard table ACL rules allow the read, write, create, and delete operations on all tables unless there are specific table ACL rules in place to restrict such operations.

You cannot reset `glide.sm.default_mode` to **Allow Access** once it has been set to **Deny Access**.

Note:
By default, the wildcard table ACL rules are the only ACL rules that check for the value of the `glide.sm.default_mode` property. If you want to control other operations with this setting, create your own ACL rules to check for this property value.

To learn more about this property, see Deny by default with empty ACLs [Updated in Security Center 1.3] in Instance Security Hardening Settings.

Advanced ACL configuration

In addition to creating new ACLs or modifying existing ones, you can configure other aspects of ACL functionality.

Deny ACL rules

Deny-Unless

Query ACL rules

Task	Description
Apply ACL script conditions to reference fields	Enable a property to allow script conditions to apply to reference fields if you want to control access to the data that a reference field displays on a form or in a list. There might be an impact to the performance of your instance if you enable this.
Apply ACLs to AJAXGlideRecord (client-side Glide record)	Apply ACLs to *`GlideAjax`* API calls so that the system queries only the data that the currently connected user has rights to access.
Evaluate the admin override at the access level	Force ACL evaluation for admin overrides at the access level. By default, users with the admin role automatically pass the permissions check for this ACL rule when the Admin Overrides option is selected on the ACL rules form.
Use ACL debugging and troubleshooting tools	Use tools like the ACL watcher, field level debugging, and access ACL rule output messages to help you troubleshoot and debug ACLs.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Provide external users access to a table

To enable users with only the snc_external role to access the list view of a table, you must create a series of ACLs.

Before you begin

Role required: security_admin

Procedure

1. Elevate to a privileged role.
2. Create an ACL rule with the following settings:
   - **Type**: ui_page
   - **Operation**: read
   - **Name**: {table_name}_list
   - **Required role**: snc_external
3. On the default **read** ACL for the table, add **snc_external** in the Required role list.
   Create the ACL if it does not already exist.
4. Use these settings to create another ACL:
   - **Type**: ui_page
   - **Operation**: read
   - **Name**: {table_name}
   - **Required role**: snc_external
5. Use these settings to create another ACL to give the user write access to a field in the table:
   - **Type**: record
   - **Operation**: create
   - **Name**: {table_name} {column_name}
   - **Required role**: snc_external

   Repeat this step for every field that you want to give the user write access to. Use an asterisk * instead of the column name to provide access to all fields at once.

Apply ACL script conditions to reference fields

Use the *glide.sys_reference_row_check* system property to enable scripted conditions for reference fields.

The default behavior is intended to improve instance performance. If you want to enable script conditions for reference fields, add the following system property.

Note:
For more information on creating system properties, see Add a system property.

System property

Property	Description
glide.sys_reference_row_check	Controls whether the script conditions of Access Control Rules apply to a table's reference fields.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

System property (continued)

Property	Description
	• Type: true | false • Default value: **false** • Location: Add a system property to the System Properties [sys_properties] table

Note:
If the *glide.sys_reference_row_check* system property is not present, or has been set to false, script conditions for Access Control Rules are not applied. This means an ACL containing scripted conditions will pass it's check as long as the other ACL criteria are met (such as role requirements).

Apply ACLs to AJAXGlideRecord (client-side Glide record)

Use a system property to perform access control list (ACL) rule validation when server-side records (for example, tables) are accessed using GlideAjax APIs within a client script.

If you choose to apply access control lists (ACL) to *GlideAjax* API calls, then you can only query data to which the currently connected user has rights to access. For example, if the user is logged in as an ESS user who has no rights to read the `cmn_location` table, then any *GlideAjax* API call by the user will fail.

If the ServiceNow AI Platform is running without GlideAjax ACL call checking, an API can return information that the currently logged in user could not otherwise access.

Use GlideRecordSecure when querying data to ensure the highest level of security. GlideRecord relies on ACL enforcement through configurations whereas GlideRecordSecure applies stricter security controls. GlideRecordSecure offers a more secure, out-of-the-box solution for handling sensitive data.

Note:
Set this property in **System Properties** > **Security**.

Property	Default
Apply standard security ACLs to *AJAXGlideRecord* calls	ACL checking enforced

Warning:
The `sys_class_name`, `sys_id` and `sys_domain` are ignored for ACL checks.

To learn more about this property, see Require AJAXGlideRecord ACL checking [Updated in Security Center 1.3] in Instance Security Hardening Settings.

Evaluate the admin override at the access level

If you want to force ACL evaluation for admin overrides at the access level, you can add a system property.

Before you begin

Role required: security_admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

About this task

ACLs are evaluated cumulatively. If there are number of ACLs on any given field and the **Admin Overrides** option is **false** (not selected) on one of them, then the effective admin overrides for all the ACLs are considered to be **false**. This causes admins to be unable to pass even the ACL where the override should be in effect.

Procedure

Add the following property to the system properties table:

Property	Description
glide.security.admin.override.accessterm	Evaluates the admin override condition at the access term level. • Type: true | false • Default value: **true** for new instances, **false** for upgrades • Location: Add to the System Properties *[sys_properties]* table **Note:** If the property is not defined on the Instance, the value evaluates as false.

ACL debugging tools

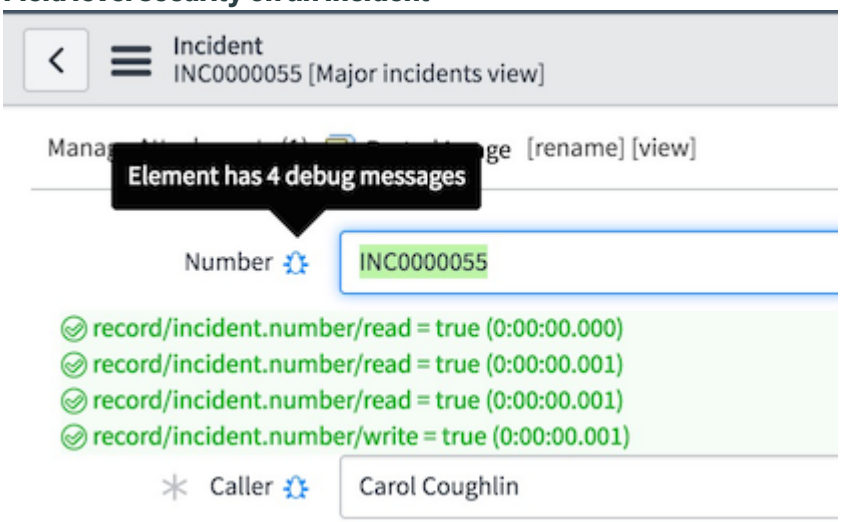
Field level debugging and access ACL rule output messages are available to help you troubleshoot and debug ACLs. The ACL configuration watcher lets you know what related ACLs exist when you modify one.

Field level debugging

When debugging is enabled, a small bug icon ( ) appears beside each field with an ACL rule. Clicking the icon lists the ACL rules that apply for the field and the evaluation results. Enable debugging by navigating to **System Security** > **Debugging** > **Debug Security Rules**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field level security on an incident



After enabling ACL debugging, you can impersonate another user to see what ACL rules the user passes and fails. When you impersonate a user, you can only see what that user is allowed to see. For example, you cannot view a record that an ACL prevents the user from seeing. To make debugging easier, read-only access to certain ACL-related tables is enabled by default, even when impersonating a user that does not have read access to the tables. To change this functionality, set the following property to **false**.

To enable ACL rule debugging, navigate to **System Security** > **Debug Security Rules**.

System property	Description	Default setting
glide.security.access_allow_impersonator	Allows read access to the following tables while impersonating a user: sys_security_acl, sys_security_operation, sys_security_type, and sys_user_role. As a result, the impersonating user can read data that the impersonated user cannot read.	true **Note:** When the property is set to false, the impersonated user might be prevented from reading ACL-related data. In this case, a second session logged in as admin or security_admin might be required to debug ACLs.

ACL rule output messages

ACL debugging displays ACL rule output messages at the bottom of each list and form. The output message displays the following:

Message element	Description
TIME	The total time used to process this ACL rule.
PATH	Information that uniquely identifies each ACL rule in the format: <ACL rule type>/<ACL rule name>/<Operation>.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Message element	Description
CONTEXT	The object being evaluated by the ACL rule.
RC	The return code of the ACL rule. A true value passes the ACL rule. A false value fails the ACL rule.
RULE	A brief summary of processors and scripts, followed by ACL results for each table-level and field-level ACL evaluation. Most ACL evaluations show an overall pass or fail result followed by a breakdown of the results for each type of ACL criteria: • iAccessHandler: An internal system check using hidden source code on the platform. This is a system security check that you cannot modify. IAccessHandler can grant or deny access to a resource without evaluating ACLs. If IAccessHandler is ignored, then the ACLs are evaluated. You cannot modify the IAccessHandler checks in any way. For example, an IAccessHandler implementation is used for access checks on application resources and this cannot be changed. This is available starting with the Istanbul release. • Roles: Verification that the user has the correct role. • Condition: Verification that the user passed the condition specified on the ACL rule (if any). • Script: Verification that the user passed the script specified on the ACL rule (if any).

The icons that appear show how the ACL was evaluated:

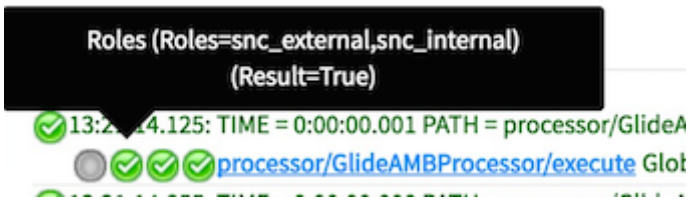
Icon	Description
A green checkmark ( )	Indicates the table or field passed the criteria.
A red x icon ( )	Indicates the table or field did not pass.
An empty gray circle icon ( )	Indicates the ACL evaluation did not need to be performed.
A blue checkmark, x, or empty circle	Indicates that the ACL was taken from a cached result of a previous ACL check. The icons mean the same as the above.

You can perform these actions on the ACL debug output:

- Select or clear these check boxes at the top of the debug output:
  - **Security rules**: Show or hide the results of the ACL checks.
  - **Others**: Show or hide other warnings or messages.
- Click the name of the ACL next to any of the output messages to open that ACL record.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Hover the cursor over any of the icons for the four ACL checks to see more information.



ACL troubleshooting reference

ACL troubleshooting includes identifying ACL rule errors and use the debugging tools to fix the ACL related problems.

Access analyzer

Access analyzer helps the administrators to view permissions for the selected user, role, or group. It is a diagnostic security tool that provides comprehensive visibility into resource permissions and access controls at the Access Control List (ACL) level, enabling you to understand who has access to their resources, identify overly permissive configurations, and maintain least-privilege access principles. To learn more about how to use the tool, see Access analyzer.

Enable debugging

Enable debugging to help troubleshoot an issue.

Troubleshoot

Error or symptom	Solution
You cannot access records from a custom table.	Create a table ACL rule for the custom table granting users access to the table. Without an explicit table ACL rule, users must pass the permissions in the table wildcard (*) ACL rule, which by default restricts access to administrators only. Enable debugging and determine what ACL rules are evaluated for the custom table.
You create a custom ACL rule that does not work properly.	The most likely problems are that another rule takes precedence over your custom rule in the processing order or that the user does not meet all the permission requirements for the object type. Enable debugging and verify that the ACL rule is being evaluated.
Your field ACL rule does not work properly.	There is likely a table ACL rule that the user has not met. Enable debugging and determine what ACL rules are evaluated for the field. Verify that there is not a conflicting table ACL rule or duplicate field ACL rule.
Your table ACL rule does not work properly.	There is either an ACL rule higher in the processing order or a duplicate table ACL rule interfering with the table ACL rule. Enable debugging and determine what ACL rules are evaluated for the table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Troubleshoot (continued)

Error or symptom	Solution
You can see a field in a list but not in form.	It is possible that the ACL rule conditions or script are being triggered in the list but not in the form. Enable debugging and determine when the ACL rules evaluate to true. Update the conditions or script to have the same behavior on the list and form.
You receive an error message when trying to execute a processor or client-callable script include.	There is an ACL rule for the processor or client-callable script include that the user has not met. If the user should have access to the object, enable debugging and determine what ACL rules are evaluated for the processor or script include. Update the ACL rule or the user roles as needed to access the object.

ACL configuration watcher

The ACL configuration watcher lets you know what related ACLs exist on a table when you insert, update, or delete an ACL on the same table.

The ACL configuration watcher is an interceptor window that displays every time you make important changes on the Access Control [sys_security_acl] table. It displays a security rules summary window where you can view ACLs related to the one you are modifying. You cannot modify any ACLs from the security rules window. To make any modifications, close the watcher window and go to those ACLs.

The ACL configuration watcher does not appear in the following situations:

- If you save or update an ACL record without actually making any changes.
- If you make minor updates (not an insert or delete), such as updating scripts, conditions, and the admin-overrides option.
- If the ACL record is not active.

ACL Security Rules window

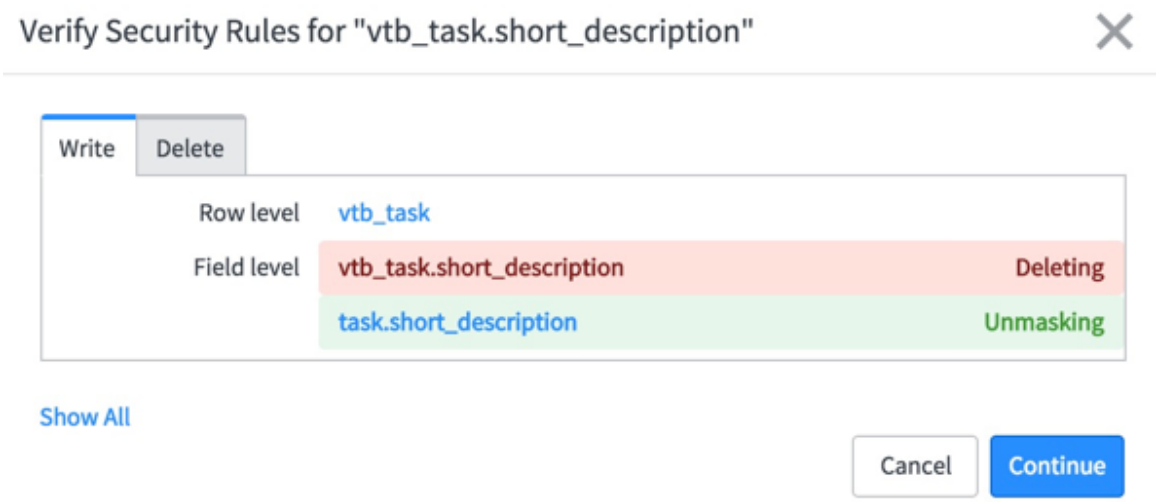
The configuration watcher shows the ACL execution plan. The execution plan is displayed in the security rules pop-up window. You can view this kind of information:

ACL configuration window elements

Item	Description
red highlight	An ACL that is deleted or deactivated.
blue highlight	An ACL that is modified.
green highlight	An ACL that is added or becomes active.
Masked	An ACL that was effective until you made a change.
Unmasked	An ACL that was just made effective when you made a change.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Configuration watcher example



Show ACL execution plan

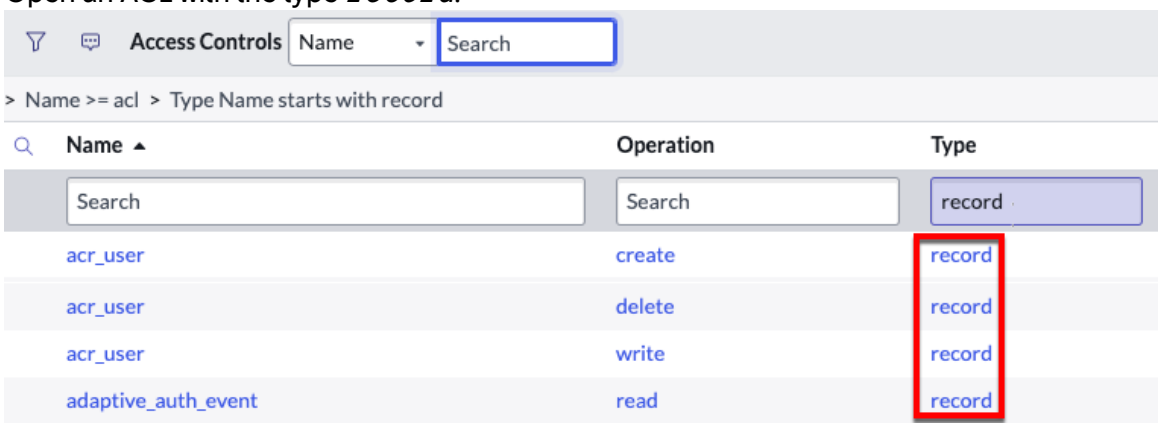
Administrators can view how ACLs relate to each other by viewing an execution plan for any ACL in the instance.

Before you begin

Role required: security_admin

Procedure

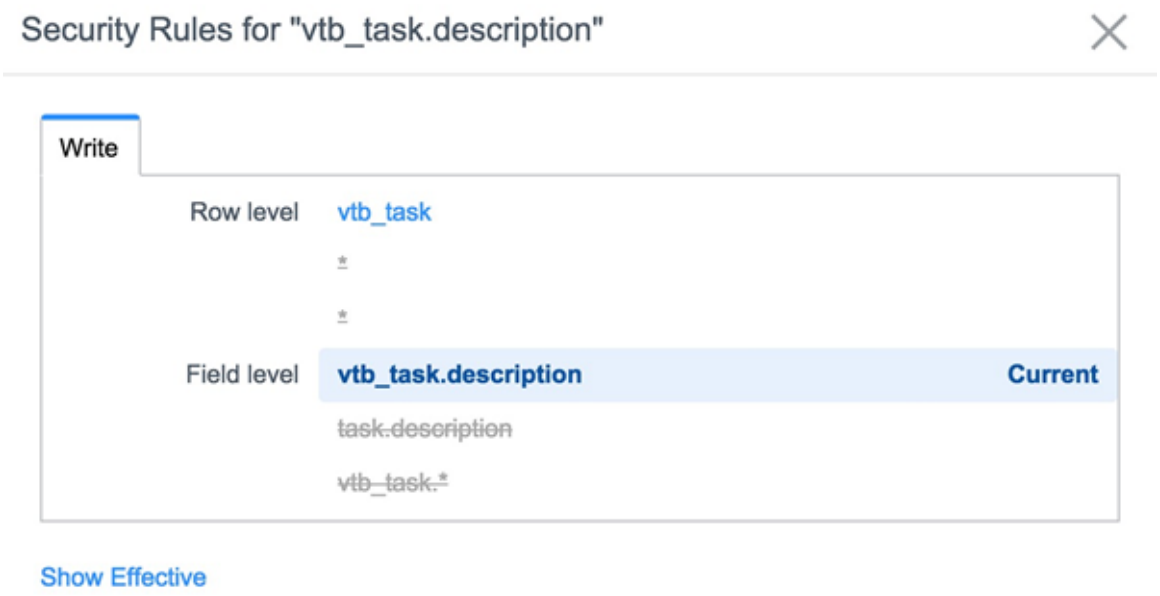
1. Elevate to a privileged role.
2. Navigate to **System Security** > **Access Control (ACL)**.
3. Open an ACL with the type *record*.



4. Click **Show ACL Execution Plan** in the Related Links section.

   The security rules window appears for the ACL. The example displays the execution plan for "vtb_task".

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



ACL execution plan window

UI item	Description
Title	The name of the ACL.
Tab name	If the ACL is create, read, write, or delete.
Row level	Row-level ACLs that run on this table.
Field level	Field-level ACLs that run only on this field (or column in the table).

5. Click **Show all** to show all related ACLs, including those ACLs that are overridden and generic ACLs that apply to all records.
   Overridden ACLs have a line through the name, and generic ACLs have the wildcard character asterisk (*) for the name.
6. Show only the immediate ACLs related to the one you are viewing and hide the ACLs on tables from which the ACL table is extended and the generic wildcard (*) ACLs by clicking **Show Effective**.

Use the ACL configuration watcher

Use the ACL configuration watcher after you elevate to security_admin role.

Before you begin

Role required: security_admin
Elevate to a privileged role

Procedure

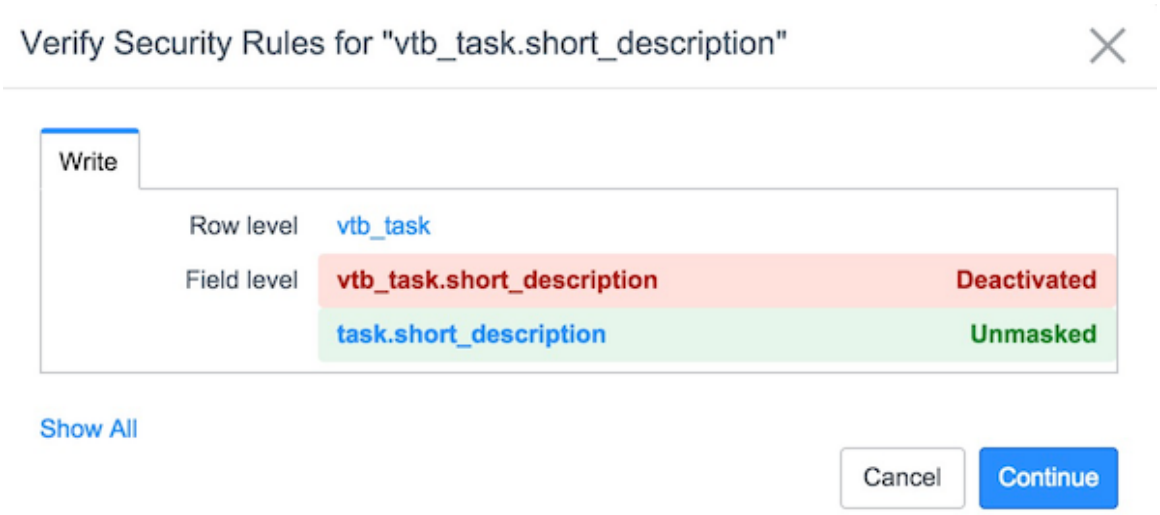
1. Open an ACL that is a record-type ACL.
2. Perform an action on the ACL, such as modifying it, or selecting an option from the context menu like **Insert**.
3. If you modified any values on the Access Control form, right-click the header and select **Save** or click **Update** or **Delete**.

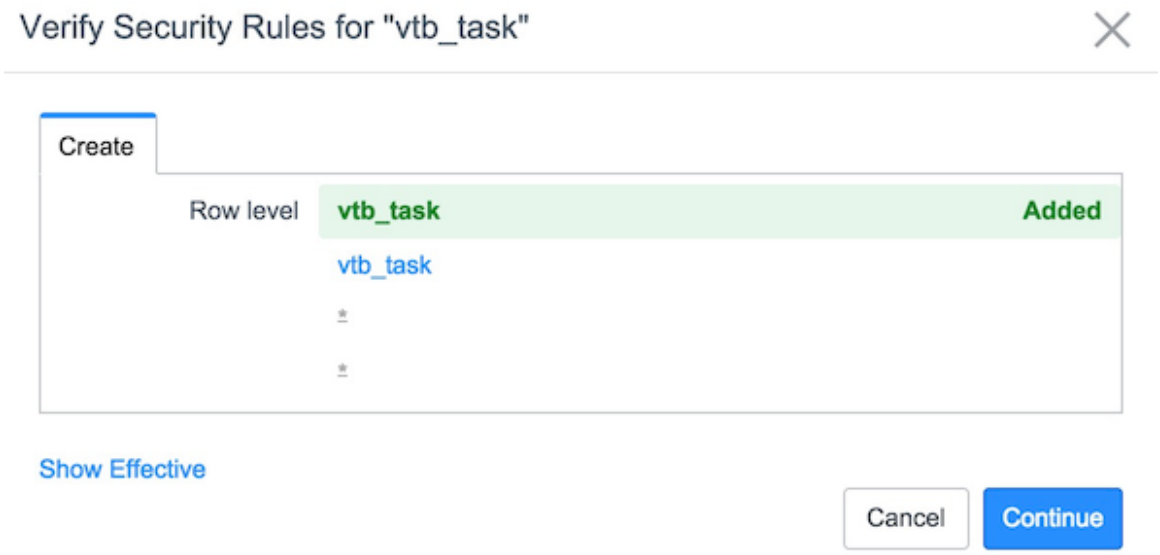
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

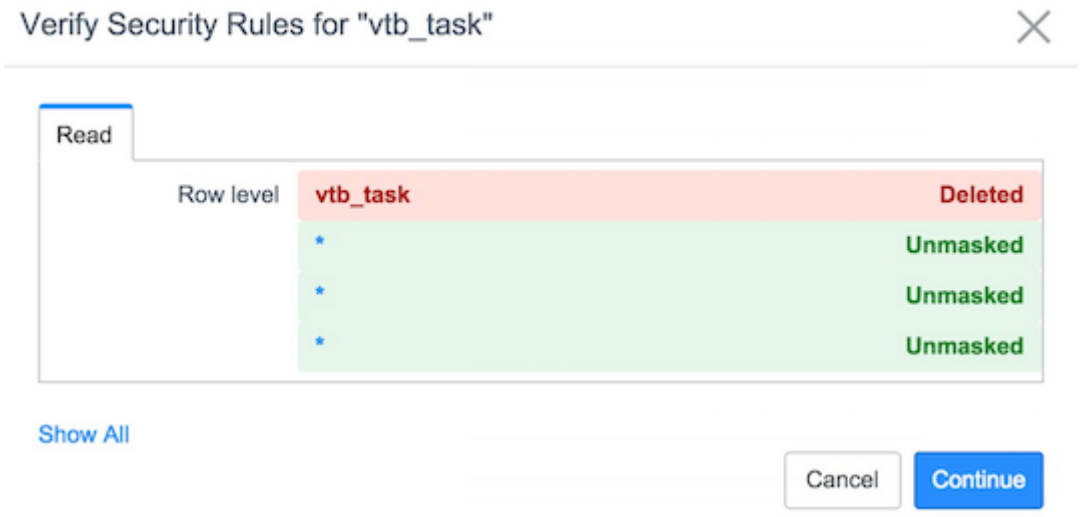
The Security Rules window appears. The system did not yet perform the database action on the ACL, so the changes are not yet saved.

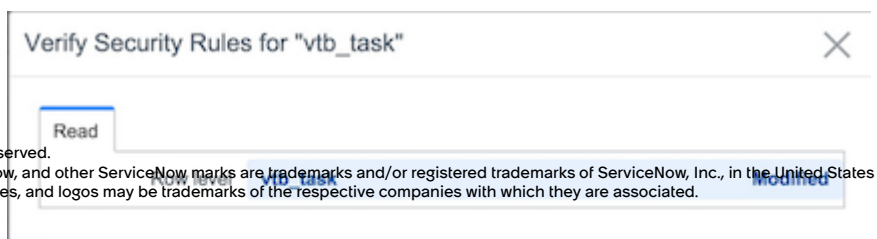
These are examples of security rules on the Visual Task Board application's Private Task [vtb_task] table. See ACL configuration watcher for a description of the items on this window.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.









© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

4. Just as with the execution plan, you can click **Show all** to show all related ACLs, including those that are overridden and generic ACLs that apply to all records, or click **Show Effective** to show only the immediate ACLs related to the one you are viewing.
5. Hover your mouse over any of the ACLs to see a description.

Access analyzer

ServiceNow® Access analyzer is an access diagnostic tool that helps to view the permissions of an identity for a resource.

Explore Learn the features and business value of Access analyzer.	Use Understand how to use Access analyzer.
Permission Evaluation Know how the permissions are evaluated.	Frequently asked questions Get details about commonly asked questions about Access analyzer.

Explore Access analyzer

Analyze identities on the ServiceNow instance.

ServiceNow Access analyzer is an application that helps the administrators to view permissions for the selected user, role, or group.

Note:

- Access analyzer is a ServiceNow Store product. Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store.
- Access analyzer impersonates the identity record to retrieve details about the permissions and doesn't read or store any personal or sensitive data of the identity.
- Access analyzer evaluation results are the same irrespective of any access policies defined for the users such as Zero trust access (ZTA). The policies are only evaluated during the actual user login and aren't evaluated during the access analyzer flow.
- Access analyzer has limitations in accurately evaluating access of the resources related to managed scope resources and delegated developer.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Evaluate Access

Evaluate Access is a capability of the ServiceNow Access Analyzer, which helps the administrators to view permissions for the selected user, role, or group.

It enables you to analyze and view the permissions of users, groups, roles for a table, client callable script includes, UI pages, and REST endpoints.

Using Access Analyzer, organizations can improve their security posture, identity governance, risk management, achieve their compliance goals, and understand who (identity) has access to what (resources).

Compare Access

Compare Access is a capability of the ServiceNow Access analyzer V2, which enables administrators to compare user access and determine the right level of access for the users on your ServiceNow instance.

Compare Access can be perform between the users for the user records and access control.

Compare Access enables you to perform the following analysis:

- Level 1: Compare user records to understand the attributes, roles, and groups.
- Level 2: Compare access controls to run the root cause analysis by finding access issues.

Benefits

The following are some of the benefits of using the Access analyzer:

- Analyze access to resources (tables).
- Compare the access of 2 users.
- Compare the roles and groups of 2 users.
- Generate a report showing whether an identity has access to a resource (table).
- Understand who has access for critical security hygiene.
- Help to prevent from over-provisioning permissions.
- Achieve the least privilege principals when implementing access controls.
- Limit access to certain data, which includes applications, tables, rows or columns, and other resources.
- Provide reporting capabilities for the analyzer results.
- Compare access between user records and access controls.
- Determine the right level of access for users on your ServiceNow instance.

Use Access analyzer

Analyze identities and their access on the ServiceNow® instance.

Before you begin
Role required: admin, access_analyzer_admin

The following procedure describes the steps for accessing Access analyzer and using various features within Access analyzer.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
Access Analyzer is a ServiceNow® Store product.

Procedure

1. Navigate to **All** > **Access Analyzer** > **Analyze Permissions**.
   The Analyze access and permissions homepage is displayed.

   Access Analyzer has the following capabilities:

   - Evaluate Access
   - Compare user records
   - Compare access controls
2. Select the respective tab to use Access analyzer based on your requirement.

Use Evaluate access

Analyze identities on the ServiceNow® instance.

Before you begin
Role required: admin, access_analyzer_admin

The following procedure describes the steps for accessing Evaluate Access in the Access Analyzer and using its various features.

Note:
Access analyzer is a ServiceNow Store product.

Procedure

1. Navigate to **All** > **Access Analyzer** > **Analyze Permissions**.
   The Analyze access and permissions homepage is displayed.
2. Select the **Evaluate access** tab.
3. Select your criteria as follows:

Select your criteria for analyzing access and permissions

Field	Description
Analyze by *	Analyze access for a user, a role, or a group
Select user *	Specify a user name to select from the list.
Rule type *	Analyze access for a table, a UI page, a REST Endpoint, or a client callable script include.
Select table *	Specify a table name to select from the list.
Select record	Specify a record name to select from the list.
Select field	Specify a field name to select from the list.

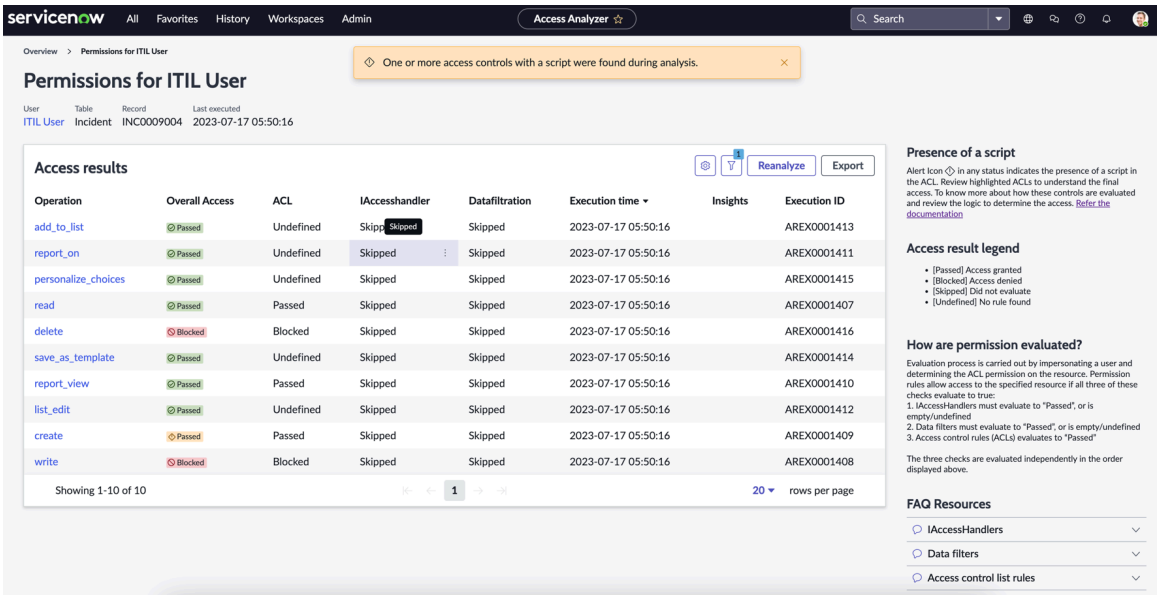
4. Specify the description in the **Description** field.
5. Select **Analyze permissions**.

   The access results for the user are displayed. Similarly you can analyze the permissions of a Group or Role for the following rule types:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Table (record)
- Client callable scripts include
- REST endpoints

The access results are displayed.



The Access results table includes the following fields:

Access results

Fields	Description
Operation	The type of operation that the user, group, or role can perform for the selected table, record, or field.
Overall Access	Result of the overall access. The results are as follows: ○ [Passed] Access granted ○ [Blocked] Access denied ○ [Skipped] Didn't evaluate ○ [Undefined] No rule found
ACL	Whether an ACL is defined for the selected operation.
Access Handler	An internal system check using hidden source code on the platform. IAccessHandler can grant or deny access to a resource without evaluating ACLs. If IAccessHandler is ignored, then the ACLs are evaluated.
Data filtration	A data filter is a form of access control designed to work along with the existing Access Control rules (ACLs) on your instance.

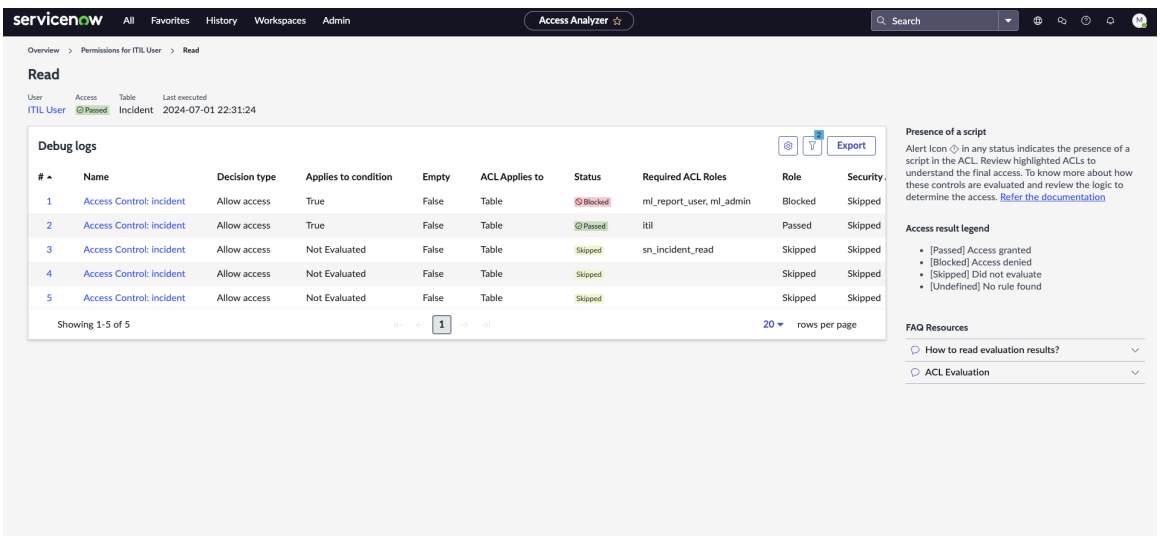
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Fields	Description
Execution time	The time at which the access results were executed.
Insights	More information about the selected operation.
Execution ID	A unique ID for each access result execution.

6. Select the Operation for more information about the ACL.
   For example, if you select **read**, the access control related to read is displayed.

ACL Details

Field	Description
Name	Name of the ACL.
Decision Type	Decision type configured for the ACL. **Allow access** or **Deny access**.
Applies to condition	Whether the ACL is applied to a condition.
ACL Applies to	Details about the resource the ACL is applied.
Status	Status of the ACL or Access result.
Required ACL Roles	Details of the role that is required to access the resource.
Role	Status of the role. Passed, Skipped, or Blocked.



View permissions for a user

Use Access Analyzer to view permissions for a selected user.

Before you begin

Role required: admin, access_analyzer_admin

The following procedure describes the sample steps to view permissions for a selected user (**ITIL User**) to view the permissions of the **Incident** table using the evaluate access in Access Analyzer.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
Access Analyzer is a ServiceNow® Store product.

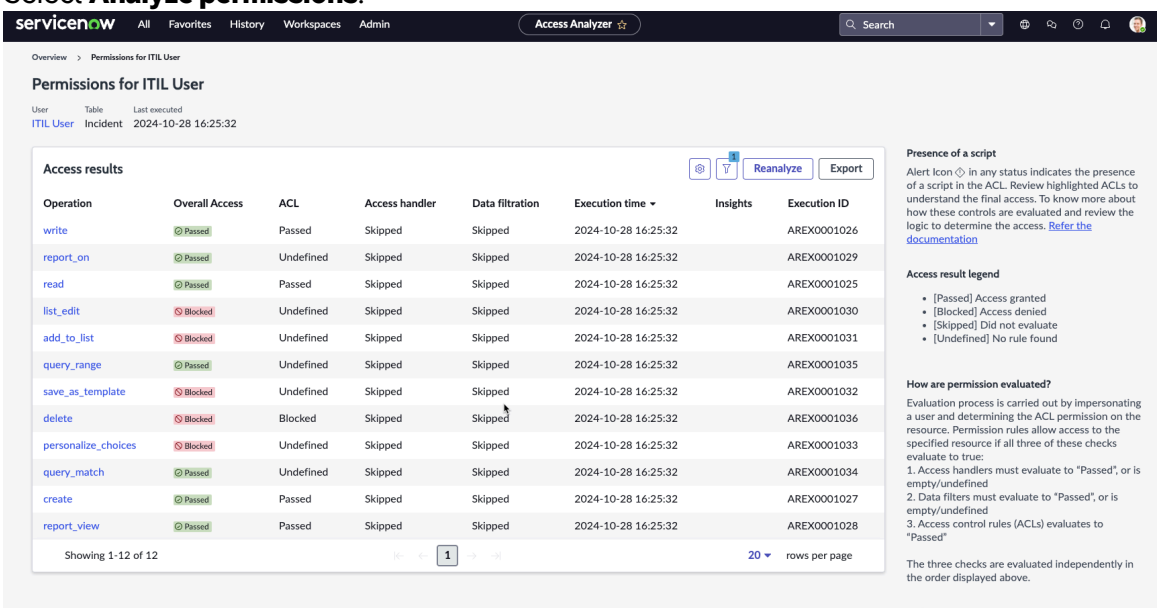
Procedure

1. Navigate to **All** > **Access Analyzer** > **Analyze Permissions**.
   The Analyze access and permissions homepage is displayed.
2. Select your criteria as follows:

Select your criteria for analyzing access and permissions

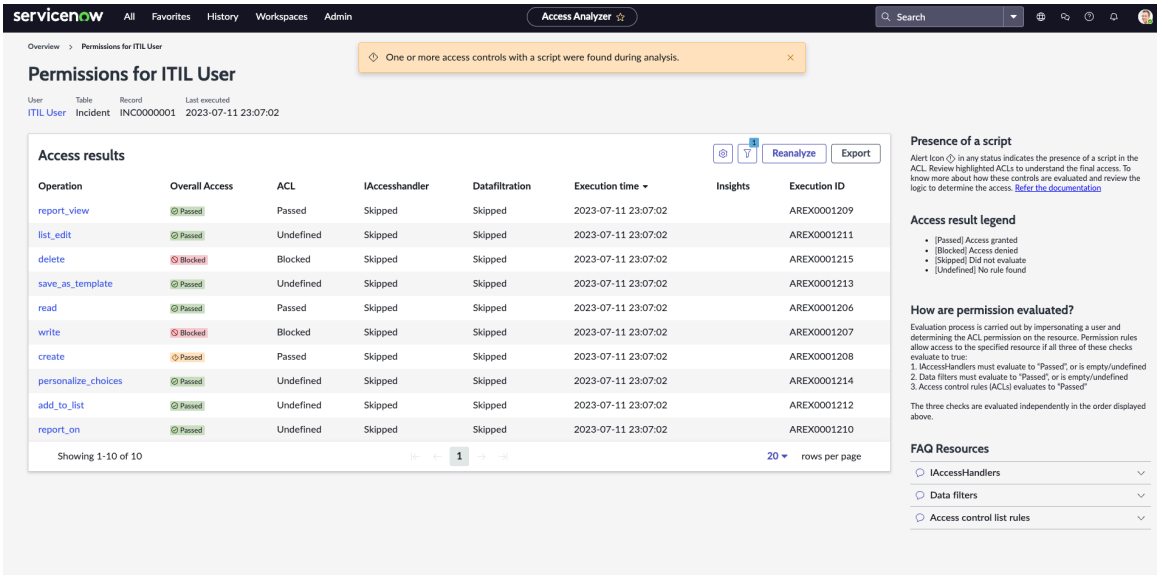
Field	Description
Analyze by *	Select **User**.
Select user *	Specify a user name to select from the list. In this example, **ITIL User**.
Rule type *	Analyze access for a **Table**, **UI page**, **REST Endpoint**, **client callable script include**, **AI agent**, or **Agentic workflow**. In the example, `Table`.
Select table *	Specify a table name to select from the list. In this example, **Incident**.
Select record	Specify a record name to select from the list. In this example, **INC0000001**.
Select field	Specify a field name to select from the list. This field can be used to analyze permission even at a field level. For example, Active, Created By, and so on.

3. Specify the description in the **Description** field.
4. Select **Analyze permissions**.



The **Access results** for the **ITIL User** is displayed.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



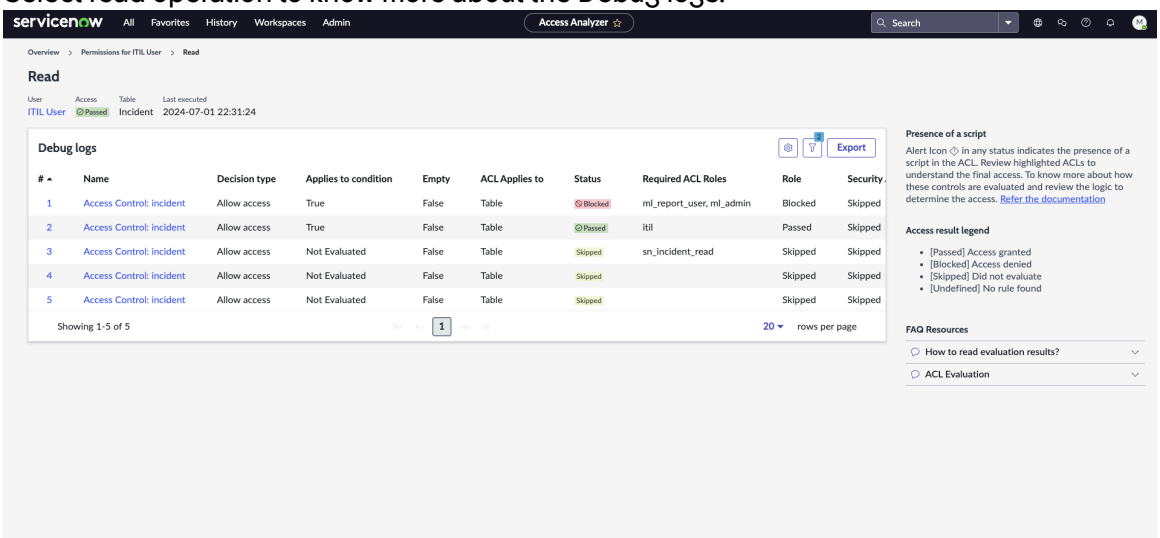
The results can be read, by referring to the Legends, access control list (ACL), IAccesshandler, and Data filters.

Let's take the example of **read** operation. For the **ITIL User** overall access is Passed, which means the user is able to read the record with the correct permissions (ACL).

Similarly for **create** operation, the overall access is passed with an alert icon, which means that there could be a presence of script for the ACL evaluation.

Note:
In the example, **write** and **delete** operations are blocked for the selected user and the user can't edit or delete the selected record (INC0000001).

5. Select read operation to know more about the Debug logs.



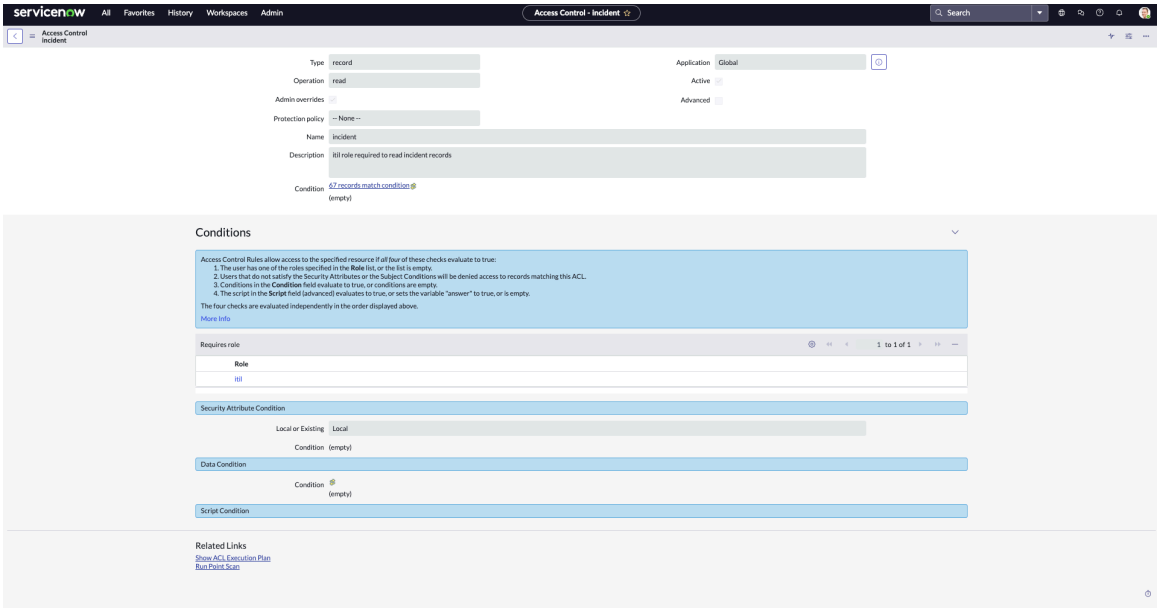
The Debug logs page displayed the business rule and associated ACLs that are required to perform the **read** operation for the record.

The Debug logs shows that there's a business rule and 4 ACLs associated for the read operation.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

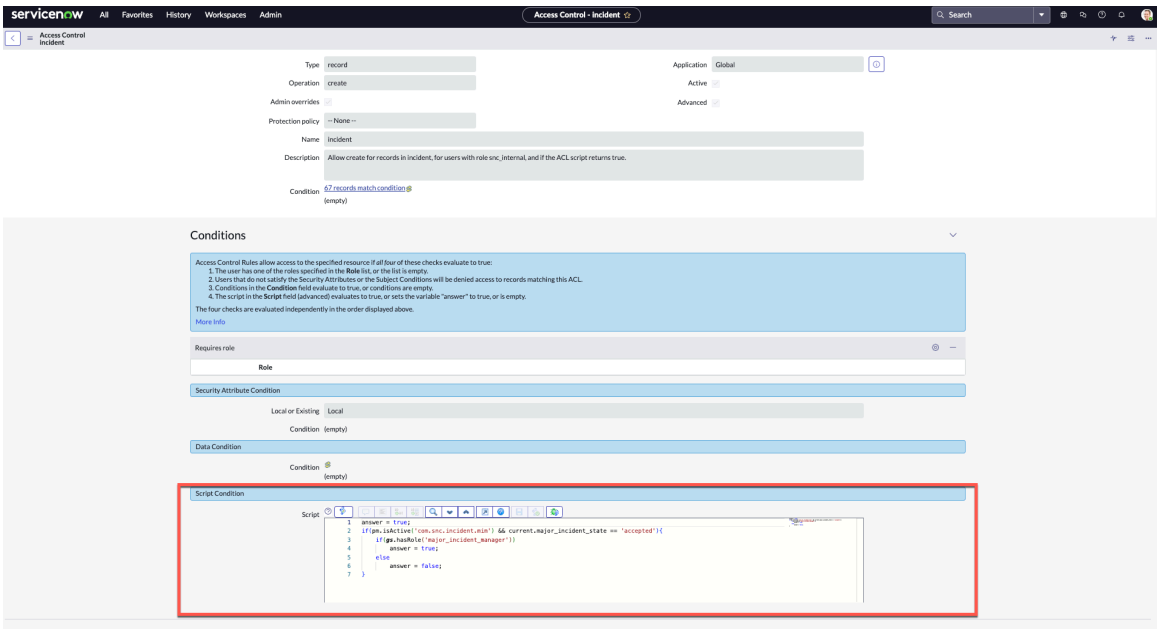
There's a status **Passed** for one of the ACL, which means to read the selected record, the user has the required ACL and can read the record. Since one of the ACL is **Passed**, the other ACL evaluations are **Skipped**.

6. Select the Access Control that is Passed to know the details of the ACL.



The details of the Access Control for the selected ACL are displayed.

For a selected operation with the **Passed** and a presence of a script. The Access Control page displays the associated script for the record.



View permissions for a role

Use Access Analyzer to view permissions for a selected role.

Before you begin

Role required: admin, access_analyzer_admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The following procedure describes the sample steps to view permissions for a selected role (**user_admin**) to view the permission for a REST API Endpoint using the evaluate access in Access Analyzer.

Note:
Access Analyzer is a ServiceNow® Store product.

Procedure

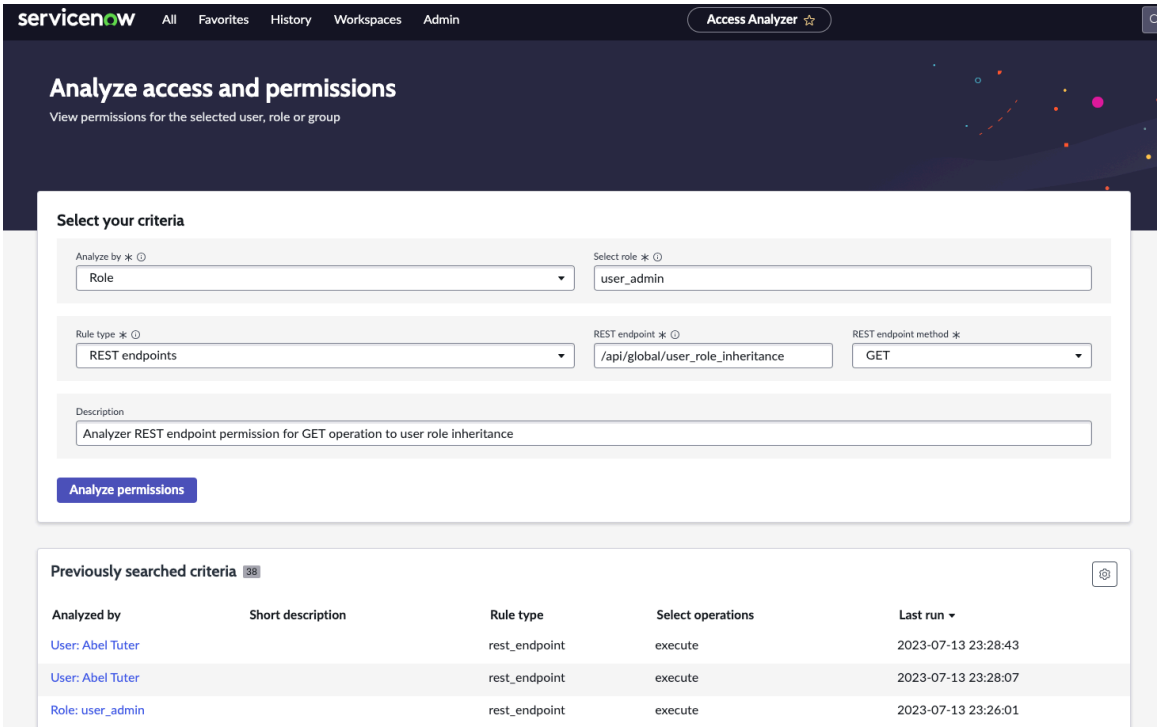
1. Navigate to **All** > **Access Analyzer** > **Analyze Permissions**.
   The Analyze access and permissions homepage is displayed.
2. Select your criteria as follows:

Select your criteria for analyzing access and permissions

Field	Description
Analyze by *	Select **Role**.
Select user *	Specify a role to select from the list. For example, **user_admin**.
Rule type *	Analyze access for a table, a UI page, a REST Endpoint, or a client callable script include. For example, **REST Endpoint**.
REST endpoint*	Specify a REST endpoint. For example, `/api/global/user_role_inheritance`. **Note:** The complete REST endpoint must be used when using the selected field.
REST endpoint method *	Specify a REST endpoint method. For example, GET.

3. Specify the description in the **Description** field.
4. Select **Analyze permissions**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



The **Access results** for the **user_admin** role is displayed.

The results can be read, by referring to the Legends, access control list (ACL), IAccesshandler, and Data filters.

The overall access for the role is passed, which means that the role (**user_admin**) is able to access the **REST endpoint** for the selected **GET** method.

View permissions for a group

Use Access Analyzer to view permissions for a selected group.

Before you begin

Role required: admin, access_analyzer_admin

The following procedure describes the sample steps to view permissions for a selected group (**Incident Management**) to view the permissions of an **Incident UI** page using the evaluate access in Access Analyzer.

Note:
Access Analyzer is a ServiceNow® Store product.

Procedure

1. Navigate to **All** > **Access Analyzer** > **Analyze Permissions**.
   The Analyze access and permissions homepage is displayed.
2. Select your criteria as follows:

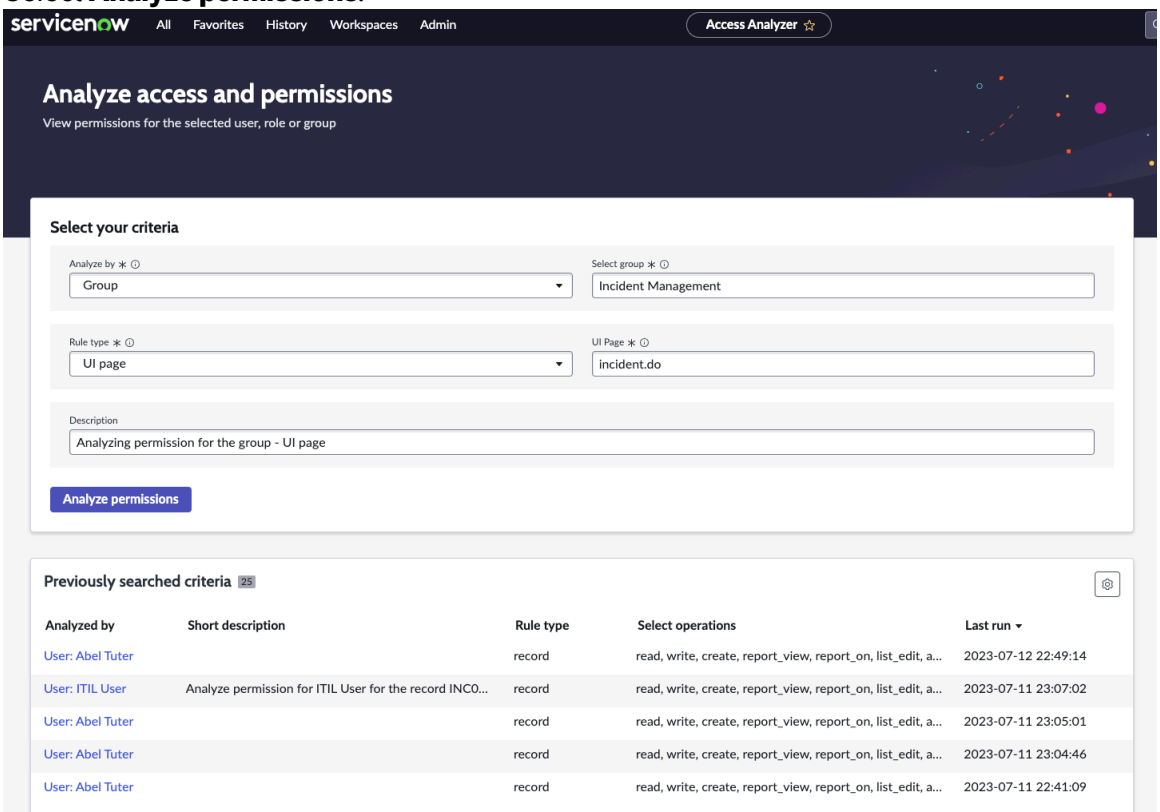
Select your criteria for analyzing access and permissions

Field	Description
Analyze by *	Select **Group**.
Select user *	Specify a user name to select from the list. For example, **Incident Management**.

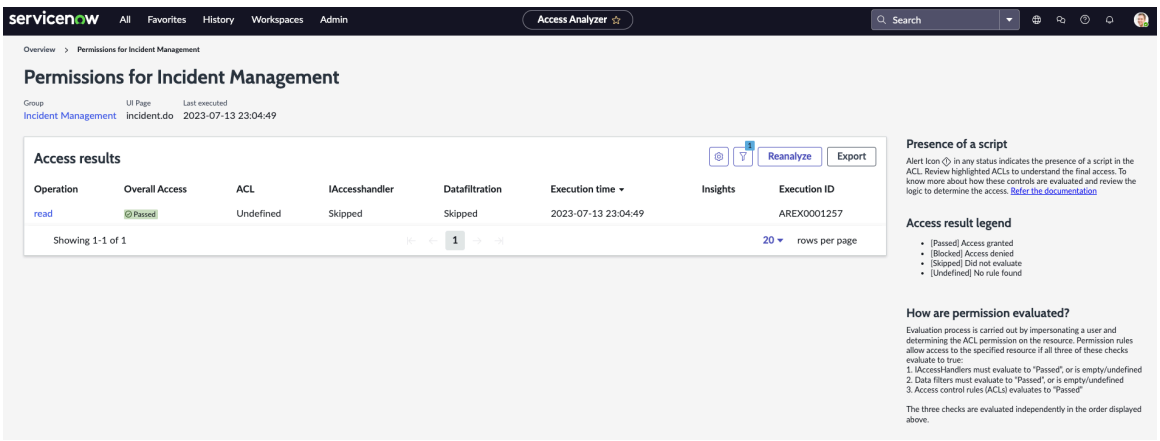
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Rule type *	Analyze access for a table, a UI page, a REST Endpoint, or a client callable script include. For example, **UI page**.
UI Page *	Specify the UI page. For example, **incident.do**.

3. Specify the description in the **Description** field.
4. Select **Analyze permissions**.



The **Access results** for the **Incident Management** group is displayed.



The results can be read, by referring to the Legends, access control list (ACL), IAccesshandler, and Data filters.

The overall access for the group is passed, which means that the users within the group (**Incident Management**) are able to access the Incident record.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Export Access Analyzer queries

Export the queries analyzed using Access Analyzer.

Before you begin

Role required: admin, access_analyzer_admin

The following procedure describes the steps for accessing Access Analyzer and using various features within Access Analyzer.

Note:
Access Analyzer is a ServiceNow® Store product.

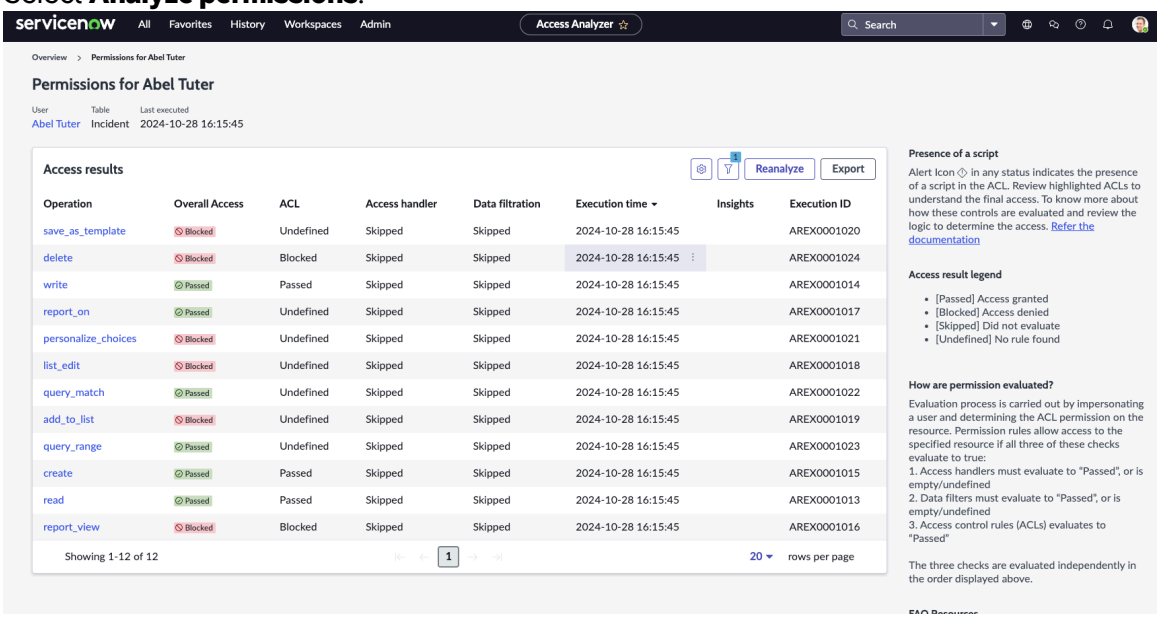
Procedure

1. Navigate to **All** > **Access Analyzer** > **Analyze Permissions**.
   The Analyze access and permissions homepage is displayed.
2. Select your criteria as follows:

Select your criteria for analyzing access and permissions

Field	Description
Analyze by *	Analyze access for a user, a role, or a group
Select user *	Specify a user name to select from the list.
Rule type *	Analyze access for a table, a UI page, a REST Endpoint, or a client callable script include.
Select table *	Specify a table name to select from the list.
Select record	Specify a record name to select from the list.
Select field	Specify a field name to select from the list.

3. Specify the description in the **Description** field.
4. Select **Analyze permissions**.

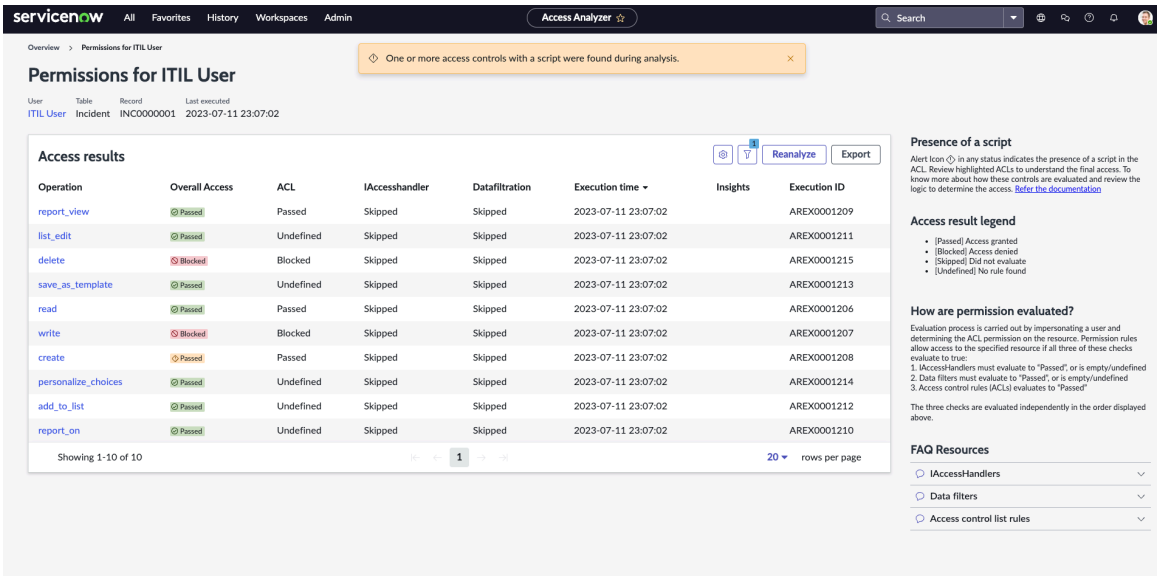


The access results for the user are displayed. Similarly you can analyze the permissions of a Group, Role for the following rule types:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Table (record)
- Client callable script include
- REST endpoints

The **Access results** for the selected rule type is displayed.



5. Click **Export**.

   a. Choose the File Type.

   Available file types are Excel, CSV, JSON, PDF.

   b. Choose the Delivery Type.

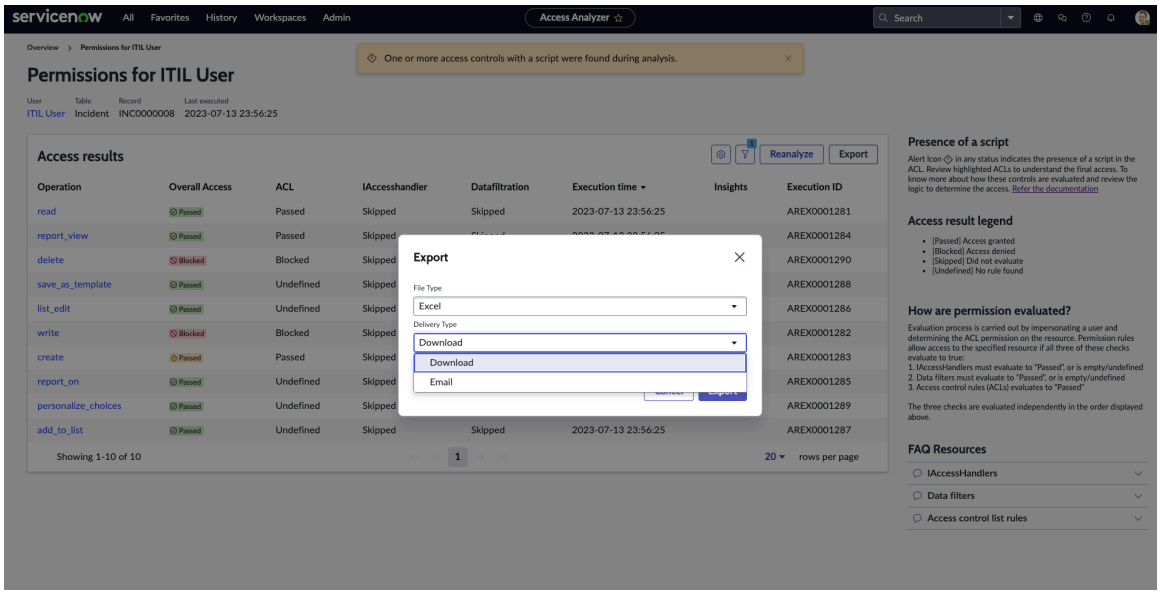
Available delivery types as Download and Email.



Compare user records

Compare user records to understand the access between two users.

Before you begin

Role required: admin, access_analyzer_admin

The following procedure describes the steps for comparing user records using the Access Analyzer.

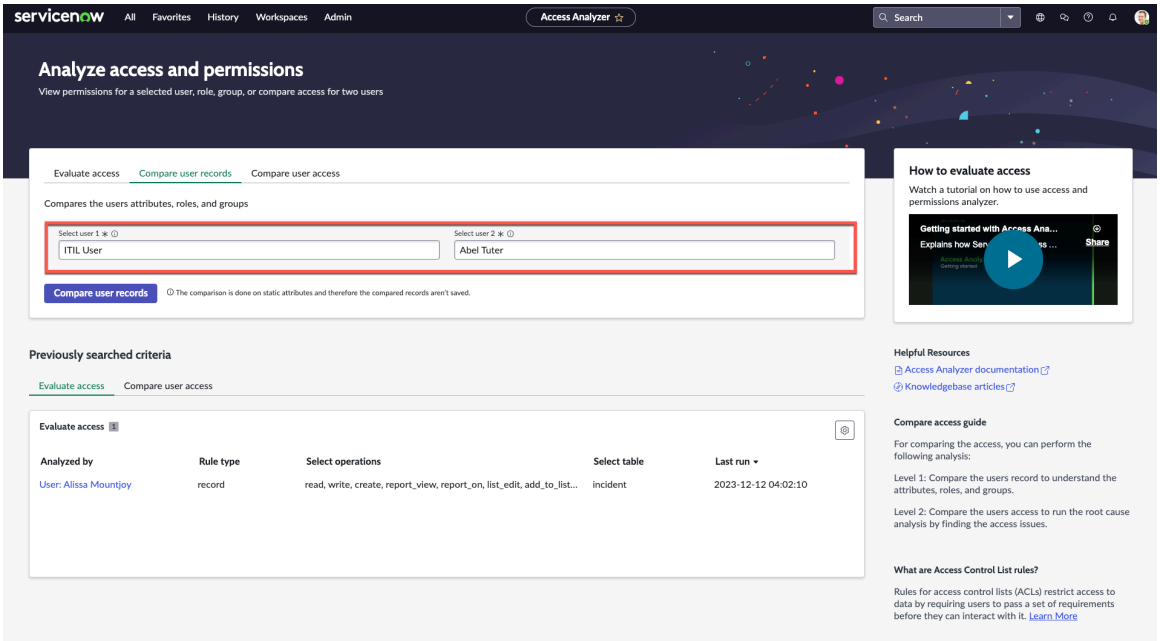
> **Note:**
> Access Analyzer is a ServiceNow® Store product.

Procedure

1. Navigate to **All** > **Access Analyzer** > **Analyze Permissions**.
   The Analyze access and permissions homepage is displayed.
2. Select the **Compare user records** tab.
3. Select **user 1** and **user 2** for comparison.

   For example, `ITIL User` as **user 1** and `Abel Tuter` as **user 2**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

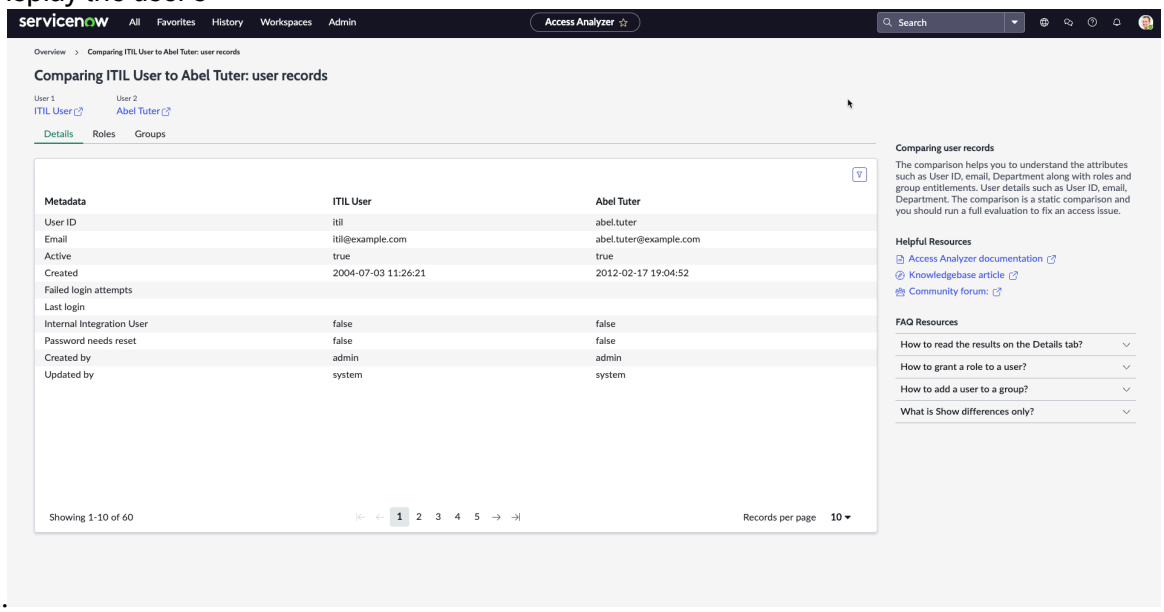


4. Select **Compare user records**.

   The results are displayed with the following tabs:

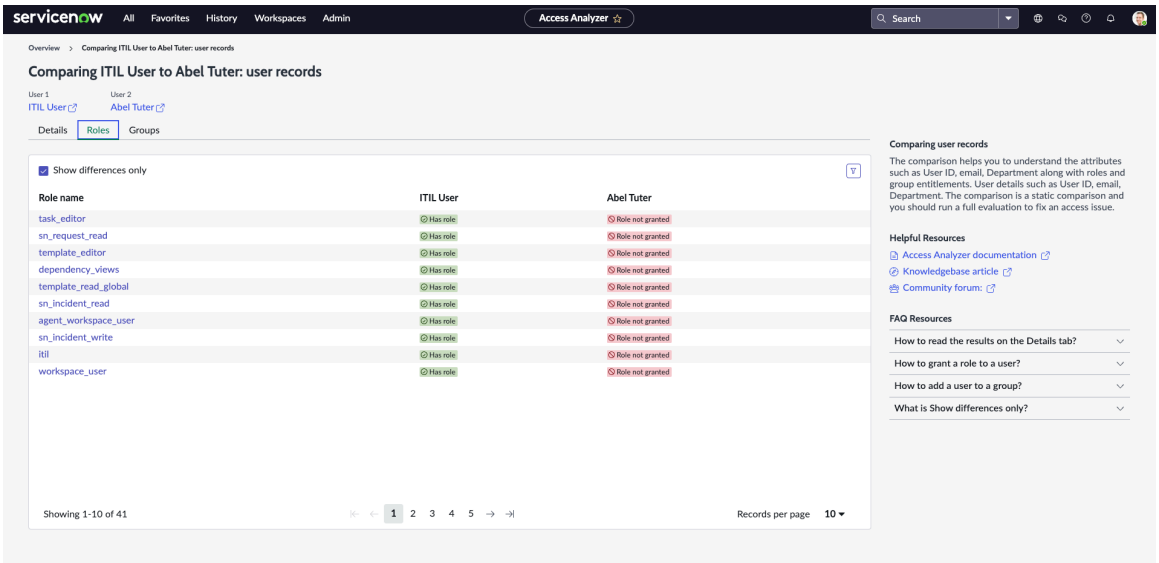
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **Details**: Display the user's



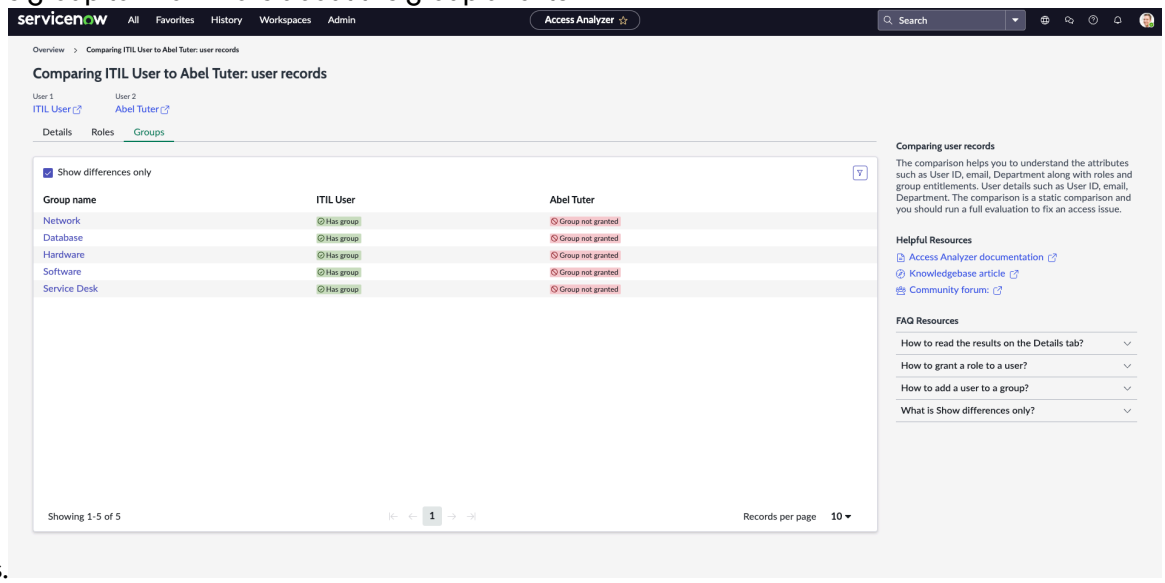
metadata.

- **Roles**: Display the roles that are assigned to the user. You can select the role to know more about the role and its entitlements.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **Groups**: Display the groups that are assigned to the user. You can select the group to know more about the group and its entitlements.



Similarly you can compare different users in the ServiceNow instance to understand the access that is assigned to the users.

Compare user access

Compare the user's access control using the Access Analyzer.

Before you begin

Role required: admin, access_analyzer_admin

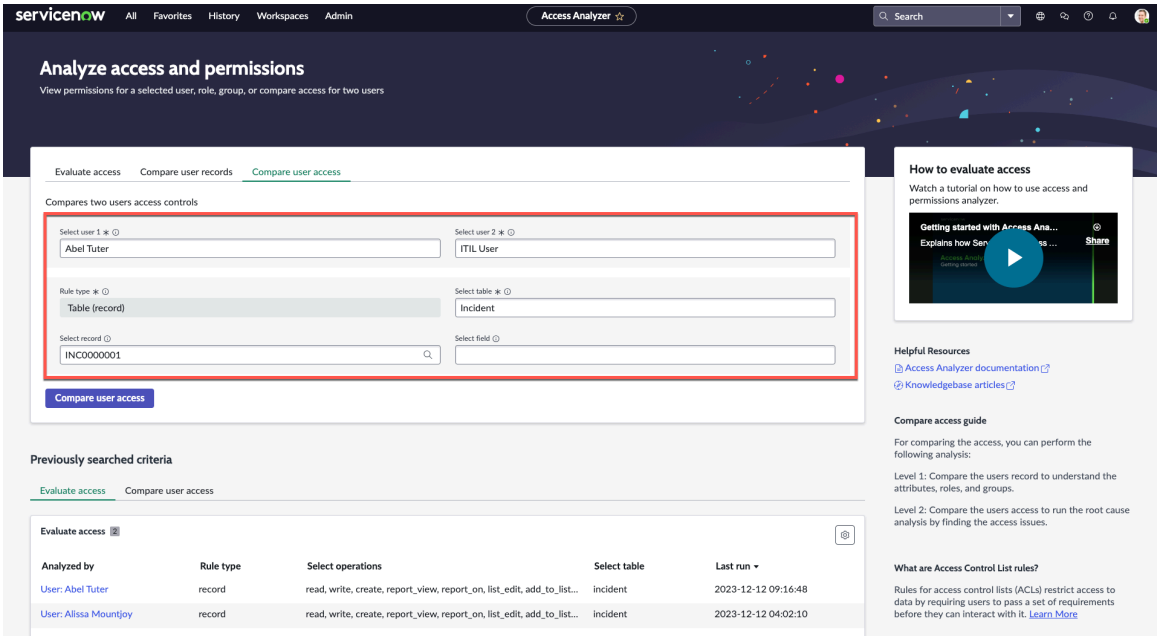
The following procedure describes the steps for comparing the access control between the users using the Access Analyzer.

Note:
Access Analyzer is a ServiceNow® Store product.

Procedure

1. Navigate to **All** > **Access Analyzer** > **Analyze Permissions**.
   The Analyze access and permissions homepage is displayed.
2. Select the **Compare user access** tab.
3. Fill in the following fields:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Compare user access

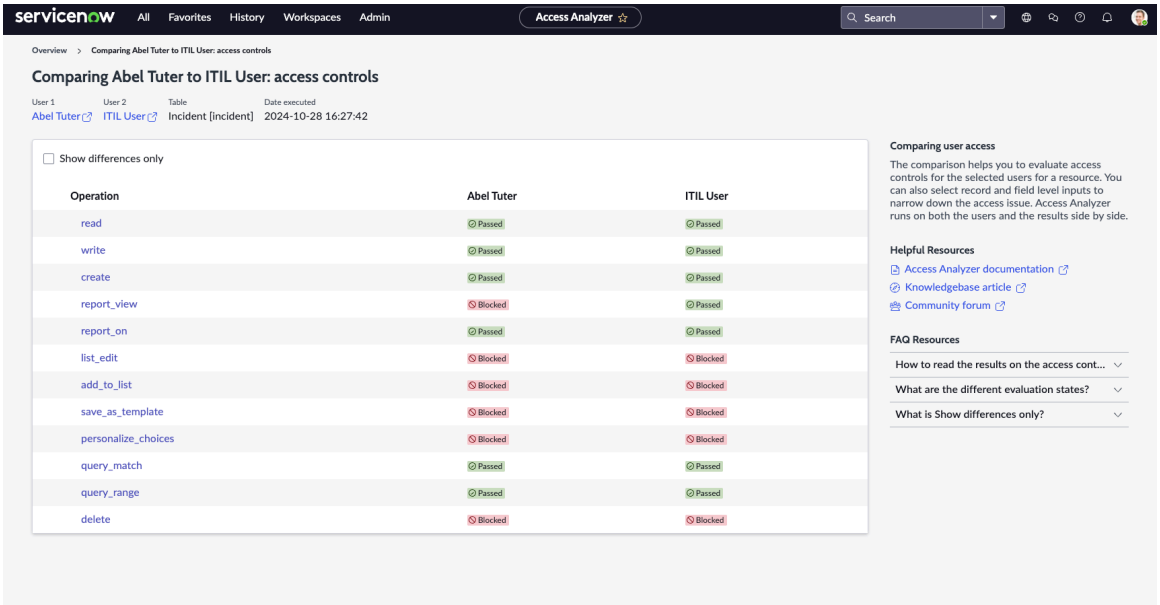
Field	Description
Select user 1*	Specify a user name to select from the list for the comparison.
Select user 2*	Specify a user name to select from the list to compare with the user 1.
Rule Type*	Analyze access permissions for a table. **Note:** Only access permissions for a table can be used in the **compare user access**.
Select table*	Specify a table name to select from the list.
Select record	Specify a record name to select from the list.
Select field	Specify a field name to select from the list.

4. Select **Compare user access**.

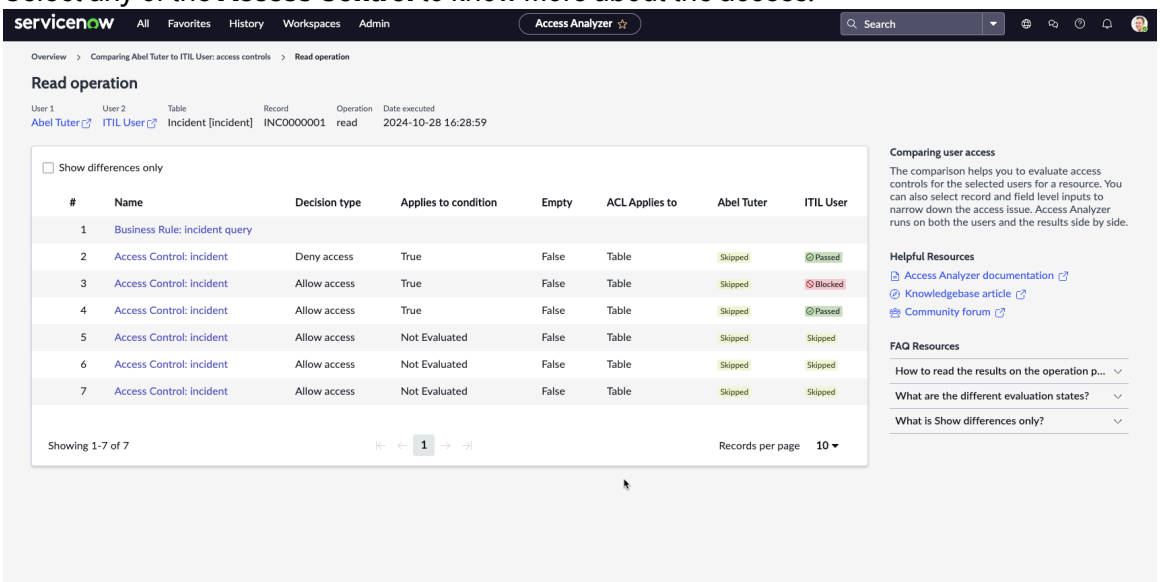
   The **compare user access** results for the selected users are displayed.

   The compare user access results show the operation and the access evaluation status for the users. For example, Abel Tuter and ITIL User.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

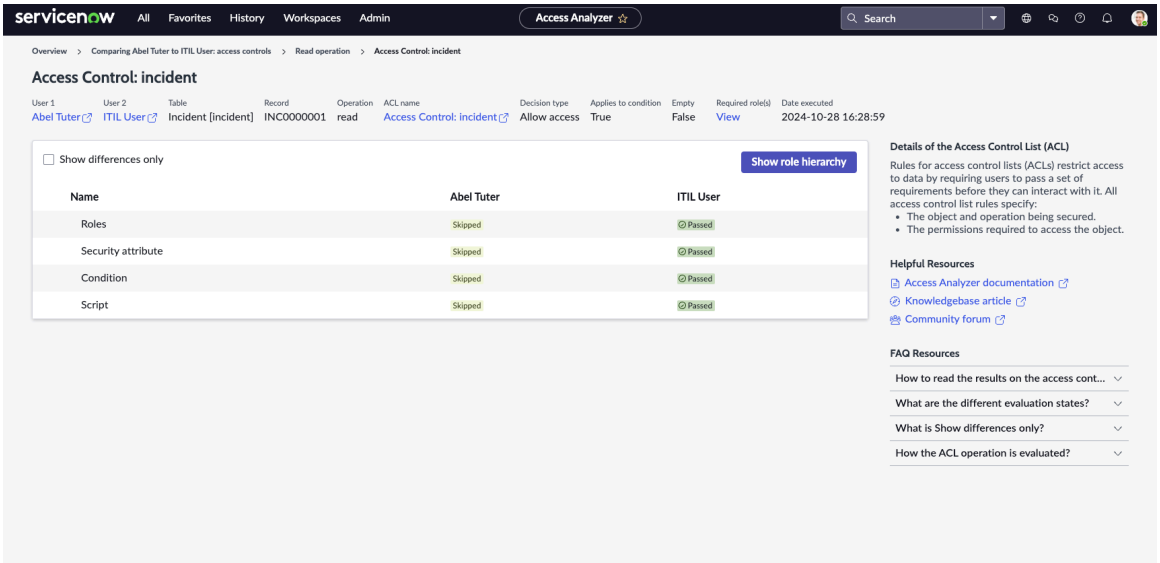


5. Select the Operation to know more about the permission evaluation and the roles the users are assigned to.
   For example, **read** operation.
6. Select any of the **Access Control** to know more about the access.



The Access Control details such as Roles, Security Attribute, Condition, and Script evaluation status are displayed.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



7. Select **Show role Hierarchy** to know more about the roles and groups the user is assigned and compare both the users.

   Based on the role hierarchy, you can assign the necessary role and group assignments to the user to have access to the resources (table).

   In the example, **Abel Tuter** doesn't have `itil` assigned. You can determine the necessary role and group assignments to the user by looking into the role hierarchy.

   You can select the node to learn more about the role, resources the role can access, or group.

View the previously searched criteria in Access Analyzer

View the previously searched criteria in Access Analyzer.

Before you begin

Role required: admin, access_analyzer_admin

> **Note:**
> Access Analyzer is a ServiceNow® Store product.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

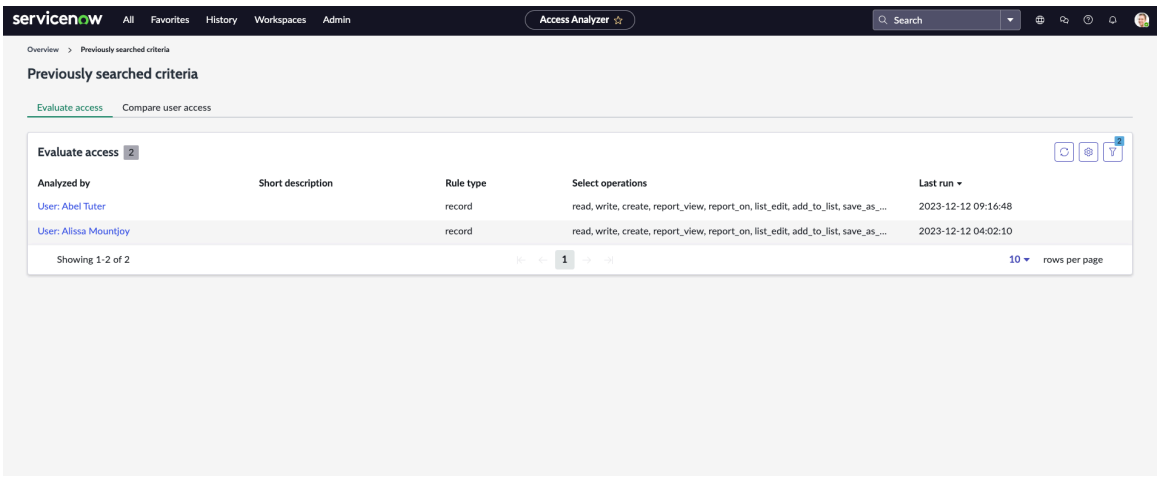
Procedure

1. Navigate to **All** > **Access Analyzer** > **Access Analyzer Queries**.

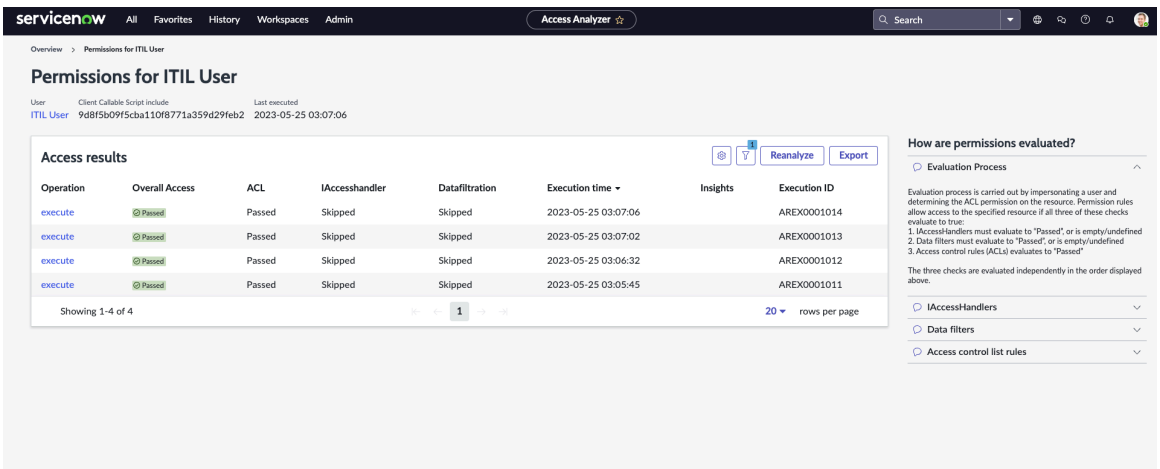
   Previously searched criteria has the following sections:

   - **Evaluate access**: Displays results based on queries made through the **Evaluate access** features.
   - **Compare user access**: Displays results based on queries made through the **Compare user access** features.

   Note:
   The previously searched criteria are not stored when using the compare user records feature.



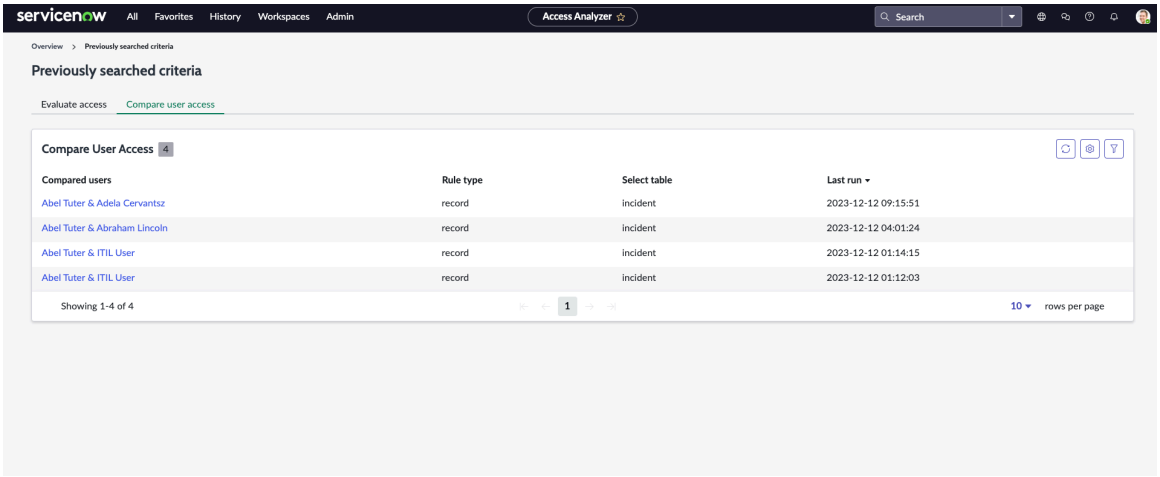
2. Select the **Analyzed by** links to view previously searched criteria from the Evaluate access section.



You can select **Reanalyze** the access for the user. Export the details using the **Export** option.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. Select the **Compared users** links to view the previously searched criteria from the Compare user access section.



Permission evaluation

Permission evaluation criteria when using the Access analyzer.

Evaluation hierarchy

Permission for the selected user, group, or role is evaluated in the following hierarchy:

- Business rule: A business rule is a server-side script that runs when a record is displayed, inserted, updated, or deleted, or when a table is queried.
- Access Handler: An internal system check using hidden source code on the platform.
- Data Filtration: Data filter is a form of access control designed to work along with the existing Access Control rules (ACLs) on your instance. Data filter support only read operation.
- Access control list (ACL): Rules for access control lists (ACLs) restrict access to data by requiring users to pass a set of requirements before they can interact with it. Within an ACL, the following hierarchy is evaluated:
  - Role
  - Security Attribute
  - Condition
  - Script

You can analyze access and permissions for the selected user, role, or group using the Access Analyzer. The permissions are evaluated based on the following rule types:

- **Table Level Evaluation**: Role and security attribute ACLs are used for Table level evaluation.
- **Record or Field level Evaluation**: Role, security attribute, condition, and script level ACLs are used for Record or Field level evaluation.
- **UI page**: Support Only ready operations. Only read level ACLs are evaluated.
- **REST Endpoint**: Support only execute operation. Only execute level ACL are evaluated.

Details about the important fields in the Access Results are as follows:

- Presence of a script
- Access result legend

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Evaluation process
- IAccessHandlers
- Data filters
- Access control list rules

Presence of a script

Alert Icon in any status indicates the presence of a script in the ACL. Review highlighted ACLs to understand the final access. To know more about how these controls are evaluated and review the logic to determine the access, see Access Analyzer Debug logs.

Legend in Access Analyzer

When Analyzing the access and permissions, legends are displayed as part of the evaluation process. Following are the legends:

- [Passed] Access granted
- [Blocked] Access denied
- [Skipped] Did not evaluate
- [Undefined] No rule found

Evaluation process

Evaluation process is carried out by impersonating a user and determining the access control list (ACL) permission on the resource. Permission rules enable access to the specified resource if the following checks are evaluated to true:

- IAccessHandlers must evaluate to “Passed”, or is empty or undefined
- Data filters must evaluate to “Passed”, or is empty or undefined
- Access control rules (ACLs) evaluate to “Passed”

IAccessHandlers

An internal system check using hidden source code on the platform. IAccessHandler can grant or deny access to a resource without evaluating ACLs. If IAccessHandler is ignored, then the ACLs are evaluated.

You can’t change the IAccessHandler checks. For example, an IAccessHandler implementation is used for access checks on application resources such as read access.

Data filter

Data filter is a form of access control designed to work along with the existing Access Control rules (ACLs) on your instance.

Access control list rules

Rules for access control lists (ACLs) restrict access to data by requiring users to pass a set of requirements before they can interact with it.

Frequently Asked Questions

Frequently asked questions while using the Access analyzer.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Evaluate Access

The following are some of the frequently asked questions while using the Evaluate Access feature in the Access Analyzer:

Frequently asked questions

Questions	Explanation
How to read the evaluation results displayed by the Access Analyzer?	Each row represents an individual access control list (ACL). The sequence (#) in the results the order in which ACLs are evaluated. The status shows whether overall access is granted (passed) or denied (blocked).
How are ACLs Evaluated?	At a table level, ACLs are evaluated only for roles and security attributes, conditions and scripts aren't evaluated. Roles are evaluated first. If Roles are blocked, conditions and scripts are skipped. For more information, see Configure an ACL rule.
What are the legends in Access Analyzer?	When Analyzing the access and permissions, legends are displayed as part of the evaluation process. The following are the legends: • [Passed] Access granted • [Blocked] Access denied • [Skipped] Didn't evaluate • [Undefined] No rule found
What is the Alert icon in the Access results mean?	Alert Icon in any status indicates the presence of a script in the ACL. Review highlighted ACLs to understand the final access. To know more about how these controls are evaluated and review the logic to determine the access, see Access Analyzer Debug logs.
What is **IAccesshandler**?	An internal system check using hidden source code on the platform. It's a system security check that you can't modify. **IAccessHandler** can grant or deny access to a resource without evaluating ACLs. If this **IAccessHandler** is ignored, then the ACLs are evaluated. You can't modify the **IAccessHandler** checks in any way. For example, an **IAccessHandler** implementation is used for access checks on application resources such as read-only access.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Frequently asked questions (continued)

Questions	Explanation
What are data filters?	Data filters are a form of access control designed to work along with the existing Access Control rules (ACLs) on your instance.
What is an ACL rule?	Rules for access control lists (ACLs) restrict access to data by requiring users to pass a set of requirements before they can interact with it.

Time limited role assignments found for the user due to which the results may be impacted. You can review the time-limited roles assigned for the user here.

Compare user records

The following are some of the frequently asked questions while using the Compare user record feature in the Access Analyzer:

Frequently asked questions

Questions	Explanation
How to read the results on the Details tab?	The Details tab displays the metadata associated to the user 1 and user 2
How to grant a role to a user?	From the Users tab, you can check the role that must be granted for the user and assign that role.
How to add a user to a group?	From the Groups tab, you can check the group the user must be added and add the user to the group.
What is Show difference only?	When you enable the Show differences only check box, only the roles or group that are different between the user 1 and user 2 is displayed.

Compare user access

The following are some of the frequently asked questions while using the Compare user access feature in the Access Analyzer:

Frequently asked questions

Questions	Explanation
How to read the results on the access control comparison page?	The access control comparison page displays the evaluation states for different ACL operations.
What are the different evaluation states?	When comparing access controls between the users, following are the different evaluation states:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Frequently asked questions (continued)

Questions	Explanation
	• Passed • Blocked
What is show differences only?	When you enable the Show differences only check-box, only the operation evaluation state that are different between the user 1 and user 2 is displayed.
How the ACL operation is evaluated?	Access control list (ACL) is the rule for access control lists (ACLs) that restrict access to data by requiring users to pass a set of requirements before they can interact with it. Within an ACL, the following hierarchy is evaluated: • Role • Security Attribute • Condition • Script
How to read the results on the showing role hierarchy page?	The showing role hierarchy page displays the role that is assigned for user 1 and user 2. You can understand the role that is required for the user for a particular ACL operation.
How can I see the details of the user?	You can select the **User (node)** > **More actions** > **View user** details to know more about the user.
How can I see the details of the role?	You can select the **Role (node)** > **More actions** > **View role** details to know more about the role.
How can I see the details of the resources the role can access?	You can select the **Role (node)** > **More actions** > **View all resources that the role has access** to know the resources the role can access.
How can I see the details of the group?	You can select the **Group (node)** > **More actions** > **View group** details to know more about the group.

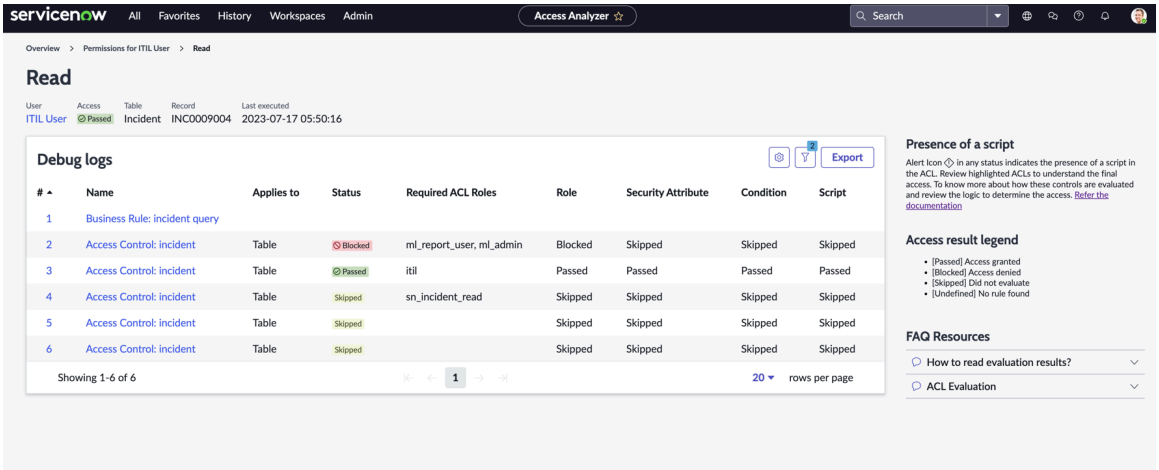
Access Analyzer Debug logs

Debug logs display the details of the select access result operation.

Fields in Debug logs

The Debug logs in the Access Analyzer displays information about the selected operation to understand the permissions, business rules, and ACLs associated with the operation.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Following are the fields and their description in the Debug logs:

Debug logs

Fields	Description
Name	The details about the business rule or ACL. You can select the business rule of ACL for more information.
Applies to	The details about the application of ACL at a field, record, or table level.
Status	Status of the ACL for the associated role and permission.
Requires ACL	The role that is required for accessing the field, record, or table.
Role	The details about the role being Blocked, Passed, Skipped for the Access Control.
Security Attribute	The details about the security attribute being Blocked, Passed, Skipped for the Access Control.
Condition	The detail about the condition being Blocked, Passed, Skipped for the Access Control.
Script	The details about the script being Blocked, Passed, Skipped for the Access Control.
Customized	The details about the customized ACL if any for the Access Control.
Application	Status of the Application. Global or Store.

Evaluation hierarchy

Permission for the selected user, group, or role is evaluated in the following hierarchy:

- Business rule: A business rule is a server-side script that runs when a record is displayed, inserted, updated, or deleted, or when a table is queried.
- Access Handler: An internal system check using hidden source code on the platform.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Data Filtration: A data filter is a form of access control designed to work along with the existing Access Control rules (ACLs) on your instance. Data filters support only read operation.
- Access control list (ACL): Rules for access control lists (ACLs) restrict access to data by requiring users to pass a set of requirements before they can interact with it. Within an ACL, the following hierarchy is evaluated:
  - Role
  - Security Attribute
  - Condition
  - Script

Access control list evaluation

ACLs for the operations are evaluated in the sequence as follows:

- Role
- Security Attribute
- Condition
- Script

Presence of a script

Alert Icon in any status indicates the presence of a script in the ACL. Review highlighted ACLs to understand the final access.

Note:
During an Access analyzer query, business rules are executed first and then the access control list.

Sequence of execution

The sequence of access result execution in different scenarios is as follows:

- **Presence of an inherited or wildcard ACL**: During the sequence of execution the inherited ACLs are evaluated first and then wildcard ACL.
- **One ACL is passed the others are skipped**: During execution and evaluation of permission if one ACL is passed the other ACL execution and evaluation is skipped. Because the overall permission for the selected operation requires one ACL to access a field, record, or table for an identity.
- **Field level ACL and table level ACLs execution**: During execution field level ACLs are executed first followed by table level ACL to provide more granular results when analyzing the access for an identity.
- **Evaluation in the presence of scripted ACL**: When there's a presence of a script, the overall access for the operation is passed with an Alert icon to indicate the script in the ACL.

Access Simulator

The Access Simulator helps you simulate how access to the specified table would change once a role or group is assigned or removed from the user.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Explore Learn the features and business value of Access Simulator.	Use Understand how to use Access Simulator.
Configure Know how to configure Access Simulator.	Frequently asked questions Get details about commonly asked questions for Access Simulator.

Exploring Access Simulator

Access Simulator helps you simulate how access to the specified table would change once a role or group is assigned or removed from the user.

Administrators can use the Access Simulator to simulate the access requirements of their users on a specified table and understand how the access controls changes for a user. It helps in quickly understanding the present access of the users and understand the impacts of providing or removing roles to the users.

https://player.vimeo.com/video/988627830?badge=0&autopause=0&player_id=0&app_id=58479

Access Simulator can be used for the simulating access on a user for the following scenarios:

- Adding Roles to users
- Removing Roles from users
- Adding users to Groups
- Removing users from Groups

To know more about the Access Simulator settings and enable take actions, see Configuring the Access Simulator (Take actions).

Configuring the Access Simulator (Take actions)

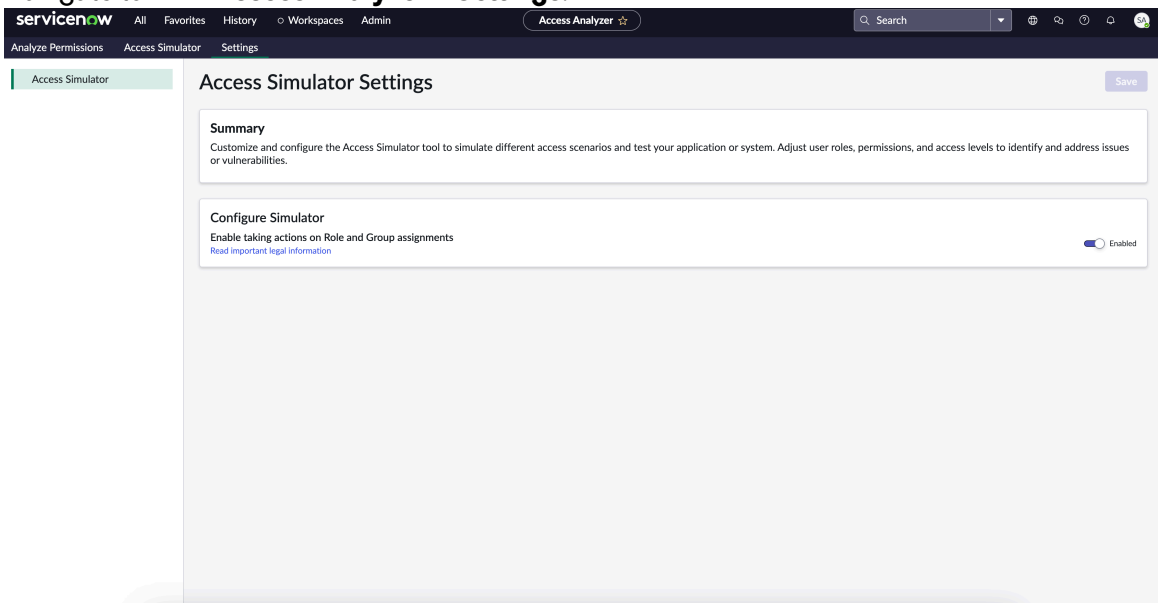
Configure the take actions options to complete the role and group assignments that you wish to add after the simulation.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin
Role required: admin, access_analyzer_admin

Procedure

1. Navigate to **All** > **Access Analyzer** > **Settings**.



2. Select the toggle switch to enable.
   Read through the legal information before enabling the Access Simulator (Take actions).
3. Select **Accept**.
4. Select **Save** to save the configuration.

Using the Access Simulator

Use the Access Simulator to simulate the user's access to the specified table would change once a role or group is assigned or removed.

Before you begin
Role required: admin, access_analyzer_admin

Enable the take actions. For more information, see Configuring the Access Simulator (Take actions).

Procedure

1. Navigate to **All** > **Access Analyzer** > **Access Simulator**.
2. Select the **Simulate** option under each section based on the following scenarios:
   - Adding Roles to users
   - Removing Roles from users
   - Adding users to Groups
   - Removing users from Groups

Adding Roles to users

Use the **Simulate Add Role** for simulating the user's access changes for a resource (tables).

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin

Role required: admin, access_analyzer_admin

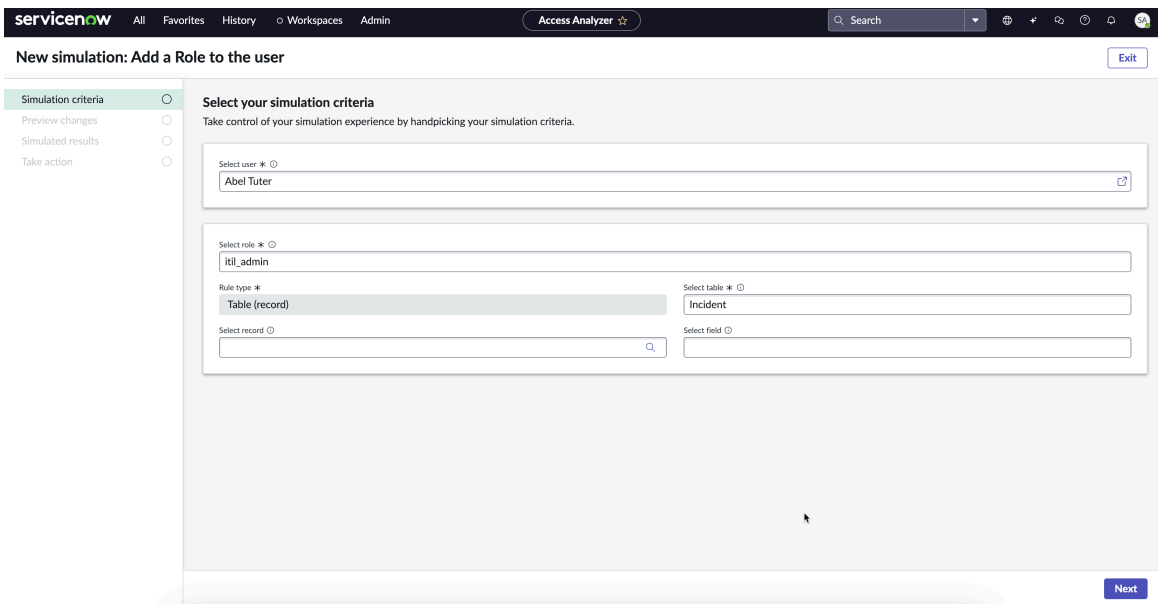
Enable the take actions. For more information, see Configuring the Access Simulator (Take actions).

Procedure

1. Navigate to **All** > **Access Analyzer** > **Access Simulator**.
2. Select **Simulate** from the Add a Role to the user section.
3. Specify the following fields for your simulation criteria:

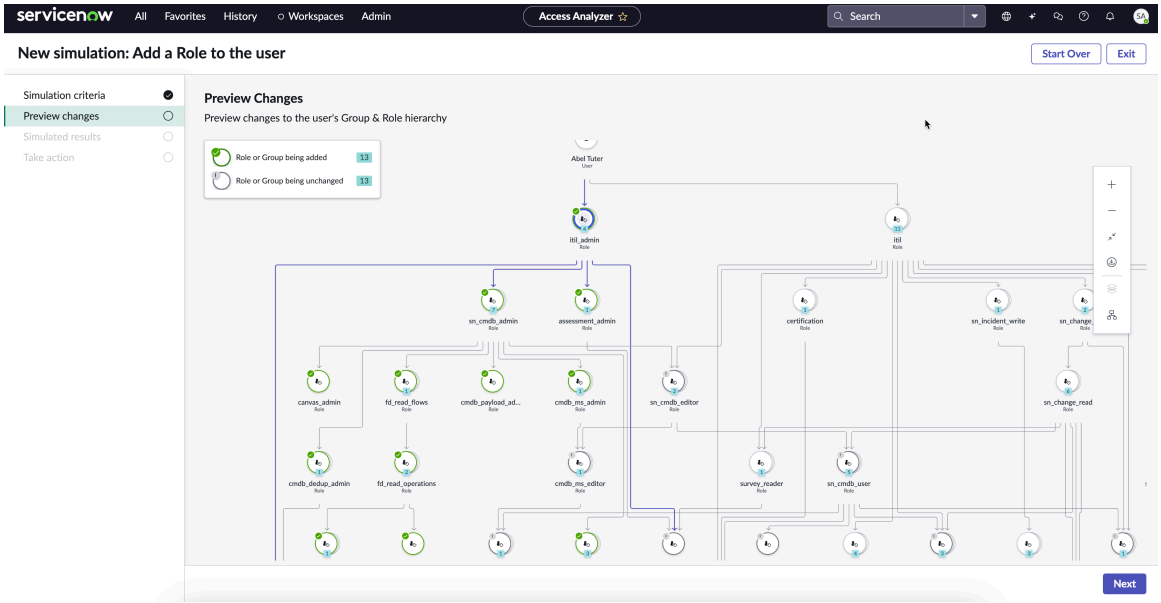
Add a Role to the user

Field	Description
Select user *	Specify a user name to select from the list. In this example, **Abel Tuter**.
Select role *	Specify a role to select from the list. In this example, **itil_admin**.
Rule type *	Rule type is auto-populated and it can't be changed.
Select table *	Specify a table name to select from the list. In this example, **Incident**.
Select record	Specify a record name to select from the list (Optional).
Select field	Specify a field name to select from the list. This field can be used to analyze permission even at a field level. For example, Active, Created By, and so on.



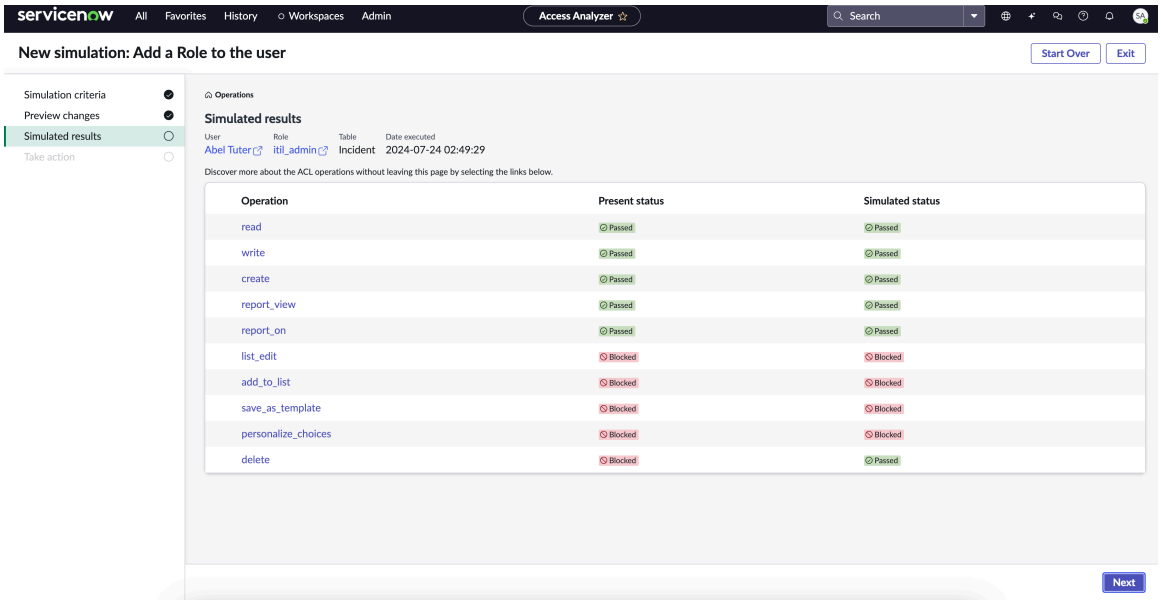
4. Select **Next**.
5. Preview the changes.
   The roles that are newly assigned are simulated in the Preview changes. You can validate the roles and child roles that are being added to the user before moving to the next step.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



You can see the new roles that are being added as part of **itil_admin** role is displayed along with the existing roles of the user.

6. Select **Next**.
7. Validate the **Present status** and **Simulated status** to verify the access that is being **Passed** or **Blocked** to the simulated user.



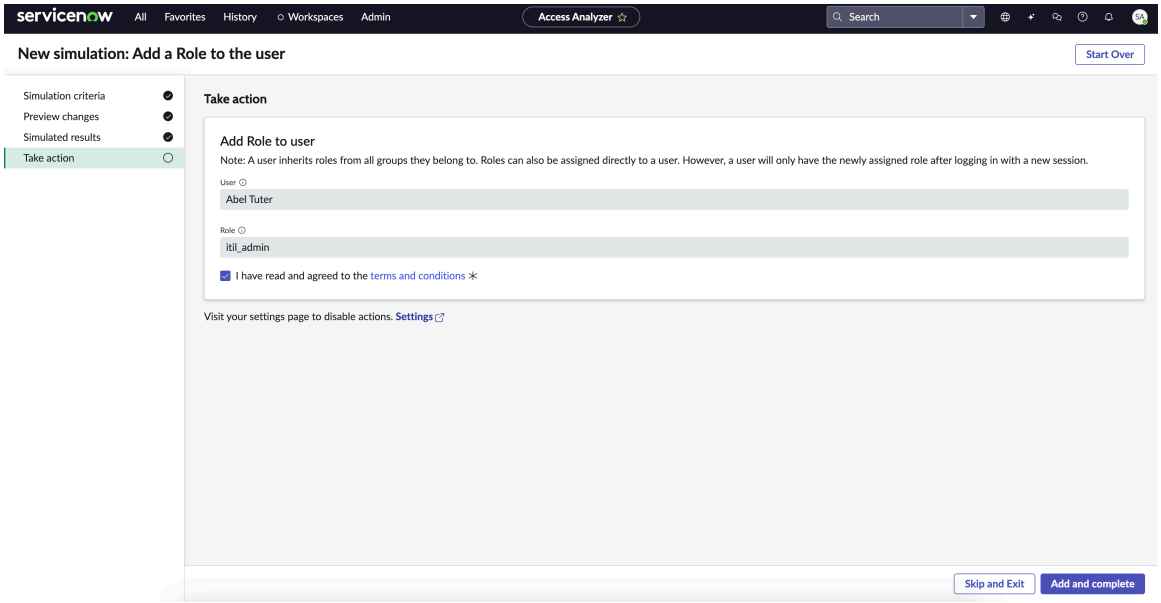
Adding the **itil_admin** enables the user to perform delete operation on the table (Incident).

Note:

- If you want to know more about the ACL (operations), select the operation links for each record.
- If you want to start the simulation again for a different role, select **Start over**.
- If you want to exit the simulation, select **Exit**.

8. Select **Next**.
9. Select **Add and complete**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Note:

- If the Access Simulator isn't enabled, you can't complete the simulation. To enable, select **Enable actions** and accept the legal information.
- If you want to hide the simulation, select **Hide actions**. To unhide and enable actions, go to the settings. For more information, see Configuring the Access Simulator (Take actions).
- If you want to exit the simulation, select **Skip and Exit**.

The roles are successfully added to the user. You can verify the access using the Access Analyzer. For more information about how to verify the access of a user, see Access analyzer.

Removing Roles from users

Use the **Simulate Remove Role** for simulating the user's access changes for a resource (tables).

Before you begin

Role required: admin, access_analyzer_admin

Enable the take actions. For more information, see Configuring the Access Simulator (Take actions).

Procedure

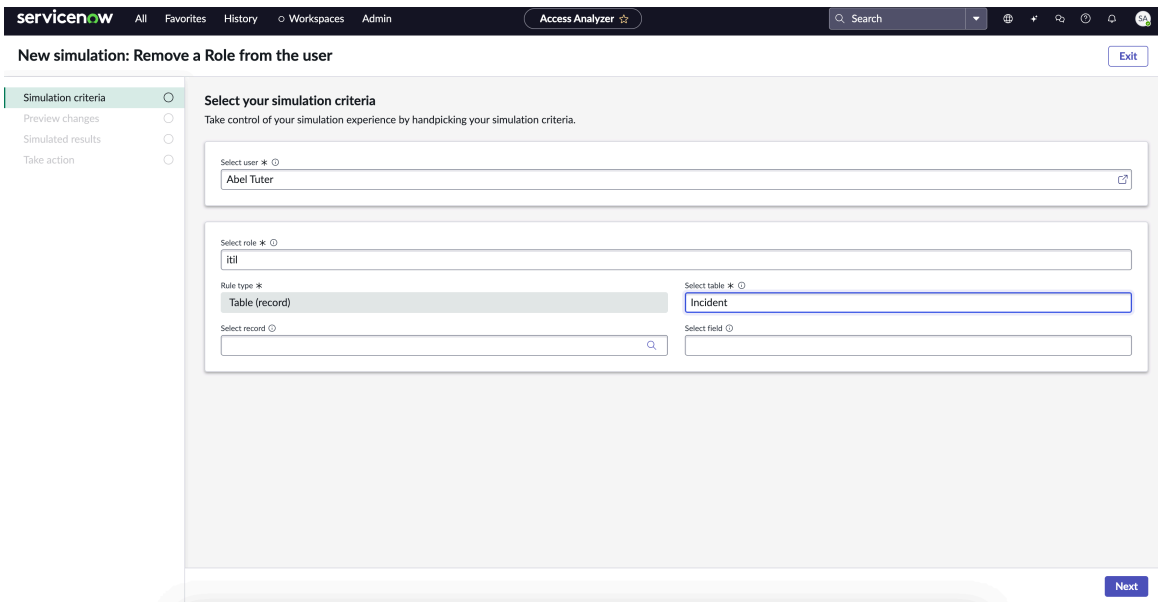
1. Navigate to **All** > **Access Analyzer** > **Access Simulator**.
2. Select **Simulate** from the Remove a Role from the user section.
3. Specify the following fields for your simulation criteria:

Remove a Role from the user

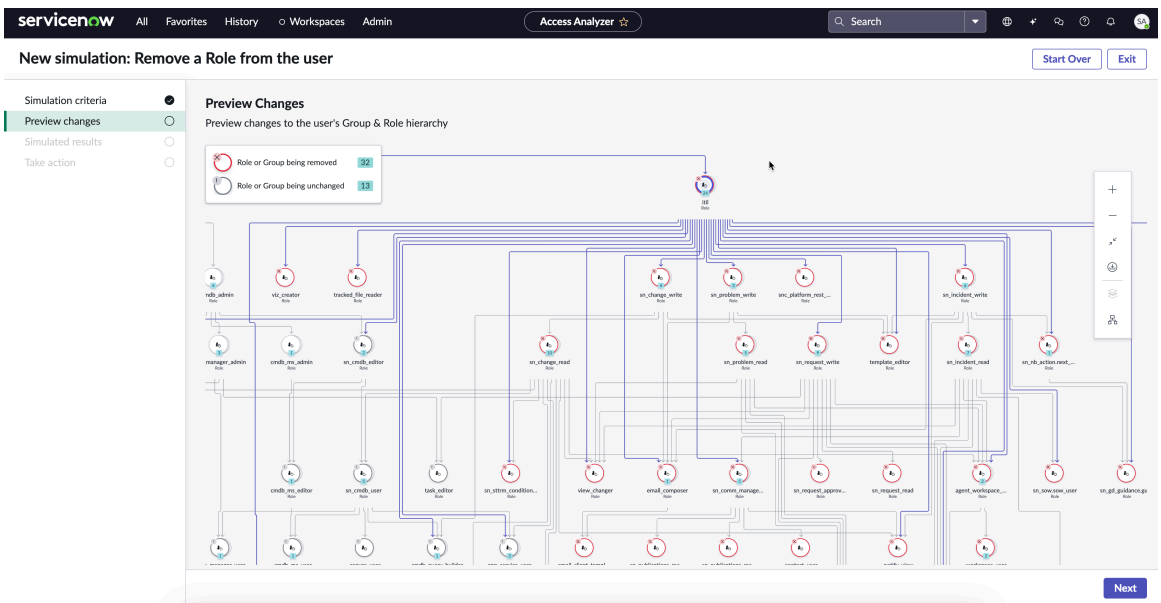
Field	Description
Select user *	Specify a user name to select from the list. In this example, **Abel Tuter**.
Select role *	Specify a role to select from the list. In this example, **itil**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Rule type *	Rule type is auto-populated and it can't be changed.
Select table *	Specify a table name to select from the list. In this example, **Incident**.
Select record	Specify a record name to select from the list.
Select field	Specify a field name to select from the list. This field can be used to analyze permission even at a field level. For example, Active, Created By, and so on.

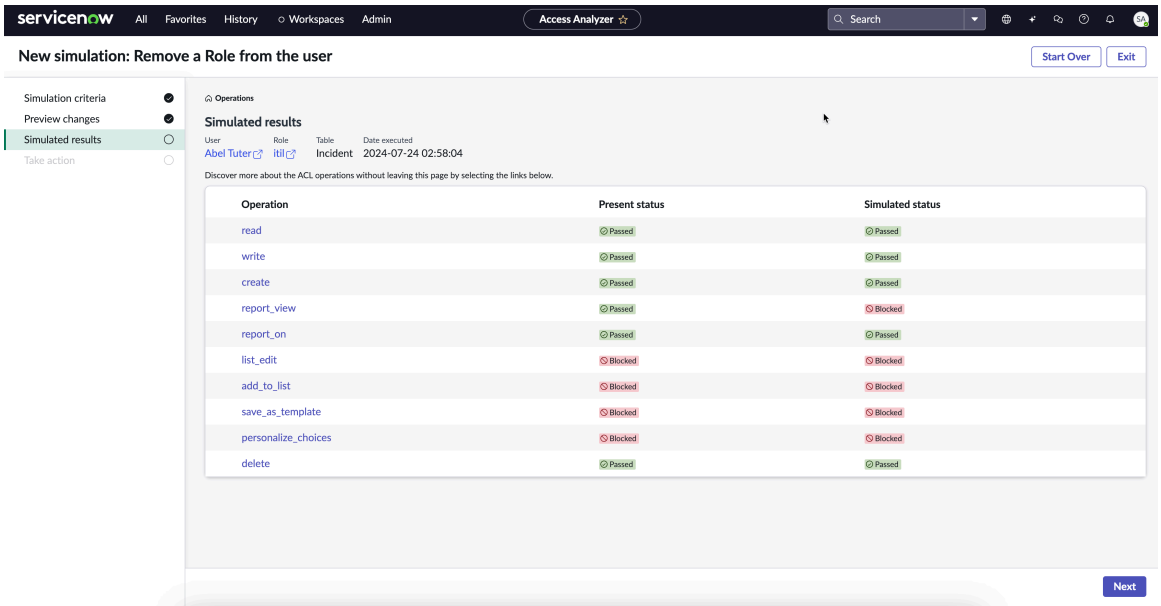


4. Select **Next**.
5. Preview the changes.
   The roles that are removed are simulated in the Preview changes. You can validate the roles and child roles that are being removed to the user before moving to the next step.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

6. Select **Next**.
7. Validate the **Present status** and **Simulated status** to verify the access that is being **Passed** or **Blocked** to the simulated user.



Note:

- If you want to know more about the ACL (operations), select the operation links for each record.
- If you want to start the simulation again for a different role, select **Start over**.
- If you want to exit the simulation, select **Exit**.

8. Select **Next**.
9. Select **Remove and complete**.

Note:

- If the Access Simulator isn't enabled, you can't complete the simulation. To enable, select **Enable actions** and accept the legal information.
- If you want to hide the simulation, select **Hide actions**. To unhide and enable actions, go to the settings. For more information, see Configuring the Access Simulator (Take actions).
- If you want to exit the simulation, select **Skip and Exit**.

The roles are successfully removed from the user. You can verify the access using the Access Analyzer. For more information about how to verify the access of a user, see Access analyzer.

Adding users to Groups

Use the **Simulate Add to Group** for simulating the user's access changes for a resource (tables) when the user is added to a group.

Before you begin
Role required: admin, access_analyzer_admin

Enable the take actions. For more information, see Configuring the Access Simulator (Take actions).

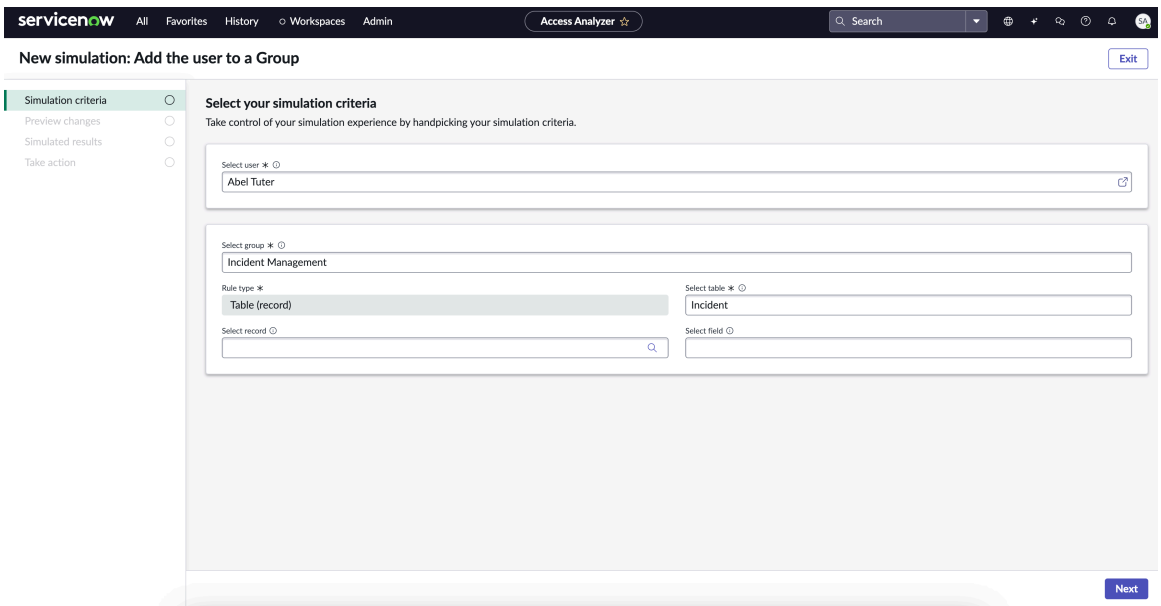
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Access Analyzer** > **Access Simulator**.
2. Select **Simulate** from the Add the user to a Group section.
3. Specify the following fields for your simulation criteria:

Add the user to a group

Field	Description
Select user *	Specify a user name to select from the list. In this example, **Abel Tuter**.
Select group *	Specify a group to select from the list. In this example, **Incident Management**.
Rule type *	Rule type is auto-populated and it can't be changed.
Select table *	Specify a table name to select from the list. In this example, **Incident**.
Select record	Specify a record name to select from the list.
Select field	Specify a field name to select from the list. This field can be used to analyze permission even at a field level. For example, Active, Created By, and so on.



4. Select **Next**.
5. Preview the changes.

   The group that the user is assigned is simulated in the Preview changes. You can validate the changes before moving to the next step.

Note:

- If the Access Simulator isn't enabled, you can't complete the simulation. To enable, select **Enable actions** and accept the legal information.
- If you want to hide the simulation, select **Hide actions**. To unhide and enable actions, go to the settings. For more information, see Configuring the Access Simulator (Take actions).
- If you want to exit the simulation, select **Skip and Exit**.

The user is successfully added to the group.

Removing users from Groups

Use the **Simulate Remove from Group** for simulating the user's access changes for a resource (tables) when the user is removed from a group.

Before you begin

Role required: admin, access_analyzer_admin

Enable the take actions. For more information, see Configuring the Access Simulator (Take actions).

Procedure

1. Navigate to **All** > **Access Analyzer** > **Access Simulator**.
2. Select **Simulate** from the Remove the user from a Group section.
3. Specify the following fields for your simulation criteria:

Remove the user from a group

Field	Description
Select user *	Specify a user name to select from the list. In this example, **ITIL User**.
Select group *	Specify a group to select from the list. In this example, **Incident Management**.
Rule type *	Rule type is auto-populated and it can't be changed.
Select table *	Specify a table name to select from the list. In this example, **Incident**.
Select record	Specify a record name to select from the list.
Select field	Specify a field name to select from the list. This field can be used to analyze permission even at a field level. For example, Active, Created By, and so on.

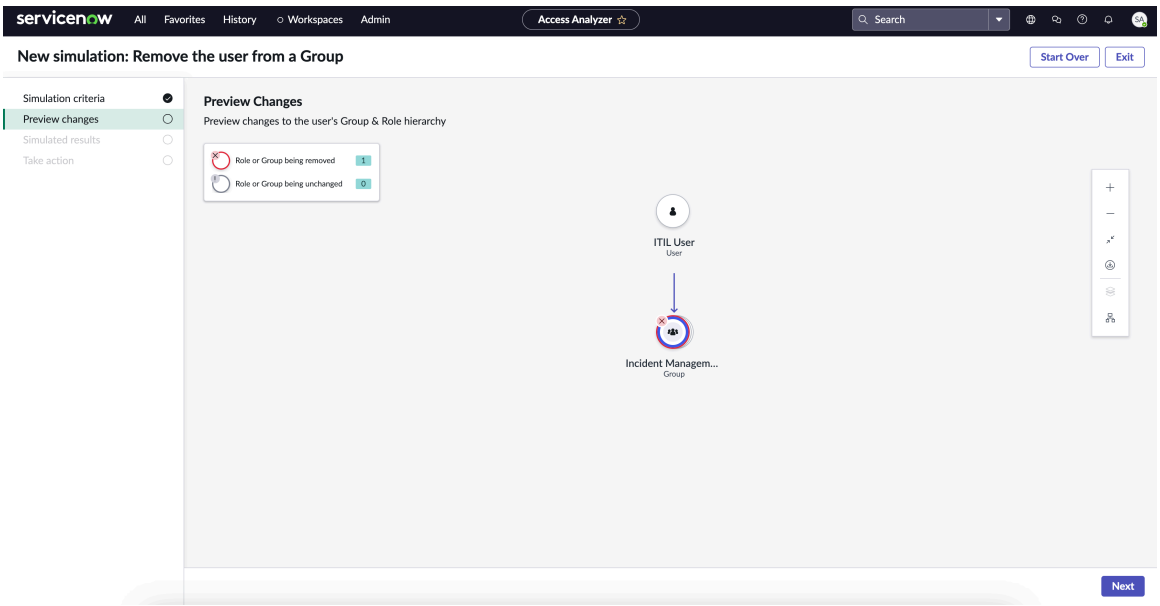
d

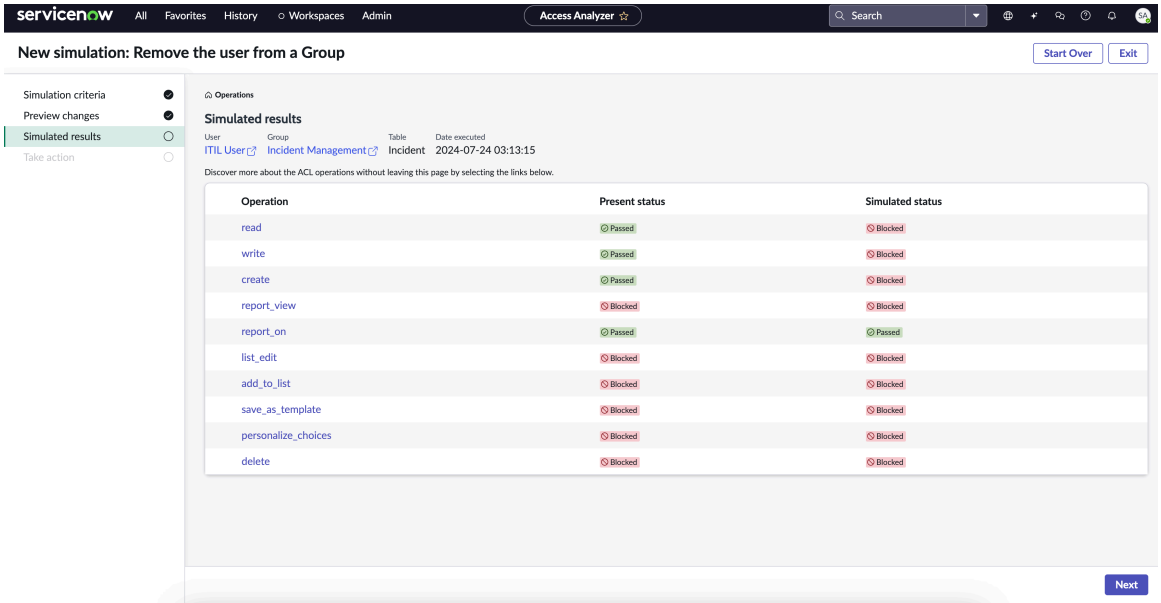
4. Select **Next**.
5. Preview the changes.

   The group from which the user is removed is simulated in the Preview changes. You can validate the changes before moving to the next step.



6. Select **Next**.
7. Validate the **Present status** and **Simulated status** to verify the access that is being **Passed** or **Blocked** to the simulated user.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Note:

- If you want to know more about the ACL (operations), select the operation links for each record.
- If you want to start the simulation again for a different role, select **Start over**.
- If you want to exit the simulation, select **Exit**.

8. Select **Next**.
9. Select **Remove and complete**.

Note:

- If the Access Simulator isn't enabled, you can't complete the simulation. To enable, select **Enable actions** and accept the legal information.
- If you want to hide the simulation, select **Hide actions**. To unhide and enable actions, go to the settings. For more information, see Configuring the Access Simulator (Take actions).
- If you want to exit the simulation, select **Skip and Exit**.

The user is successfully removed from the user.

Frequently Asked Questions

Frequently asking question about using Access Simulator.

Frequently Asked Questions

Questions	Explanation
How do I get started with the Simulator?	You can select the Simulate option for the different scenario that you would like to simulate for the users and follow through the steps.
How does Simulator work?	The Access Simulator simulates access to the specified table to the selected user and

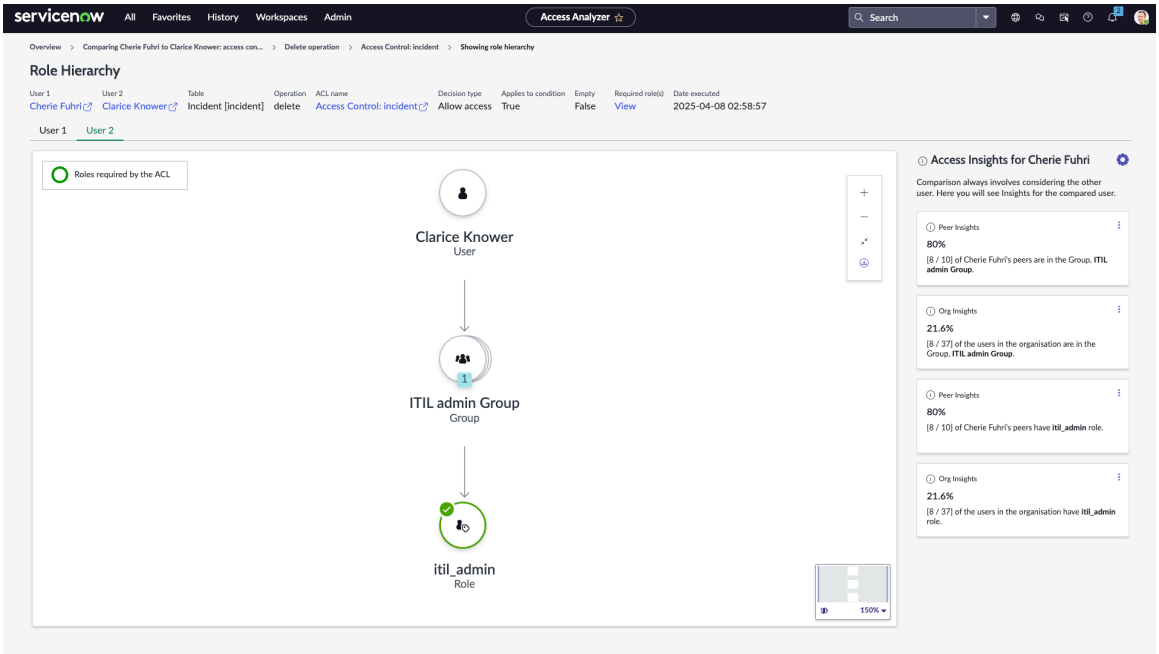
Explore Access Insights

The Access Insights in the Access Analyzer helps you gain confidence in your Role or Group assignments.

The Access Insights displays the statistics of your user's peer and organizational level access to a resource. It enables you to see if the role or group can be assigned to the user that you're currently reviewing for additional entitlements. It helps you to compare the role and group assignments withing the same peer group.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The Access Insights is displayed only while comparing user's access using the compare user access feature in the Access Analyzer. To learn more about using Access Insights, see Use Access Insights.



Based on the statistics, you can decide to provide the correct role or group assignments to the users you're comparing within their peers.

Note:

- Access Insights is available with Access Analyzer V4.
- You should compare users at a peer-level (same organization, same department, same manager), while viewing the statistics within the Access Insights feature.

To enable Access Insights in the Access Analyzer, you must navigate to the Settings. To learn more, see Configure Access Insights.

Configure Access Insights

Enable the Access Insights feature in the Access Analyzer.

Before you begin

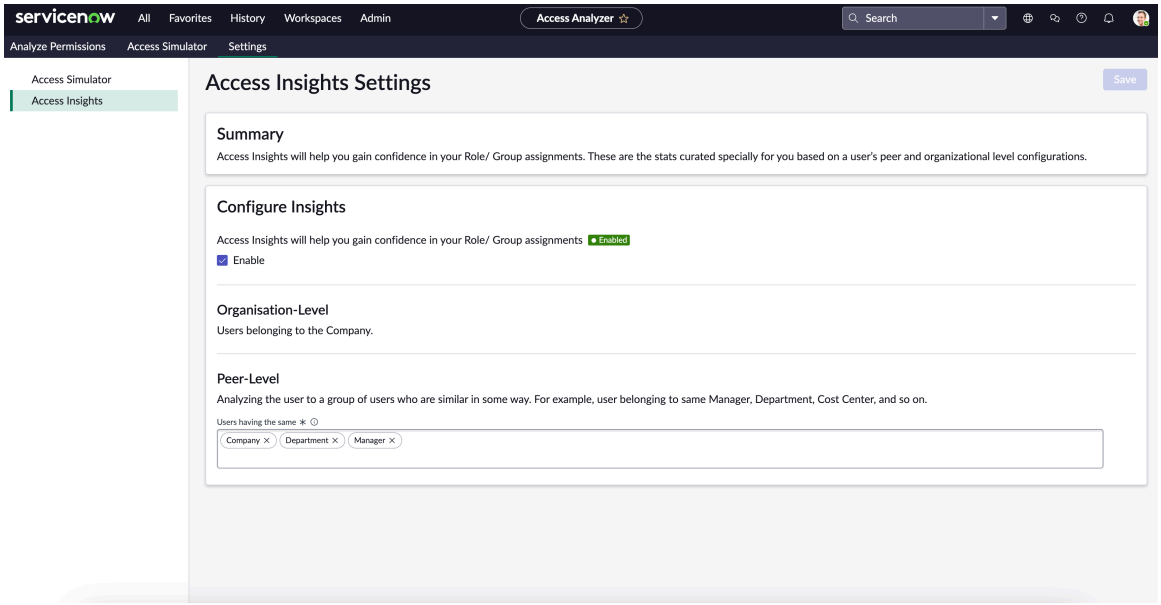
Role required: admin, access_analyzer_admin

The following procedure describes the steps for enabling Access Insights.

Procedure

1. Navigate to **All** > **Access Analyzer** > **Analyze Access**.
2. Select **Settings** tab.
3. Select **Access Insights**.
4. Enable **Access Insights**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Note:
By default, Peer-Level fields are selected with **Company**, **Department**, **Manager**. You can add more fields such as **Cost Center**, **Country Code**, **Location**, and **Title**.

5. Select **Save**.

Result
The Access Insights feature is enabled and displayed when you're viewing the **Role Hierarchy** while comparing user access to a resource. To know more about using Access Insights, see Use Access Insights.

Use Access Insights

Use Access Insights to understand the users peer level access to a selected resource.

Before you begin
Role required: admin, access_analyzer_admin

Note:
To view the details of though Access Insights feature, you must use the Compare user access feature.

The following procedure describes the steps for viewing the peer level role or group assignments statistics within the Access Insights feature.

Procedure

1. Navigate to **All** > **Access Analyzer** > **Analyze Permissions**.
   The Analyze access and permissions home page is displayed.
2. Select the **Compare user access** tab.
3. Fill in the following fields:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Compare user access

Field	Description
Select user 1*	Specify a user name to select from the list for the comparison.
Select user 2*	Specify a user name to select from the list to compare with the user 1.
Rule Type*	Analyze access permissions for a table. **Note:** Only access permissions for a table can be used in the **compare user access**.
Select table*	Specify a table name to select from the list.
Select record	Specify a record name to select from the list.
Select field	Specify a field name to select from the list.

4. Select **Compare user access**.

   The **compare user access** results for the selected users are displayed.

   The compare user access results show the operation and the access evaluation status for the users. For example, Charlier Fuhri and Charlie Knower.

5. Select an operation.
   For example, **read** operation.
6. Select any of the **Access Control** to learn more about the access.
7. Select **Show role Hierarchy** to view the access comparison at a peer level access.

   The Access Insights is displayed as follows:

   - **Peer Insights**: Displays how many users have the same role assigned within their peers (the same manager or department).
   - **Org Insights**: Displays how many users have the same role assigned within the organization.

Security Attributes fundamentals

A Security Attribute is a highly configurable piece of information about a Subject or its Environment. When used in access controls, they enable fine grain security configuration in a non-complex way.

Security Attributes offer an alternative method for access control via role definitions to currently practiced ACL(Access Control Lists) configuration. Security Attributes offer several advantages to ACL-based configurations:

Better security

Improved permissions evaluation obfuscation ensures that your organization remains secure.

Human readable

Security Attributes are designed to simplify the creation and ease of use of security permissions.

Flexible security

Build persona definitions from both Out-of-Box configuration in combination with customer defined personas.

Logging and auditing

Security Attributes offer detailed auditing and logging to give more insight to security measures and theory.

Create Security Attributes

Create new Security Attributes with a step-by-step guide.

Before you begin

Role required: security_admin

Procedure

1. Navigate to **System Security** > **Security Attributes**.
2. In the Security Attributes list, select **New**.
3. On the Security Attributes fields form, fill in the fields.

Security Attribute fields

Field	Description
Label	Label of Security Attribute.
Name	Name of Security Attribute.
Type	The type of Security Attribute. ○ compound **Note:** For further information about Compound Security Attributes see Compound Security Attributes ○ integer ○ list

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	○ string ○ boolean(true|false)
Is dynamic	If the Security Attribute value needs to be re-evaluated per each
Description	User generated description of Security Attribute
Application	Static field, application Scope.
Lookup Table	Reference an external table for evaluation.
Lookup Table Column	Reference a table column for evaluation.
Script	Derive a value from a script.

OOB (Out-of-Box) Security Attributes

Commonly used, generalized Security Attributes roles ready for use.

Overview

The OOB(Out-of-Box) Security Attributes are an easy way to begin using and learning the capabilities of Security Attributes with a series of preconfigured Security Attribute roles. The OOB Security Attribute roles are commonly used access control roles.

To create your own Security Attribute, or expand an OOB Security Attributes capabilities see Compound Security Attributes

OOB Security Attributes

Attribute	Description
Group	User is member of a specified group
GroupExplicit	User is an explicit member of a specific group
HasAdminRole	User has the admin persona
Impersonating	User is impersonated
InteractiveSession	Current session interactive
LoggedIn	User is logged-in and authenticated
NetworkCriteria	Additional Network Criteria
Role	User has specific role
RoleExplicit	User has specific role explicitly defined

Security attributes for client session

Following security attributes are added for client session (plugin: `com.glide.client_session_security_attributes`):

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- **IsIframeEmbeddedSession**: The attribute is used in embedded iframe in third party portals. For example, Engagement messenger, Virtual Agent Web Client, Embedded Session, and so on.
- **IsIntegrationAsAServiceSession**: The attribute is used in messaging apps like Virtual Agent in teams, Virtual Agent in slack, Virtual Agent in whatapp.
- **IsIntegrationAsAUserSession**: The attribute is used in integration account user or web service user.
- **Is Servicenow Web Session**: The attribute is used in web interactive session.
- **Is Mobile App Session**: The attribute is used if the **mobile_client** property is true in the **oauth_entity** record.

Note:
You must use the **IsIframeEmbeddedSession**, **IsIntegrationAsAServiceSession**, and **IsIntegrationAsAUserSession** only while configuring client type for OAuth and SSO records. To learn more, see Configure client type for OAuth and SSO records.

Non-explicit and explicit behavior explained

Security Attributes address nuanced permission needs with an explicit vs. non-explicit (inherited) evaluation of roles permissions.

Compound Security Attributes

Compound Security Attributes enable you to create consistent and reusable Security Attribute profiles suit your business needs

Overview

Compound Security attributes are defined from one or more pre-existing Security Attributes to create a single reference combination of Security Attributes for permissions evaluation.

Create compound Security Attributes

Create a compound Security Attribute for easy reuse.

Before you begin
Role required: security_admin

Procedure

1. Navigate to **System Security** > **Security Attributes**.
2. In the Security Attributes list, select **New**.
3. Select `Compound` in the **Type** field.
4. On the Security Attributes fields form, fill in the fields.

Security Attribute fields

Field	Description
Label	Label of Security Attribute.
Name	Name of Security Attribute.
Description	User generated description of Security Attribute

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Condition	The specific Security Attribute conditions used to the define the Security Attributes evaluation.
New Criteria	Add additional set of **Or** conditions for evaluation.

Security Attribute Scope

Security Attributes supports scoping capabilities.

Security Attribute Scoping

Security Attributes scoped behavior is consistent with Platform's scoping behaviors. Security Attributes created within a scope are only available in access controls in the same scope.

Local and Existing Security Attributes

Existing and Local Security Attributes enable customers to reuse Security Attribute condition sets.

Local & Existing Attributes

The ACL Security Attribute Condition Builder enables customers to specify if a Security Attribute is either existing or local.

Note:
Security Attributes conditions are defaulted to local.

A local defined Security Attribute is saved only to the single ACL where it is created in.

The existing option enables users to reference an existing Security Attributes conditions to the condition builder.

Field Query Roles and Restrictions

The **Field Query Roles** and **Field Query Restrictions**attribute enable you to better control what information is available to users in tables.

Overview

The **Field Query Roles** and **Field Query Restrictions** attributes enable more fine tuned control over what actions users can take on tables.

Field Query Roles

Prevents querying sensitive fields based on user role.

Field Query Restrictions

Restrict access to the record if the access to the applicable field is denied.

Configure a Field Query Role

Learn how to enable and configure a Field Query Role attribute.

Before you begin
Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **System Definition** > **Tables**.
2. Select a **Table**.
3. Select a **Column Label** to view its **Dictionary** entry.
4. Select the **Attributes** tab.
5. **Tip:**
   If you do not have the **Field Query Roles** field, select **New** to create one

   Select the **Field Query Roles** attribute.
6. Enter the roles required to view this table column in the **Value**
7. Select **Update**

Result

The table column can only be queried by the roles defined in the **Field Query Roles** attribute. If a user without the defined roles queries the table column they will be denied access to the operation.

Configure Field Query Restrictions

Learn how to configure a Field Query Restriction

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Definition** > **Tables**.
2. Select a **Table**.
3. Select a **Column Label** to view its **Dictionary** entry.
4. Select the **Attributes** tab.
5. **Tip:**
   If you do not have the **Field Query Restrict Record Access** field, select **New** to create one

   Select the **Field Query Restrict Record Access** attribute.
6. Enter `true` in the **Value** field to restrict record access to only users who can who can view the field, otherwise enter `false`.
7. Select **Update**

Result

The table column will restrict the results of any queries. Restricted users will be informed how many results a query returned, but no further information.

Scripting Governance Tool

Use the Scripting Governance Tool (SGT) to provide a single, centralised control for managing scripting access across your ServiceNow AI Platform.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Explore	Use
Learn the features and business value of Scripting Governance Tool.	Understand how to use the Scripting Governance Tool.

Explore Scripting Governance Tool

The Scripting Governance Tool (SGT) provides a single, centralised control for managing scripting access across your ServiceNow AI Platform.

The Zurich release introduces a feature that gives administrators centralised control over who can edit script fields on the ServiceNow AI Platform. The feature adds a new permission layer built on the **Conditional Script Writer** group and its child role, `snc_required_script_writer_permission`. Users must be members of this group to edit any script field, regardless of their existing ACL-based access. This permission layer is enforced through data-type ACLs and maintained by scheduled jobs and system properties.

To manage this feature, ServiceNow AI Platform provides the **Scripting Governance Tool (SGT)** — a dashboard where administrators can see which users have scripting access, scan the instance for users who have edited script fields, and directly add or revoke scripting access from users.

Why it matters

Scripting can read and write data across tables, bypass business logic, and alter platform behaviour at a fundamental level making scripting access one of the most important permissions to govern on any instance.

Before Zurich, scripting access was controlled solely by ACLs on individual script fields. To determine which users could edit scripts, administrators had to check each ACL individually. There was no single place to view or manage scripting access across the instance.

Scripting governance feature addresses it by adding a mandatory second layer of access control on top of existing ACL-based permissions. Satisfying a field-level ACL alone is no longer sufficient to edit a script field. Now, security administrators can manage scripting access centrally by adding or removing users from the **Conditional Script Writer** group.

The two-layer access model

Scripting governance feature enforces a two-layer access model. Both layers must pass independently before a user can edit any script field. Passing one layer alone is not sufficient.

Layer 1 — Existing field-level ACL

The user must pass the existing ACL on the scripting field (out-of-the-box or custom). This check is unchanged from pre-Zurich behaviour.

Layer 2 — SGT role check

The user must also hold the `snc_required_script_writer_permission` role, which is granted through membership in the **Conditional Script Writer** group.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Important:

A user who could edit script fields before the Zurich upgrade — because their roles satisfied the field-level ACL — will be blocked after the upgrade unless they also satisfy Layer 2. The `snc_required_script_writer_permission` role does not grant new scripting access on its own. It only unlocks access for users who already pass Layer 1.

The following table summarises access outcomes under the two-layer model:

Passes field-level ACL (Layer 1)?	Holds `snc_required_script_wr` (Layer 2)?	Can edit script field?
Yes	Yes	# Yes
Yes	No	# No
No	Yes	# No
No	No	# No

Data type ACLs

Scripting governance feature introduces 9 data type ACLs to enforce Layer 2. These are **deny unless** ACLs that require the `snc_required_script_writer_permission` role for the following data types:

Data type

- script
- script_client
- script_plain
- script_server
- email_script
- html_script
- html_template
- xml
- condition_string

Note:
The admin role does not have scripting access by default. Admin users are subject to the same two-layer check and cannot edit script fields unless they are members of the **Conditional Script Writer** group or explicitly hold the `snc_required_script_writer_permission` role.To know more, see Datatype ACL.

Scheduled jobs and properties

As part of the scripting governance feature, the **Conditional Script Writer** group is introduced, which has the `snc_required_script_writer_permission` role as a child role. When the Zurich upgrade completes, a one-time scheduled job runs to auto-populate all eligible users to this group ensuring no one loses scripting access after the upgrade. Once that job completes, a recurring weekly job is created to keep the group membership up to date. Both jobs and their eligibility criteria are described as follows:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Add users to Conditional Script Writer group

A job that runs once immediately after the Zurich upgrade completes. It adds all users who meet the eligibility criteria to the **Conditional Script Writer** group, ensuring no user loses scripting access after the upgrade. After the job completes, the platform disables it.

The job uses the property `glide.security.scripting_role.provisioning_job_running`, which is set to true while the job is running and false after it completes. When the job finishes, it creates the property `glide.security.scripting_role.auto_provisioning` and sets it to **true**.

Update users in Conditional Script Writer group

A weekly job that adds new users who meet the eligibility criteria to the group and removes users who no longer meet the eligibility criteria. It is controlled by the `glide.security.scripting_role.auto_provisioning` property:

Update behaviour based on the property

Value	Behaviour
true (default)	The weekly job runs on schedule and adds qualifying users to the group automatically.
false	The job does not run. Users are only added to the group manually by an administrator.

To disable automatic provisioning, set `glide.security.scripting_role.auto_provisioning` to **false** in System Properties.

Note:
The `glide.security.scripting_role.auto_provisioning` property is created at runtime and has a different **sys_id** on every instance. Always reference it by a property name.

Eligibility criteria

Both scheduled jobs use the same criteria to determine which users are added to the **Conditional Script Writer** group:

Eligibility criteria

Explicit Role plugin	User type	Requirement	Added to group?
Enabled	External	—	No
Enabled	Internal	Must have snc_internal and at least one additional role	Yes
Disabled	Any user	Must have at least one role	Yes

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

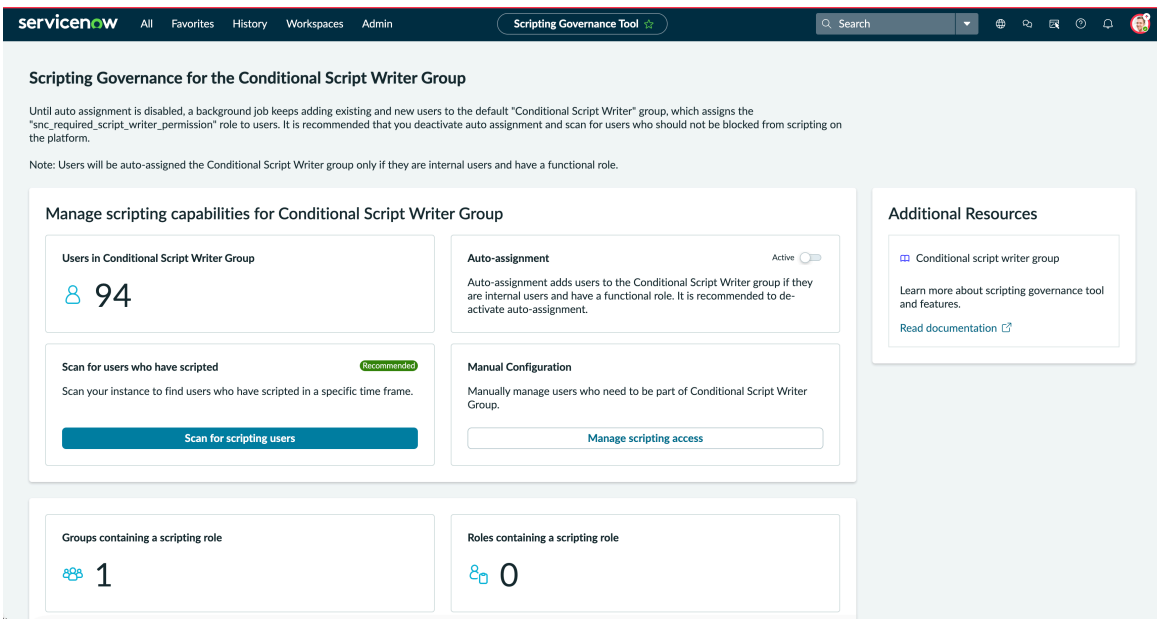
Note:
The **snc_external** role and the `snc_required_script_writer_permission` role are conflicting roles. ServiceNow AI Platform does not allow both role to the same user. External users cannot have scripting access.

Scripting Governance Tool

The **Scripting Governance Tool** is a dashboard that helps administrators manage scripting access on the ServiceNow platform. It provides visibility into users who are members of the **Conditional Script Writer** group — giving a clear picture of how many users can script on your instance.

You can also view which groups contain the scripting role and which roles contain it as a child role. There are two ways to manage scripting access through the tool:

- **Manual configuration**: Manually add or remove users from the **Conditional Script Writer** group to control who has scripting access.
- **Scan for users who have scripted**: Scan your instance to find users who have scripted within a specific time frame. The scan queries the audit logs and identifies any user who has performed write or update to a table having script field.



Note:
It is recommended to manage scripting access exclusively through the **Conditional Script Writer** group. Adding the `snc_required_script_writer_permission` role as a child role to other roles or groups reduces your ability to centrally control who can script on your instance.

Use SGT

Use the Scripting Governance Tool (SGT) to provide a single, centralised control for managing scripting access across your ServiceNow AI Platform.

Before you begin

Role required: security_admin

Important:
You must have elevate your role `security_admin`. See Elevate to a privileged role.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The **Scripting Governance Tool** helps you review user scripting governance your ServiceNow AI Platform. The **Conditional Script Writer** group grants scripting permissions to its members via the `snc_required_script_writer_permission` role. Users are added to the group by either an automated assignment or manual configuration. You can manage both of these settings from the **Scripting Governance Tool**.

Procedure

1. Navigate to **All** > **System Security** > **Scripting Governance Tool**.
2. Use the following features to learn more:

Scripting Governance Tool

Features	Description
Users in Conditional Script Writer Group	Displays the number of users in the **Conditional Script Writer** group. These users are granted the `snc_required_script_writer_permission` until removed from the group.
Auto-assignment	Auto-assignment assigns new users to the **Conditional Script Writer** group if the users are `internal users` and has one functional role. You can select the slider to de-activate. **Note:** It is recommended to de-activate auto-assignment.
Scan for users who have scripted (Recommended)	Scans for users in the ServiceNow AI Platform who have modified records containing script fields such as business rules, script includes, or client scripts. When running the scan, you can define a time period for which the scan checks.
Manual Configuration	You can manually select users that stay in the **Conditional Script Writer** group. Select the **Manage scripting access** button and enter the users into the text field for manually managing the user removal process from the **Conditional Script Writer** group.
Groups containing a scripting role	Displays the number of groups that contain a scripting role. By default the **Conditional Script Writer** group has a scripting role.

© 2026 ServiceNow, Inc. All rights reserved.

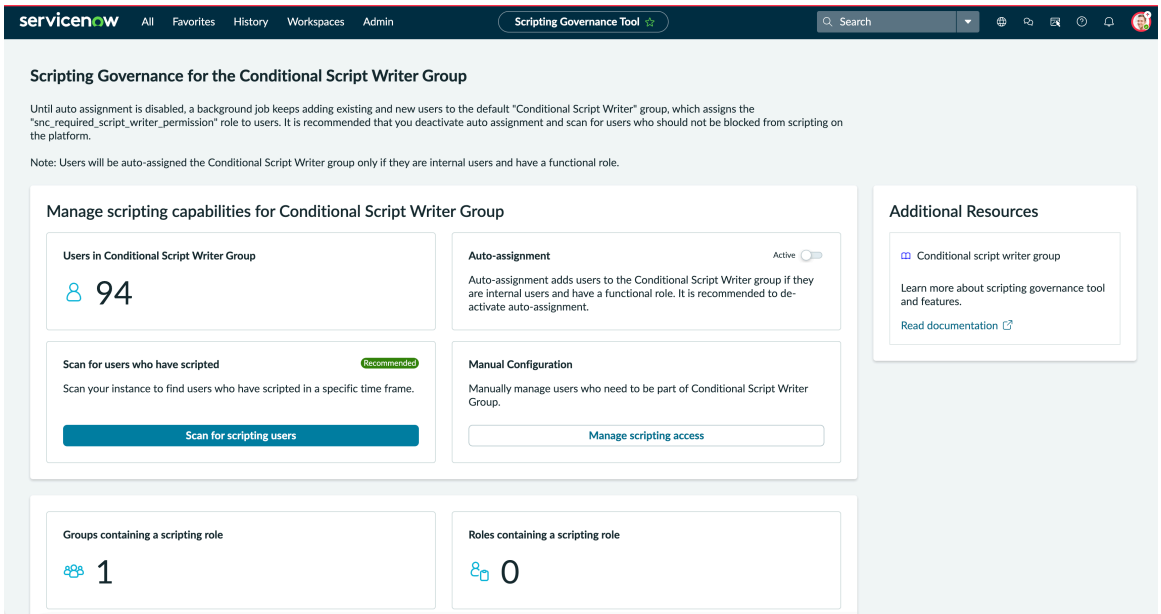
Features	Description
	Note: It is recommended to manage scripting access exclusively through the **Conditional Script Writer** group. Adding the `snc_required_script_writer_permission` role as a child role to other roles or groups reduces your ability to centrally control who can script on your instance.
Roles containing a scripting role	Displays the number of roles that contain a `snc_required_script_writer_permission` role. **Note:** It is recommended to manage scripting access exclusively through the **Conditional Script Writer** group. Adding the `snc_required_script_writer_permission` role as a child role to other roles or groups reduces your ability to centrally control who can script on your instance.
View scans	After you run the scan, the details of the scan are displayed on the View scans.
View removals	When you schedule for removal of user from the **Conditional Script Writer** group, the details are displayed on the View removals.



Result

You can view the following topics to understand how you can:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Scan for users who have scripted
- Remove users from the Conditional Script Writer group

Scan for users who have scripted

Scan your instance to find users who have scripted within a specific time frame. The scan queries the audit logs and identifies any user who has performed write or update to a table having script field.

Before you begin

Role required: security_admin

> **Important:**
> You must have elevate your role `security_admin`. See Elevate to a privileged role.

Procedure

1. Navigate to **All** > **System Security** > **Scripting Governance Tool**.
2. Select **Scan for scripting users**.
3. Select a time period from the drop-down list.
   - 7 days
   - 15 days
   - 30 days
   - 90 days
   - 120 days
   - 180 days

   The default value is **180 days**.

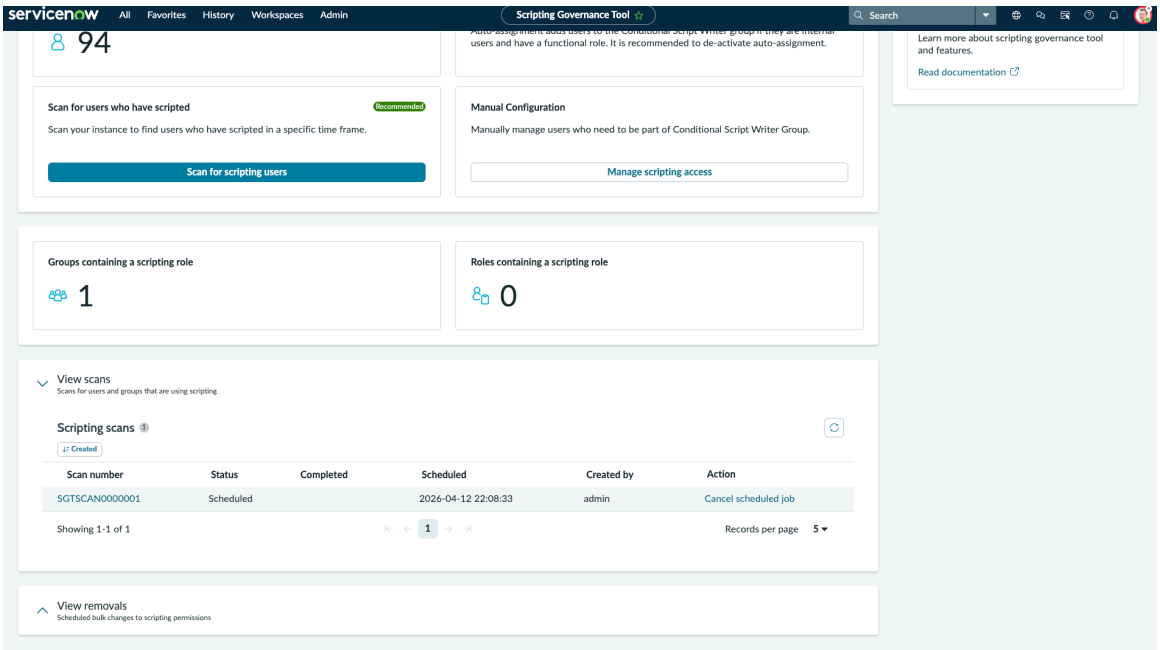
4. Select how you want to run the scan.
   - Run this scan now — starts the scan immediately.
   - Schedule this scan — runs the scan at a time you specify.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

5. Select **Done** to scan.
6. Select the scan record from **View scan** section.
   The following details are available on the **View scan** section.

Scripting scan table fields

Label	Description
Scan number	A unique identifier for the scan, for example SGTSCAN0000001.
Status	Status of the scan
Completed	Completion state of the scan
Scheduled	Scheduled time of execution for the scan
Created by	User who initiated the scan
Action	Actions the scan took



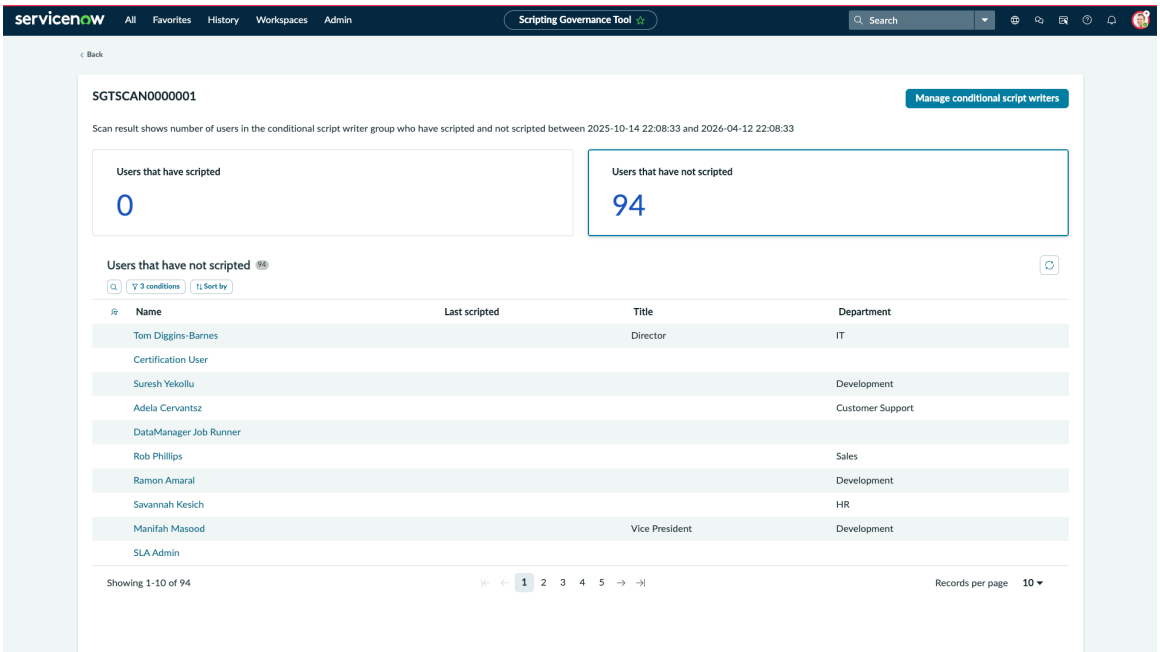
7. Select the scan record to open the scan results page.

   The scan results page opens and displays the following information:

   - Scan record number — a unique identifier for the scan, for example SGTSCAN0000001.
   - Date range — the start and end timestamps of the period that was scanned.
   - Users that have scripted — the total count of users in the **Conditional Script Writer** group and has <> role who modified at least one script field within the scanned period.
   - Users that have not scripted — the total count of users in the group who made no scripting changes within the scanned period. These users are candidates for access review and removal.
   - Users that have scripted table — a detailed list of active scripters, showing each user's Name, Last scripted date, Title, and Department.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
If the **Users that have scripted count** is zero and the table shows `No data to display`, no users in the ServiceNow AI Platform have scripted within the selected time period.



8. Review the results and identify users who require action.
9. To act on the results, select **Manage conditional script writers** on the scan results page. The **Manage users in the conditional script writer group** opens, where you can review group membership and remove users who no longer require scripting access using the **Schedule removal** option. To learn more about how to schedule removal, see Remove users from the Conditional Script Writer group.

Result
The scan produces a clear picture of active and inactive scripters on the ServiceNow AI Platform.

What to do next
After reviewing the scan results, remove any users from the **Conditional Script Writer** group who no longer require scripting access. Removing a user from the group does not affect any other permissions they hold on the ServiceNow AI Platform.

Remove users from the Conditional Script Writer group

Use the Manage scripting access to manually add or remove users from the **Conditional Script Writer** group to control who has scripting access.

Before you begin
Role required: security_admin

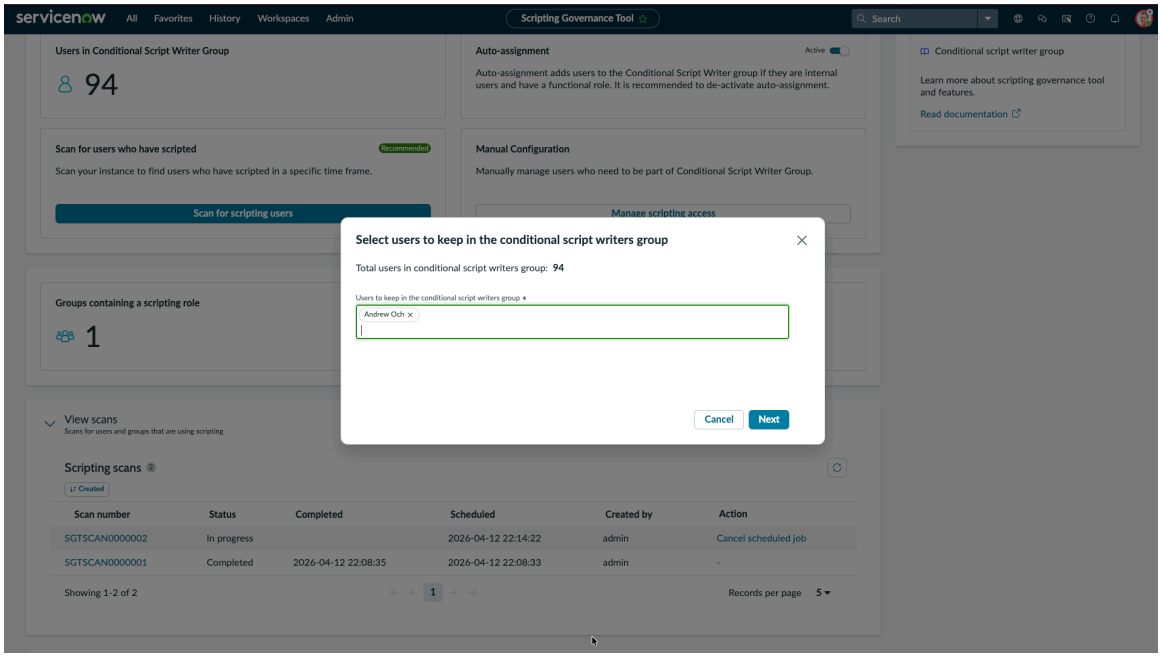
Important:
- You must have elevate your role `security_admin`. See Elevate to a privileged role.
- Until auto-assignment is turned off, a background job continues adding existing and new users to the **Conditional Script Writer** group, which assigns the `snc_required_script_writer_permission` role. It is recommended that you deactivate auto-assignment and manage the removal process to confirm only users with a legitimate scripting need remain in the group.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

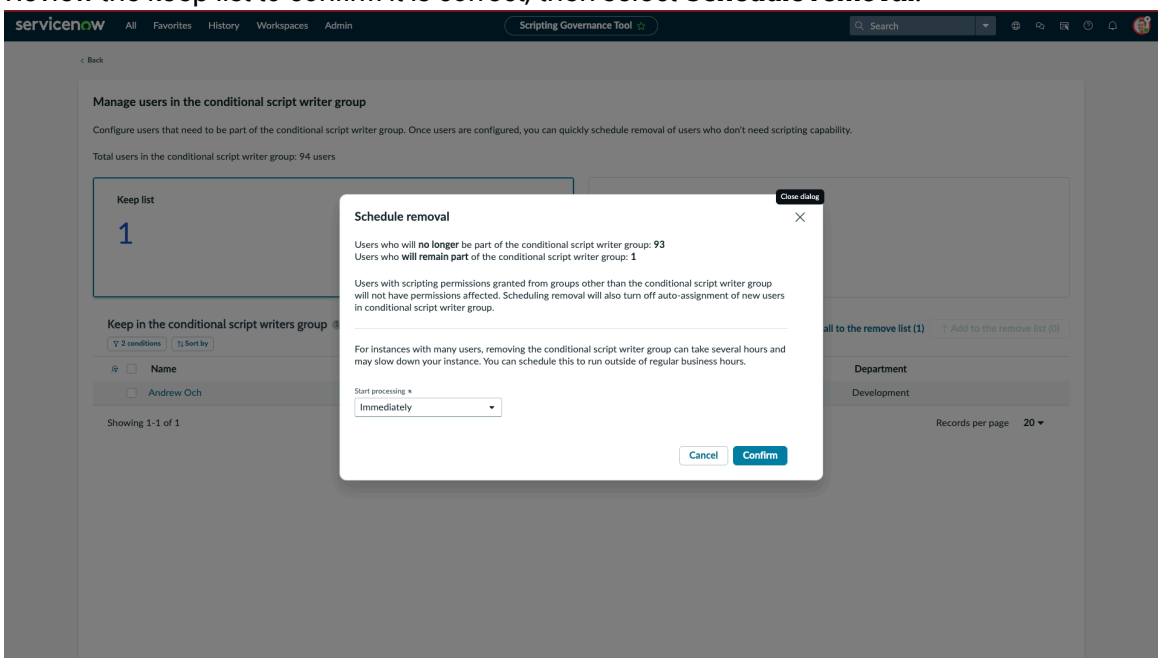
Procedure

1. Navigate to **All** > **System Security** > **Scripting Governance Tool**.
2. Select **Manage scripting access**.
3. Add the users who should retain scripting access in the **Users to keep in the conditional script writers group** field.

   Only users added to this field are retained in the group after the removal job runs. All other group members are removed. Search and select users by name.



4. Select **Next**.
   The Manage users in the conditional script writer group page opens with the **Keep list** card displays the number of users retained, and the **Keep in the conditional script writer group** table lists the users you selected.
5. Review the keep list to confirm it is correct, then select **Schedule removal**.



The **Schedule removal** dialog opens and displays a summary of the pending changes:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

6. Select when the removal job should run in the **Start processing** field:

   The following options are available:

   - Immediately — runs the removal job as soon as you confirm.
   - In 1 hour
   - In 2 hours
   - In 3 hours
   - In 5 hours
   - In 8 hours
   - In 13 hours

7. Select **Confirm** to schedule the removal.
   A banner confirms that the `Conditional script writer group member removal job is running or scheduled`. The removal job removes all users not on the keep list from the **Conditional Script Writer** group and disables auto-assignment.

Result

Users not included in the keep list are removed from the **Conditional Script Writer** group at the scheduled time and lose the `snc_required_script_writer_permission` role. Removal does not affect any other permissions those users hold on the instance. Auto-assignment is also disabled, preventing the background job from re-adding users to the group automatically.

What to do next

After the removal job completes, verify the outcome using the **View removals** section at the bottom of the SGT dashboard.

Machine identity access controls

Define and enforce granular access control policies on specific resources for integration users.

Machine identity access controls enable administrators to create granular access control policies for integration users. This additional layer of security allows admins to specify the exact resources (REST APIs, SOAP APIs, and tables) an integration user can access, ensuring tighter access governance.

Note:
Applicable to users flagged with Web Service Access Only.

See Create a machine identity access control to learn how to create a machine identity access control

Create a machine identity access control

Enable administrators to define and enforce granular control for integration users by introducing User Access Profiles. This feature provides an additional layer of security and control, allowing admins to specify the exact resources (REST APIs and SOAP APIs) that an integration user can access, ensuring tighter governance and minimizing security risks.

Before you begin

Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **System Security** > **Machine Identity Access Controls**.
2. Select the **New** button.
3. Fill in the fields of the form.

Machine Identity Access Control fields

Field	Description
Name	Name of the access control record.
Application	Application containing the record.
Description	Description of the record.
Active	Determines if the policy is active
REST API Policy	Select the target REST API policy. **Note:** Select the and the icon to add a policy.
SOAP API Policy	Select the target SOAP API policy. **Note:** Select the and the icon to add a policy.
Tables	Select the tables this policy applies to
Applies to Child Table	Check this to apply the policy to child tables of the **Tables** field

4. Select the `Insert a row below` prompt and add users to apply the control to.
   You can add multiple users to the access control.

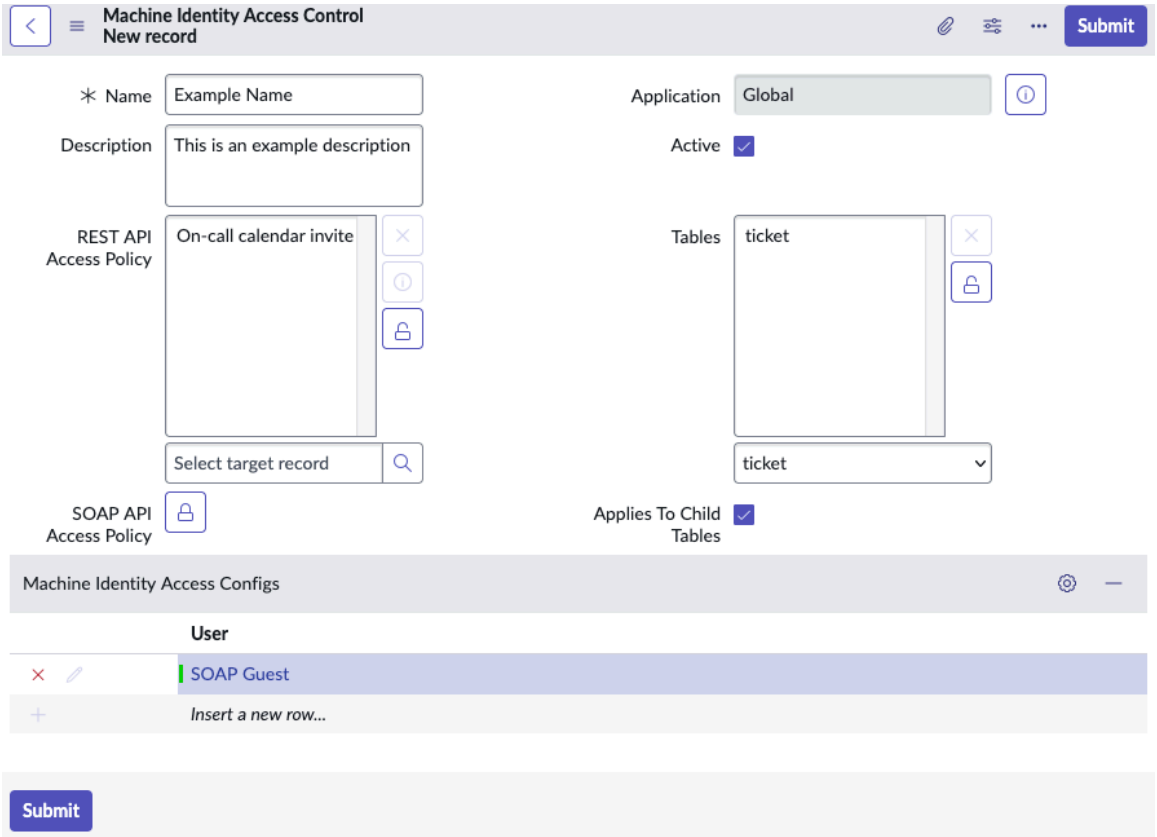
   Note:
   You can only select users with Web Service Access.

5. Select **Submit**.

Result

The following is an example of a machine identity access control form that has been filled out:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



A user with an machine identity access control cannot access any other APIs (REST or SOAP) and will only be able to access the resources explicitly stated in the access control, even if they have the required roles.

Data filtration

Use data filtration to control access to tables and records based on subject attributes when performing read queries.

Important:

Starting with the Yokohama release, Data filtration is being prepared for future deprecation. It will be hidden and no longer activated on new instances. Consider using Security data filters to restrict access to records based on role, or security-attribute related assertions. For details see Data filtration.

Explore Data filtration	Create Data filtration Rules
Learn about Data filtration.	Create your own Data filtration rules to suit your needs.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Debug Data

Learn how to debug your Data filtration results.

Explore Data filtration

Use Data filtration to control access to tables and records based on subject attributes when performing read queries.

Data filtration is a separate form of access control designed to work along with the existing Access Control rules (ACLs) on your instance. Data filtration denies access to tables and records that do not match subject attributes defined by an administrator. Data filtration is designed to make auditing, reporting, and troubleshooting easier.

This is an optional feature that administrators can activate on their instance.

Data filtration features

Data Filters

Use data filters to grant access based on information within a record. Data filters use data in a tables field to determine whether a record is available to your users.

Subject attribute based condition builder

Use subject attributes to evaluate user role, group, subject criteria, or IP network address.

Data filtration uses a deny based model

Data filtration uses a deny based model to control access to records. With Data filtration, your instance denies access to records unless a record meets the criteria defined by Data filtration.

Data filtration enforcement

Data filtration rules run after the database query for read operations and are evaluated before ACLs. A record denied by any Data filtration rule will not proceed and be evaluated by ACL rules. Data filtration rule enforcement is consistent with that of read ACLs.

Data filtration and reporting

Data filtration and ACL's are both applied only when creating list view reports. Reporting does not apply access control when collecting aggregated data. In this case, neither Data filtration nor ACLs are checked.

For aggregated reports, Data filtration works in conjunction with existing *`Report_view access control list`* behaviors. See Report_view access control for further details on configuring these report controls.

Session debugging

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Data filtration supports session debugging. Use session debugging to see which Data filtration records apply for a given query. Admins can use this information to troubleshoot user access to records.

Components of Data filtration

Data filtration works using the following record types:

Data filtration records

Create a Data filtration [sys_df_data_filtration] record to grant table access on your instance. The Data filtration record contains the **Data filter** and **Subject attribute** conditions described above to limit the scope of the rule and the affected users.

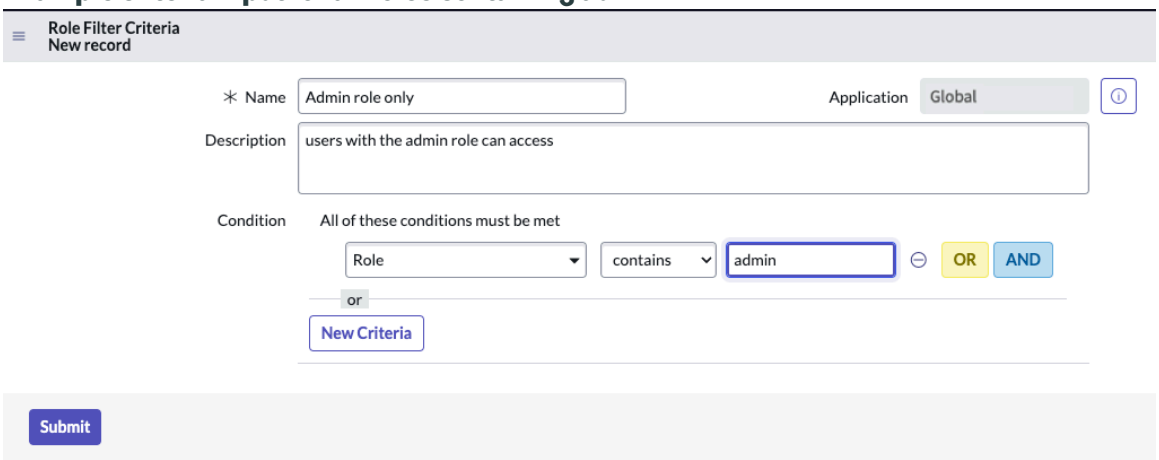
Subject criteria records

Subject criteria [sys_df_subject_criteria] records represent specific user attributes you can use to determine whether to grant access with a Data filtration rule. These attributes can be a user's groups, roles, or IP address. To create a subject criteria, you must create the subject criteria record, as well as criteria input and criteria conditions records. For details on this process, see Create subject criteria.

After creating a subject criteria records, you can apply them to a rule. This is done on the **Subject Condition** tab of your Data filtration rule.

Criteria input records examples

Example criteria input for all roles containing admin

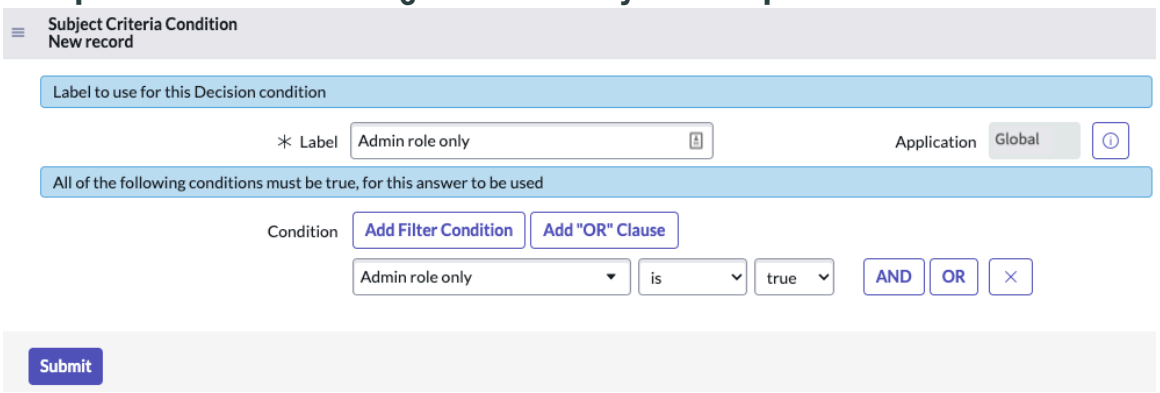


Criteria inputs [sys_df_subject_filter_criteria_m2m] are records that contain criteria to compare with the user. This can be a list of user groups or roles, an IP address range, or an IP address subnet. These records are used along with subject criteria condition records to evaluate against a user's groups, roles, or IP address to determine access to a table or it's records.

Subject criteria condition records

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Example criteria condition using the Admins Only criteria input



Use subject criteria condition [sys_df_subject_criteria_condition] records to define how to compare user attributes with the roles, groups, or IP addresses defined in you criteria inputs. You can use multiple criteria inputs in a single subject criteria condition to further narrow down access to your records.

Activate data filtration

Learn how to activate data filtration on your instance.

Before you begin

Important:

Starting with the Yokohama release, Data filtration is being prepared for future deprecation. It will be hidden and no longer activated on new instances. Consider using Security data filters to restrict access to records based on role, or security-attribute related assertions. For details see Data filtration.

Role required: security_admin

Procedure

1. Navigate to **All** > **System Definition** > **Plugins**.
2. Use the search field to find the Data Filtration (com.glide.data_filtration) plugin.
3. Click **Install**, and then in the Activate Plugin dialog box, click **Activate**.

Create data filtration rules

Learn how to create data filtration rules to grant your users' access to records are tables.

Before you begin

Role required: security_admin

Note:

To create or modify data filtration rules you, must elevate to the privileged role. For details on this process, see Elevate to a privileged role.

Procedure

1. Navigate to **All** > **Data Filtration** > **Data Filtration Records**.
2. Click **New** in the **Data Filtration** list.
   A new data filtration form displays.
3. In the form, fill in the fields as needed.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Data filtration form

Field	Description
Table	Table to which this data filtration rule applies. **Note:** Non-maint users cannot create data filtration on some tables, to work-around this remove the tableChoicesScript=DataFiltrationTableList attribute, but make sure that no filters will be created on any of the sys_df_xxx tables or any tables in the sys_df_table_exclusion.
Active	Sets the data filtration rule as active. **Note:** Keep data filtration rules inactive until you are ready to test to avoid unintentionally locking users out of records.
Description	Description of the data filtration rule.
Cascading	Select to set the data filtration rule to apply to extended tables. For example, you select the Task[task] table, and enable cascading. In this case, the data filtration rule also applies to all tables extended from task, such as Incident[incident] and Change Request[change_request]. For detail on table extension, see Table extension and classes **Note:** This field is enabled by default.

4. **Optional:** To narrow the scope of the rule fill in the **Conditions** fields as needed.

Field	Description
Subject Condition	All conditions must be met for access.
Security Attribute Condition	All conditions must be met for access. **Local** The attribute is defined only in the scope of the data filtration rule. **Existing** The attribute is defined by reference to an already existing **Security Attribute**
Data condition	Defines the conditions for data to be subject to the rule. **Note:** An empty Data Condition will apply to all records in the selected table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

5. Select **Save** from the form menu.
   After you have saved your data filtration rule, this rule automatically applies to all records on the selected table, unless specified otherwise by the data condition.

Add a data filter for your data filtration rule

You can optionally use a data filter to narrow the scope of your data filtration rule to apply only to specific records on a table.

Before you begin

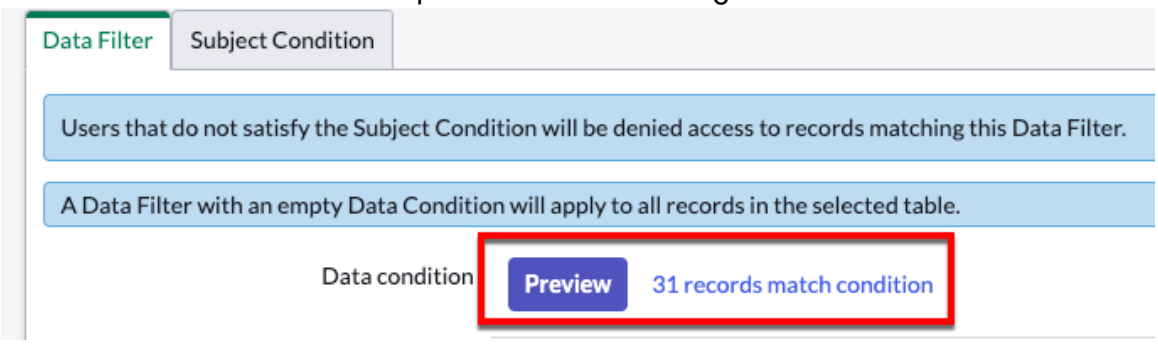
Role required: admin

Procedure

1. On your data filtration record, open the **Data Filter** tab.
2. Use the condition builder to filter the table records their field values.
   The data filter uses the same condition builder used in other parts of the platform. For details on using this interface, see Condition builder.

   Important:
   The **Data Filter** tab appears empty until you select a table in the **Table** field.

3. Use the **Preview** button to see a count of how many records match your data filter.
4. Select the number of records to open a list of the matching records.

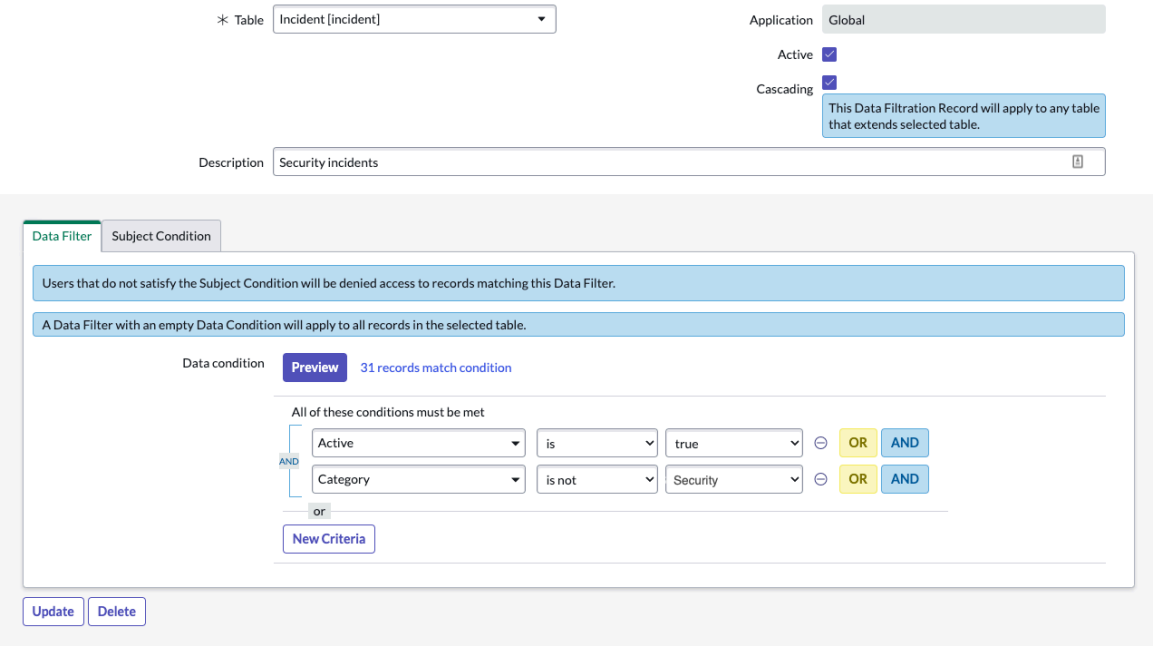


5. Select **Save**.

Example:

This example shows a data filtration rule for the Incident[incident] table. The data filter is set to select all active records that are not in the **Security** category. With this rule active, users can see these records. See the section below to further using criteria outside the contents of the record.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Important:

The **not** operation in your conditions may return unexpected results, depending on the type of database your instance uses. For example, take the following condition:

For this condition, the expected result would be that the result set would be all records where the company is not `ServiceNow` and all records that do not have a value in the **company** field. Instances using databases other than MySQL and Maria do not return values records with an empty **company** field. When using **not** queries for these instances, include conditions to ensure empty values are returned.

Add subject attributes to your data filtration rule

Optionally, use subject attributes to narrow the scope of your data filtration rule based on attributes such as IP network address, user groups and roles, or subject criteria.

Before you begin

Role required: admin

Procedure

1. On your data filtration record, open the **Subject Criteria** tab.
2. Use the condition builder to filter the table records based on one or more of the following criteria.

Subject criteria options

Option	Description
Network Criteria	Allows access to records based on network IP range or IP subnet.
Subject Criteria	Allows access to records based on subject criteria. Select a subject criteria record to apply it's conditions to your data filtration rule. For details on creating subject criteria records, see Create subject criteria.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Option	Description
Subject Group	Allow access if the user is a member of a specific group. Select a group from the **Groups**[sys_user_group] table.
Subject Role	Allow access if the user is a member of a specific group. Select a group from the **Roles**[sys_user_role] table.

Important:
Subject criteria conditions only support the **is** operator.

3. After adding your subject criteria click **Save**.

Create subject criteria

Create subject criteria records for use in data filtration rules.

Before you begin
Role required: security_admin

Important:
To create or modify data filtration rules you, must elevate to a privileged role. For details on this process, see Elevate to a privileged role.

Procedure

1. Navigate to **All** > **Data Filtration** > **Subject Criteria**.
2. In the **Subject Criteria** list, click the **New** button.
   A new subject criteria form displays.
3. In the form, fill in the fields as needed.

Subject criteria fields

Field	Description
Name	Name for the subject criteria.
Application	Scoped application for the subject criteria. This field is read-only, and automatically populates with the current scoped application.
Description	Description for the subject criteria.

4. Right-click the form header and click **Save** from the context menu.
   After saving, the **Criteria Inputs** and **Criteria Conditions** fields appear.

Create a subject criteria input

Create a subject criteria input to define criteria that your data filtration rules filter against.

Before you begin
Role required: security_admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. On your subject criteria record, open the **Criteria Inputs** tab.
2. In the **Criteria Inputs** list, click **New**.
3. Select the policy Input for the criteria you want to create.

Policy inputs

Policy input	Description
IP filter criteria	Create a policy input based on IP address
Role filter criteria	Create a policy input based on use role
Group filter criteria	Create a policy input based on user group

A **IP Filter Criteria**, **Role Filter Criteria**, or **Group Filter Criteria** form displays, depending on your selection in this step.

4. In the filter criteria form, fill in the fields as needed.

Filter criteria fields

Field	Description
Name	Name for the filter criteria
Application	Scoped application for the subject criteria. This field is read-only, and automatically populates with the current scoped application.
Description	Description of the filter criteria

5. Below the form fields are tabs used to define the IP addresses, groups, or roles for the filter criteria inputs.

Filter criteria fields for specific input types

Policy input type	Description	Creation
IP filter criteria	User IP filter criteria to create a range or subnet of IP addresses. Your subject criteria can then compare with the user's IP address against this range or subnet.	Use the **IP Range** or **Subnet (CIDR)** to define IP addresses for your input. **IP Range** In the **IP Ranges** list, double-click **Insert a new row**, and enter a starting IP address in the **Start IP**. Then, press the tab key, and enter an ending IP address in the **End IP** field. Finally, press Enter to save the list entry. **Subnet (CIDR)**

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Policy input type	Description	Creation
		In the **Subnets** list, double-click **Insert a new row**, and enter a network IP in the **Network IP** field. Then, press the tab key, and enter a netmask in the **Netmask** field. Finally, press Enter to save the list entry. **Note:** Scheduled jobs being triggered by a scheduler are not intended to have data filtered using a network criteria since they do not have the context of the requesting client IP. A more appropriate type of filtration may be the Role/Group subject condition.
Role filter criteria	Use role filter criteria to create a selection of roles. Your subject criteria can then compare with the user's assigned roles against this selection.	Use the condition builder in the **Condition field** to select roles for your input.
Group filter criteria	Use group filter criteria to create a selection of user groups. Your subject criteria can then compare with the user's assigned groups against this selection.	In the **Groups for criteria** table, double-click **Insert a new row**, and select a user group. Press Enter or click the green check mark icon to save the group. Click the **Insert a new row** text below the first entry to create additional entries.

6. After defining your input, click **Submit**.

Note:
In addition to creating criteria inputs for your subject criteria, you can also add existing ones. Click **Edit** in the **Criteria Inputs** tab, and select from any existing input.

Create a subject criteria condition

Create a condition to compare a user information against existing subject criteria input.

Before you begin

Role required: security_admin

Criteria conditions compare user attributes against existing criteria inputs to determine whether to allow access to records. In order to create a criteria condition, you need to have created subject criteria. For details on that process see, Create a subject criteria input.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. On your subject criteria record, open the **Criteria Conditions** tab.
2. In the **Criteria Conditions** list, click **New**.
3. On the **Subject Criteria Condition** form, fill in the fields as needed.

Subject criteria condition form

Field	Description
Label	A descriptive label for your condition
Application	Scoped application for the subject criteria. This field is read-only, and automatically populates with the current scoped application.

4. Create a condition for your subject criteria condition using the condition builder by selecting from the following condition options.
   These condition options include any subject criteria inputs you have created.
5. **Optional:** Create more conditions by clicking the **Add filter condition** or **Add "OR" clause** buttons.

   Note:
   Unless your conditions are separated by an **or** clause, all conditions must evaluate to true in order for the subject criteria condition to evaluate to true.

6. Click **Submit** to save the subject criteria condition.

What to do next

Use subject criteria in your data filtration rules to limit access to tables and records. For details on how to use subject criteria in data filtration rules, see Create subject criteria.

Data filtration debugging

Use the session log to see how data filtration affects your records and debug user access issues.

Before you begin

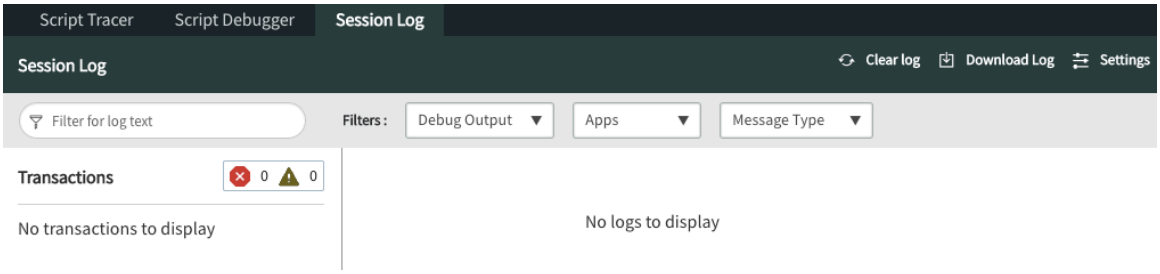
Role required: admin

Output information appears in the session logs when users access records. You can use this logging information along with impersonation to learn why users see or do not see records. You can then use that information to adjust your data filtration rules and ensure that users only see what you intend.

Procedure

1. Navigate to **All** > **System Security** > **Debugging** > **Debug All Security**.
   The **Script Debugger** opens in a new browser tab or window.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



2. In the **Script Debugger** window, select the **Session Log** tab.
3. In another browser tab or window, impersonate a user to troubleshoot that user's access.

> **Note:**
> Impersonation allows an admin to see an instance with another users settings and access. For details on impersonation, see Impersonate a user.

4. While impersonating a user, access a list or record where you see unexpected behavior. This behavior may be a record the user sees, but should not see, or a list of records that are not appearing as expected for a user.
   After accessing records with the impersonated user, you should begin to see output in the session debugger.
5. Look for data filtration information in the session debugger.

This example shows two log messages where a data filter denied access to records. The log entries appear as red text, and include why the data filter denied access, as well as the sys_id of the data filter. You can click on this sys_id to open the data filtration record.

This example shows a log message where a data filter allowed access to a record. These log entries appear as green text. As with the first message, you can click this sys_id to open the data filtration record.

6. Use this information to make any adjustments to your data filtration rules.
   Repeat these steps to refine your rules and give users the access they need.

Security data filters

Security data filters restrict access to records based on role, or security-attribute related assertions.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Exploring security data filters

Security data filters enable access restriction to records based on a users' role, or other security attribute related assertions. Security data filters ensure only authorized users can view records regardless of how data is accessed.

Security data filters are applied before a query is executed so restricted data never leaves the database. In contrast conditional ACLs filter data after a query is executed possibly leaking data.

Note:
Pair security data filters with Deny-Unless ACL to ensure consistent security

Features of security data filters

The key features of security data filters are:

- Security data filters are applied in-query.
- Security data filter conditions AND to the query on the target table and with each other.
- Security data filters are not checked by `canRead`. See When to use security data filters for more details
- Data filter scoping rules are based on the scope of the table, data filters do not follow ScopeMaster or sys_scope scope rules

Security data filter application and enforcement

Generally security data filters are applied after absolute ACLs (also called table-level ACLs), and after row ACLs. Security data filters are applied by default, and impact system behavior if not used carefully. See Default security filters for a list of the default security data filters.

Security data filters are applied only to GlideRecordSecure, GlideRecordSandbox and GlideAggregateSandbox queries by default. There are two new GlideRecord APIs `enableSecurityFeature` and `disableSecurityFeature` that can be used in both Java and server-side scripts to enable or disable data filters for a specific query.

Important:
You should explicitly enable data filters for user-facing queries that are not using GlideRecordSecure.

When to use security data filters

Security data filters are best suited to:

- Prevent sensitive data from leaving the database
- Suppress the "rows hidden by security" message
- Prevent sensitive data from leaking through reports

When not to use security data filters

Security data filters should not be used:

- As visibility control
- As replacement for ACLs
- With a large number of filter conditions
- On unindexed columns

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Security data filter behavior

Multiple security data filters combine together for evaluation, like an AND combines operands. As an example,given three security data filters:

- Filter 1: `active=true
- Filter 2: `priority=1`
- Filter 3: `state=open`

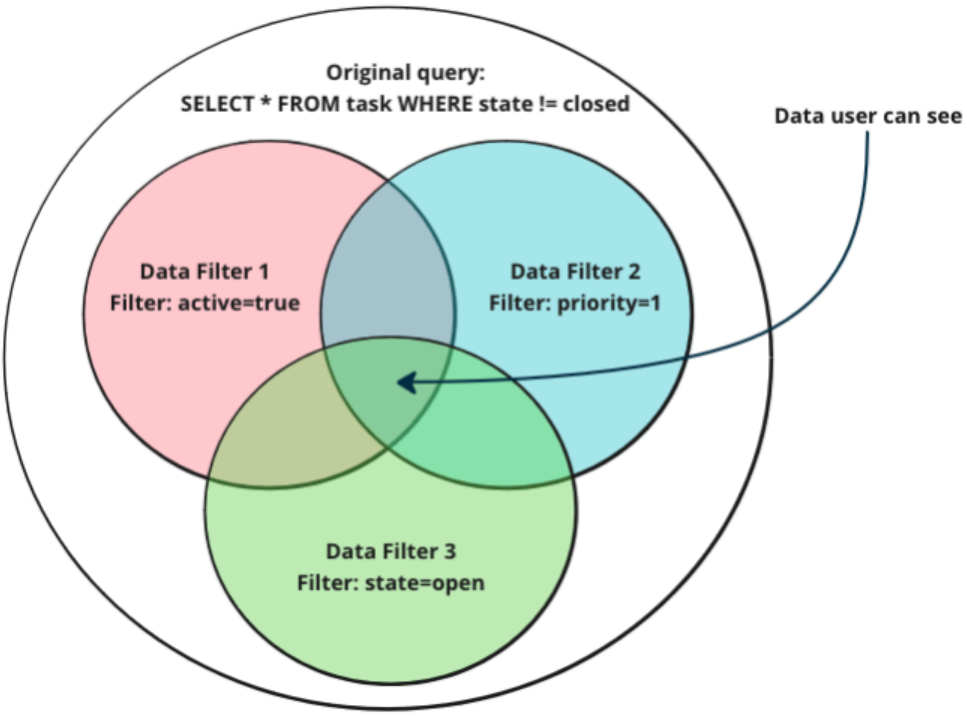
And an initial query:

```
SELECT * FROM task WHERE state != closed AND active = true AND
        priority = 1
```

The final query is:

```
SELECT * FROM task WHERE state != closed
        AND active = true AND priority = 1 AND state = open
```

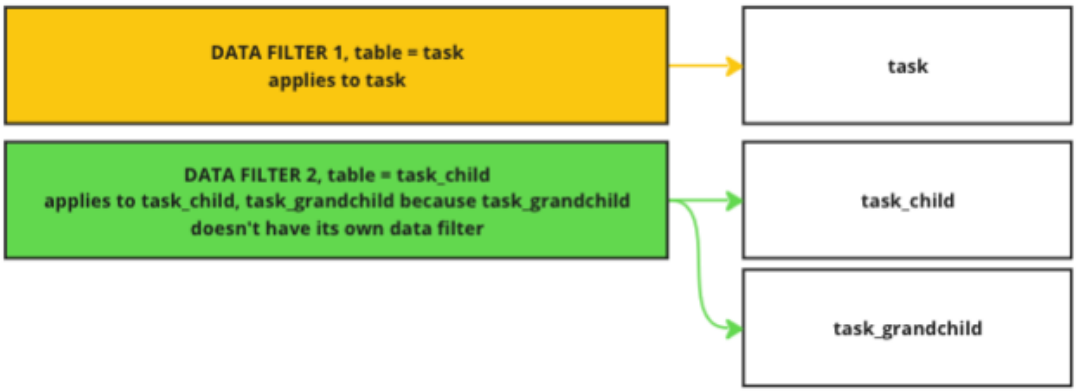
See the diagram below for a visual representation of this example:



One important difference in how security data filters and ACLs are applied is, data filters on a child table do not apply to the parent table when data is queried from the parent table. Add a data filter on both child and parent tables to

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

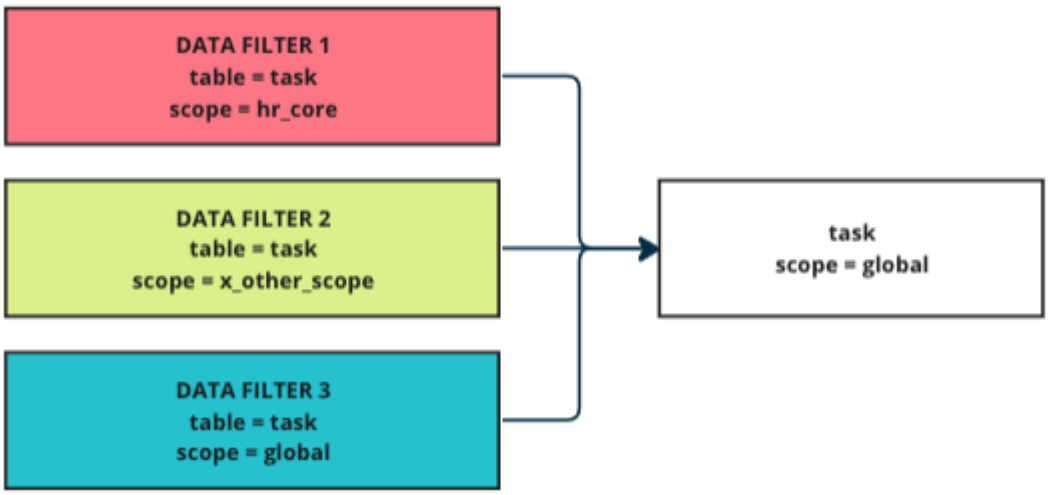
restrict access to records in the parent table. The diagram below highlights the



hierarchy:

Note:
A common solution for this is to add a data filter on the parent that completely hides child records in the parent table.

Data filters are applied with scoping rules similar to ACLs, but with some key differences because data filters apply before-



query.

Create a security data filter

Learn how to create security data filter rules to grant your users' access to records are tables.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Security** > **Security Data Filters**.
2. Click **New** in the **Security Data Filters** list.
3. In the form, fill in the fields as needed.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Data filtration form

Field	Description
Table name	The table that the security data filter applies to.
Description	Description of the security data filter rule.
Active	Sets the security data filter rule as active. **Note:** Keep security data filter rules inactive until you are ready to test to avoid unintentionally locking users out of records.
Show in UI	Determines whether a notification will be displayed in the UI if the security data filter applies to a query
Application	The application scope of the security data filter.
Mode	The mode of the data filter.
Filter	The filter condition that determines which records the data filter applies to
Security Attributes	The security attributes that control if the data filter will apply or not

4. Select **Save** from the form menu.

Result
After you have saved your security data filter rule, this rule automatically applies to all records on the selected table, unless specified otherwise by the data condition.

Default security filters

Generally data filters are applied after absolute ACLs (also sometimes called table-level ACLs), and after row-level ACLs. They are applied by default, and can be impactful to system behavior if not used carefully.

Default applied security data filters

Security data filters are applied by default to the following places:

Category	Application
List and Forms	• UI16 • Workspaces • Service Catalog • Service Portal • Mobile
Reports and Dashboards	• Reports • Data visualizations

Category	Application
	• Core UI Dashboards • Platform Analytics experience dashboards
Data Export	• Export XML • CSV • Excel • JSON • PDF
Flow Engine	Record Lookup steps
Search	• AI Search • Text Search
GlideRecord	• GlideRecordSecure • GlideRecordSandbox • GlideAggregateSandbox
REST and GraphQL APIs	• REST table API • REST stats API • GraphQL table and stats API equivalent

Security Roles

Security Roles provide added security, every user must have at least one role so that the instance can distinguish between internal and external users.

Explore Explicit Roles

Learn the key features and business value of Explicit Roles.

Explore Elevated Privilege

Learn how the Elevated privilege role enables session based privileges.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Explicit Roles

You can give both internal users and external users access to your instance. However, you might not want both types of users to have the same level of access. To provide added security, every user must have at least one role so that the instance can distinguish between internal and external users.

As of the Paris release, no user can have both of the explicit roles (snc_internal and snc_external). Groups and role containment cannot include both roles, either, since that would cause any group member or user who is assigned to such a group or such a role to automatically have both roles. The ServiceNow AI Platform aborts any operation that would create such a scenario.

Note:
You cannot add any other roles as contained roles to the "*snc_external*" or "*snc_internal*" roles.

External users must obtain, at minimum, the snc_external role. The snc_external role indicates that the user is external to your organization. They should not have any access to resources unless explicitly allowed through ACLs for the snc_external role or additional roles that inherit the snc_external role. By default, users with the snc_external role cannot access:

- Tables without the role that inherits the snc_external role or the public role.
- Non-record type resources, such as processors and UI pages without granting access to the snc_external role or a role that inherits the snc_external role.
- Platform Analytics dashboards.

Do not mark the snc_internal role as elevated. Otherwise, internal users cannot access the instance.

Explicit Roles plugin

When the Explicit Roles plugin is activated:

- All users must have the snc_internal role to access internal resources or the snc_external role to access external resources. Users without either explicit role can access only public resources.
- All existing users are automatically assigned the snc_internal role. This role does not change existing access levels or system behavior. Instead, it provides a category to differentiate internal users from external users. All internal users maintain the same level of access as before the plugin was activated.

  Tip:
  To prevent changing existing functionality for users, activating the Explicit Roles plugin assigns the snc_internal user role to all existing users in the instance. This includes any external users added before the Explicit Roles plugin was activated. After the Explicit Roles plugin is activated, do the following for all external users added before the Explicit Roles plugin was activated:

  - Remove the snc_internal role.
  - Add the snc_external role.

  Doing the preceding ensures that external users added before activating the Explicit Roles plugin do not have access to internal resources that should be available only to internal users.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Newly created users are automatically assigned the snc_internal role when they first attempt to log in to the instance, unless they have been explicitly assigned the snc_external role. You can add the snc_external role to a new user before they first log in to the instance to provide external user rights.

  Important:

  Activate this plugin during a maintenance window or when few users are logged in. Users currently logged in when the plugin is activated will not be dynamically assigned the snc_internal role. Rather, users must log out and log back in to be assigned the snc_internal role. Once the plugin is activated, you can add or remove the snc_internal and snc_external roles at any time to change user rights.

  After the plugin is activated, any time a user logs in, the user is given the snc_internal role if the account does not already have that role, or the snc_external role. This includes users logged in via impersonation.

- All existing ACLs that do not have a role requirement are automatically assigned the snc_internal role. Because both existing ACLs and users are assigned the snc_internal role, existing access levels do not change.
- Newly created ACLs that do not have a role requirement are automatically assigned the snc_internal role. This role assignment does not apply to a newly created ACL with a role assigned.
- For all existing Processor [sys_processor] records or newly created Processor [sys_processor] records with **Type=script**, the snc_internal role is automatically added to the **Roles** field if the field is empty.
- To restrict access to UI pages to internal users, the plugin automatically assigns the snc_internal role to the * ACL with a **Type** of **ui_page**.
- To restrict access to processors to internal users, the plugin automatically assigns the snc_internal role to the * ACL with a **Type** of **processor**.
- External users must obtain, at minimum, the snc_external role to access the instance. This role must be manually granted to external users. Access to records is granted through ACLs.

Do not move system update sets among instances with and without the Explicit Roles plugin enabled. For more information, see System update sets.

Note:
This plugin also requires the Contextual Security Manager plugin.

glide.security.explicit_roles.do_not_fix behavior

As of the Xanadu release the `glide.security.explicit_roles.do_not_fix` has been adjusted with changes to snc_internal. The snc_internal role is now the same both in memory and in sys_user_has_role. The new behavior for `glide.security.explicit_roles.do_not_fix` is:

glide.security.explicit_roles.do_not_fix new behavior

Value	Result
False	Add snc_internal role both in memory and sys_user_has_role

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

glide.security.explicit_roles.do_not_fix new behavior (continued)

Value	Result
True	Do not add snc_internal role in memory or sys_user_has_role

To exclude snc_internal role for certain users, use the `glide.security.explicit_roles.ignore.snc_internal.exclude_role_list` property.

Tip:
To revert to previous `glide.security.explicit_roles.do_not_fix` behavior use the `glide.security.explicit_roles.do_not_fix_in_memory` property.

Providing table access to external users

You can provide external users access to a table by adding a role to the table that inherits the snc_external role. For more information, see Provide external users access to a table.

The hasRoles() method

The `hasRoles()` method is still available, but is deprecated in the Geneva release. Use the `hasRole(role name)` method instead.

If you do use the `hasRoles()` method, note these changes:

- This method automatically excludes the default snc_internal role when it checks for roles. This means that if a user has only the snc_internal role, the `hasRoles()` method still returns **false**.
- If the user has the snc_external role, the method returns **false** because the instance considers external users to be without a role.

Mutual exclusion: snc_external versus snc_internal

The ServiceNow AI Platform prevents users from having both the snc_external role and the snc_internal role. The ServiceNow AI Platform applies this mutual exclusion everywhere in the system and writes error messages to the logs for each conflict.

Note:
ACLs can have both roles if the ACL resources should be accessible to all users.

Example: Adding both explicit roles to a user (direct collision):

1. Assign user Abel Tuter the snc_internal role.
2. Assign user Abel Tuter the snc_external role.

Result: Adding the snc_external role fails because Abel Tuter has the snc_internal role.

Example: Adding both explicit roles to a group (direct collision):

1. Consider a group called Test Group that currently has no explicit roles assigned to the group.
2. Add Abel Tuter to the Test Group.
3. Add the snc_external role to Test Group.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Result: Adding the snc_external role fails because Abel Tuter already has the snc_internal role and can't have both roles.

Example: Adding an explicit role to a group where a group member has the conflicting explicit role (indirect collision):

1. Assign user Abel Tuter the snc_internal role.
2. Consider a group called Test Group that currently has no explicit roles assigned to the group.
3. Add Abel Tuter to the Test Group.
4. Add the snc_external role to the Test Group.

Result: Adding the snc_external role to the group fails because Abel Tuter would inherit the snc_external role through group membership. Both explicit roles would be assigned to the same user, which isn't allowed.

For other examples, see the following table:

Role	Attempted action	Result
Direct collision		
The user has the snc_internal role.	Add the snc_external role.	The action is aborted.
The user has the snc_external role.	Add the snc_internal role.	The action is aborted.
The user has no explicit role.	Add the snc_internal or snc_external role.	The role is added.
The user has both explicit roles (existing collision).	Add the user to a group with no roles.	The action is aborted.
A role not associated with any users contains the snc_internal role.	Add the snc_external role.	The action is aborted.
A role not associated with any users contains the snc_external role.	Add the snc_internal role.	The action is aborted.
A role contains both explicit roles (existing collision).	Add the role to a user, role, or group.	The action is aborted.
A group with no members has the snc_internal role.	Add the snc_external role.	The action is aborted.
A group with no members has the snc_external role.	Add the snc_internal role.	The action is aborted.
A group with no members has no roles.	Add the snc_internal or snc_external role.	The role is added.
Indirect collision		

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Role	Attempted action	Result
Role containment with collision	1. Grant a role called Test Role to a user with the snc_internal role. 2. Add the snc_external role Test Role.	The action is aborted.
Role containment without collision	1. Grant a role called Test Role to a user with no roles. 2. Add the snc_external role to Test Role.	The role is added to both the user and Test Role.
Group containment with collision	1. Add a user who has the snc_internal role to a group called Test Group 2 (child of Test Group 1). 2. Add the snc_external role to Test Group 2. 3. Add the snc_external role to a parent group called Test Group 1 (parent of Test Group 2).	The action is aborted.
Group containment without collision	1. Add a user with no roles to a group called Test Group 2 (child of Test Group 1). 2. Add the snc_external or snc_internal role to Test Group 1 (parent of Test Group 2).	The role is added to the parent group, the child group, and the user.
Group containment plus role containment with collision	Add contains_external to Test Group 1, the parent of Test Group 2.	Test Group 1 and Test Group 2 both get contains_external, but don't explicitly get the snc_external role.
	Add the snc_internal role to Test Group 2, the child of Test Group 1.	The action is aborted.
Group parent change plus group containment	1. Remove Test Group 1 as the parent of Test Group 2. 2. Add the snc_internal role to Test Group 1. 3. Add the snc_external role to Test Group 2. 4. In Test Group 2, set Test Group 1 as the parent group and save.	The action is aborted. Repeat for already nested groups, with the same expectation.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The cause of an aborted action appears in the error message and must be addressed before another attempt succeeds.

For direct cases, such as adding an explicit role to an individual user, verify which explicit role the user should have. If the user has the wrong explicit role, it must first be removed, and then the correct explicit role must be added.

For indirect cases,such as adding an explicit role to a group (so that a group member would be assigned both explicit roles), evaluate whether that user should be in the group. Also determine whether the group should be given the explicit role, including any inheritance through group hierarchy and role containment.

Note that the ServiceNow AI Platform reports only the first potential collision encountered. If repeated attempts continue to fail after remediation, with a new root cause each time, re-evaluate the relevant user/group/role interdependence more broadly. You may want to rethink how groups and role containments are structured.

Request Explicit Roles

Activate Explicit Roles by requesting the Explicit Roles plugin (com.glide.explicit_roles) through the Now Support Service Catalog.

Before you begin

Role required: admin

Important:
Activate this plugin during a maintenance window or when few users are logged in. Users currently logged in when the plugin is activated will not be dynamically assigned the snc_internal role. Rather, users must log out and log back in to be assigned the snc_internal role. Once the plugin is activated, you can add or remove the snc_internal and snc_external roles at any time to change user rights.

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Select **Request plugin** to open the **Activate Plugin** form on Now Support.
3. On the **Activate Plugin** form, provide the following information.

Activate Plugin form

Field	Description
What is your target instance	Select the instance that you want to activate the plugin on.
Which plugin would you like to activate	Select the name of the plugin to activate. **Note:** If the system doesn't list the plugin you want or if you're activating the plugin on an OEM or on-premise instance, select the **Plugin I'm looking for is not listed** check box and then enter the name of the plugin.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Select Maintenance Date and Time	Select the date and time to activate the plugin.

Example

For example, see the following form to activate the Event Management plugin on an instance named SNC Instance.

4. Select **Submit**.
   After the maintenance window, the system installs the plugin on your instance. To confirm the installation, go to the Installed tab in the Application Manager.

Elevated privilege roles

Elevated privilege roles require you to manually accept the responsibility of using the role before you can access the features of the role.

By default, you do not have elevated privilege roles upon login. You must manually elevate to the privilege of the role. An elevated privilege role lasts only for the duration of your user session. Session timeout or logout removes the role.

You can designate any role as an elevated privilege role, and then assign that role to one or more users. Do this when you want to restrict users from having access to the rights that the role provides immediately after login. You can designate the privilege role on the Role form. See Create a role for instructions.

To use an elevated role, you must meet these conditions:

- The elevated role must be assigned to you.
- You must manually elevate to a specific elevated role to get its privileges, even if you are already elevated to a second elevated role that contains the first elevated role.

  For example, if elevated role A contains elevated role B, even if you elevate to role A, you must still elevate to role B to get its privileges.

The admin role

To grant the admin role to a user, the granting user must also have the admin role. For example, a user with only the user_admin role cannot grant the admin role to other users.

- Non-admin users cannot add a user to a group that contains the admin role.
- To grant the security_admin role to a user, the granting user must also have the admin role and must elevate to the security_admin role before granting the security_admin role to other users. A user with only the admin role cannot grant the security_admin role to other users.
- A user without the security_admin role cannot add a user to a group that contains the security_admin role.

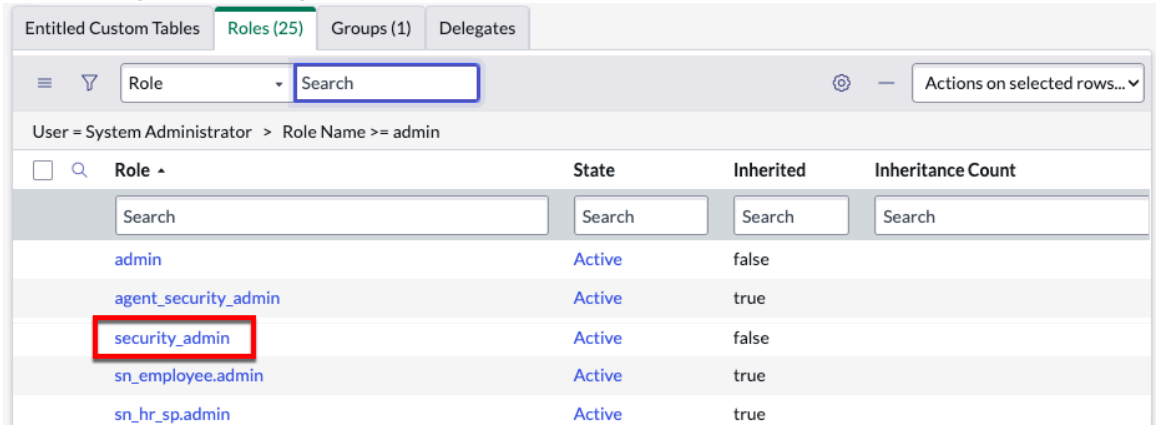
Warning:
The use of elevated privilege on an admin role is not supported. Instead, require admins to manually elevate, see Force administrators to manually elevate

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The security_admin role

In the base system, the security_admin role is the only role that has elevated privileges. This role is automatically assigned to the user who is the default System Administrator (admin) user. It provides access to ACLs and High Security Settings.

Roles assigned to the System Administrator (admin) user



Note:
To see this role, you must actually elevate to the security_admin role first. If you are logged in as the System Administrator (admin) user only, you cannot see the security_admin record in the list of roles.

Security_admin role

The security_admin role is an elevated privilege role provided with High Security Settings that lets users create and change access controls and change High Security Settings.

In the base system, only the default System Administrator (admin) user has the security_admin role. Since it requires elevating privileges, the admin user does not have this role at login. After elevating privileges, the admin user has the security_admin role for the duration of the user session. See Elevate to a privileged role for more information.

To maintain high security, the security_admin role requires elevating privileges. Limit the users and groups to which you assign this role.

Elevate to a privileged role

The base system admin can elevate to a privileged role to have access to the features of High Security Settings.

Before you begin

Role required: admin

Note:
If you grant additional users the admin role, they cannot elevate to a privileged role. Only the base system admin can elevate.

Procedure

1. In the banner frame, click your image, or click your initials if you do not have an image uploaded.
2. Select **Elevate Roles**.
   A dialog box appears that contains available roles for elevation.
3. Select the elevated roles to be assigned and click **OK**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

This role grants the user elevated privileges to all resources controlled by the role for the remainder of the session. When the user logs out, the elevated privileges are terminated with the session but may be reestablished at the next login.

4. End role elevation by returning to the dialog box in step 2, and deselecting the role.

Force administrators to manually elevate

A property is available to force all users with the administrator role to manually select the role that they want to elevate to.

Before you begin
Role required: security_admin

Procedure

1. Log in as admin.
2. Elevate your role to security_admin.
3. Navigate to **sys_properties.list**.
4. Search for and select the *glide.security.strict_elevate_privilege* property.
5. Set the Value field to **true** and click **Submit**.

Result
When the user logs in, they are presented with a dialog window to select the role to which they can elevate.

Connections and Credentials

Credentials and connection information are required to gain access to a computer or network device for Discovery, Service Mapping, and Cloud Management or to perform work using Orchestration. When adding content to Share or AppStore, you can configure connections and credentials relevant to your environment without modifying built content.

Get details about Credentials.

Troubleshoot

Learn how to troubleshoot issues in connections and credentials.

Explore credentials, connections, and aliases

All application integrations in the ServiceNow AI Platform use connections, credentials, and aliases to enable applications to access resources.

Before you can execute an application integration in the ServiceNow AI Platform, you must create and configure connection information, corresponding credentials, and add an alias. To understand how ServiceNow defines these terms:

Connection

A connection is an integration with a system, such as an IP address or endpoint with protocols. It contains specific details, such as database particulars, when integrating with a database.

Credential

A credential is the authentication data required to make the connection, such as an ID and password.

Alias

An alias is a naming convention, or tag, that ties to a set of connections or credentials on your instance. An alias contains the necessary connection and credential information to make an application integration. Rather than enter that information every time you integrate, you can use an alias. For example, you can designate an alias to house your QA, development, and production credentials for the same application integration. The alias resolves the application integration for each environment.

The ServiceNow AI Platform distinguishes different types of aliases:

Credential Alias

This alias associates to credential data only, and resolves during runtime.

Connection and Credential Alias

This alias associates to connection information and the credential data required to complete the integration, and resolves during runtime.

Within connection and credential aliases, you can also create additional aliases called child aliases. Child aliases allow you to create multiple connections within the same application integration. When you create a child alias, the alias you created it under becomes a parent alias. While child aliases inherit properties from their parent alias, child aliases carry their own connection and credential information.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Benefits to using Connections, Credentials, and Aliases

- Central location to store and manage credentials to an external service
- Define once and reuse for multiple platform features
- Minimize configuration of other platform features
- Allow non-administrators to use predefined connections and credentials
- Increased security

Features using Connections, Credentials, and Aliases

The following features use connections, credentials, and aliases:

- Flow Designer
- IntegrationHub
- Cloud Management
- Discovery
- Orchestration
- Service Mapping

You can set up aliases on the ServiceNow AI Platform in one of two ways:

- Using the Connections and Credentials module. See Create a Connection & Credential alias.
- In the Connections dashboard of Integration Hub. See Add a connection.

> **Note:**
> Integration Hub requires a separate subscription. For more information, see Request Integration Hub.

Credential synchronization on MID Servers

Each MID Serverin your network synchronized with the instance keeps a copy of every credential that you create. The Management, Instrumentation, and Discovery (MID) Server is a Java application that enables communication and the movement of data between a ServiceNow instance and external applications, data sources, and services. This synchronization speeds up the reading of credentials when applications like Discovery or Service Mapping need to access multiple devices on the network. The MID Servers synchronize when they find a *credentials_reload* job in the ECC Queue. The reload job instructs the MID Server to make a SOAP call to the instance to get the entire list of credentials in the Credentials [discovery_credentials] table, including all the field values. To learn more, see MID Server.

The SOAP response that your instance sends to each MID Server also includes custom fields that you added to any credential form that you customized. If you added reference fields, the data in the referenced table is also sent as part of the SOAP response. This can lead to performance issues when credential synchronization occurs with multiple MID Servers. To control this, manually add these properties to the System Properties [sys_properties] table:

> **Note:**
> To change the values in these properties, add them to the System Properties [sys_properties] table. If you do not add them, the system uses the default value.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Property	Description
com.snc.credentials_user_fields	Includes all customized fields in credential sync. Set this property to false if you do not want to include the fields that you added to credential forms. • **Type**: true | false • **Default value**: true
com.snc.credentials_recursion_depth	Defines the number of tables to traverse when the credential-sync mechanism collects fields from reference tables. Lower this number if you are experiencing performance issues and you have customized credential forms that include reference fields to tables that also have reference fields. • **Type**: integer • **Default value**: 3

Scope protections for Credentials and Connections

You can classify certain types of Connection & Credential records as belonging to a scope, and extend scope protections to them. These scope policies protect records you create in a table, and prevent interactions with records that are private to another scope.

An **Application** field is available in the Connection [sys_connection] and Discovery Credentials [discovery_credentials] tables for associating these types of records to specific scopes. It is not visible on UI forms in Zurich, but you can easily add it to them. To learn more about these record types, and adding the field to their UI forms, see:

- Get started with connections
- Get started with credentials
- Credential aliases for Discovery
- Configuring the form layout

Restricting the use of a Connection & Credentials record to a specific scope is important for managing applications that require enforced security. These applications include HR Service Delivery or Security Operations Connection & Credentials records created in scoped administered applications are not visible to admin users. Associating a Connection & Credentials record to a specific application scope affords the following protections:

- Applies Access Control List rules (ACLs) to restricted scopes. To learn more about scoped ACLs, see Access control list rules.

  Note:
  Some applications using scope administration and enforced security may require additional setup. To learn more, see Manage HR roles

- Protects records when queried using a script. If you do a query from the Global scope, and the Connection & Credential record is in a protected scope, it doesn't appear in the query, unless given access to it.

You can customize and grant access to query-restricted records by using Restricted Caller Access. To learn more, see Restricted caller access privilege settings. Scoping restrictions

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

also apply to all children tables of the Connection [sys_connection] and Discovery Credentials [discovery_credentials] tables. Empty fields and other scopes are not restricted.

Note:
Scope protections are only enabled for specific secured scopes to avoid confusion when setting up new records. If someone makes a connection in their scoped application scope, it doesn't have automatic scope restriction.

Domain separation and Credentials and Connections

Domain separation is supported in Credentials and Connections. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: Standard

- Includes all aspects of **Basic** level support.
- Application properties are domain-aware as needed.
- Business logic: The service provider (SP) creates or modifies processes per customer. The use cases reflect proper use of the application by multiple SP customers in a single instance.
- The instance owner must configure the minimum viable product (MVP) business logic and data parameters per tenant as expected for the specific application.

Sample use case: An Admin must be able to make comments required when a record closes for one tenant, but not for another.

For more information on support levels, see Application support for domain separation.

Overview

Credentials are tied to various ServiceNow features which access systems outside the instance. Credentials follow the domain separation tied to the feature employing the credentials.

Connections are protocol-specific information referencing a target host outside the instance. A connection can specify the domain to run an activity.

How domain separation works in Credentials and Connections

Credentials access resources outside of the instance, and are used by the Discovery, Orchestration, Service Mapping, and Cloud Provisioning and Governance applications. These credentials are not tied to a specific domain, rather, they can be bound to an application and then follow the domain separation that the application uses. Credentials can also be assigned to a MID Server, and then follow the domain separation specified by the MID Server configuration.

Connections access a target host using a JMS, JDBC, or HTTP(s) connection. You can specify global or a specific domain to which the connection belongs.

Domain separation for service providers

Connection & Credential configuration templates

Enable users with the admin and flow_designer roles to set up spoke integrations with third-party systems using a single, customizable form.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

For example, you can set up an OAuth integration, which registers an OAuth provider, generates a token, and creates connection and credential records. An action designer or developer can use a configuration template to set up the spoke in one place and the system creates the associated records.

Benefits

Configuration templates enable:

- Admins or flow designers to set up a complex integrations using a single form.
- Developers to set static values in an integration, simplifying the setup process for admins and flow designers.

Supported credential types

You can create configuration templates for integrations with these credential types:

- Basic auth
- API key
- OAuth JWT Bearer grant type
- OAuth Authorization Code grant type
- Custom authentication

Configuration template components

Default Data Template

Sets static information that applies to every integration. For example, you can set the API and token URL if the value applies to every integration.

Dynamic Data Template

Defines the information that the user must complete to set up the integration. For example, you can add user name and password key-value pairs to gather user-defined values.

Post Processing Script

Creates additional records required by the integration. For example, if your spoke includes custom tables, you can create records in those tables based on user input in the configuration template. This script executes after the connection and credential records are created.

Pre Edit Script

Pre-populates the custom fields in the **Additional Information** section when you edit an existing connection. Pre-populating the custom fields enables you to view the current value associated to the custom field.

Test Action

Enables you to test a connection directly from an integration action in the flow view of Workflow Studio. The test action uses an action definition to test the alias that the template is currently attached to. For details, see Create a test action to test a connection alias from a configuration template.

Demo data

The Connection & Credential Templates [sys_alias_templates] table includes example templates to demonstrate how to set up templates for common authentication types. Use these examples as a guide when creating your own.

Configure a template for OAuth JWT Bearer grant type

This example configuration template sets up Credential and Connection records using the JWT Bearer grant type to authenticate requests to Docusign.

Default data template

Each top-level item in the default data template creates an associated record. The template includes these sections:

- `Credential`: Creates a record in the Credentials table.
- `Connection`: Creates a record in the Connections [sys_connection] table and any associated connection records.
- `Additional`: Optionally creates records in a custom table. The post processing script tells the system what to do with these records.

The following example creates the records required for OAuth JWT Bearer grant type authentication.

```
{
  "credential": {
    "oauth_entity": {
      "oauth_entity_profile": [
        {
          "grant_type":
 "urn:ietf:params:oauth:grant-type:jwt-bearer",
          "name": "Docusign Profile",
          "default": true,
          "oauth_entity_profile_scope": [
            "users:read.email"
          ]
        }
      ],
      "code_challenge_method": "S256",
      "type": "consumer",
      "oauth_entity_scope": [
        {
          "oauth_entity_scope": "users:read.email",
          "name": "email"
        }
      ],
      "client_id": "<provider-client-id>",
      "use_mutual_auth": false,
      "revoke_token_url":
 "https://<provider-domain-name>.com/oauth2/revoke",
      "default_grant_type":
 "urn:ietf:params:oauth:grant-type:jwt-bearer",
      "public_client": false,
      "oauth_api_script": "3e3a3a11c333210016194ffe5bba8f70",
      "name": "Docusign Spoke OAuth",
      "client_secret": "<provider-client-secret>",
```

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
      "auth_url":
 "https://<provider-domain-name>.com/oauth2/auth",
      "token_url":
 "https://<provider-domain-name>.com/oauth2/token",
      "redirect_url":
 "https://<instance-name>.service-now.com/oauth_redirect.do"
    },
    "jwt_provider": {
      "jwt_keystore_aliases": {
        "kid": "<provider-key-id>",
        "name": "Docusign Spoke JWT Key",
        "signing_keystore": "<signing-keystore-sys-id>",
        "signing_algorithm": "rsa_256",
        "signing_key_password": "password"
      },
      "jwt_claim_validation" : [ {
        "name" : "iss",
        "is_standard" : true,
        "data_type" : "string",
        "value":"<docusign-iss-claim>"
      }, {
        "name" : "sub",
        "is_standard" : true,
        "data_type" : "string",
        "value":"<docusign-sub-claim>"
      }, {
        "name" : "aud",
        "is_standard" : true,
        "data_type" : "string",
        "value":"<docusign-aud-claim>"
      }, {
        "name" : "scope",
        "is_standard" : false,
        "data_type" : "string",
        "value" : "signature impersonation"
      } ],
      "name": "Docusign Spoke JWT Provider",
      "jwt_api_script": "9ef6af86ff10330001d3cd6bd53bf144"
    },
    "name": "Docusign Spoke Credential",
    "table": "oauth_2_0_credentials"
  },
  "connection": {
    "use_mid": false,
    "connection_url": "https://<provider-domain-name>.com",
    "name": "Docusign Spoke Connection",
    "table": "http_connection"
  },
"additional":{
    "docusign_account_name": "<docusign-account-name>",
    "docusign_account_email": "<docusign-account-email>"
}
}
```

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Dynamic data schema

The dynamic data schema defines what the user sees when they create a Connection & Credential alias and collects their input. Use dot-walking syntax to map user input to fields created in the default data template. For example, `connection_fields` maps user input to the `connection_url` field in the `connection` object created by the default data template.

```
{
  "connection_fields": [
    {
      "name": "connection.connection_url",
      "label": "Connection URL",
      "type": "text",
      "defaultValue": "https://demo.docusign.net",
      "hint": "Connection URL for Docusign"
    }],
"additional_fields":[
    {
      "name": "additional.docusign_account_id",
      "label": "Docusign Account Number",
      "type": "text",
      "hint": "Docusign Account Number"
    },
    {
      "name": "additional.docusign_account_name",
      "label": "Docusign Account Name",
      "type": "text",
      "hint": "Name to identify the Docusign account"
    },
    {
      "name": "additional.docusign_account_email",
      "label": "Docusign Account Email",
      "type": "text",
      "hint": "Docusign Account Email"
    }
  ],
  "credential_fields": [
    {
      "name": "credential.oauth_entity.client_id",
      "label": "OAuth Client ID",
      "type": "text",
      "hint": "Client ID for Docusign"
    },
    {
      "name": "credential.oauth_entity.redirect_url",
      "label": "OAuth Redirect URL",
      "type": "text",
      "defaultValue":
 "https://<instance-name>.service-now.com/oauth_redirect.do",
      "hint": "Callback URL for Docusign"
    },
 {
      "name":
 "credential.jwt_provider.jwt_claim_validation[0].value",
      "label": "Issuer (iss) Claim value",
      "type": "text",
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
      "hint": "The integrator key (also known as client ID) of
 the application"
    },
 {
      "name":
 "credential.jwt_provider.jwt_claim_validation[1].value",
      "label": "Subject (sub) Claim value",
      "type": "text",
      "hint": "The user ID of the user to be impersonated"
    },
 {
      "name":
 "credential.jwt_provider.jwt_claim_validation[2].value",
      "label": "Audience (aud) Claim value",
      "type": "text",
      "defaultValue": "account-d.docusign.com",
      "hint": "The URI of the authentication service instance to
 be used e.g. account.docusign.com"
    },
    {
      "name":
 "credential.jwt_provider.jwt_keystore_aliases.kid",
      "label": "Key ID (kid)",
      "type": "text",
      "hint": "Indicates which key was used to secure the JWS"
    },
    {
      "name":
 "credential.jwt_provider.jwt_keystore_aliases.signing_keystor
e",
      "label": "Key Store",
      "type": "file"
    }
  ]
}
```

Post processing script

The following post processing script maps user input to fields in the sn_docusign_spoke_accounts table.

```
(function execute(aliasId, connectionSysId, jsonDefaultData,
 jsonDynamicData) {
 var jsonDynamicDataP = JSON.parse(jsonDynamicData);
 var accountGR = new GlideRecord("sn_docusign_spoke_accounts");
    accountGR.setValue("account_name",
 jsonDynamicDataP["additional.docusign_account_name"]);
    accountGR.setValue("alias", aliasId);
    accountGR.setValue("email",
 jsonDynamicDataP["additional.docusign_account_email"]);
    accountGR.setValue("id",
 jsonDynamicDataP["additional.docusign_account_id"]);
    accountGR.insert();
})(aliasId, connectionSysId, jsonDefaultData, jsonDynamicData);
```

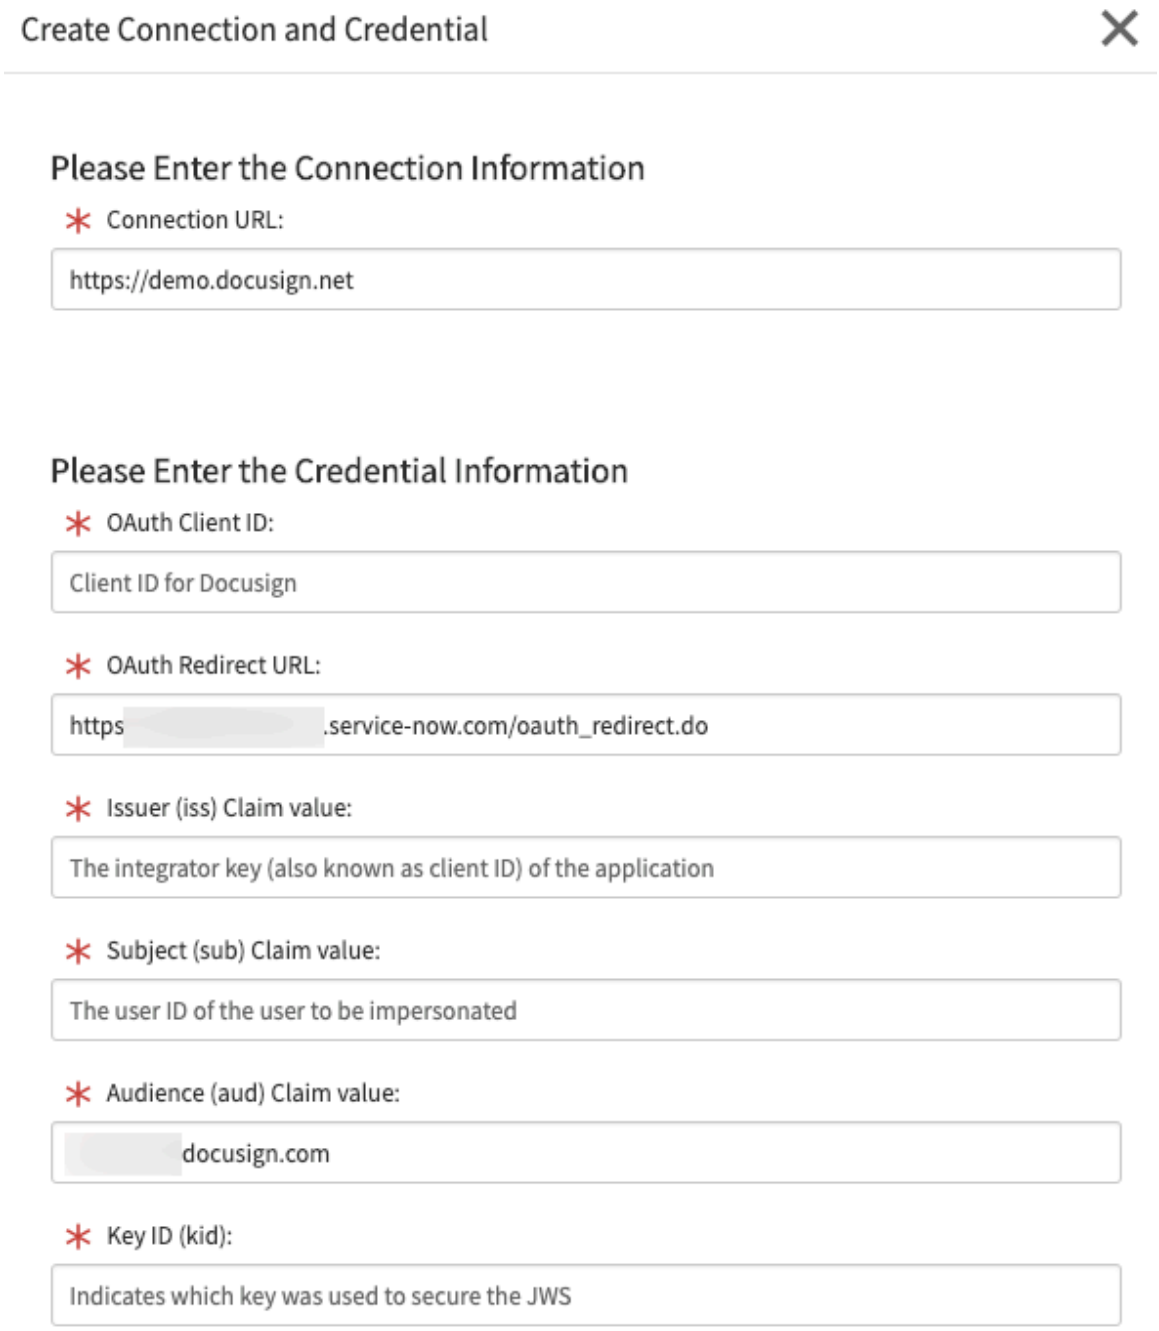
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Resulting Docusign Connection and Credential configuration form

When the user navigates to the associated Docusign Connection & Credential Alias and selects **Create New Connection & Credential**, the following dialog appears.



Create a configuration template

Create a template that defines the inputs required to set up a spoke. Set static key-value pairs to create records and set values that apply to every integration. Set dynamic key-value pairs to gather user input and set field values that may vary. Using this template, admins and flow designers can set up the spoke from a single form.

Before you begin
Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **IntegrationHub** > **Connections & Credentials** > **Configuration Templates**.
2. Select **New**.
3. Select the type of configuration template that you want to create.

4. In the **Name** field, add a name to identify the template.
5. In the **Default Data Template** field, make any required changes.

   This field sets static information that applies to every integration. For example, you can set the API and token URL if the value applies to every integration.

   These objects in the default data template are required:

   - `credential`: Creates a credential record with the required fields.
   - `connection`: Creates a connection record with the required fields. Access connection attributes using the `extended_attributes` child object. For example:

```
"connection": {
            "extended_attributes": {
                "api_version": "v1"

             },
        "connection_url":
 "https://<provider-domain-name>.com",
        "name": "Spoke Connection",
        "table": "http_connection"
    }
```

   You can use the `additional` object to set up data for a custom table, and use the post processing script to insert the data into the table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
In the default data template for the OAuth Authorization Code grant type, the values for the `oauth_entity_profile_scope` and the `oauth_entity_scope` keys must match. In the following example, both keys have the `Read user's email` value.

```
"oauth_entity_profile": [
        {
          "grant_type": "authorization_code",
          "name": "<provider-name> Profile",
          "default": true,
          "oauth_entity_profile_scope": [
            "Read user's email"
          ]
        }
      ],
      "code_challenge_method": "S256",
      "type": "consumer",
      "oauth_entity_scope": [
        {
          "oauth_entity_scope": "Read user's email",
          "name": "email"
        }
      ],
```

6. In the **Dynamic Data Schema** field, make any required changes.

   This field Defines the information that the user must complete to set up the integration. For example, you can add user name and password key-value pairs to gather user-defined values.

   Fields in the dynamic data schema include these properties:

   - `name`: The field that the user's input maps to. For example, to map user input to the Connection URL field in the Connection record, enter `connection.connection_url`.
   - `label`: The field label that the user sees when completing the template.
   - `type`: The field type. Make sure that this data type matches the data type of the field you are mapping the value to.
   - `defaultValue`: Optional. The field's default value. If no default is provided, the hint displays.
   - `hint`: Optional. Hint text to display when there is no default value.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
If setting up a template for OAuth JWT Bearer grant type authentication, you may want user input for a single key-value pair in the `jwt_claim_validation` array. You can refer to a single key-value pair in the dynamic data schema by referring to its index in the array. For example, your default data template might include this snippet.

```
"jwt_claim_validation" : [ {
       "name" : "iss",
       "is_standard" : true,
       "data_type" : "string",
       "value":"<docusign-iss-claim>"
     }, {
       "name" : "sub",
       "is_standard" : true,
       "data_type" : "string",
       "value":"<docusign-sub-claim>"
     }, {
       "name" : "aud",
       "is_standard" : true,
       "data_type" : "string",
       "value":"<docusign-aud-claim>"
     }, {
       "name" : "scope",
       "is_standard" : false,
       "data_type" : "string",
       "value" : "signature impersonation"
     } ],
```

Refer to the `iss` key-value pair using the item's zero-based index: `credential.jwt_provider.jwt_claim_validation[0].value`.

7. **Optional:** In the **Post Processing Script** field, add a script that c Creates additional records required by the integration. For example, if your spoke includes custom tables, you can create records in those tables based on user input in the configuration template. This script executes after the connection and credential records are created.
   The post-processing script has access to these global objects.

Global object	Description
aliasId	Sys_id of the alias record from the Connection & Credential Alias [sys_alias] table.
connectionSysId	Sys_id of the connection record created by the template.
jsonDefaultData	JSON content from the **Default Data Template** field in String format.
jsonDynamicData	JSON content from the **Dynamic Data Template** field in String format.

8. In the **Pre-Edit Script** field, add a script to pre-populate the additional fields when you edit a connection.

   This script returns an array of objects. Each object has a name-value pair for populating the additional fields. For example, if the connection requires fields that are in a custom table, you can map these fields to the custom table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The **Pre-Edit Script** has access to the following global objects:

Global object	Description
aliasId	Sys_id of the alias record from the Connection & Credential Alias [sys_alias] table.
connectionSysId	Sys_id of the connection record created by the template.
jsonDefaultData	JSON content from the **Default Data Template** field in String format.
jsonDynamicData	JSON content from the **Dynamic Data Template** field in String format.

Each object in the script has the following properties:

- `name`: Name of the custom field to specify the value in the connection.
- `value`: Value that you want to map to populate the custom field. You can map the field either by using a function, variable, or by hard-coding it.

The following data types are supported for the fields:

Supported data types for the fields

Type	Description
Text	String value.
Boolean	Selection box. Selection indicates true value and unselection indicates false value.
Number	Numerical value.
Date	Date value in yyyy-mm-dd format. You can also use the GlideDate object.
Choice	List of valid choices defined in the **Dynamic Data Schema** field.
Reference	Valid GlideRecord.
Radio group	Groups that contains a different set of fields. These groups are available as a choice in a drop-down list when you edit a connection. The fields in each group appear when you select the required group from the drop-down list. For example, consider the following structure of radio group defined in the **Dynamic Data Schema** field: `{ "name": "radio_groups", "label": "Radio Groups", "type": "radio", "groups": [{ "name": "radio_group1", "label": "Radio Group 1", "fields": [{ "name": "radio_field1", "label": "Radio Field 1", "type": "text",`

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Type	Description

	<pre>"defaultValue": "efgh",
	"mandatory": true
	}]
	}, {
	"name": "radio_group2",
	"label": "Radio Group 2",
	"fields": [{
	"name": "radio_field2",
	"label": "Radio Field 2",
	"type": "text",
	"defaultValue": "abcd",
	"mandatory": true
	}],
	"default_group": true
	}</pre> For this example, you can use the following code snippet to understand how radio groups are used in the script by using dot-walking: <pre>{
	name:
	"radio_field.first_radio_group.radio_field1",
	value: "radio field 1"
	}, {
	name:
	"radio_field.second_radio_group.radio_field2",
	value: "radio field 2"
	}, {
	name: “radio_groups”,
	value:
	gr.getValue(‘radio_groups’)
	}</pre> For more information on how to use dot-walking, see Dot-walking.

Tip:
If the pre-populated values are not appearing in the fields while editing a connection, navigate to **System Diagnostics** > **Session Debug** > **Debug Log** to diagnose the issue.

9. **Optional:** In the **Test Action** field, enter the name of the test action.
   Creating a test action enables you to test a connection directly from an integration action in the flow view of Workflow Studio. The test action uses an action definition to test the alias that the template is currently attached to. For details, see Create a test action to test a connection alias from a configuration template.
10. Add the template to a Connection & Credential alias.
    a. Navigate to **IntegrationHub** > **Connections & Credentials** > **Connection & Credential Aliases**.
    b. Open the alias record for the spoke.
    c. In the **Configuration Template** field, click the Lookup icon.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

d. Select the template that you created from the list.

e. Click **Update**.

Result

When the user navigates to the associated Connection & Credential alias and selects **Create New Connection & Credential**, a dialog appears to collect their input. If you created a template for the OAuth Authorization Code grant type, you can also retrieve an OAuth token from this dialog.

What to do next

Test the template by navigating to the associated Connection & Credential alias and selecting **Create New Connection & Credential**. Verify that the dialog collects the expected data and creates the required records in the system.

Get started with connections

Use the connections table to set up a Basic, JMS, JDBC, or HTTP(s) connection to a target host.

Connection Table

The Connection table (sys_connection) is the base table for all connection tables. You can set up connections for the following protocols:

- Basic connection for PowerShell and SSH
- JDBC
- JMS
- HTTP(s)

The connection table references the connection alias table, which couples the connection alias to connection information. Every connection records the following information:

Base connection properties

Field	Description
Name	Name of the connection. This field must be unique on the table.
Credential	Specify the credential to use with this connection. This is optional.
Connection alias	The connection alias resolves your connection and credentials at run time. Only one connection is active per Connection alias at any one time.
Active	Check to make the current connection active.
Domain	Domain to which the connection belongs.

Credential is unique across active connections, if not empty.

Upgrading connection information

- The JDBC connection [jdbc_connection] and JMS connection [orch_jms_ds] tables are existing Orchestration connection tables that now extend from the Connection [sys_connection] table. The tables originally extended from sys_metadata. The sys_metadata related data is removed.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- The tables move from the Orchestration run time plugin [com.snc.runbook_automation.runtime] to the Credentials & Connections plugin.
- The upgrade process obtains JDBC and JMS connection information and creates corresponding connection aliases and assigns the alias to its corresponding connection.
- JDBC field name changes:
  - JDBC server is renamed to host
  - Database port is renamed to port
  - Data of the JDBC server and database migrates to host and port during the upgrade

Create a basic connection for PowerShell and SSH

Configure connection information to use with a custom activity or action that uses the PowerShell or Secure Shell (SSH) protocol.

Before you begin

Role required: admin or connection_admin

Procedure

1. Navigate to **All** > **Credentials & Connections** > **Connections**.
2. Click **New**.
3. Select **Basic Connection for PowerShell & SSH**.
4. Complete the form.

Field	Description
Name	Unique name of the connection record.
Credential	Select the credential record used to authorize the connection.
Connection alias	Select the alias record to associate with this connection. Using an alias enables you to update the connection record without having to reconfigure any actions or activities that use the alias.
Host	Fully qualified domain name of the target host where the system runs the activity or action. For example, host.domain.com.
Active	Select to make this connection active.
Domain	Determines the domain the activity runs in. Flow Designer does not support domain separation and ignores this field.
Override default port	Target port used by the connection. If you leave this field blank, the system uses the default port value.
Use MID Server	Select to connect to the target host through a MID Server. If selected, define fields in the Advanced MID Server Configuration section. **Note:** PowerShell requires a MID Server.
MID Selection	Option to select a specific MID Server or MID Cluster. Choose any one of the following options.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	○ **Auto-Select MID Server**: Your ServiceNow instance selects the MID Server without manual input. ○ **Specific MID Server**: Your ServiceNow instance uses MID Server that you specify. ○ **Specific MID Cluster**: Your ServiceNow instance uses the MID Cluster that you specify. A MID Cluster is a group of MID Servers that enables your ServiceNow instance to handle multiple integrations, and improve integration speed. For more information, see Configure a MID Server cluster. This field is available when **Use MID Server** is checked. **Note:** Ensure that the Integration Hub connection record is referred, not an Orchestration connection record.
Capabilities	The capabilities the MID Server must support to be eligible for selection. The system runs the action or activity from a MID Server that supports the selected capabilities. Only displays if **Use MID server** is selected. Required capabilities determine which MID Server is selected at runtime. To learn more about how a MID Server is selected during runtime, see MID Server selection. This field is visible only when **Auto-Select MID Server** is selected from the MID Selection list.
MID Application	The application the MID Server must support to be eligible for selection. The system runs the action from a MID Server that supports the selected application. Only displays if **Use MID server** is selected. To learn more about how a MID Server is selected during runtime, see MID Server selection.
MID Server	Specific MID Server on which the step runs. This field is visible only when **Specific MID Server** is selected from the MID Selection list.
MID Cluster	The specific MID Cluster you want to use. This field is available when **Use MID Server** is checked, and **Specific MID Cluster** is selected from the MID Selection list.

5. Click **Submit**.

Create an HTTP(s) connection

The HTTP(s) connection provides the information custom HTTP(s) actions or activities use to connect.

Before you begin

Role required: connection_admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Credentials & Connections** > **Connections**, click **New**, and select **HTTP(s) Connection**.
2. Add the following connection information and click **Submit**:

Field	Description
Name	Unique name of this HTTP(s) connection.
Credential	Select the credential record used to authorize the connection.
Connection Alias	Select the alias record to associate with this connection. Using an alias enables you to update the connection record without having to reconfigure any actions or activities that use the alias.
URL builder	Either manually enter the connection URL or use system to build the URL based on the inputs. Default is unchecked. If checked, the connection URL is calculated from the following fields: ○ Mutual authentication — Check box if mutual authentication is used. ○ Protocol — If mutual authentication is not used, enter protocol. The default is HTTPs. ○ Protocol profile — If mutual authentication is used, enter protocol profile from sys_protocol_profile. ○ Host ○ Port ○ Base path — Path of the connection string. **Note:** If mutual authentication is checked, connection URL is built: Protocol + :// + host:port +URL. If mutual authentication is unchecked, connection URL is built: Protocol profile + :// + host:port +URL
Connection URL	If URL builder is unchecked, enter the connection URL into this field. **Note:** If mutual authentication is checked, connection URL is built: Protocol + :// + host:port +URL. If mutual authentication is unchecked, connection URL is built: Protocol profile + :// + host:port +URL
Active	Check the box to make this connection active.
Domain	Determine the domain the action or activity runs in.
Use MID Server	Check to use a MID Server for this action or activity. If selected, define fields in the Advanced MID Server Configuration section.
MID Selection	Option to select a specific MID Server or MID Cluster. Choose any one of the following options.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	○ **Auto-Select MID Server**: Your ServiceNow instance selects the MID Server without manual input. ○ **Specific MID Server**: Your ServiceNow instance uses MID Server that you specify. ○ **Specific MID Cluster**: Your ServiceNow instance uses the MID Cluster that you specify. A MID Cluster is a group of MID Servers that enables your ServiceNow instance to handle multiple integrations, and improve integration speed. For more information, see Configure a MID Server cluster. This field is available when **Use MID Server** is checked. **Note:** Ensure that the Integration Hub connection record is referred, not an Orchestration connection record.
Capabilities	The capabilities the MID Server must support to be eligible for selection. The system runs the action or activity from a MID Server that supports the selected capabilities. Only displays if **Use MID server** is selected. Required capabilities determine which MID Server is selected at runtime. To learn more about how a MID Server is selected during runtime, see MID Server selection. This field is visible only when **Auto-Select MID Server** is selected from the MID Selection list.
MID Application	The application the MID Server must support to be eligible for selection. The system runs the action from a MID Server that supports the selected application. Only displays if **Use MID server** is selected. To learn more about how a MID Server is selected during runtime, see MID Server selection.
MID Server	Specific MID Server on which the step runs. This field is visible only when **Specific MID Server** is selected from the MID Selection list.
MID Cluster	The specific MID Cluster you want to use. This field is available when **Use MID Server** is checked, and **Specific MID Cluster** is selected from the MID Selection list.
Connection Timeout	Number of milliseconds the system waits for a successful host connection. If a successful connection does not occur during this time, the connection request times out. Leave this field empty to use the system default connection timeout value. **Note:** Avoid setting the **Connection Timeout** value to zero, as this may cause a stale connection.
additional_http_headers (Attributes tab)	Include any additional headers required, such as sap-client=100. If adding multiple headers, separate them with a semi-colon.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
odata_ping_url (Attributes tab)	The default OData ping URL is /sap/bc/ping. To edit the ping URL for OData heartbeat, select the lock icon, edit the URL, and select the lock icon again.

3. Click **Submit**.
   You are ready to create a custom HTTP(s) action or activity.

Create a JDBC connection

The JDBC Connection provides the information custom JDBC actions or activities use to connect to various target databases.

Before you begin

You must have an appropriate JAR file, whether it is supplied with the instance or a custom JAR file.

Note:
The ServiceNow instance supplies `mysql-connector-java-5.1.21.jar`, `sql-server-jdbc-4.0.jar`, and `ojdbc6.jar` files as part of the current release, which supports MySQL, SQLServer, and Oracle databases. Other databases, such as Sybase or DB2 Universal, must use a custom JAR file that must be uploaded to the instance before setting the JDBC connection.

Role required: connection_admin

About this task

JDBC credentials are retrieved separately by the activity designer template and support external credential storage, such as CyberArk.

Procedure

1. Navigate to **All** > **Credentials & Connections** > **Connections**, click **New** and select **JDBC Connection**.
2. Complete the form using the fields in the table.
   The database selection in the **Format** field determines which fields are available.

JDBC connection fields

Field	Database Format	Description
Name	All	Unique name of this JDBC connection. For example, you might enter **JDBC MySQLProd**.
Credential	All	Add credentials for JDBC provider.
Connection alias	All	Select the alias record to associate with this connection. Using an alias enables you to update the connection record without having to reconfigure any actions or activities that use the alias.
Query timeout	All	Maximum elapsed time the JDBC query is allowed to run without a response.
Connection timeout	All	Number of seconds the system waits before closing a JDBC connection or connection request.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Database Format	Description
		For example, if the **Connection Timeout** value is 10 seconds, the system waits 10 seconds for a successful connection. If a successful connection does not occur during this time, the connection request times out. If a successful connection does occur, the connection remains open until there is a 10-second period of inactivity. Once the connection has been inactive for 10 seconds, the connection is closed. **Note:** Avoid setting the **Connection Timeout** value to zero, as this may cause a stale connection.
Active	All	Check the box to make this an active connection.
Domain	All	Domain for this table. By default, the JDBC Connection [jdbc_connection] table runs in the **global** domain.
Format	All	Database type for this connection. The default choices are: ○ **MySQL** ○ **Oracle** ○ **SQLServer** ○ **None** You can add **Sybase** or **DB2 Universal** to the choice list by uploading the appropriate JDBC driver JAR file to the instance. Orchestration automatically recognizes these drivers when they are loaded into the system and adds them to this list.
Host	Oracle, MySQL, SQLServer	Host name or IP address of the database server.
Oracle sid	Oracle	The Oracle database site identifier. The default value is **orcl**.
Oracle port	Oracle	Port that the Oracle database is using. The default value is **1521**.
Database name	MySQL, SQLServer	Name of the database.
Port	My SQL, SQLServer	Port that the selected database is using.
Instance name	SQLServer	Instance name for the selected SQLServer
Connection URL	All	URL that the MID Server uses to connect to the specified database. The URL is created automatically when you save the form, and is read-only for the default databases.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Database Format	Description
		Note: If the format selected is not one of the default databases, you must create the connection URL manually so that the MID Server knows how to create the connection.
JDBC driver	None, DB2 Universal, Sybase	The JDBC driver to use for this connection when it is not a default database. **Note:** If you add a Sybase or DB2 Universal database, you must enter the driver name in this field and upload the driver JAR file to the instance.
Use MID server	All	Check to use a MID server for this action or activity. If selected, define fields in the Advanced MID Server Configuration section.
MID Selection	All	Option to select a specific MID Server or MID Cluster. Choose any one of the following options. ○ **Auto-Select MID Server**: Your ServiceNow instance selects the MID Server without manual input. ○ **Specific MID Server**: Your ServiceNow instance uses MID Server that you specify. ○ **Specific MID Cluster**: Your ServiceNow instance uses the MID Cluster that you specify. A MID Cluster is a group of MID Servers that enables your ServiceNow instance to handle multiple integrations, and improve integration speed. For more information, see Configure a MID Server cluster. This field is available when **Use MID Server** is checked. **Note:** Ensure that the Integration Hub connection record is referred, not an Orchestration connection record.
Capabilities	All	The capabilities the MID Server must support to be eligible for selection. The system runs the action or activity from a MID Server that supports the selected capabilities. Only displays if **Use MID server** is selected. Required capabilities determine which MID Server is selected at runtime. To learn more about how a MID Server is selected during runtime, see MID Server selection. This field is visible only when **Auto-Select MID Server** is selected from the MID Selection list.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Database Format	Description
MID Application	All	The application the MID Server must support to be eligible for selection. The system runs the action from a MID Server that supports the selected application. Only displays if **Use MID server** is selected. To learn more about how a MID Server is selected during runtime, see MID Server selection.
MID Server	All	Specific MID Server on which the step runs. This field is visible only when **Specific MID Server** is selected from the MID Selection list.
MID Cluster	All	The specific MID Cluster you want to use. This field is available when **Use MID Server** is checked, and **Specific MID Cluster** is selected from the MID Selection list.

3. Click **Submit**.

JDBC credentials

Create a JMS connection

Configure your system to use Java Messaging Service (JMS) with a custom JMS activity or action.

Before you begin

Role required: connection_admin

About this task

The MID Server must have the correct JMS connection factories for your organization. Configure those values in the *mid.property.jms.command.allowed_factory_names* property, found in **MID Server** > **Properties**. The default values for this property can be changed to any value or comma-separated list of values that the third-party JMS provider advertises.

Procedure

1. Navigate to **Credentials & Connections** > **Connections**.
2. Click **New**, select **JMS Connection**, fill in the form, and then click **Submit**.

Option	Description
Name	Unique name of this connection factory.
Credential	Add credentials for JMS provider.
Connection Alias	Select the alias record to associate with this connection. Using an alias enables you to up date the connection record without having to reconfigure any actions or activities that use the alias.
Initial Context Factory	Name of the JNDI class that is used to create the InitialContext.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Option	Description
	Note: For example, to connect to Active MQ V5.10 (JMS Provider), the value is `org.apache.activemq.jndi.ActiveMQInitialContextFactory`.
Provider URL	Location of the running JMS provider installation. **Note:** For example, to connect to ActiveMQ V5.1: `tcp://ipAddressOrHostName:61616`.
Active	Check the box to make this an active connection.
Domain	Determine the domain the action or activity runs in.
Use MID server	Check to use a MID Server for this action or activity. If selected, define fields in the Advanced MID Server Configuration section.
MID Selection	Option to select a specific MID Server or MID Cluster. Choose any one of the following options. ○ **Auto-Select MID Server**: Your ServiceNow instance selects the MID Server without manual input. ○ **Specific MID Server**: Your ServiceNow instance uses MID Server that you specify. ○ **Specific MID Cluster**: Your ServiceNow instance uses the MID Cluster that you specify. A MID Cluster is a group of MID Servers that enables your ServiceNow instance to handle multiple integrations, and improve integration speed. For more information, see This field is available when **Use MID Server** is checked.
MID Cluster	The specific MID Cluster you want to use. This field is available when **Use MID Server** is checked, and **Specific MID Cluster** is selected from the MID Selection list.
Capabilities	The capabilities the MID Server must support to be eligible for selection. The system runs the action or activity from a MID Server that

Option	Description
	supports the selected capabilities. Only dis plays if **Use MID server** is selected. To learn more about how a MID Server is se lected during runtime, see MID Server selec
MID Application	The application the MID Server must support to be eligible for selection. The system runs the action from a MID Server that supports the selected application. Only displays if **Use MID server** is selected. To learn more about how a MID Server is se lected during runtime, see MID Server selec

3. Navigate to **Connections & Credentials** > **Credentials**.
4. Click **New**, select **JMS Credentials**, and then provide the user name and password the MID should use to communicate with the JMS provider.
   For more information, see JMS credentials.
5. Click **Submit**.
   You are ready to create a custom JMS action or activity.

Create connection attributes for IntegrationHub

Define connection-specific variables that you can use in Integration Hub integration steps.

Before you begin

Role required:

- The admin role is required to create connection attributes.
- The connection_admin or admin role is required to assign attribute values.
- The action_designer or admin role is required to use attributes in a custom action.

Connection attributes are only used by integration steps, which require a subscription to Integration Hub. For more information about activating Integration Hub, see Request an Integration Hub plugin.

About this task

When using an integration step, you must establish a connection with an external system. Use a Connection & Credential alias instead of defining the connection inline. An alias enables you to update the connection details once without having to reconfigure every action. Any action step that uses an alias inherits the attributes associated with it. Workflow Studio displays attributes as data pills that you can drag into your action step. For example, you can create a page size attribute that becomes a REST step query parameter.

For more information about building custom Workflow Studio actions, see Workflow Studio.

Procedure

1. Navigate to **All** > **Credentials & Connections** > **Connection & Credential Aliases**.
2. Create or select an alias record.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. From the Connection Attributes related list, click **New**.
4. Define the attribute label and field type.
   For a list of field types, see field types.
5. Click the Advanced view related link to set advanced dictionary preferences for the attribute.
   For example, to create an attribute with a dynamically calculated value. See Dictionary entry form.
6. Click **Submit**.
7. Define the attribute values in the connection record.
   a. Navigate to **Credentials & Connections** > **Connections**.
   b. Create or select a connection record with the same connection type as the alias.
   c. From **Connection alias**, select the alias with connection attributes.
   d. Save the record.
      The Attributes tab populates with the connection attributes defined in the alias record.
   e. Set values for the attributes.
      If the alias has **Support Multiple Active Connections** enabled, you can associate more than one connection record with an alias and define attribute values in each connection record. If there are multiple connection records with attribute values for the same alias, the connection used when the flow executes determines the attribute values. For example, suppose that you have one action that uses an alias with two active connections endpoints: production and test. The attribute resolves to the value defined by the connection used at runtime.
8. Add the alias to an integration step in Workflow Studio.
   a. Navigate to Workflow Studio and create or select an action.
   b. Add an integration step to the action.
   c. Under Connection Details, add the alias you created attributes for.

   The connection attributes associated with the alias display as data pills in the Data pane.

Note:
The system does not track changes to connection attribute labels and data types after you associate the alias to a step. To refresh the connection attribute label or data type, delete the alias from the step and add it again.

Get started with credentials

The MID Server uses the credentials you create in the Credentials [discovery_credentials] table to access resources for Discovery, Orchestration, Service Mapping, and Cloud Management.

How MID Servers use credentials

By default, Windows MID Servers use the login credentials of the MID Server service on the host machine to discover Windows devices in the network. You should Configure Windows MID Server service credentials so that they have at least local administrator privileges. For Linux and UNIX machines and network devices, the MID Server uses the SSH and SNMP credentials configured in the instance in **Discovery** > **Credentials**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

MID Servers that Orchestration uses must have access to the necessary credentials to execute commands on computers in the network, as specified by the Workflow activities. Orchestration can use the same SSH and SNMP credentials as Discovery, but has two additional credentials designed for specific Workflow activities: Windows (for PowerShell activities) and VMware.

Encryption and decryption

The platform stores credentials in an encrypted field on the Credentials [discovery_credentials] table. Once they are entered, they cannot be viewed.

When the MID Server requests credentials, the ServiceNow AI Platform decrypts the credentials using the following process:

1. The credentials are decrypted on the instance with the password2 fixed key.
2. The credentials are re-encrypted on the instance with the MID Server's public key.
3. The credentials are encrypted on the load balancer with SSL.
4. The credentials are decrypted on the MID Server with SSL.
5. The credentials are decrypted on the MID Server with the MID Server's private key.

Note:
The platform does not have separate encryption keys for multi-tenant instances.

Credential order

Credentials can be assigned an order value in the Credentials Form, which forces the application to try all the credentials at their disposal in a certain sequence. If you do not specify an order value, the application tries the credentials in the Credentials [discovery_credential] table randomly, until it finds one that works. For example, when:

- Orchestration attempts to run a command on an SSH server, such as a Linux or a UNIX machine.
- Discovery attempts to query an SNMP device, such as a printer, router, or UPS.

After identifying the credentials for a device, Discovery and Orchestration create an affinity between the credentials and the device using the Credential Affinity `[dscy_credentials_affinity]` table. All subsequent discoveries or Orchestration activities attempt to match the credentials in this table with a device for which an affinity exists. If credentials for a device change, Discovery and Orchestration try all available credentials again until they create a new affinity.

Note:
If Orchestration and Discovery are installed, and credential alias is enabled, multiple affinities can exist. In this case, the platform looks up credentials for each affinity and inserts the credential for the affinity with the lowest order into the probe.

Ordering credentials is useful in the following situations:

- The credentials table contains many credentials, with some used more frequently than others. For example, the table contains 150 SSH credentials, and five of those credentials are used to log in to 90% of the devices. It is good practice to configure those five credentials with low-order numbers, which place them at the top of the execution list. Discovery and Orchestration work faster when they try these common credentials first. After the first successful connection, the ServiceNow AI Platform knows which credentials to use the next time for each device.
- The ServiceNow AI Platform has aggressive login security. For example, configure database credentials with a low-order value if Solaris database servers in the network only provide three failed login attempts before locking out the MID Server.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Credential aliases

Credential aliases are available for Discovery and Orchestration.

Aliases for Discovery enable an administrator to:

- Employ a credential filtering behavior with configurable levels of compliance.
- Assign multiple credential aliases to a Discovery schedule.
- Prevent the creation of credential affinities that use inappropriate or sensitive credentials. To learn more, see credential affinities.

Aliases for Orchestration enable workflow creators to:

- Assign individual credentials to any activity in an Orchestration workflow
- Assign individual credentials to any action in Flow Designer
- Assign different credentials to each occurrence of the same activity type in an Orchestration workflow.
- Assign different credentials to each occurrence of the same action in designer flow.

External credential stores

If you do not want credentials stored in your instance, you can use external credential repositories. External credential stores save the credentials in an external site that your instance can access. CyberArk is the only supported external credential store. However, other external stores can be configured using the ServiceNow API.

Create a Connection & Credential alias

Define an alias to label a credential or connection record.

Before you begin

Role required:

- The admin role is required to create an alias.
- The credential_admin and connection_admin roles have read access to the alias record.

About this task

The Connection & Credential alias defines an alias that labels a credential or connection record. The alias contains these fields.

Procedure

1. Navigate to **All** > **Connections & Credentials** > **Connection & Credential Aliases**.
2. Click **New**.
3. Complete the fields on the form.

Connection & credential aliases

Field	Description
Name	Name of the alias. An alias can only contain alpha, number, and underscore characters. During an upgrade, the tag in the credential record migrates to a Connection & Credential Alias. If the credential tag contains special

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	characters other than alphabets, numbers, and underscores, it preserves the tag name after the upgrade. You can still use this migrated alias, but you cannot update the alias until you change the name to meet the naming restrictions.
ID	Unique identifier for the Connections & Credentials alias, based on the format `scope_name.alias_name`. ○ If the scope is Global, the ID is the alias name. For example, if you create a Workday alias in the global scope, it sets the ID to `workday`. ○ If you create a workday alias in the HR app scope, it sets the ID to `x_hr_app.workday`.
Type	Select either **Credential** or **Connection and Credential**. The default is Connection and Credential.
Application	Application scope against which the Connection & Credentials alias is assigned. The current session scope you last selected in the application picker appears. ○ For example, **Global** appears if it is the current scope for this session. ○ You can change the scope in the application picker before creating an alias. To learn more application scopes and how to select them, see: ▪ Application scope ▪ Select an application from the application picker
Connection type	Name of the connection type, either Basic, HTTP, JDBC, JMS, or Kafka. The default is HTTP.
Support Multiple Active Connections	Designator that indicates whether the alias supports multiple active connections. Add connections using the Connections table and associated them to the alias using the Connections related list.
Default Retry Policy	Retry policy for the alias. For more information, see Retry policy.
Configuration Template	Configuration template to use to create a connection and credential record.

4. Click **Save**.
The Connections and Connection Attributes related list appears.

Related List	Description
Connections	Related connection records associated with this alias. After creating the alias, you can define connection records and associate them with the alias. If **Support Multiple Active Connections** is selected, you can associate more than one connection with an alias.
Connection Attributes	Attributes for the connection. Define data specific to a connection and use it in an Integration Hub integration step. For more information, see Create connection attributes for IntegrationHub.
Child Aliases	Child aliases associated with the parent alias. After creating a connection and credential alias, you can create child alias to configure multiple connections for the same application integration.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Related list	Description
Connections	Related connection records associated with this alias. After creating the alias, you can define connection records and associate them with the alias. If **Support Multiple Active Connections** is selected, you can associate more than one connection with an alias.
Connection Attributes	Attributes for the connection. Define data specific to a connection and use it in an Integration Hub integration step. For more information, see Create connection attributes for IntegrationHub.

5. **Optional:** If you want to create a new credential and connection associated with your credential alias, under *Related Links*, click **Create New Connection & Credential**. The resulting connection and credential records are based on a pre-defined configuration template. See connection and credential configuration templates.
6. **Optional:** If you want to create a child alias for your connection and credential alias, under the **Child Aliases** related list, select **New**.

   a. Enter a name for the child alias and select **Submit**.
   The child alias inherits properties from the parent alias. You can then configure a child alias to contain its own set of connection and credential information.

What to do next

Create one or more connection records to associate with the alias or child aliases. For more information about creating connections, see Get started with connections. Add connection attributes to the alias to make connection meta data available to flows in Workflow Studio.

Set up OAuth integration via MID Server

Create a connection record that enables the sending of an OAuth token request to a third-party server via a MID Server.

Before you begin

Confirm that you have subscribed to the ServiceNow IntegrationHub Standard Pack Installer. For more information, see https://www.servicenow.com/content/dam/servicenow-assets/public/en-us/doc-type/legal/snc-addendum-integrationhub.pdf.

Role required: Admin

Procedure

Configure the connection with a configuration template.

a. Navigate to **All** > **IntegrationHub** > **Configuration Templates**.

b. Select **New**.

c. Select **HTTP Connection with OAuth Client Credentials grant type**.

d. Update the form, as required.
For example, you can provide the scope in the `oauth_entity_profile_scope` and `oauth_entity_scope` fields in the Default Data Template section. To learn to create a configuration template, see Create a configuration template.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

e. Select **Submit**.
You have created the configuration template.

f. Navigate to **All** > **IntegrationHub** > **Connection & Credential Aliases**.

g. Update the form.

Connection and credential alias

Field	Description
Name	Name of the alias. An alias can only contain alpha, number, and underscore characters. During an upgrade, the tag in the credential record migrates to a Connection & Credential Alias. If the credential tag contains special characters other than alphabets, numbers, and underscores, it preserves the tag name after the upgrade. You can still use this migrated alias, but you cannot update the alias until you change the name to meet the naming restrictions.
Application	Unique identifier for the Connections & Credentials alias, based on the format `scope_name.alias_name`. ○ If the scope is Global, the ID is the alias name. For example, if you create a Workday alias in the global scope, it sets the ID to `workday`. ○ If you create a workday alias in the HR app scope, it sets the ID to `x_hr_app.workday`.
Parent Alias	Option to select the alias under which you're creating this connection and credential alias. The connection and credential alias that you're creating is a child alias. A child alias is listed under the **Child Aliases** tab on the parent connection and credential alias page. Type	Option to indicate the type of alias you're creating. Choose from the following options. ○ Credential: Alias that contains a credential record. ○ Connection and Credential: Alias that contains both connection and credential record. This option is selected by default.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Confirm that Connection and Credential is selected.
Support Multiple Active Connections	Designator that indicates whether the alias supports multiple active connections. Add connections using the Connections table and associated them to the alias using the Connections related list.
Default Retry Policy	Retry policy for the alias. For more information, see Retry policy.
Configuration Template	Option to select the configuration template based on which you're creating the connection and credential alias. Select the template of the type **HTTP Connection with OAuth Client Credentials grant type** that you had created.

h. Select **Submit**.
You have created the connection and credential alias record.

i. Navigate to **All** > **IntegrationHub** > **Connections Dashboard**.

j. In the Search all connections field, enter the name of the connection and credential alias record that you created.

k. On the connection and credential alias record, select **View Details**.

l. Select **Configure**.

m. Fill the form.

Connection record

Field	Description
Connection Name	Name of the connection record. You can't update the name.
Connection URL	Option to provide the URL that connects with the third-party server.
Use MID	Option to specify that you want to send OAuth token requests via a MID Server. **Important:** Confirm that the option is selected.
MID Selection	Option to specify whether you want to use a specific MID Server or enable auto-selection of MID Server, or use a MID Cluster. Choose one of the following options.

Field	Description
	○ Auto-Select MID Server ○ Specific MID Server ○ Specific MID Cluster
Capabilities	Option to select one or more MID Server capabilities. Capabilities define the specific functions of a MID Server within an IP address range, allowing an application to select the most appropriate MID Server. Select the MID capabilities icon ( ) to select one or more capabilities. **Note:** This option appears if you select **Auto-Select MID Server** in the MID Selection field.
MID Application	Option to specify a MID application or accept the default application choice. **Note:** This option appears if you select **Auto-Select MID Server** in the MID Selection field. By default, the **ALL** option is selected.
MID Server	Option to select a MID Server. **Note:** This option appears if you select **Specific MID Server** in the MID Selection field.
MID Cluster	Option to select a MID Cluster. **Note:** This option appears if you select **Specific MID Cluster** in the MID Selection field.
OAuth Client ID	Option to specify the client ID.
OAuth Client Secret	Option to specify the client secret.
Connect to Auth Server via MID Server	Option to specify that the connection between the ServiceNow instance and the Auth server takes place via the MID Server. **Important:** Confirm that the option is selected.
OAuth Token URL	Option to specify the OAuth token URL that is used to request OAuth tokens.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

n. Select **Configure and Get OAuth Token**.
The connection and credential record is created.

Credential aliases for Discovery

Credential aliases for Discovery allow an administrator to use specific credentials on Discovery schedules. You can configure behaviors for your aliases that determine how strictly the system enforces their use.

Without credential aliases, Discovery schedules can access all credentials that are defined in the instance. This behavior might not be desirable in some circumstances, particularly for credentials with elevated privileges. Credential aliases provide more control over which credentials a Discovery schedule is allowed to use and prevents the unnecessary exposure of credentials with elevated privileges.

How credential aliases work

A business rule called *Insert Discovery Affinity & Cred Aliases* (previously named *Insert Discovery Affinity*) runs when a record (a task for performing Discovery) is inserted into the ECC Queue.

The business rule attaches the credential aliases defined in the Discovery schedule to the probe, so when the probe reaches the MID Server on its way to performing discovery, the MID Server knows exactly which credentials it can use to attempt to access the device the probe was sent to scan.

The MID Server filters credentials by affinity and then by tags, if any exist. Credentials must match all credential tags. The MID Server iterates until it finds a credential that works.

If the business rule determines that an affinity exists for the device, the rule identifies the proper *credential_id* to use. This is the *sys_id* of the record in the Credentials `[discovery_credentials]` table.

When the platform encounters an affinity with a credential alias value, defined as *credential_alias* in the business rule, the business rule determines whether or not the credential referenced by the affinity has the specified alias. If it does, the business rule selects the *credential_id* of the alias and passes that value to the MID Server.

If a credential alias is defined for a schedule and the schedule is configured to use that alias, the schedule will ignore any previously existing credential-to-target affinity—but only if the credential itself is not associated with any other credential alias. If the credential does not have any credential alias, any other affinities that exist for the target system are checked.

Create a Discovery credential alias

Create the alias and then add that alias to a credential in the credential record. You can add a credential to multiple aliases and add multiple credentials to a single alias.

Before you begin
Role required: admin, credential_admin (read access only), connection_admin (read access only)

About this task
A Discovery schedule only uses credentials that are contained in the aliases defined for that schedule.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
If a credential alias is defined for a schedule, it will ignore any previously existing credential affinity between the credential and the target that is discovered in a schedule that is setup to use that credential alias.

Procedure

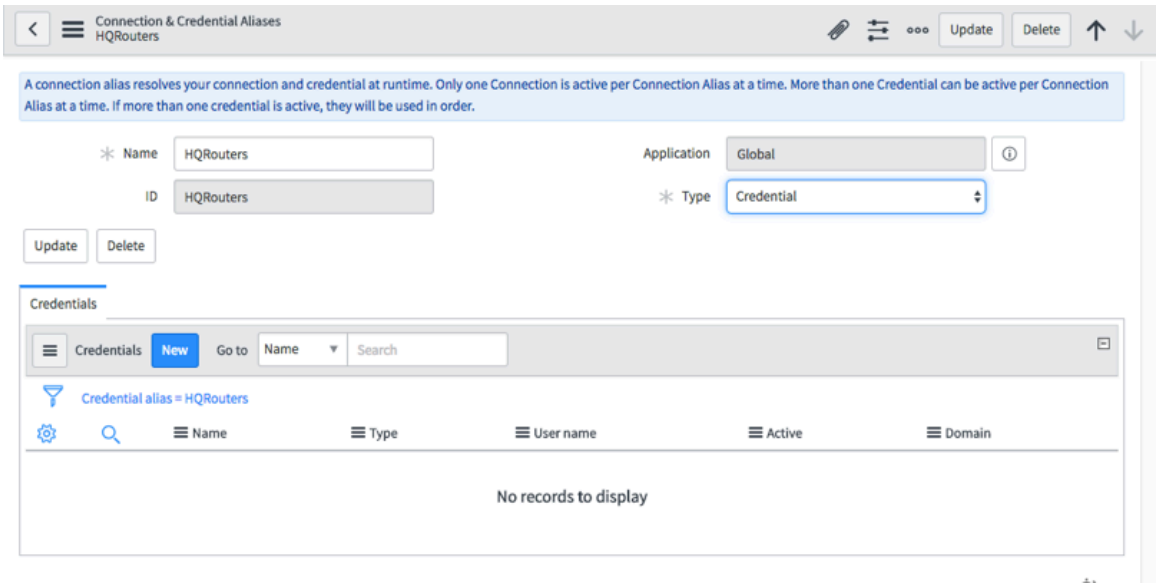
1. Create an alias.

   a. Navigate to **Connections & Credentials** > **Connection & Credential Aliases**.

   b. Click **New**.

   c. Enter a unique name for the alias and select **Credential** for the alias **Type**.

   d. Click **Submit**.
   The **Credentials** related list appears. You can add new credentials for this alias in this list but not existing credentials.



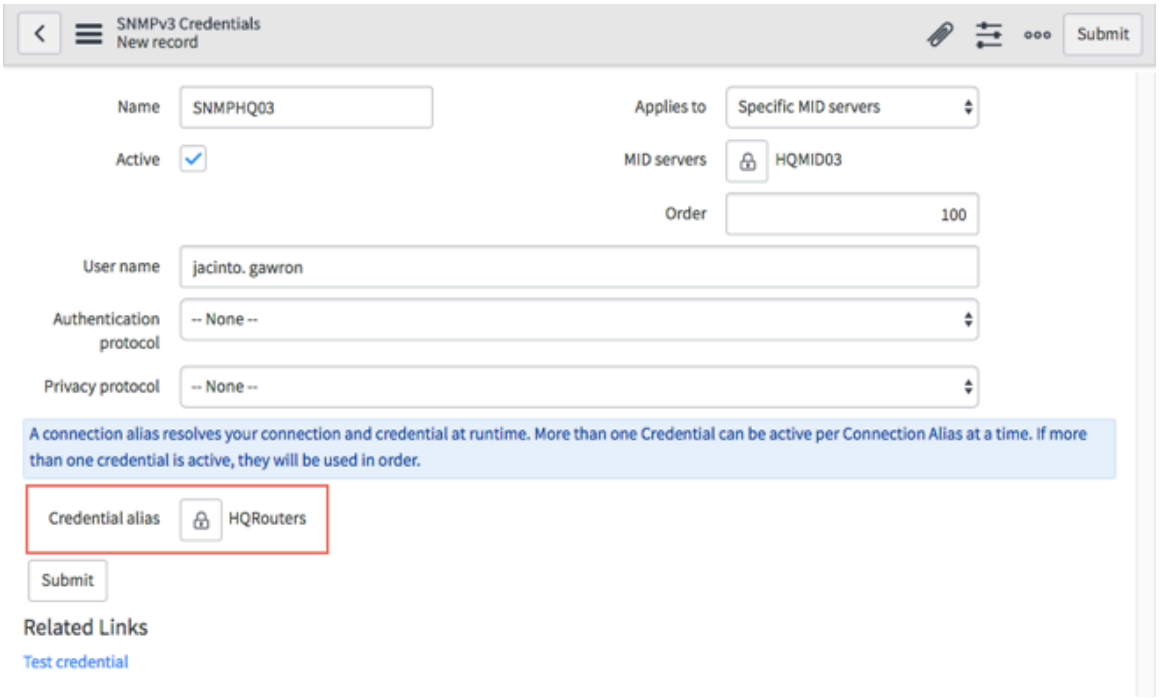
2. Configure a credential for the new alias.

   a. Navigate to **Connections & Credentials** > **Credentials**.

   b. Select an existing credential from the list or click **New** to create a new credential.

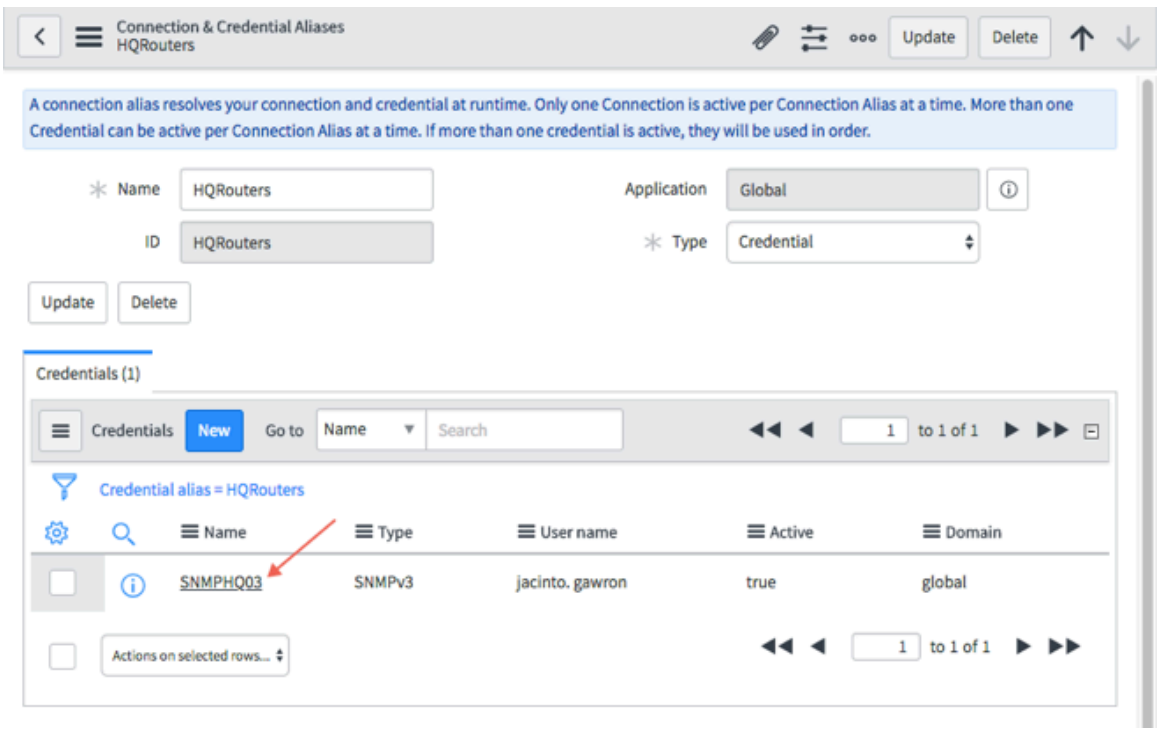
   c. In the credential record, unlock the **Credential alias** field and select the alias you created.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



d. Save or submit the record.

3. Return to **Connections & Credentials** > **Connection & Credential Aliases** and open your new alias.
   The credential you attached to the alias now appears in the related list.



4. To create an additional credential for this alias, click **New** in the related list and select a credential type.
   The alias name is pre-populated in the **Credential alias** field of the credential record.
5. Complete the fields in the form and submit the record.

© 2026 ServiceNow, Inc. All rights reserved.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Credential aliases for Orchestration activities

Credential alias gives an administrator more control over the credentials used in Orchestration activities.

This is useful when an activity requires specific credentials to perform a task. You can use a credential tag to assign individual credentials to any activity in a Orchestration workflow or assign different credentials to each occurrence of the same activity type in an Orchestration workflow.

Credential alias interacts with credential affinity to determine which credentials should be used for an Orchestration activity.

How credential alias works

A business rule called *Insert Discovery Affinity* (renamed from Insert Credential Affinity in the Geneva release) runs when a record is inserted into the ECC Queue. This rule determines whether a credential affinity exists for the device and identifies the proper *credential_id* (the *sys_id* of the record in the Credentials `[discovery_credentials]` table) to use. When the platform encounters an affinity with a credential alias value defined (*credential_alias* in the business rule), the business rule determines if the credential referenced by the affinity has the specified alias. If it does, the business rule selects the *credential_id* of the credential alias and passes that value to the MID Server. If the credential does not have the specified credential alias, any other affinities that exist for the target system will be checked. If no affinity references an appropriately tagged credential, the MID Server iterates through the Credentials *[discovery_credentials]* table and selects the credential with the appropriate tag. The MID Server then creates a new affinity for this credential.

Create and test your credentials

Create and test the credentials that Discovery, Service Mapping, Cloud Management, and Orchestration require to access hardware and software in your network.

Before you begin

Role required: admin
Review your security policy and options with your organization's security team.

About this task

This task contains general procedures for creating credentials. Refer to the documentation for your credential type for details on specific fields and requirements.

Supported credential types

Applicative credentials	Basic authentication credentials	Chef server credentials
CIM credentials	Cloud credentials	Container image repository credentials
Infoblox credentials	JDBC credentials	JMS credentials
OAuth 2.0 credentials	SAP credentials	SNMP credentials
SSH credentials	VMware credentials	Windows credentials

Note:
To improve security, limit the scope of credentials to a specific MID Server or schedule to avoid unnecessary credentials.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to one of these modules:
   - **Discovery** > **Credentials**
   - **Service Mapping** > **Credentials**
   - **Orchestration** > **Credentials**
2. Click **New**.
3. On the Credentials page, click a link for the credential type and complete the form.

   Refer to the documentation for the credential type you selected for details.

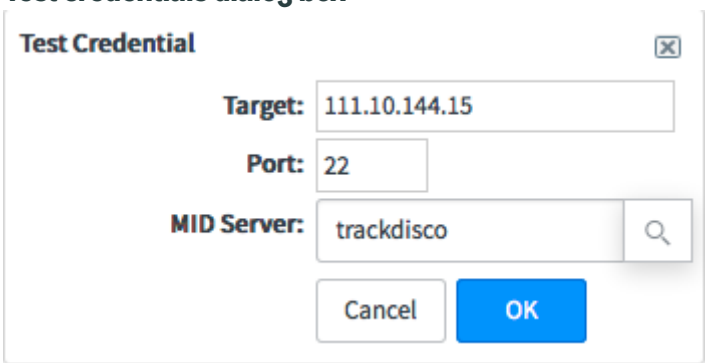
   You can submit a credential record first and then test it later, or test the credential immediately before saving it.

   Credential testing is supported for these credential types:
   - SSH private keys
   - Windows
   - SNMP v3
   - VMware
   - JDBC
   - JMS
4. Under **Related Links**, click **Test credential**.

   Note:
   Credentials are encrypted at all times during the test.

5. Complete the fields in the Test Credential dialog box.

Test credentials dialog box



Credential test fields

Field	Description	Credential type
Target	Target host on which these credentials are run. This value must be an IP address for all credential types except VMware, which can be the host URL. You can not target any MID servers.	All

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

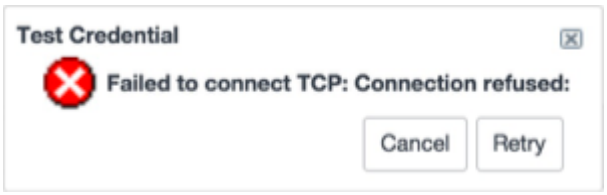
Field	Description	Credential type
	Note: For JMS, this is the provider URL. The information in this URL tells JNDI how to find and access the JMS Provider. An example value for connecting to ActiveMQ V5.1, is `tcp://ipAddressOrHostName:61616`.	
Port	Port on the target to use for this test. The system pre-populates this field with the default port for the selected credential type.	All
MID Server	MID Server to use for this test. You must use a Windows MID Server to test Windows credentials. Only **Up** and **Validated** MID Servers are available.	All
DB Type	Type of database on which to test these credentials.	JDBC
DB Name	Name of the database on which to test these credentials.	JDBC
Initial Context Factory	Name of the JNDI class that is used to create the InitialContext. Using this **Initial Context Factory**, various JMS objects, such as JMS Connection, are created. For example, to connect to ActiveMQ V5.10, (JMS Provider), the value in this field would be `org.apache.activemq.jndi.ActiveMQInitialContextFactor`	JMS

6. Click **OK** to begin the test.
   An indicator appears, showing that the system is attempting to contact the target using the credentials you have provided. When the instance connects to the target it displays a success message. If the instance encounters a problem with the test inputs you have provided, it displays the appropriate error message. The following are some common error messages.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

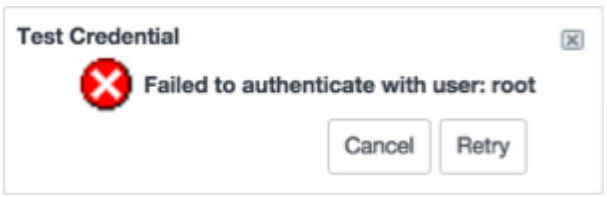
- Incorrect target or port number:

  TCP connection failure

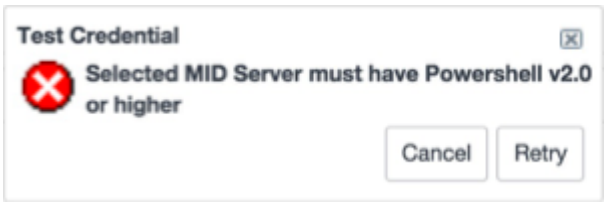
- Incorrect user name or password:

  Authentication failure

- Incorrect MID Server for Windows credentials:

  MID Server error

7. Click **Retry** to open the test Credential dialog box and correct the input error.
8. When your credentials test is successful, click **Submit** to save the record.

> **Important:**
> Testing credentials does not ensure that the credentials have the necessary privileges required for the intended Discovery or Orchestration workflow tasks.

Ansible Tower credentials

Ansible Tower credentials are required to access your Ansible configuration management account. Use these credentials to manage Ansible resources through the Cloud Management application.

To integrate Cloud Provisioning and Governance with the Ansible configuration management account, you must configure the user name and password for the administrator account in Ansible.

Form fields for Ansible Tower credentials

Field	Description
Name	Provide a descriptive name.
User name/ Password	Enter the authentication credentials for the Ansible Tower user with administrator rights.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
You do not need to configure the other fields.

API key credentials

An API key is a unique code that is passed in to an API to identify the calling application or user.

API key credentials

API key credentials form fields

Field	Input value
Name	Enter a unique and descriptive name for this credential.
Active	Enable or disable these credentials for use.
API Key	Enter the API key.
Credential alias	Allow flow and workflow creators to assign individual credentials to any activity in a flow or workflow or assign different credentials to each occurrence of the same activity type in a flow or workflow.
Applies to	Select whether to apply these credentials to **All MID servers** in your network, or to one or more **Specific MID servers**. Specify the MID Servers that should use these credentials in the **MID servers** field.
Order	Order (sequence) in which Discovery tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order.

Applicative credentials

Some applications require credentials in addition to the credentials the that host machine requires. Credentials required to access these applications are referred to as applicative credentials.

A typical credential contains a user name and a password for logging in to a device or application. While most applications require only one credential for accessing them, sometimes hosts and applications have separate credentials for extra security. For example, ABAP SAP Central Services (ASCS) requires applicative credentials in addition to the SSH or Windows host credentials for the server that hosts ASCS.

Note:
ServiceNow applications refer to devices and applications that comprise a service instance as configuration items (CIs).

As with host credentials, you assign applicative credentials to MID Servers.

You create applicative credentials per CI type, for example, the CI type for ASCS is SAP ASCS Application [cmdb_ci_appl_sap_ascs]. The preconfigured pattern for discovering CIs belonging to this CI type contains commands that require a MID Server to use the applicative credential for this CI type. If there's more than one credential configured for this CI type, the MID Server tries using these credentials in the order you define until it finds the credential that fits.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Check the Discovery requirements information in the ServiceNow documentation to determine if you need to configure applicative credentials for specific application CIs. There's no need to configure applicative credentials, if Discovery prerequisites don't mention it.

Applicative credentials form fields

Field	Description
Name	Name of the credential. Use a descriptive name like Oracle DB or London Oracle DB (for an Oracle database). Don't use spaces or special characters for the credential name.
Active	Select the check box to use the credential.
User name	Enter the actual user name of the applicative credential.
Password	Enter the actual password of the applicative credential. Don't use spaces or special characters for the credential name.
CI type	Select a CI type to which the CI belongs.
Credential Alias	Create an alias to assign specific credentials for specific discovery schedules. When assigning an alias, you must identify the table name for the CI type whose applicative credentials the application uses. Applications may use applicative credentials of a CI type different from their own. For a specific application, see the list for the appropriate table: • ABAP SAP Central Services (ASCS): cmdb_ci_appl_sap_ascs • IBM Security Access Manager appliance: cmdb_ci_app_server_webseal • SAP Central Instance: cmdb_ci_appl_sap_ascs • SAP Central Services (SCS): cmdb_ci_appl_sap_ascs • SAP Evaluated Receipt Settlement (ERS): cmdb_ci_appl_sap_ascs • SAP Java Cluster: cmdb_ci_appl_sap_ascs • SAP NetWeaver Dialog Instance: cmdb_ci_appl_sap_ascs • Microsoft Exchange Mailbox (for Microsoft Exchange): cmdb_ci_exchange_mailbox • Microsoft SQL Database: cmdb_ci_db_mssql_instance • MySQL Server: cmdb_ci_db_mysql_instance • Oracle Advanced Queue Queue: cmdb_ci_db_ora_instance • Oracle Database: cmdb_ci_db_ora_instance • Oracle E-Business Suite: cmdb_ci_db_ora_instance • Oracle WebLogic Module: cmdb_ci_app_server_weblogic • Tibco Enterprise Message Service (EMS): cmdb_ci_appl_tibco_message
Applies to	Select whether to apply these credentials to **All MID servers** in your network, or to one or more **Specific MID servers**. Specify the MID Servers that should use these credentials in the **MID servers** field.
Order	Order (sequence) in which Discovery tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Applicative credentials form fields (continued)

Field	Description
	Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order.

Basic authentication credentials

The basic authentication credential type manages access to store basic authentication credentials.

These fields are available in the Credentials form for basic authentication.

Basic Auth credentials form

Field	Input value
Name	Enter a unique and descriptive name for this credential. For example, you might call it **Basic Authentication**.
User Name	Enter the user name.
Password	Enter the password.
Credential ID	Enter the unique key configured for these credentials in the CyberArk external credential storage system. The credential ID may be used as a safe override when multiple safes are in use. By default, the syntax in the **Credential ID** field is this: *<safe name>:<Credential ID>*. If the safe name is omitted, there must be a safe name defined in the `config.xml` file. To change the separator character from the default colon to another character, override the value with the optional *ext.cred.safe_name* parameter. The **Credential ID** field has a limit of 40 characters. This field is only visible when the **External storage** check box is selected.
External credential store	Select this check box to use an external credential storage system. When you select this option the **User name** and **Password** fields are replaced with the **Credential ID** field. Currently, the only supported external storage system is CyberArk.
Order	Order (sequence) in which Discovery tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order.

Chef server credentials

Chef server credentials access chef integrations with the instance.

These fields are available on the Credentials form for Chef server type credentials. This information comes from the settings you configured when you performed Chef server installation.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Name	Enter a unique and descriptive name for this credential.
Active	Enable or disable these credentials for use.
Admin Name	Provide the administrator name that you created during Chef server installation.
Admin Key	Enter the RSA private key that the Chef server generated when you created the administrator.
Validator Name	Enter the validator.
Validator Key	Enter the RSA private key that the Chef server generated when you created an organization.
Cert Name	Enter the certification name.
Cert Key	Enter the certification key.

CIM credentials

The CIM credential type manages access to a CIM server (also referred to as a CIMOM - Common Information Model Object Manager) for information about VMware ESX servers. This credential type is available for Discovery.

These fields are available in the Credentials form for CIM.

Field	Description
Name	Enter a unique and descriptive name for this credential.
Active	Enable or disable these credentials for use.
User name	Enter the user name to create in the Credentials table. Avoid leading or trailing spaces in user names. A warning appears if the platform detects leading or trailing spaces in the user name. For CIM discovery, the user must have the admin role.
Password	Enter the password.
Credential ID	Enter the unique key configured for external credentials in the JAR file uploaded to the MID Server for an external credential system. The **Credential ID** field has a limit of 40 characters. This field is only visible when the **External credential store** check box is selected.
Credential alias	Allow workflow creators to assign individual credentials to any activity in an Orchestration workflow or assign different credentials to each occurrence of the same activity type in an Orchestration workflow. To use the credential for discovering CIs not belonging to this CI type using Service Mapping and Discovery patterns, enter the table name for the CI type to which the CI belongs, for example cmdb_ci_apache_web_server.
External credential store	Select this check box to use an external credential storage system. When you select this option the **User name** and **Password** fields are replaced with the **Credential ID** field. External credential storage is only available when the External Credential Storage plugin in activated.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Note: Currently, the only supported external storage system is CyberArk.
Applies to	Select whether to apply these credentials to **All MID servers** in your network, or to one or more **Specific MID servers**. Specify the MID Servers that should use these credentials in the **MID servers** field.
MID servers	Select one or more MID Servers from the list of available MID Servers. The credentials configured in this record are available to the MID Servers in this list. This field is available only when you select **Specific MID servers** from the **Applies to** field. **Note:** Selecting Specific **Specific MID servers** doesn't affect mid server selection. It's used only to decide which mid servers should have visibility to the credential. **Specific MID servers** isn't supported in Orchestration activities.
Order	Order (sequence) in which Discovery tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order.
Windows MID Server Service Account	When active, the defined credential represents the MID Server service account.

Configure NetApp storage devices for CIM credentials

NetApp storage devices require additional configuration for Discovery to explore them.

Before you begin

Role required: admin

Procedure

1. Install the SMI-S Provider on the storage device host.

   See the Download the NetApp SMI-S Provider software package for instructions and requirements.

   Note:

   ServiceNow doesn't maintain the documentation on this site. This document can change without notice.

2. Create a user account and password for the SMI-S agent.
3. Create a credential record for the SMI-S agent credentials.
   Set the credential type to **CIM**.

© 2026 ServiceNow, Inc. All rights reserved.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Cloud credentials

Cloud credential types manage access to cloud-based applications, including Amazon Web Services and the Microsoft Azure cloud.

AWS Identity and Access Management (IAM) roles

If you have a MID Server installed on Amazon EC2 in an AWS cloud, and if that MID Server is configured to discover resources within the cloud, you can use security credentials provided by AWS Identity and Access Management (IAM) roles rather than credentials managed on your instance. These AWS credentials grant permissions in the cloud through an instance profile, based on roles. These credentials are temporary and rotate automatically on a configurable interval. When an IAM role is defined on the MID server. For details, see Configure the MID Server for AWS IAM roles.

Discovery ignores any credentials stored on the instance in favor of the credentials granted by the role in the instance profile. For more information on AWS instance profiles, see IAM Roles for Amazon EC2.

AWS credentials

AWS Credentials form fields

Field	Input value
Name	Unique and descriptive name for the AWS credentials.
Active	Option to use the credential.
Access Key ID	The **Access key ID** that you generated on the AWS Management Console, such as: APIAIOSFODNN7EXAMPLE.
Secret access key	The **Secret access key** that you generated on the AWS Management Console, such as: wPalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY.

Azure Service Principal credential form fields

Field	Value
Name	Enter the name of the service principal to register with the instance.
Tenant ID and	Paste the Azure **Directory ID** value from the Azure portal into the Cloud Management **Tenant ID** field.
Client ID	Paste the Azure **Application ID** value of the application that you registered in Azure into the Cloud Management **Client ID** field.
Authentication Method	Select **Client secret**. **Note:** **Client assertion** is not supported.
Secret key	Paste the secret key that was generated while creating the Azure Service Principal.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Value
	This field appears when **Authentication method** is **Client secret**.

Azure Enterprise Agreement credentials

Azure Enterprise Agreement credentials are necessary for the billing functionality that the Cloud Management application provides.

Azure Enterprise Agreement credentials form fields

Field	Description
Name	Enter a descriptive name.
Enrollment number	Enter the enrolment number from Azure.
Access Key	Paste the access key that Azure provides.

Cloud Management credentials

This credential type is available for Orchestration.

Cloud Management credentials form fields

Field	Input value
Name	Enter a unique and descriptive name for this credential. For example, you might call it **Cloud Atlanta**.
Active	Enable or disable these credentials for use.
Type	Specify **AWS**.
User name	Enter the CIM user name to create in the Credentials table. Avoid leading or trailing spaces in user names. A warning appears if the platform detects leading or trailing spaces in the user name.
Password	Enter the CIM password.
SSH Passphrase	Enter a memorable phrase for key generation. For example, you might enter **Friday is a good day**.
SSH private key	Enter the SSH private key.
Authentication protocol	Select the **MD5**or **SHA** authentication protocol that was used to generate the **Authentication Key**.
Authentication Key	Enter a SSH-generated authentication key.
Privacy protocol	Enter one of the following privacy protocols that describes encryption for the **Privacy Key**: • **3DES** for Triple Data Encryption Standard (DES) • **AES128** for Advanced Encryption Standard (AES) with 128 bit encryption • **AES192** for AES with 192 bit encryption

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Cloud Management credentials form fields (continued)

Field	Input value
	• **AES256** for AES with 256 bit encryption • **DES** for legacy DES encryption
Enter an additional privacy key.	
Credential alias	Allow workflow creators to assign individual credentials to any activity in an Orchestration workflow or assign different credentials to each occurrence of the same activity type in an Orchestration workflow.
External credential store	Select this check box to use an external credential storage system. When you select this option the **User name** and **Password** fields are replaced with the **Credential ID** field. Currently, the only supported external storage system is CyberArk.
Applies to	Select whether to apply these credentials to **All MID servers** in your network, or to one or more **Specific MID servers**. Specify the MID Servers that should use these credentials in the **MID servers** field.
Classification	Enter the Application Classification for CI discovery.
Order	Order (sequence) in which Discovery tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order.

Cloud Management (CMP) node credentials

Cloud Management (CMP) node credentials associate credentials for a virtual server that Cloud Management provisions. The Cloud Management application automatically creates these credentials.

Note:
You might need to deactivate these credentials if you no longer want them used, change the order precedence, or select a MID Server that is allowed to access them. Otherwise, you do not need to manually create or modify this type of credential.

CMP node credentials form fields

Field	Description
Name	The automatically generated name based on the datacenter where the virtual machine is located.
Active	If the credentials are active.
Applies to	Choose whether this credential is available to a specific MID Server or a all MID Servers.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

CMP node credentials form fields (continued)

Field	Description
Order	Order (sequence) in which Discovery tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order.
User Name and Password	The virtual server user name and password.
SSH passphrase and SSH private key	The private key and the passphrase that protects the key if the virtual server requires it.
Authentication Protocol and Authentication Key	The private key and the passphrase that protects the key if the virtual server requires it.
Privacy Protocol and Privacy Key	The encryption protocol used with the virtual server and enter the privacy key.
Credential alias	Allow workflow creators to assign individual credentials to any activity in an Orchestration workflow or assign different credentials to each occurrence of the same activity type in an Orchestration workflow.

Cloud Management (CMP) SSH key pair credentials

Cloud Management (CMP) SSH key pairs store the keys that the Cloud Management application automatically generates when users provision stack resources.

Note:
You might need to deactivate these credentials if you no longer want them used. Otherwise, you do not need to manually create or modify this type of credential.

CMP SSH key pair credentials form fields

Field	Description
Name	The automatically generated name.
Active	If the credentials are active.
SSH Public Key	The public key.
SSH Private Key	A secure private key that can be used instead of a password for SSH logins.

Container image repository credentials

The container image repository credentials manage access to private repositories for container image scanning. This credential type is available for Discovery.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

These fields are available in the Credentials form for credential image repository type credentials.

Container Image Repository Credentials form

Field	Description
Name	User-assigned credential name.
User name	User name with read permissions for the repository.
Password	Password with read permissions for the repository.
Repository	Fully qualified domain name of the repository. For example: `docker.io/snow_images`.

Infoblox credentials

Infoblox credentials are required to set up IP pools (IPAM) in the Cloud Management application.

These fields are available on the Credentials form for Infoblox type credentials.

Field	Description
Name	Enter a unique and descriptive name for this credential.
Active	Enable or disable these credentials for use.
Applies to	Choose whether this credential is available to a specific MID Server or a all MID Servers.
Order	Order (sequence) in which Discovery tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order. Order (sequence) in which Discovery tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order.
wAPI Version	Enter the version of wAPI you are using.
User Name and Password	Enter the InfoBlox user name and password.

JDBC credentials

The JDBC credential type manages access to a Java Database Connectivity (JDBC) connection. This credential type is available for Discovery and Orchestration.

These fields are available in the Credentials form for JDBC type credentials.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Name	Enter a unique and descriptive name for this credential.
Active	Enable or disable these credentials for use.
User name	Enter the user name to create in the Credentials table. Avoid leading or trailing spaces in user names. A warning appears if the platform detects leading or trailing spaces in the user name. For CIM discovery, the user must have the admin role.
Password	Enter the password.
Credential ID	Enter the unique key configured for external credentials in the JAR file uploaded to the MID Server for an external credential system. The **Credential ID** field has a limit of 40 characters. This field is only visible when the **External credential store** check box is selected.
Credential alias	Allow workflow creators to assign individual credentials to any activity in an Orchestration workflow or assign different credentials to each occurrence of the same activity type in an Orchestration workflow. To use the credential for discovering CIs not belonging to this CI type using Service Mapping and Discovery patterns, enter the table name for the CI type to which the CI belongs, for example cmdb_ci_apache_web_server.
External credential store	Select this check box to use an external credential storage system. When you select this option the **User name** and **Password** fields are replaced with the **Credential ID** field. External credential storage is only available when the External Credential Storage plugin in activated. **Note:** Currently, the only supported external storage system is CyberArk.
Applies to	Select whether to apply these credentials to **All MID servers** in your network, or to one or more **Specific MID servers**. Specify the MID Servers that should use these credentials in the **MID servers** field.
MID servers	Select one or more MID Servers from the list of available MID Servers. The credentials configured in this record are available to the MID Servers in this list. This field is available only when you select **Specific MID servers** from the **Applies to** field. **Note:** Selecting Specific **Specific MID servers** doesn't affect mid server selection. It's used only to decide which mid servers should have visibility to the credential. **Specific MID servers** isn't supported in Orchestration activities.
Order	Order (sequence) in which Discovery tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have

Field	Description
	the same order number (or none), the instance tries the credentials in a random order.
Windows MID Server Service Account	When active, the defined credential represents the MID Server service account.

JMS credentials

The JMS credentials type manages access to a Java Message Service (JMS). This credential type is available for Discovery and Orchestration.

These fields are available in the Credentials form for JMS.

Field	Description
Name	Enter a unique and descriptive name for this credential.
Active	Enable or disable these credentials for use.
User name	Enter the user name to create in the Credentials table. Avoid leading or trailing spaces in user names. A warning appears if the platform detects leading or trailing spaces in the user name. For CIM discovery, the user must have the admin role.
Password	Enter the password.
Credential ID	Enter the unique key configured for external credentials in the JAR file uploaded to the MID Server for an external credential system. The **Credential ID** field has a limit of 40 characters. This field is only visible when the **External credential store** check box is selected.
Credential alias	Allow workflow creators to assign individual credentials to any activity in an Orchestration workflow or assign different credentials to each occurrence of the same activity type in an Orchestration workflow. To use the credential for discovering CIs not belonging to this CI type using Service Mapping and Discovery patterns, enter the table name for the CI type to which the CI belongs, for example cmdb_ci_apache_web_server.
External credential store	Select this check box to use an external credential storage system. When you select this option the **User name** and **Password** fields are replaced with the **Credential ID** field. External credential storage is only available when the External Credential Storage plugin in activated. **Note:** Currently, the only supported external storage system is CyberArk.
Applies to	Select whether to apply these credentials to **All MID servers** in your network, or to one or more **Specific MID servers**. Specify the MID Servers that should use these credentials in the **MID servers** field.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
MID servers	Select one or more MID Servers from the list of available MID Servers. The credentials configured in this record are available to the MID Servers in this list. This field is available only when you select **Specific MID servers** from the **Applies to** field. **Note:** Selecting Specific **Specific MID servers** doesn't affect mid server selection. It's used only to decide which mid servers should have visibility to the credential. **Specific MID servers** isn't supported in Orchestration activities.
Order	Order (sequence) in which Discovery tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order.
Windows MID Server Service Account	When active, the defined credential represents the MID Server service account.

OAuth 2.0 credentials

OAuth 2.0 credentials enable ServiceNow to obtain access to user accounts on an HTTP service.

These fields are available in the Credentials form for OAuth 2.0.

OAuth 2.0 credentials form

Field	Input value
Name	Enter a unique and descriptive name for this credential. For example, you might call it **OAuth2 credential**.
Active	Specify whether this credential is active.
OAuth Entity Profile	An OAuth profile is a combination of a grant type and at least one scope.
Connect to Auth Server via MID Server	Connects your ServiceNow instance to an on-premise OAuth server that resides behind a firewall through a MID Server. It can also connect your ServiceNow instance to a cloud-based OAuth server through a MID server. When this option is enabled, the request for an OAuth token is sent through the MID Server.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

OAuth 2.0 credentials form (continued)

Field	Input value
	Important: • The option appears when the value in the **Grant type** field in the OAuth Entity Profile is set to either**Client Credentials**, **Authorization Code**, or **Resource Owner Password Credentials**. To learn how to set an OAuth entity profile for a third-party OAuth provider, see Connect to a third-party OAuth provider. • If you select the **Connect to Auth Server via MID Server** checkbox, you must identify the required MID Server or MID Servers from the **Applies to** list.
Applies to	Specify if the credential record is applicable for all MID Servers, or a specific MID Server. If specific, add the MID servers as necessary. **Important:** Ensure that you are aware of these considerations if you have selected the **Connect to Auth Server via MID Server** check box. • Ensure that all the MID Servers selected in Applies to can communicate with the Auth server. This is required to execute the token request against the **Token URL** mentioned in the OAuth provider record (that is linked to the OAuth entity profile specified in the OAuth 2.0 credential record).  • Ensure that there is at least one MID Server (in the MID Servers selected in **Applies to**) with these configurations: ○ The value of the **Status** field is **Up**. ○ The value of the **Validated** field is **Yes**. ○ The capability of the MID Server is set to **REST** or **ALL**. To learn how to configure the MID server, see https://www.servicenow.com/docs/access?context=configure-capabilities&version=zurich&pubname=zurich-integrate-applications&ft:locale=en-US  . To learn more about these statuses, see MID Server dashboard.

OAuth 2.0 credentials form (continued)

Field	Input value
Order	Order (sequence) in which Discovery tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order.
Credential alias	Specify the credential alias that you want to tie to the OAuth 2.0 credential.
Integration Type	Indicates the integration type for the credential. Invoke an API of a third-party with an OAuth request that generates an OAuth token that is system or user specific. Following are the integration types: • **System**: Pull the token information based on the requester profile. The **System** integration type supports the following authentication mechanisms: **1.** Security Assertion Markup Language (SAML) **2.** JSON Web Token (JWT) • **Personal**: Pull the token information that is user-specific. The MID Server user must have the `oauth_admin` role. The **Personal** and **System** integration types support the following grant types: **1.** Authorization Code **2.** Resource Owner Password Credentials If this **Personal** is selected on the OAuth Requestor Profile page, an additional flag called as **Personal** is displayed. **Note:** • Any information that is related to a user can only be accessed with user-specific OAuth tokens with the Integration Type as **Personal**. • To use the session user-related token, you have to select the **Run As** filed in the Flow properties as **User who initiates session**.

SAP credentials

The SAP credential type manages access to SAP JCo systems. This credential type is available for Discovery and Orchestration.

These fields are available in the Credentials form for SAP type credentials.

Field	Description
Name	Enter a unique and descriptive name for this credential.
Active	Enable or disable these credentials for use.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
User name	Enter the user name to create in the Credentials table. Avoid leading or trailing spaces in user names. A warning appears if the platform detects leading or trailing spaces in the user name. For CIM discovery, the user must have the admin role.
Password	Enter the password.
Credential ID	Enter the unique key configured for external credentials in the JAR file uploaded to the MID Server for an external credential system. The **Credential ID** field has a limit of 40 characters. This field is only visible when the **External credential store** check box is selected.
Credential alias	Allow workflow creators to assign individual credentials to any activity in an Orchestration workflow or assign different credentials to each occurrence of the same activity type in an Orchestration workflow. To use the credential for discovering CIs not belonging to this CI type using Service Mapping and Discovery patterns, enter the table name for the CI type to which the CI belongs, for example cmdb_ci_apache_web_server.
External credential store	Select this check box to use an external credential storage system. When you select this option the **User name** and **Password** fields are replaced with the **Credential ID** field. External credential storage is only available when the External Credential Storage plugin in activated. **Note:** Currently, the only supported external storage system is CyberArk.
Applies to	Select whether to apply these credentials to **All MID servers** in your network, or to one or more **Specific MID servers**. Specify the MID Servers that should use these credentials in the **MID servers** field.
MID servers	Select one or more MID Servers from the list of available MID Servers. The credentials configured in this record are available to the MID Servers in this list. This field is available only when you select **Specific MID servers** from the **Applies to** field. **Note:** Selecting Specific **Specific MID servers** doesn't affect mid server selection. It's used only to decide which mid servers should have visibility to the credential. **Specific MID servers** isn't supported in Orchestration activities.
Order	Order (sequence) in which Discovery tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order.
Windows MID Server	When active, the defined credential represents the MID Server service account.

Field	Description
Service Account	

SNMP credentials

Discovery explores many kinds of devices (switches, routers, printers, and so on) using the SNMP protocol. Credentials for SNMP don't include a user name, just a password, called the *community string*.

The default read-only community string for many SNMP devices is public, and Discovery will try that automatically. Enter the appropriate SNMP credentials if they differ from the *public* community string.

Discovering SNMP uses all community strings that are configured. This behavior does not apply to discovering SNMPv3.

The default Orchestration activity SNMP Query returns the object identifier (OID) of a device and requires SNMP credentials.

SNMP community credentials

The SNMP Community credential type manages access to discover many kinds of devices (switches, routers, printers, etc.) using the SNMP protocol. This credential type is available for Discovery, Service Mapping, and Orchestration.

Credentials for SNMP do not include a user name, just a password (the community string). The default read-only community string for many SNMP devices is public, and the system will try that automatically. Enter the appropriate SNMP credentials if they differ from the public community string.

These fields are available in the Credentials form for SNMP community.

Field	Description
Name	Enter a unique and descriptive name for this credential.
Active	Enable or disable these credentials for use.
User name	Enter the user name to create in the Credentials table. Avoid leading or trailing spaces in user names. A warning appears if the platform detects leading or trailing spaces in the user name. For CIM discovery, the user must have the admin role.
Password	Enter the password.
Credential ID	Enter the unique key configured for external credentials in the JAR file uploaded to the MID Server for an external credential system. The **Credential ID** field has a limit of 40 characters. This field is only visible when the **External credential store** check box is selected.
Credential alias	Allow workflow creators to assign individual credentials to any activity in an Orchestration workflow or assign different credentials to each occurrence of the same activity type in an Orchestration workflow.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	To use the credential for discovering CIs not belonging to this CI type using Service Mapping and Discovery patterns, enter the table name for the CI type to which the CI belongs, for example cmdb_ci_apache_web_server.
External credential store	Select this check box to use an external credential storage system. When you select this option the **User name** and **Password** fields are replaced with the **Credential ID** field. External credential storage is only available when the External Credential Storage plugin in activated. **Note:** Currently, the only supported external storage system is CyberArk.
Applies to	Select whether to apply these credentials to **All MID servers** in your network, or to one or more **Specific MID servers**. Specify the MID Servers that should use these credentials in the **MID servers** field.
MID servers	Select one or more MID Servers from the list of available MID Servers. The credentials configured in this record are available to the MID Servers in this list. This field is available only when you select **Specific MID servers** from the **Applies to** field. **Note:** Selecting Specific **Specific MID servers** doesn't affect mid server selection. It's used only to decide which mid servers should have visibility to the credential. **Specific MID servers** isn't supported in Orchestration activities.
Order	Order (sequence) in which Discovery tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order.
Windows MID Server Service Account	When active, the defined credential represents the MID Server service account.

SNMPv3 credentials

SNMPv3 credentials accept a privacy protocol and an additional privacy key and are available for Discovery and Orchestration. For external storage in CyberArk, you can select a privacy account key.

These fields are available in the Credentials form for SNMPv3.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

SNMPv3 credential fields

Field	Input value
Name	Unique and descriptive name for this credential. For example, you might call it **SNMP Community Atlanta**.
Active	Enable or disable these credentials for use.
Applies to	Select whether to apply these credentials to **All MID servers** in your network, or to one or more **Specific MID servers**. Specify the MID Servers that should use these credentials in the **MID servers** field.
MID servers	Select one or more MID Servers from the list of available MID Servers. The credentials configured in this record are available to the MID Servers in this list. This field is available only when you select **Specific MID servers** from the **Applies to** field.
Order	Order (sequence) in which Discovery tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order.
User name	Enter the SNMP user name. Avoid leading or trailing spaces in user names. A warning appears if the platform detects leading or trailing spaces in the user name.
Authentication protocol	Select the authentication type to use for this credential. The choices are: • MD5 • SHA-1 • SHA-224 • SHA-256 • SHA-384 • SHA-512
Authentication Key	Enter the authentication key to use for this credential.
Privacy protocol	Select the encryption protocol for this credential. The choices are: • 3DES • AES128 • AES192 • AES256 • DES
Privacy key	Enter the key associated with the selected privacy protocol.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

SNMPv3 credential fields (continued)

Field	Input value
Credential ID	Enter the unique key configured for external credentials in the JAR file uploaded to the MID Server for an external credential provider. The **Credential ID** field has a limit of 40 characters. This field is only visible when the **External credential store** check box is selected.
Privacy Credential ID	Enter the privacy account key configured for SNMPv3 credentials in CyberArk. If you are using a privacy protocol in CyberArk, this field must have the same value as the **Name** field for the CyberArk SNMPv3 Privacy Account. This field is only visible for SNMPv3 when you select **CyberArk** from the **Credential Store Type** field. If you are not using a privacy key for CyberArk, leave this field empty.
Credential alias	Allow workflow creators to assign individual credentials to any activity in an Orchestration workflow or assign different credentials to each occurrence of the same activity type in an Orchestration workflow.
External credential store	Select this check box to use an external credential storage system. When external storage is enabled, the **Credential ID** field appears. External credential storage is only available when the External Credential Storage plugin is activated and the **External Storage** view is selected.
Credential Store Type	Select the external storage provider. Select **CyberArk** only if you are using a CyberArk SNMPv3 privacy key. The **Privacy Credential ID** field appears to allow entry of the key.
Use Context	Select this check box to add a context value for this credential. This field is visible in the **Discovery** view. Contexts are not currently supported for external credential storage. **Note:** A context is a collection of management information accessed by an SNMPv3 credential that references a specific OID. Contexts are sometimes referenced to collect information about the device that cannot be accessed by the normal credential. A context can be provided by the manufacturer or configured separately. If you have multiple SNMPv3 credentials with the same user name and keys, but some of your devices need a context and some do not, then you will need to create separate records for each device.
Context Name	Enter the context name value for this credential. This should only be used if you have devices that require this value for full access. This field is visible when the **Use Context** check box is selected.

SSH credentials

Discovery, Orchestration, and Integration Hub explore UNIX and Linux devices by using SSH credentials to execute commands over Secure Shell (SSH). SSH commands must run with root privileges, either with root credentials or through the use of sudo. SSH private key credentials provide additional security.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Granting root privileges

Before granting root privileges, review your security policy and options with your organization's security team.

Use either of these approaches to allow users to run SSH commands with root privileges:

- Give other credentials for Discovery, Orchestration, or Integration Hub, but grant the user in those credentials the right to execute certain commands with root privileges, using sudo. This is a secure way to grant limited privileges. Discovery, Orchestration, or Integration Hub use sudo on any probe that has the `must_sudo`parameter set to **true** (it defaults to **false**). However, each system must be configured to allow sudo to work. This is done by editing the **/etc/sudoers** file using the **visudo** command.
- Give **root** credentials. These are obviously the most powerful credentials, but may not be desirable from a security perspective. If Discovery, Orchestration, or Integration Hub have the root credentials to any UNIX or Linux system, no further configuration is required.

Privileged commands

The platform provides default privileged commands for the MID Server to use and the ability to add additional commands to the system. For details about using sudo and other privileged commands, see MID Server privileged commands.

SSH private key credential type

Note:
SSH private key credentials should be used in most cases. They provide better security than SSH password credentials, including against MitM (man-in-the-middle) attacks in which communications between two parties are intercepted.

Field	Input value
Name	Unique and descriptive name for this credential. For example, you might call it **SSH Atlanta**.
Active	Enable or disable these credentials for use.
User name	Enter a UNIX or Linux user name. Avoid leading or trailing spaces in user names. A warning appears if the platform detects leading or trailing spaces in the user name.
Password	Enter the UNIX or Linux password. For **SSH Private Key** type credentials, enter the sudo password if one is required for the user name.
SSH passphrase	Type a secure SSH passphrase. This field is available only for **SSH Private Key** credentials.

SSH private key	Enter a secure, RSA, DSA, ECDSA or ED25519 private key.
	
	The private key must be entered in the proper format to ensure it is correctly encrypted. The private key must start with the string `-----BEGIN`.
	
	Here is an example of a correctly formatted RSA private key:
	`-----BEGIN RSA PRIVATE KEY-----`
	`MIIEogIBAAKCAQEAsEK65scPssPSobpDFMpR+Btv3MS4Q7NP8ERaSt`
	`RZsh3IWz+x...`
	`...7hrxV2dbSug60FahyupGWBGtPnXm5PaE2X5WPLuUj94ue48i1Fs`
	`-----END RSA PRIVATE KEY-----`

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Input value

	An example of a DSA key:
	`-----BEGIN DSA PRIVATE KEY-----`
	`MIIEogIBAAKCAQEAsEK65scPssPSobpDFMpR+Btv3MS4Q7NP8ERaSt`
	`RZsh3IWz+x...`
	`...7hrxV2dbSug60FahyupGWBGtPnXm5PaE2X5WPLuUj94ue48i1Fs`
	`-----END DSA PRIVATE KEY-----`
	An example of a ECDSA key:
	`-----BEGIN EC PRIVATE KEY-----`
	`MIIEogIBAAKCAQEAsEK65scPssPSobpDFMpR+Btv3MS4Q7NP8ERaSt`
	`RZsh3IWz+x...`
	`...7hrxV2dbSug60FahyupGWBGtPnXm5PaE2X5WPLuUj94ue48i1Fs`
	`-----END EC PRIVATE KEY-----`
	And an example of an ED25519 private key:
	`-----BEGIN OPENSSH PRIVATE KEY-----`
	`b3BlbnNzaC1rZXktdjEAAAAABG5vbmUAAAAEbm9uZQAAAAAAAAABAA`
	`AAMwAAAAtzc2gtZW`
	`QyNTUxOQAAACAlYlqhcdwx8VQzZ5XaIC5ltQpjRr3lIlq/aE66mufm`
	`iwAAAKDQUtxZOFLc`
	`WQAAAAtzc2gtZWQyNTUxOQAAACAlYlqhcdwx8VQzZ5XaIC5ltQpjRr`
	`3lIlq/aE66mufmiw`
	`AAAECuvsTkFUPdpTh0kw23i8TYx19qsFOZ3TRgowkkHBh6wSViWqFx`
	`3DHxVDNnldogLmW1`
	`CmNGveUiWr9oTrqa5+aLAAAAGmFiaGluYXYuc3V0YXJATVJFTUE3OT`
	`AzMkI3AQID`
	`-----END OPENSSH PRIVATE KEY-----`
	Note:
	For an ED25519 private key, only the OpenSSH key format is supported, which is generated using OpenSSH SSH-keygen utility.
	The ServiceNow AI Platform supports private keys in the PEM format generated by the OpenSSH ssh-keygen utility. To convert PPK keys that were generated by PuTTY:
	• Open your private key in PuTTYGen.
	• Export it in OpenSSH format from the menu **Conversions** > **Export OpenSSH key**.
	• Save the new OpenSSH key.

SSH Certificate	Enter an RSA or ED25519 based OpenSSH certificate. When the certificate is entered, a private key is used for certificate based authentication. This authentication is supported from OpenSSH 7.8 onwards.
Credential alias	• Allow flow designers to use aliases to manage connection and credential information. Using an alias eliminates the need to configure multiple credentials and connection information profiles when using multiple environments. If the connection or credential information changes, you do not need to update any

Field	Input value
	actions that use the connection. For more information, see Connections and Credentials. • Allow workflow creators to assign individual credentials to any activity in an Orchestration workflow or assign different credentials to each occurrence of the same activity type in an Orchestration workflow.
External credential store	Select this check box to use an external credential storage system. When you select this option the **User name** and **Password** fields are replaced with the **Credential ID** field. Currently, the only supported external storage system is CyberArk.
MID servers	Select one or more MID Servers from the list of available MID Servers. The credentials configured in this record are available to the MID Servers in this list. This field is available only when you select **Specific MID servers** from the **Applies to** field.
Applies to	Select whether to apply these credentials to **All MID servers** in your network, or to one or more **Specific MID servers**. Specify the MID Servers that should use these credentials in the **MID servers** field.
Order	The order (sequence) in which the platform tries this credential as it attempts to log onto devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), Discovery or Orchestration tries the credentials in a random order.

SSH credential type

These fields are available in the SSH credentials form.

Field	Description
Name	Enter a unique and descriptive name for this credential.
Active	Enable or disable these credentials for use.
User name	Enter the user name to create in the Credentials table. Avoid leading or trailing spaces in user names. A warning appears if the platform detects leading or trailing spaces in the user name. For CIM discovery, the user must have the admin role.
Password	Enter the password.
Credential ID	Enter the unique key configured for external credentials in the JAR file uploaded to the MID Server for an external credential system. The **Credential ID** field has a limit of 40 characters. This field is only visible when the **External credential store** check box is selected.
Credential alias	• Allow flow designers to use aliases to manage connection and credential information. Using an alias eliminates the need to configure multiple credentials and connection information profiles when using multiple environments. If the connection or credential information changes, you do not need to update any actions that use the connection. For more information, see Connections and Credentials.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	• Allow workflow creators to assign individual credentials to any activity in an Orchestration workflow or assign different credentials to each occurrence of the same activity type in an Orchestration workflow. To use the credential for discovering CIs not belonging to this CI type using Service Mapping and Discovery patterns, enter the table name for the CI type to which the CI belongs, for example cmdb_ci_apache_web_server.
External credential store	Select this check box to use an external credential storage system. When you select this option the **User name** and **Password** fields are replaced with the **Credential ID** field. External credential storage is only available when the External Credential Storage plugin in activated. **Note:** Currently, the only supported external storage system is CyberArk.
Applies to	Select whether to apply these credentials to **All MID servers** in your network, or to one or more **Specific MID servers**. Specify the MID Servers that should use these credentials in the **MID servers** field.
MID servers	Select one or more MID Servers from the list of available MID Servers. The credentials configured in this record are available to the MID Servers in this list. This field is available only when you select **Specific MID servers** from the **Applies to** field.
Order	Order (sequence) in which Discovery tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order.

Commands that require root privileges for Discovery, Orchestration, and Integration Hub

These examples assume that the user name is **Disco**. Substitute the actual user name and ensure that the paths for the commands match the paths on the system.

Note:
Sudo commands do not work with private key credentials, because there is no password to supply to the sudo command. A solution is to add the *NOPASSWD* option to the sudo configuration. For example, you might enter: `disco ALL=(root) NOPASSWD: /usr/sbin/dmidecode,/usr/sbin/lsof,/sbin/ifconfig`.

UNIX and Linux commands requiring root privileges

Command	Purpose
HP-UX	
adb	Gathers CPU speed and memory.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

UNIX and Linux commands requiring root privileges (continued)

Command	Purpose
	• **/etc/sudoers line example**: Disco ALL=(root) /usr/bin/adb • **Used by**: Discovery
All Linux and UNIX versions	
chage	Changes the number of days between password changes and the date of the last password change. • **/etc/sudoers line example**: Disco ALL=(root) /usr/bin/chage • **Used by**: Orchestration and Integration Hub
chpasswd	Changes user passwords. • **/etc/sudoers line example**: Disco ALL=(root) /etc/chpasswd • **Used by**: Orchestration and Integration Hub
All Linux	
dmidecode	Gathers several pieces of information about the hardware, including the serial number embedded within the motherboard. • **/etc/sudoers line example**: Disco ALL=(root) /sbin/dmidecode • **Used by**: Discovery
fdisk	Gathers the disks and size information on the system. • **/etc/sudoers line example**: Disco ALL=(root) /usr/bin/fdisk -l • **Used by**: Discovery
multipath	Gathers device mappings for MPIO. • **/etc/sudoers line example**: Disco ALL=(root) /usr/bin/multipath -ll • **Used by**: Discovery
ls	Gathers the contents of a directory. • **/etc/sudoers line example**: Disco ALL=(root) /usr/bin/ls, /bin/ls • **Used by**: Discovery
Linux and Solaris	

dmsetup	Examines a low level volume.
	• **/etc/sudoers line example**:
	  ○ Disco ALL=(root) /usr/bin/dmsetup table *
	  ○ Disco ALL=(root) /usr/bin/dmsetup ls
	• **Used by**: Discovery

© 2026 ServiceNow, Inc. All rights reserved.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

UNIX and Linux commands requiring root privileges (continued)

Command	Purpose
All UNIX versions	
lsof	Determines the relationship between processes and the connections being made to the system. • **/etc/sudoers line example**: Disco ALL=(root) /sbin/lsof • **Used by**: Discovery
oratab	Grants read access to the oratab file for locating the Oracle Home and pfile. • **/etc/sudoers line example**: N/A • **Used by**: Discovery
Solaris	
iscsiadm	Gets iSCSI IQNs • **/etc/sudoers line example**: ${sudo:iscsiadm list target -S} • **Used by**: Discovery
fcinfo	Gets WWPNs for ports. • **/etc/sudoers line example**: ${sudo:fcinfo remote-port -sl -p $port} • **Used by**: Discovery
prtvtoc	Reports information about disk partitions. • **/etc/sudoers line example**: Disco ALL=(root) /usr/bin/prtvtoc • **Used by**: Discovery
pfiles	Used for gathering TCP connections information. • **/etc/sudoers** line example: Disco ALL=(root) /usr/bin/pfiles • **Used by**: Discovery
pgrep	Used for listing process IDs of a particular region to run pfiles on. • **/etc/sudoers line** example: Disco ALL=(root) /usr/bin/pgrep • **Used by**: Discovery
/usr/bin/ps	Lists running process. As an alternative to running with root access, add a proc_owner role.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

UNIX and Linux commands requiring root privileges (continued)

Command	Purpose
	• **/etc/sudoers line example**: Disco ALL=(root) /usr/bin/ps • **Used by**: Discovery
/usr/ucb/ps	Lists running process. As an alternative to running with root access, add a proc_owner role. The use of the `/usr/ucb/ps` command is deprecated as of Solaris 11. Because Discovery, Orchestration, and Integration Hub require the use of this command for all Solaris versions, you must install the ucb utility manually on Solaris 11 systems. For instructions, see KB0564262. • **/etc/sudoers line example**: Disco ALL=(root) /usr/ucb/ps • **Used by**: Discovery

For a list of privileged commands that you need for Discovery and Service Mapping, see Service Mapping commands requiring a privileged user. This list includes commands that require elevated rights to discover and map Unix-based hosts in your organization.

Access Requirements for Non-Root Credentials

If you do not provide Discovery with root access credentials, you must provide credentials with the following access requirements.

Application	File or Directory	Access Required
Apache	httpd.conf	Read
Hbase	hbase-site.xml	Read
JBoss	jboss-service.xml	Read
	JBoss home directory	Read
	web.xml	Read
MySQL	my.cnf	Read
NGINX	nginx.conf	Read
Oracle	oratab	Read
	Associated (s) pfiles	Read
Oracle Listener	lsnrctl	Execute
	listener.ora	Read
Tomcat	catalina.jar	Read
	server.xml	Read
	web.xml	Read
Unix	/etc/*release	Read
	/etc/bashrc	Read

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Application	File or Directory	Access Required
	/etc/profile	Read
	/proc/cpuinfo	Read
	/proc/vmware/sched/ncpus	Read
	/var/log/dmesg	Read
	APD directory	Read
WebSphere	cell.xml	Read
	server.xml	Read
	serverindex.xml	Read

VMware credentials

The VMware credentials type manages access to vCenter credentials.

Applications that access VMware cloud resources need access to VMware credentials. For example, the VMware credential type enables Discovery to explore VMware's vCenter running on a Windows machine to discover ESX machines, virtual machines, and resource pools. The VMware Discovery and automation API (vCenter API) now provides the globally unique serial number for computer CIs. CIM credentials aren't needed to enable access to each VMware host.

Note:
Windows credentials aren't necessary for vCenter Discovery, when valid VMware credentials are used.

Important:
Do not use **VMware** Type credentials for Orchestration activities that perform work on the individual virtual machines cloned by vCenter (for example, restarting a Linux VM). For these activities, the credential **Type** depends on the operating system of the virtual machine (either **SSH** or **Windows**).

VMWare credentials form

Field	Description
Name	Enter a unique and descriptive name for the VMware credentials.
Active	Enable or disable these credentials for use.
User name	Enter the user name that you use for your VMware account. Avoid leading or trailing spaces in user names. A warning appears if the platform detects leading or trailing spaces in the user name. The VMware credentials must have the read-only role in vCenter.
Password	Enter the password for the VMware account.
Applies to	Select one or more MID Servers from the list of available MID Servers. The credentials configured in this record are available to the MID Servers in this list. This field is available only when you select **Specific MID servers** from the **Applies to** field.
Order	Order (sequence) in which Discovery tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

VMWare credentials form (continued)

Field	Description
	Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order.

Windows credentials

Windows credentials provide access to Windows computers. This credential type is available for Discovery and Orchestration.

Credential requirements

Discovery and Orchestration have the following requirements for Windows credentials:

- Install a MID Server on a Windows host as a service.
- Add Windows credentials to one of these locations:
  - An entry in the Credentials `[windows_credentials]` table
  - A MID Server service account to run as a specific Windows user or domain account.

Granting proper permissions

To provide sufficient permissions, Windows credentials must be one of the following:

- A domain user with local administrator access on the target Windows hosts.

> **Important:**
> If User Account Control (UAC) is enabled on the Windows operating system where discovery runs, and the user account is part of the local Administrators group, administrator tasks may fail. To avoid interruptions, we recommend disabling UAC. For more information, see the Why does the User Access Control (UAC) need to be disabled for Windows Discovery? article in the Now Support Knowledge Base

- A local account that has administrator privileges and UAC disabled on the same target host.
- A user who meets the requirements of Windows probes and permissions (Discovery only).
- A user who meets the requirements of the Orchestration activity to be run (Orchestration only).

> **Note:**
> No logon privileges are needed. Account does NOT need to be interactive.

Security around granting privileged access can be enhanced by using JEA profiles to run Discovery. For more information, see Microsoft Just Enough Administration (JEA) for Discovery.

Workgroup computers

To run Powershell commands to discover a Workgroup computer, configure the MID Server credentials for either of these users:

- Built-in administrator account on the Workgroup computer.
- Domain user on the Workgroup computer.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Multi-domain configuration

To enable Windows credentials to function across multiple domains, make sure to sure to use the correct name formats and MID Server configuration.

Discovery and Orchestration support Windows domain credentials in both **User Principal Name** and **Down-Level Logon Name** user name formats. For example, **Domain\UserName** or **UserName@example.domain.com**. You can provide Windows workgroup credentials in the following format: WORKGROUP\UserName.

Note:
You can also provide a local account by using the **.** user name.

These additional actions are required to enable credentials to function across multiple Windows domains.

Condition	Additional actions required
MID Server host on the same domain as the Windows target.	None
MID Server host on a different domain than the Windows target.	Ensure that PowerShell 3.0 (or higher up to 5.1) is installed on the MID Server host.
MID Server host on a different domain than the Microsoft SQL Server target.	See MSSQL server discovery .

Windows credentials type

These fields are available in the Credentials form for Windows:

Field	Description
Name	Enter a unique and descriptive name for this credential.
Active	Enable or disable these credentials for use.
User name	Enter the user name to create in the Credentials table. Avoid leading or trailing spaces in user names. A warning appears if the platform detects leading or trailing spaces in the user name. For CIM discovery, the user must have the admin role.
Password	Enter the password.
Credential ID	Enter the unique key configured for external credentials in the JAR file uploaded to the MID Server for an external credential system. The **Credential ID** field has a limit of 40 characters. This field is only visible when the **External credential store** check box is selected.
Credential alias	Allow workflow creators to assign individual credentials to any activity in an Orchestration workflow or assign different credentials to each occurrence of the same activity type in an Orchestration workflow. To use the credential for discovering CIs not belonging to this CI type using Service Mapping and Discovery patterns, enter the table name for the CI type to which the CI belongs, for example cmdb_ci_apache_web_server.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
External credential store	Select this check box to use an external credential storage system. When you select this option the **User name** and **Password** fields are replaced with the **Credential ID** field. External credential storage is only available when the External Credential Storage plugin in activated. **Note:** Currently, the only supported external storage system is CyberArk.
Applies to	Select whether to apply these credentials to **All MID servers** in your network, or to one or more **Specific MID servers**. Specify the MID Servers that should use these credentials in the **MID servers** field.
MID servers	Select one or more MID Servers from the list of available MID Servers. The credentials configured in this record are available to the MID Servers in this list. This field is available only when you select **Specific MID servers** from the **Applies to** field. **Note:** Selecting Specific **Specific MID servers** doesn't affect mid server selection. It's used only to decide which mid servers should have visibility to the credential. **Specific MID servers** isn't supported in Orchestration activities.
Order	Order (sequence) in which Discovery tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order.
Windows MID Server Service Account	When active, the defined credential represents the MID Server service account.

Configure Windows credentials for the MID Server

Configure the MID Server to use either the credentials of its own Windows service or credentials from the Credentials [discovery_credentials] table.

Before you begin

Role required: admin

Procedure

1. Configure the MID Server to use credentials from the MID Server service account.
   a. Set the Configure Windows MID Server service credentials to a user who meets the permission requirements.
   b. Verify the user name meets the name format requirements.
   c. Fill in the fields on the form, as appropriate.
   d. Verify the credentials meet domain requirements.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

2. Configure the MID Server use credentials from the Credentials [discovery_credentials] table.

   a. Add individual Windows credentials to the Credentials `[windows_credentials]` table.
      - Verify each credential meets the permission requirements.
      - Verify each username meets the name format requirements.
      - Verify each credential meets the Windows domain requirements.

   b. **Optional:** Configure the MID Server to use Powershell by setting the `mid.use_powershell` parameter to **true**.
   See Configuring MID Servers.

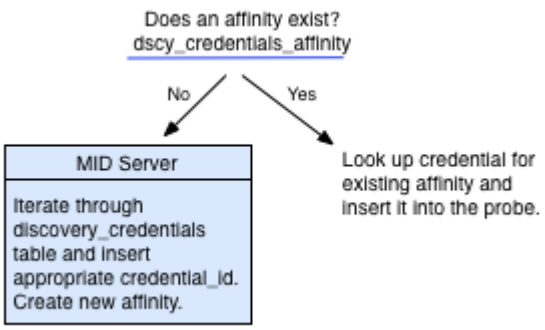
   c. Select the Windows MID Server Service Account check box to create a credential that represents the windows MID Server service account to run as a specific Windows user or domain account.

Credential affinity for Discovery and Orchestration

Credential affinity is an association between a set of credentials and a device on your network.

When Discovery or Orchestration first attempts to access a device, they try all available credentials until they find the correct ones. After identifying the credentials for a device, Discovery and Orchestration create an affinity between the credentials and the device using the Credential Affinity `[dscy_credentials_affinity]` table. All subsequent discoveries or Orchestration activities attempt to match the credentials in this table with a device for which an affinity exists. If credentials for a device change, Discovery and Orchestration try all available credentials again until they create a new affinity.

Credential Affinity diagram



Note:
If Orchestration and Discovery are installed, and credential alias is enabled, multiple affinities can exist. In this case, the platform looks up credentials for each affinity and inserts the credential for the affinity with the lowest order into the probe.

Credentials troubleshooting

Review the `<credentials_debug>` section of the ECC queue payload to troubleshoot issues with credentials.

Certain probes support credential debugging. Credential debugging inserts a `<credentials_debug>` section in the payload that the MID Server returns to the instance ECC queue. You can view the `<credentials_debug>` section to see detailed information about the credential lookup.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

The `<credentials_debug>` section appears in the payload if:

- Credentials fail for WMIRunner probe, PowerShell probe, JMS, or SSHCommand probe.
- You set the *credentials_debug* parameter to **true** for the WMIRunner, PowerShell, or SSHCommand probes. If you set the parameter to true, the `<credentials_debug>` section appears even if the credential lookup is successful.

The `<credentials_debug>` section shows:

- Information about the credential search, such as the credential types, tags, and affinities.
- The IP address targeted.
- Information about each credential (in order) that the MID Server used, including the type, classification, tag, name, Sys ID, and external credential ID if present.

Sample payload showing invalid credentials

```

Details appear for the PowerShell parameter:

- If the local MID Server credentials were used after all the Windows credentials failed.
- If the credentials were skipped because you are trying to discover the same machine that the MID Server is on.
- If the mid.powershell.use_credentials parameter is set to `true`.

Details appear for the SSHCommand:

- If the credential search was skipped because the target IP is excluded.
- If the target IP was added to the exclusion list.

Note:
The MID Server saves IP addresses for failed credential searches in an exclusion list in cache memory. This exclusion list specifies which devices the MID Server should stop trying to access. IP addresses are added to the exclusion list after every credential has failed. The IP addresses are cleared from the exclusion list cache either after five minutes, if the MID Server is restarted, or if the credential records on the instance are updated.

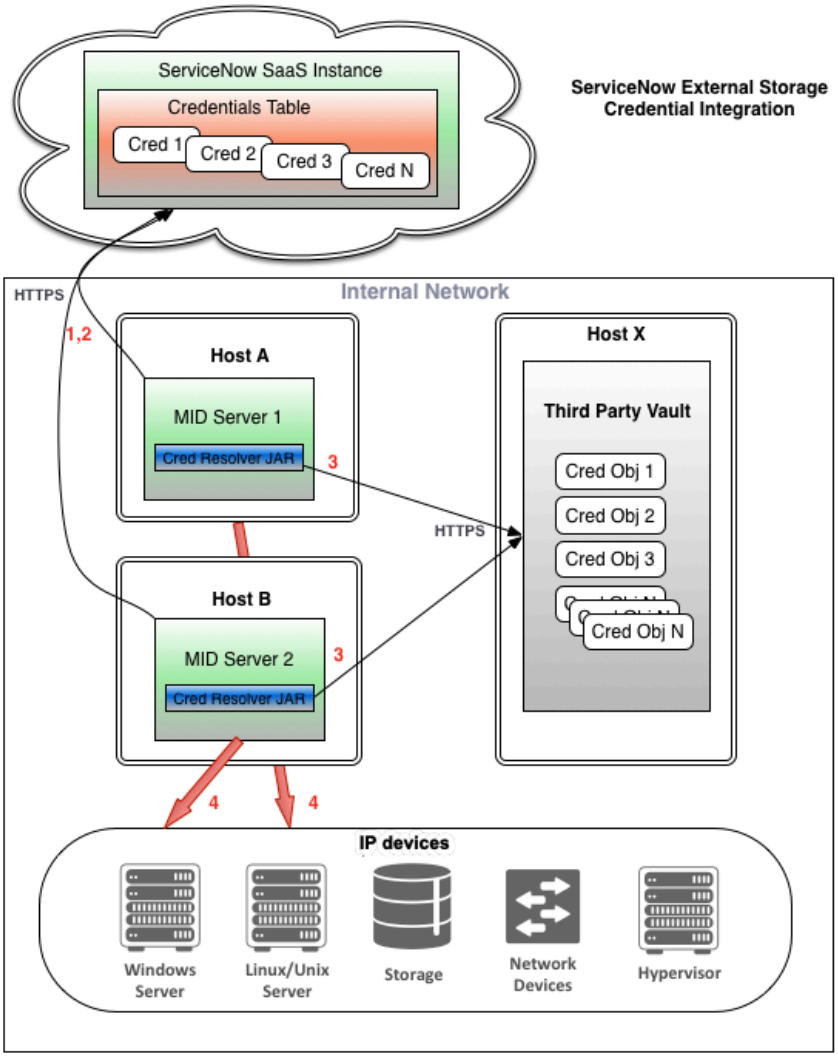
External credential storage

An instance can store credentials used by Discovery, Orchestration, and Service Mapping in an external credential repository rather than directly in a ServiceNow credentials record.

The instance maintains a unique identifier for each credential, the credential type (such as SSH, SNMP, or Windows), and any credential affinities. The MID Server obtains the credential identifier from the instance, and then uses a customer-provided JAR file to resolve the identifier from the repository into a usable credential. Currently, the ServiceNow® platform supports the use of the CyberArk vault or BeyondTrust for external credential storage.

External credential storage architecture

External credential storage architecture



Credential process flow

The MID Server retrieves credentials from an external store using this process:

1. MID Server downloads credential objects from the ServiceNow Credentials [discovery_credentials] table that contain the corresponding credential ID from the target vault.
2. As each probe or pattern runs from Discovery or Orchestration jobs, the MID Server requests the credential by passing information such as credential ID, target IP address, and credential

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

type to the Credential Resolver Java Jar file. The details about the correct credential object to retrieve from the vault are determined by the Credential Resolver.

Many Credential Resolvers such CyberArk call an application supplied by the third-party vault vendor running on same machine as the MID Server. That application can often be configured to cache credentials and knows to update the cache when a credential changes in the vault, which is very important to avoid unnecessary network calls to the vault each time MID Server requests a credential. The Credential Resolver (using optional vendor application if present) makes a call to the vault to get the actual user name, password, etc.

For Credential Resolvers supplied out-of-box (only CyberArk today), the MID Server only caches a credential for up to several seconds using encryption in MID Server process memory. This means the MID Server can make multiple requests to the Credential Resolver for the same credential even when discovering a single device. Contact third party vendors for information about caching implementations for other Credential Resolvers.

3. MID Server executes the probe with the appropriate credential.

Note:
Credential affinity still applies. The mechanism remains the same, since the only real difference from the MID Server's perspective is that the real credential details (user name and password) come from the third party vault.

External credential storage logging

The MID Server posts log messages about external credential storage.

If the repository encounters an error while attempting to resolve a credentials request, the MID Server posts log messages with this prefix: `Problem with client's CredentialResolver:`

Components installed with External Credential Storage

Business rule

The External Credential Storage business rule performs the following tasks when an administrator makes any change to the Enable External Credential Storage property:

- Changes the view for the Credentials record list and form to the External Storage view. This view enables users to see the **Credential ID** column in the list.
- Instructs the MID Server to refresh its credentials cache in preparation for a change in the way credentials are obtained.

Property

A property called Enable External Credential Storage [com.snc.use_external_credentials] enables or disables the External Credential Storage plugin after it's activated. The property is located in **Discovery Definition** > **Properties** and **Orchestration** > **MID Server Properties**, and is enabled when you activate the plugin.

If you disable external credential storage with the system property, the system automatically sets all the external credentials to inactive in the instance. If you re-enable the feature with this property, the system doesn't reset the external credential records to active. You must reactivate each credential record manually.

Request external credential storage for Discovery and Orchestration

The External Credential Storage plugin is available by request.

Before you begin

Role required: admin

About this task

There are two ways to request a plugin:

- Access the Now Support Service Catalog directly by selecting **Automation Store** > **Service Catalog** > **Activate Plugin** on Now Support.
- Access the Now Support Service Catalog through the All Applications page on your instance by following these steps.

For additional details about requesting a plugin, see Requesting a Plugin from the Service Catalog [KB0751715] article in the Now Support Knowledge Base.

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Select **Request plugin** to open the **Activate Plugin** form on Now Support.
3. On the **Activate Plugin** form, provide the following information.

Activate Plugin form

Field	Description
What is your target instance	Select the instance that you want to activate the plugin on.
Which plugin would you like to activate	Select the name of the plugin to activate. **Note:** If the system doesn't list the plugin you want or if you're activating the plugin on an OEM or on-premise instance, select the **Plugin I'm looking for is not listed** check box and then enter the name of the plugin.
Select Maintenance Date and Time	Select the date and time to activate the plugin.

Example

For example, see the following form to activate the Event Management plugin on an instance named SNC Instance.

4. Select **Submit**.
   After the maintenance window, the system installs the plugin on your instance. To confirm the installation, go to the Installed tab in the Application Manager.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

External credential storage configuration

Configure your instance to obtain credentials from a remote repository.

These procedures assume that you already have an external repository configured with the credentials you want to protect. The credential identifier configured in the ServiceNow instance must be mapped to the actual credential in the repository through the JAR file.

Note:
ServiceNow supports two external vaults at a time: one default CyberArk credential resolver, and one custom external credential resolver. Creating a custom CyberArk credential resolver still uses the second, custom external vault, and no additional custom external vaults can be used.

To configure External Credential Storage, complete the following tasks in order.

Create a JAR file to resolve credentials

Create a JAR file to resolve credential identifiers sent from the MID Server into actual credentials from the repository.

Before you begin
Role required: agent_admin or admin

Make sure to include all the credential elements that the instance expects, such as the private key.

To create a JAR file to resolve credentials:

Procedure

Use either the templates provided on the ServiceNow github or the sample Java file.

Caution:
These samples are intended as a template only. Do **NOT** use this code in production without modifying it for your environment.

a. Download the open source JAR files with instructions from the ServiceNow github:

- HashiCorp External Credential Resolver
- CyberArk External Credential Resolver

b. Use the following sample Java file as a template and modify it to suit your environment:

Example

```
package com.snc.discovery;

import java.util.*;
import java.io.*;

/**
 * Basic implementation of a CredentialResolver that uses a
 properties file.
 */

public class CredentialResolver {
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
private static String ENV_VAR = "CREDENTIAL_RESOLVER_FILE";
private static String DEFAULT_PROP_FILE_PATH =
"C:\\dummycredentials.properties";

// These are the permissible names of arguments passed INTO
the resolve()
// method.

// the string identifier as configured on the ServiceNow
instance...
public static final String ARG_ID = "id";

// a dotted-form string IPv4 address (like "10.22.231.12") of
the target
// system...
public static final String ARG_IP = "ip";

// the string type (ssh, snmp, etc.) of credential as
configured on the
// instance...
public static final String ARG_TYPE = "type";

// the string MID server making the request, as configured on
the
// instance...
public static final String ARG_MID = "mid";

// These are the permissible names of values returned FROM the
resolve()
// method.

// the string user name for the credential, if needed...
public static final String VAL_USER = "user";

// the string password for the credential, if needed...
public static final String VAL_PSWD = "pswd";

// the string pass phrase for the credential if needed:
public static final String VAL_PASSPHRASE = "passphrase";

// the string private key for the credential, if needed...
public static final String VAL_PKEY = "pkey";

// the string authentication protocol for the credential, if
needed...
public static final String VAL_AUTHPROTO = "authprotocol";

// the string authentication key for the credential, if
needed...
public static final String VAL_AUTHKEY = "authkey";

// the string privacy protocol for the credential, if
needed...
public static final String VAL_PRIVPROTO = "privprotocol";

// the string privacy key for the credential, if needed...
```

```
 public static final String VAL_PRIVKEY = "privkey";

 private Properties fProps;

 public CredentialResolver() {
 }

 private void loadProps() {
  if(fProps == null)
   fProps = new Properties();

  try {
   String propFilePath = System.getenv(ENV_VAR);
   if(propFilePath == null) {
    System.err.println("Environment var "+ENV_VAR+" not found.
 Using default file: "+DEFAULT_PROP_FILE_PATH);
    propFilePath = DEFAULT_PROP_FILE_PATH;
   }

   File propFile = new File(propFilePath);
   if(!propFile.exists() || !propFile.canRead()) {
    System.err.println("Can't open
 "+propFile.getAbsolutePath());
   }
   else {
    InputStream propsIn = new FileInputStream(propFile);
    fProps.load(propsIn);
   }

 //fProps.load(CredentialResolver.class.getClassLoader().getRes
ourceAsStream("dummycredentials.properties"));
  } catch (IOException e) {
   System.err.println("Problem loading credentials file:");
   e.printStackTrace();
  }
 }

 /**
  * Resolve a credential.
  */
 public Map resolve(Map args) {
  loadProps();
  String id = (String) args.get(ARG_ID);
  String type = (String) args.get(ARG_TYPE);
  String keyPrefix = id+"."+type+".";

  if(id.equalsIgnoreCase("misbehave"))
   throw new RuntimeException("I've been a baaaaaaaaad
 CredentialResolver!");

  // the resolved credential is returned in a HashMap...
  Map result = new HashMap();
  result.put(VAL_USER, fProps.get(keyPrefix + VAL_USER));
  result.put(VAL_PSWD, fProps.get(keyPrefix + VAL_PSWD));
  result.put(VAL_PKEY, fProps.get(keyPrefix + VAL_PKEY));
```

```
 result.put(VAL_PASSPHRASE, fProps.get(keyPrefix +
VAL_PASSPHRASE));
 result.put(VAL_AUTHPROTO, fProps.get(keyPrefix +
VAL_AUTHPROTO));
 result.put(VAL_AUTHKEY, fProps.get(keyPrefix + VAL_AUTHKEY));
 result.put(VAL_PRIVPROTO, fProps.get(keyPrefix +
VAL_PRIVPROTO));
 result.put(VAL_PRIVKEY, fProps.get(keyPrefix + VAL_PRIVKEY));

 System.err.println("Error while resolving credential
id/type["+id+"/"+type+"]");

 return result;
}

/**
 * Return the API version supported by this class.
 */
public String getVersion() {
 return "1.0";
}

public static void main(String[] args) {
 CredentialResolver obj = new CredentialResolver();
 obj.loadProps();

 System.err.println("I spy the following credentials: ");
 for(Object key: obj.fProps.keySet()) {
  System.err.println(key+": "+obj.fProps.get(key));
 }

 }
}
```

Import a JAR file to resolve credentials

Import a JAR file created to resolve credential identifiers sent from the MID Server into actual credentials from the repository.

Before you begin

Role required: agent_admin or admin

After you create the JAR file, import it into the instance, where it becomes accessible to the MID Server.

Procedure

1. After creating the JAR and properties files, copy the properties file to the MID Server.
2. Navigate to **MID Server** > **JAR Files**.
3. Click **New**.
4. Complete the following fields:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Name	A unique and descriptive name for identifying the file in the instance.
Version	A version number for the file, if one is available.
Source	Location of the JAR file for reference purposes. Source information is not used by the system.
Description	Short description of the JAR file and its purpose in the instance.

5. Click the paper clip icon in the banner and attach the JAR file to the record.

Example

Attaching a JAR file

6. Click **Submit**.
7. Restart the MID Server service.
   The platform makes the JAR file available to any MID Server configured to communicate with the instance.

Configure the credential identifier

Configure the credential identifier in the instance.

Before you begin

Role required: admin
Verify the following items:

- The External Credential Storage plugin must be active.
- The Enable External Credential Storage Discovery property is enabled.

Procedure

1. Navigate to **All** > **Discovery** > **Credentials** or **Orchestration** > **Credentials**.
2. Click **New**.
3. Select a credential type.
4. Select the **External credential store** check box.
   The **User name** and **Password** fields disappear, and the **Credential ID** field and **Credential storage vault** menu appear.
5. From the **Credential storage vault** menu, select either None, the CyberArk vault, or a custom external credential storage vault.

Note:

If CyberArk vault is selected, the **Lookup key** menu appears with four lookup key choices: Credential ID, IP Address, FQDN, All of the above. Selecting All of the above can degrade performance because it requires accessing the vault multiple times.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

a. To use a custom external credential storage vault, navigate to Vault Configurations [vault_configuration.list] in the instance.

b. Create a new record using a name associated an imported JAR file for a custom credential resolver.

See the procedures Create a JAR file to resolve credentials and Import a JAR file to resolve credentials for information on creating a custom external credential storage vault.

6. Complete the Credentials form using the fields from the following table.

Field	Description
Name	Enter a unique and descriptive name for this credential.
Active	Enable or disable these credentials for use.
Credential ID	Enter the unique key configured for external credentials in the JAR file uploaded to the MID Server for an external credential system. This is the ID passed to the Java class in the parameter map: `public static final String ARG_ID = "id";` The MID Server uses this identifier to resolve the actual credentials on the repository. **Note:** This field is only visible when the **External credential store** check box is selected.
Tag	Allow workflow creators to assign individual credentials to any activity in an Orchestration workflow or assign different credentials to each occurrence of the same activity type in an Orchestration workflow.
External credential store	Select this check box to use an external credential storage system. When you select this option the **User name** and **Password** fields are replaced with the **Credential ID** field. External credential storage is only available when the External Credential Storage plugin in activated.
Credential storage vault	Choose the external credential storage vault from a list of available vaults. The menu is composed of records from the Vault Configurations [vault_configuration.list]. New records can be added and use names associated with custom credential resolver JAR files. See the procedures Create a JAR file to resolve credentials and Import a JAR file to resolve credentials for information on creating a custom external credential storage vault.
Applies to	Select whether to apply these credentials to **All MID servers** in your network, or to one or more **Specific MID servers**. Specify the MID Servers that should use these credentials in the **MID servers** field.
MID servers	Select one or more MID Servers from the list of available MID Servers. The credentials configured in this record are available to the MID Servers in this list. This field is available only when you select **Specific MID servers** from the **Applies to** field.
Order	Enter the order (sequence) in which the platform tries this credential as it attempts to log onto devices. The smaller the number, the

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), Discovery or Orchestration tries the credentials in a random order.

7. Click **Submit**.

Configure the credential identifier for AWS

Configure your instance to obtain credentials from a remote repository.

Before you begin

Role required: cloud_admin

Verify that these plugins are active, and the MID Server has been installed:

- Discovery [com.snc.discovery]
- Cloud Provisioning and Governance [com.snc.cloud.mgmt]
- External Credential Storage [com.snc.discovery.external_credentials]

About this task

These procedures assume that you already have an external repository configured with the credentials you want to protect. The credential identifier configured in the ServiceNow instance must be mapped to the actual credential in the repository through the JAR file.

Procedure

1. Navigate to **All** > **Discovery** > **Credentials**.
2. Select a credential that your external credential storage provider supports.
3. Complete the form, using the fields from the table.

Field	Description
Name	A unique and descriptive name for this credential. For example, Amazon Web Services.
Active	Check box to enable or disable the credential.
Credential ID	Enter the Name under which this credential is stored in the external credential storage provider.
MID Servers	Select one or more MID Servers that can use these credentials.
External credential store	Select this check box to use an external credential storage system. When external storage is enabled, the **Credential ID** field appears. If this check box is not visible, click the menu icon in the header bar and select **View** > **External Storage** from the context menu.
Credential storage vault	Select **CyberArk**.

4. Click **Submit**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

CyberArk credential storage integration

The MID Server integration with the CyberArk vault enables ServiceNow® Orchestration, ServiceNow® Discovery, and ServiceNow® Service Mapping to run without storing any credentials on the instance.

Introduction to CyberArk

CyberArk Application Identity Management (AIM) product uses the Privileged Account Security solution to eliminate the need to store application passwords embedded in applications, scripts or configuration files, and allows these highly sensitive passwords to be centrally stored, logged, and managed within the CyberArk vault. This approach enables organizations to comply with internal and regulatory requirements of periodic password replacement and to monitor activities associated with all types of privileged identities, whether on-premise or in the cloud.

The instance maintains a unique identifier for each credential, the credential type (such as SSH, SNMP, or Windows), and any credential affinities. The MID Server obtains the credential identifier, credential type, and IP address from the instance, and then uses the CyberArk vault to resolve these elements into a usable credential. The credential resolver can also look up the hostname, fqdn, and use reverse DNS lookup to get fqdn.

The CyberArk integration requires the ServiceNow® External Credential Storage plugin, which is available in **System Definitions** > **Plugins**. The MID Server and CyberArk AIM/API client must be installed on the same machine. CyberArk Application Access Manager (AAM) Credential Providers version 12.0.1 and later is supported.

Installed with CyberArk

- **Business rule**: The External Credential Storage business rule performs the following tasks when an administrator makes any change to the external credential storage property:
  - Changes the view for the Credentials record list and form to the External Storage view. This view enables users to see the Credential ID column in the list.
  - Instructs the MID Server to refresh its non-external credentials cache in preparation for a change in the way that credentials are obtained.
- **System property**: A property called Enable External Credential Storage [com.snc.use_external_credentials] enables or disables the External Credential Storage plugin after it is activated. This property is located in **Discovery Definition** > **Properties** and **Orchestration** > **MID Server Properties**, and is enabled when you activate the plugin.

  Note:
  If you disable external credential storage with the system property, the system automatically sets all the external credentials to inactive in the instance. If you re-enable the feature with this property, the system does not reset the external credential records to active. You must reactivate each credential record manually.

Supported credential types

The CyberArk integration supports these ServiceNow credential types:

- GCP
- Azure
- CIM
- JMS

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- SNMP forum
- SNMPv3
- Basic Auth
- SSH Key Pair
- SSH Private Key (with key, pass phrase, and password)
- VMware
- Windows
- Applicative Credentials

Note:
To use CyberArk integration with the GCP credential type, you must modify the external credential storage jar. For details see ServiceNow GCP Credential Resolver using CyberArk.

ServiceNow AI Platform features that use these network protocols also support the use of credentials stored on a CyberArk vault.

Credentials supported by network protocol

Network protocol	ServiceNow® Workflow Studio support	Orchestration support
SOAP	SOAP Step	Create a SOAP web service activity with basic authentication overrides
REST	REST Step	Create a REST web service activity with basic authentication overrides
JDBC	JDBC Step	JDBC activity
SSH	SSH Step	SSH activity
PowerShell	PowerShell Step	PowerShell activity
SFTP	SFTP Step	SFTP activity
JMS		JMS activity

Important:
You cannot manage credentials stored on a CyberArk vault and a custom external credential storage system using the same MID Server. The MID Server and CyberArk AIM/API client must be installed on the same machine.

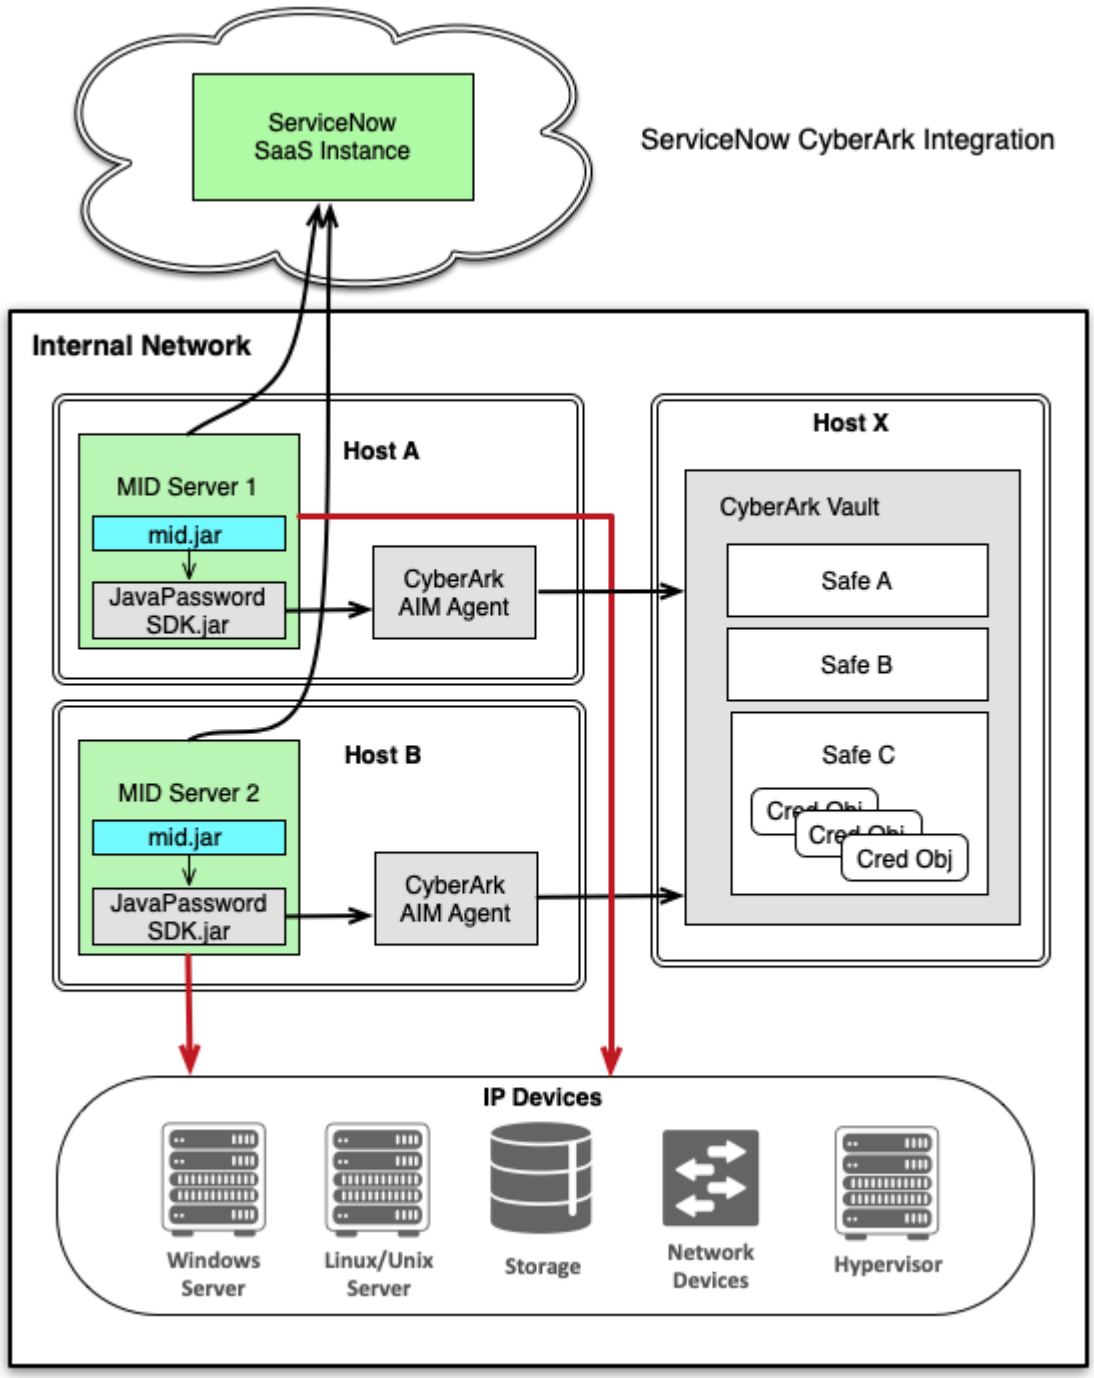
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

CyberArk architecture

CyberArk storage architecture



Note:
CyberArk uses the base system `mid.jar` file for resolving credentials.

How the MID Server handles Windows accounts

Credential lookup initially attempts to match the specified credential ID to an existing value in the CyberArk vault **Name** field. If a match is found, that credential is returned. If no match is found, the credential lookup attempts to find a match using the IP address. If the IP address lookup

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

matches more than one credential, such as Windows and Tomcat on the same server, the lookup fails. To avoid this issue, set the *ext.cred.type_specifier* parameter in the MID Server config.xml file to **true** to force CyberArk to return credentials that match both the credential type and the IP address. For example, if an IP address is shared by both Windows and Tomcat, a credential type of Windows returns the Windows credential only.

Upgrade the CyberArk library

You can upgrade the CyberArk library if a secured configuration parameter is needed.

Check the following configuration parameter in the **config.xml**:
`<parameter name="mid.secure_config.provider" value="com.service_now.mid.services.config.CyberArkSecuredConfigProvider"/>`

Perform the following steps to perform the upgrade if a secured config parameter provider is configured.

1. Rename the CyberArk client version to `JavaPasswordSDK_MajorVersion_minorVersion_patchNum.jar`.
2. Create a new jar entry in the `ecc_agent` table where the rename jar can be attached. This new entry downloads to the MID Server. This step results in two jar (Passworsdk.jar and JavaPasswordSDK _12_X_X.jar).
3. Delete old ecc_agent entry from instance. This step deletes Passworsdk.jar from the MID Server, and the JavaPasswordSDK _12_X_X.jar remains in the system.

CyberArk integration configuration

These procedures include both CyberArk and ServiceNow configuration tasks, including references to the appropriate CyberArk documentation.

The credential identifier configured in the ServiceNow instance must be mapped to the credential name in the CyberArk vault. When looking up a credential, the MID Server finds the credential by matching the credential identifier to a name in vault, which must be unique. If the credential identifier is blank, then the MID Server finds the credential by IP address. To identify the credential by IP address, the system looks at the credential type to ensure that there is only one credential of that type at that address. An example of this might be when a Windows server and vCenter are both running on the same IP address. To support strict credential requirements like this in an SSH environment, a MID Server configuration parameter allows you to require that the credential type requested matches the type returned by CyberArk.

Note:
The **Credential ID** field is the only field necessary to map your credentials to CyberArk, in all cases except for SNMPv3. The **Privacy Credential ID** field is optional and is required only when using SNMPv3 credentials and using a privacy protocol for the credentials. See Configure the CyberArk credential identifier for more details.

To configure your instance to obtain credentials from a CyberArk vault, complete these tasks in the order in which they appear below.

Configure the CyberArk vault and install the AIM API

Configure the CyberArk vault to allow MID Server access and install the CyberArk AIM API on the MID Server machine.

Before you begin
Role required: admin

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before starting this procedure, ensure that the External Credential Storage plugin is activated. CyberArk Application Access Manager (AAM) Credential Providers version 12.0.1 and later is supported.

Procedure

1. Configure the CyberArk vault with the application ID and authentication details that all MID Servers requesting credentials will use.
   For details, refer to the CyberArk Credential Provider and ASCP Implementation Guide.

   a. Ensure that CyberArk is configured to allow the MID Server to access the vault by creating an App-ID in CyberArk called *`ServiceNow_MID_Server`*.

   b. Make sure that every credential the MID Server needs is granted access to the *`ServiceNow_MID_Server`* App-ID.

   Note:
   You can override the default **ServiceNow_MID_Server** App-ID in the MID Server `config.xml` file using the ext.cred.app_id parameter. If you change the value in this parameter, make sure to configure a matching value in the vault.

2. Install the CyberArk Credential Provider, including the AIM API, on each machine that hosts a MID Server service that is used to access the credential store.
3. Provision CyberArk accounts and set permissions for application access.
   For details, refer to the CyberArk Privileged Account Security Implementation Guide.
   a. In the CyberArk Password Safe, create the privileged accounts required by Discovery, Orchestration, or Service Mapping to access different devices and ensure that these accounts are members of the safes in which the necessary credentials are stored.
   b. Add the Credential Provider and application users as members of the Password Safes where the application passwords are stored.

Import the CyberArk JAR file

Import the CyberArk JavaPasswordSDK.jar file into the instance to make it accessible to the MID Server.

Before you begin

Role required: agent_admin or admin
Before starting this procedure, ensure that CyberArk is configured to allow the MID Server access to credentials. Ensure that the CyberArk AIM API is installed on each server hosting a MID Server that is used to access the vault.

Note:
Two separate CyberArk integrations are not supported by the MID Server. The same version of the CyberArk AIM API must be installed on all MID Servers connected to the same instance.

About this task

Use this process even if the JavaPasswordSDK.jar file already exists on the MID Server.

Procedure

1. Navigate to **All** > **MID Server** > **JAR Files**.
2. Click **New**.
3. Complete the form using the fields in the table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

JAR File form fields

Field	Description
Name	Unique and descriptive name for identifying the file in the instance.
Version	Optional version number for the file, if one is available.
Source	Provider of the JAR file. Source information is not used by the system.
Description	Optional short description of the JAR file and its purpose in the instance.

4. Attach the JAR file to this record.
   The AIM `JavaPasswordSDK.jar` file comes with the AIM SDK installation files and is typically located on the MID Server in the AIM installation directory at `<install_dir>/CyberArk/ApplicationPasswordSdk`.

   Note:
   The attached AIM JavaPasswordSDK.jar must match the installed version of the CyberArk AIM API. Any mismatch in JavaPasswordSDK.jar files may lead to unpredictable behavior and potential functionality issues.

5. Click **Submit**.
6. Restart the MID Server service.
   The platform makes the JAR file available to any MID Server configured to communicate with the instance.

Configure the MID Server for CyberArk AIM

Configure the `config.xml` file to grant the MID Server access to the CyberArk vault with AIM API.

Before you begin

Role required: admin

Before starting this procedure, import the `JavaPasswordSDK.jar` file into the instance.

Procedure

Manually configure the MID Server Add a MID Server parameter file with these parameters.

This configuration cannot be done from the instance.

Required configuration parameters

Parameter	Value	Description
ext.cred.safe_folder	NameOfFolder	Folder to use for all credential lookups. For example, **root**.
ext.cred.use_cyberark	true	Boolean parameter indicating that this MID Server is integrated with CyberArk.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Optional configuration parameters

Parameter	Value	Description
ext.cred.safe_timeout	5 (sec)	Timeout of each credential lookup in the vault, specified in seconds.
ext.cred.safe_name	NameOfSafe	Default safe name used for all credential lookups. If parameters are in multiple safes, the credential ID may be specified in the format *<safeName>:<CredentialID>*. When configured like this, the **NameOfSafe** field is ignored. If all external credentials have their credential IDs specified in this format, then leave out the **NameOfSafe** field. **Note:** By default the separator character in this format is a colon. To assign any character you want as a separator, add this line to the `CredMap.properties` file: `safe.cred.split.string=<string>`.
ext.cred.app_id	ServiceNow_MID_Server	Specifies the App-ID used to grant permission to the MID Server to access the CyberArk vault. The default value, **ServiceNow_MID_Server**, must be defined in the CyberArk vault. You can use this parameter to override the default and specify your own App-ID. If you edit the App-ID in this parameter, make sure to configure CyberArk to match.
ext.cred.type_specifier	true	Forces an IP address lookup to return credentials that match both the CyberArk platform ID and the IP address. For example, if an IP address is shared by both Windows and Tomcat, a credential with a platform ID starting with **Win** returns the Windows credential only. When this parameter is set to true, CyberArk looks for platform IDs that begin with: • Win: Windows • Unix: SSH • VMWare: VMware
ext.cred.check_ssh_type	false	When set to true, requires that the type of SSH credential returned from CyberArk matches the type of credential requested. For example, if a normal SSH username/password credential is requested and only SSH keys are available, the credential lookup fails.

Configure the MID Server for CyberArk CCP

Configure the `config.xml` file to grant the MID Server access to the CyberArk CCP vault.

Before you begin
Role required: admin

About this task

Note:

In the Zurich family release, the instance needs an additional Update Set that can be downloaded from Enable CyberArk Central Credential Provider (CCP) Integration in Zurich Release [KB2682524]. Follow the provided installation steps. The Australia family release includes this script by default.

Procedure

Manually configure the MID Server Add a MID Server parameter file with these parameters.

This configuration cannot be done from the instance.

Required configuration parameters

Parameter	Value	Description
ext.cred.safe_folder	NameOfFolder	Folder to use for all credential lookups. For example, **root**.
ext.cred.use_cyberark	true	Boolean parameter indicating that this MID Server is integrated with CyberArk.
ext.cred.ccp_endpoint	CCPendpointURL	The CCP endpoint URL, which must use HTTPS. For example: `https:// /AIMWebService/api/Accounts`
ext.cred.cyberark.cert_path	/path/on/mid/agent/security/EXAMPLE-cyberark-client.pfx	Path to the certificate file.
ext.cred.cyberark.cert_password	example-password	Password for the certificate file.

Optional configuration parameters

Parameter	Value	Description
ext.cred.timeout	30	Timeout of each credential lookup in the vault, specified in seconds.
ext.cred.safe_name	NameOfSafe	Default safe name used for all credential lookups. If parameters are in multiple safes, the credential ID may be specified in the format *<safeName>:<CredentialID>*. When configured like this, the **NameOfSafe** field is ignored. If all external credentials have their credential IDs specified in this format, then leave out the **NameOfSafe** field.

Parameter	Value	Description
		this property to map the attribute in the credential to the community string.

Configure CyberArk for SNMPv2 credentials

If your system uses SNMPv2, you can create a special file to map the attribute in a credential to the community string.

Before you begin

Role required: admin
Before starting this procedure, configure the MID Server to have access to the CyberArk vault.

About this task

Note:
If the community string appears in the password field of the CyberArk credential, it is not necessary to perform this procedure.

SNMPv2 is not natively supported in CyberArk. If your organization has created custom SNMPv2 credentials in which the community string does not appear in the password field of the credential, use this procedure to map the attribute in the credential to the community string.

Procedure

1. For CyberArk CCP configurations:
   a. Open the `config.xml` file.
   b. Set the property `snmpv2_community_property` to the attribute name.
2. For CyberArk AIM API configurations:
   a. In a text editor, create a file called: `CredMap.properties`.
   b. Add the code: `SNMPv2.Community=attribute_name`
   c. Save the file to the `/agent` directory of your MID Server installation.

Result

On credential look-up, the MID Server attempts to find this attribute for the credential. If the attribute is not found, the MID Server then looks in the password field. If the password field is empty, the credential look-up fails.

Configure the CyberArk credential identifier

Create the unique key that CyberArk can use to identify specific credentials in the external repository.

Before you begin

Role required: admin
Before starting this procedure, ensure that the External Credential Storage plugin is activated, and the com.snc.use_external_credentials system property is set to true.

Procedure

1. Navigate to **All** > **Discovery** > **Credentials** or **Orchestration** > **Credentials**.
2. Click **New**.
3. From the list of credential types, select a type that supports CyberArk external storage.
4. Complete the form using the fields from your credential type.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

5. Select the **External credential store** check box.
   The **User name** and **Password** fields are replaced with the **Credential ID** field.

   Note:
   If the check box is not visible, click the menu icon in the header bar and select **View** > **External Storage**.

6. In the **Credential ID** field, enter an expression using one of these formats:
   - If all your credentials are in the same safe, configure this safe name in the MID Server `config.xml` file using the ext.cred.safe_name parameter, and then specify the credential ID by name only, as **<credential ID>**.
   - To name credentials for a given platform that reside is a specific safe, define the credential ID as **<safe>:<credential ID>:<platform ID>**.
   - If your credentials are in multiple safes, specify the credential ID in this format: **<safe>:<credential ID>**.
   - If you want CyberArk to look up the credential by IP address, using an alternate safe, specify the credential ID in this format: **<safe>:**.
   - If you want CyberArk to look up the credential for an alternate platform ID in the same safe, use this format: **::<platform ID>**
   - If you want CyberArk to look up the credential in a configured safe by the IP address rather than the credential ID, leave this field blank. This is the best practice for handling installations in which each server has a unique credential. Without this type of lookup, you must create a credential ID record in your instance for every server in your environment.

   Note:
   The credential ID must match the value in the **Name** field for the CyberArk account. The **Credential ID** field has a limit of 160 characters.

7. If you are storing SNMPv3 credentials in CyberArk and are using the privacy protocol and privacy key, configure the ID as follows:

   a. In the **Credential Store Type** field, select **CyberArk**.
   The **Privacy Credential ID** field appears.

   b. Enter the **Name** of the CyberArk SNMPv3 privacy account in the **Privacy Credential ID** field.

   Note:
   Character limits for Credential ID and Privacy Credential ID vary by vault. ServiceNow supports up to 180 characters. CyberArk supports 160. Verify the limit in your vault.

8. Click **Submit**.

Configure AWS credentials on a CyberArk vault

Configure your CyberArk vault with the AWS credentials to be retrieved for use by your instance.

Before you begin
Role required: admin

About this task
Store the credentials as an Account on the CyberArk vault. When you configure access to the vault on your instance, the name you give to the Account must also be used as the credential ID.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
The procedure that follows references CyberArk Password Vault v14.2.1. If you are using a different version, set up configuration as per official CyberArk Password Vault documentation.

Procedure

1. In CyberArk, go to **Accounts** > **Accounts & Requests** > **Accounts View** > **Add Account**.
2. Select system type: **Cloud Service**.
3. Assign to platform: **Amazon Web Services - AWS - Access Keys**.
4. Store in Safe: Select a safe from the list.
5. Define properties: Enter the following information:

CyberArk credentials

Field	Value
AWS IAM Username	Enter the AWS Access Key, as provided by AWS.
AWS Access Key Secret (optional)	Enter the AWS Secret Access Key, as provided by AWS.
Customize account name	Toggle slider to enter a custom name for this key.
AWS Access Key ID	Enter the AWS Access Key again, as provided by AWS.
AWS Account ID Number	Enter the 12-digit AWS Account number.
AWS Account Alias Name (optional)	Enter an alias name for the account.

6. Choose **Add**.

What to do next
If you have not done so already, create a credential identifier on your instance to configure access to the CyberArk vault. For more details, see Configure access to external credential storage for AWS.

Configure AWS Credentials on a CyberArk Vault using Classic UI

Configure your CyberArk vault with the AWS credentials to be retrieved for use by your instance.

Before you begin
Role required: admin

About this task
CyberArk Password Vault v14.2.1 includes both Accounts View and Accounts View (Classic UI) configuration options to store the credentials as an Account. When you configure access to the vault on your instance, the name you give to the Account must also be used as the credential ID.

Note:
The procedure that follows references CyberArk Password Vault v14.2.1. If you are using a different version, set up configuration as per official CyberArk Password Vault documentation.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. In CyberArk, go to **Accounts** > **Accounts & Requests** > **Accounts View (Classic UI)** > **Add Account**.
2. Enter the following information:

CyberArk credentials

Field	Value
Device Type	Select **Cloud Service**.
Platform Name	Select **Amazon Web Services - AWS - Access Keys**.
AWS IAM Username	Enter the AWS Access Key, as provided by AWS.
AWS Access Key ID	Enter the AWS Access Key again, as provided by AWS.
AWS Account ID Number	Enter the 12-digit AWS Account number.
AWS Access Key Secret	Enter the AWS Secret Access Key again, as provided by AWS.
Name	Enter a custom name for this key.

3. Choose **Save**.

What to do next

If you have not done so already, create a credential identifier on your instance to configure access to the CyberArk vault. For more details, see Configure access to external credential storage for AWS.

Configure Azure credentials on a CyberArk vault

Configure your CyberArk vault with the Azure credentials to be retrieved for use by your instance.

Before you begin

Role required: admin

About this task

To store an Azure credential, first create an Azure credential template in the CyberArk vault. This process only needs to be completed once for the vault.

Procedure

1. Log in to CyberArk in Administration mode.
2. Navigate to the **Administration** tab.
3. In **System Configuration**, edit **Platform Management**.
4. Navigate to **Cloud Provider Template** and duplicate it.
5. Edit the template for Azure credentials.
6. Add the following two properties:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- *Name* as *Username* and *Display Name* as *Client ID*
- *Name* as *Address* and *DisplayName* as *Tenant ID*

7. Apply the changes.
8. Navigate to the **Account** section and select **Add account**.
9. Select **Safe**.
10. Set the **Device Type** to **Cloud Service**.
11. Select the Azure template that was previously edited.
12. Fill in the information in for the **Client ID**, **Tenant ID**, and **Password** fields.
13. Select **Save**.

OAuth 2.0 authentication via MID Server using external credential storage

Store OAuth 2.0 credentials-client ID and client secret-in the CyberArk vault instead of the ServiceNow instance. The MID Server gets the credentials from the CyberArk vault, when required to get the OAuth token. The token is stored in the MID Server and refreshed automatically upon expiry.

The CyberArk Application Identity Management (AIM) product uses the Privileged Account Security solution to eliminate the need to store application passwords embedded in applications, scripts or configuration files, and allows these highly sensitive passwords to be centrally stored, logged, and managed within the CyberArk vault. You can configure the CyberArk vault to store OAuth 2.0 credentials rather than directly in a ServiceNow credentials record. To know more about CyberArk, see CyberArk credential storage integration.

Architecture of OAuth 2.0 authentication of MID Server request

The architecture has two parts: ServiceNow instance and the environment where the Application Identity Manager (AIM) client and the MID Server are configured. Examples of environment are the cloud or a customer environment.

The MID Server and the Application Identity Manager (AIM) client must be configured on the same environment and the Application Identity Manager (AIM) must be configured to interact with the CyberArk external vault. The CyberArk external vault could be hosted in the same environment as that of MID Server and the Application Identity Manager (AIM) or a different environment.

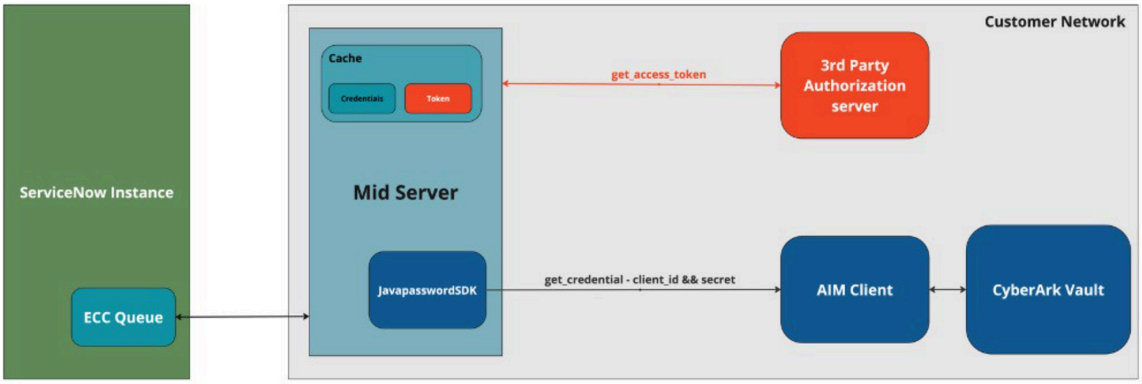
The ServiceNow instance maintains credential identifiers that map to specific OAuth 2.0 credentials stored in the CyberArk vault. Before sending an OAuth token request, the MID Server obtains the credential identifier from the instance, and then uses a customer-provided JAR file to send the identifier to the AIM client. The AIM client sends the request to CyberArk vault. The CyberArk vault sends the OAuth 2.0 credentials back to the MID server through the AIM client. After receiving the OAuth 2.0 credentials, the MID server sends the OAuth token request to the third-party authorization server. The token request comprises information such as client and client secret that CyberArk stores, and OAuth scope, and token URL that the instance stores. After the authorization server issues the OAuth token, the MID server stores it in its cache memory.

Note:
This feature supports the Client Credentials Grant Type.

The image shows the MID server request authentication process.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
It's assumed that the third-party authorization server and the CyberArk vault are hosted in the customer network.



Configure a JAR file and credential identifiers

Configure a JAR file and credential identifiers so that the JAR file resolves the credential identifiers into actual credentials from the CyberArk external vault. The process enables the MID Server to get and include OAuth 2.0 credentials in the OAuth token request.

Before you begin

Role required: agent_admin or admin

The CyberArk external vault stores sensitive credentials and the ServiceNow instance stores credential identifiers that map to the specific credential names that the vault stores. The JAR file enables the mapping of a credential identifier to a specific credential name in the external vault. The mapping enables the MID Server to acquire and include the required credential in the OAuth token request. You must configure the credential identifiers and the JAR file in the ServiceNow instance and the MID Server respectively.

Procedure

1. Import the CyberArk JAR file.
2. Configure a connection to send OAuth request via the MID Server using external vault.

Configure CyberArk

Configure the CyberArk vault to store OAuth 2.0 credentials and respond to requests for OAuth 2.0 credentials from the MID Server.

Before you begin

Confirm that you have subscribed to the ServiceNow IntegrationHub Standard Pack Installer. For more information, see https://www.servicenow.com/content/dam/servicenow-assets/public/en-us/doc-type/legal/snc-addendum-integrationhub.pdf.

Role required: agent_admin or admin

Procedure

1. Configure the CyberArk vault and install the AIM API.
2. Import the CyberArk JAR file.
3. Configure OAuth 2.0 credentials on CyberArk.
4. Configure a connection to send OAuth request via the MID Server using external vault.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Configure OAuth 2.0 credentials on CyberArk

Configure your CyberArk vault with OAuth 2.0 credentials that the ServiceNow instance requests.

Before you begin

Role required: Admin

About this task

To store OAuth 2.0 credentials, first create an OAuth 2.0 credential template in the CyberArk vault. This process must only be completed once for the vault.

Procedure

1. Do the following steps, if you're configuring the OAuth 2.0 credentials for the first time.
   a. Log in to CyberArk in Administration mode.
   b. Navigate to the **Administration** tab.
   c. Select **Platform Management**.
      The Platform Management page displays the platforms under the Targets tab.
   d. Expand a platform type.
   e. Select the settings icon (⋯) that corresponds to a platform template and select **Duplicate**.
   f. In the Duplicate Platform window, enter a name for the template and select **Create**.

      Note:
      Note the system type under which you had created a duplicate template. For example, Cloud Service is a system type.

   g. Select the settings icon (⋯) that corresponds to the duplicate platform template that you created and select **Edit**.
   h. Add the property.
      Name as Username and Display Name as Client ID.
   i. Rename the other properties.

      Tip:
      Choose property names relevant to OAuth 2.0.

   j. Select **Apply**.
      The updates are applied.
   k. Select **OK**.
   l. On the left panel, navigate to Accounts.
   m. Select **Add Account**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

n. Under the System Type heading, select the system type under which you had created the platform template.
The System Type shows the platform templates.

o. Under the Select Platform heading, select the platform template that you had created.

p. Select Safe.
Save the Safe value for later use.

q. Fill in the information in for the Client ID, Password (provide Client Secret as value), and other fields as required.

r. Select **Add**.
The account is added.

s. On the Account View page, open an account.

t. Select the **Details** tab.

u. Copy the value stored under the Account name section and save it for later use.
The value that you copied and stored is used as the credential identifier in the ServiceNow instance.

2. Do the following steps, if you're not configuring the OAuth 2.0 credentials for the first time.

a. Log in to CyberArk in Administration mode.

b. Navigate to the **Account** section and select **Add account**.

c. Select the system type from **System Type** under which the template for storing OAuth 2.0 exists.

d. Select the required platform template that you had created and select **Safe**.
Save the Safe value for later use.

e. Fill in the information in for the Client ID, Password (provide Client Secret as value), and other fields as required.

f. Select **Add**.
The account is added.

g. On the Account View page, open an account.

h. Select the **Details** tab.

i. Copy the value stored under the Account name section and save it for later use.
The value that you copied and stored is used as the credential identifier in the ServiceNow instance.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Configure a connection to send OAuth request via the MID Server using external vault

Configure a connection to send requests for OAuth 2.0 tokens to a third-party auth server via the MID Server. The MID Server adds OAuth 2.0 credentials (Client ID and Client Secret) from the CyberArk external vault, OAuth scope, and token URL from the instance to the request and sends them to the third-party auth server.

Before you begin

Verify the following items.

- Confirm that you have subscribed to the ServiceNow IntegrationHub Standard Pack Installer. For more information, see https://www.servicenow.com/content/dam/servicenow-assets/public/en-us/doc-type/legal/snc-addendum-integrationhub.pdf.
- You have created a JAR file that enables the MID Server to resolve credentials with the CyberArk external vault. See Create a JAR file to resolve credentials.
- You have imported the JAR file to the MID Server.
- The MID Server is set up for CyberArk. See Configure the MID Server for CyberArk AIM.
- OAuth 2.0 are configured on the CyberArk external storage. See Configure OAuth 2.0 credentials on CyberArk.

Role required: none

About this task

You can configure the connection and credential with a configuration template or manually. A configuration template defines the connection record form components and is reusable for other connection records. Manually, you can configure the connection for this purpose only. The topic shows both approaches.

Procedure

1. Configure the connection with a configuration template.

   a. Navigate to **All** > **IntegrationHub** > **Configuration Templates**.

   b. Select **New**.

   c. Select **HTTP Connection with OAuth Client Credentials grant type (External Storage)**.

   d. Update the form, as required.
   For example, you can provide the scope in the `oauth_entity_profile_scope` and `oauth_entity_scope` fields in the Default Data Template section. To learn to create a configuration template, see Create a configuration template.

   e. Select **Submit**.
   You have created the configuration template.

   f. Navigate to **All** > **IntegrationHub** > **Connection & Credential Aliases**.

   g. Update the form.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Connection and credential alias

Field	Description
Name	Name of the alias. An alias can only contain alpha, number, and underscore characters. During an upgrade, the tag in the credential record migrates to a Connection & Credential Alias. If the credential tag contains special characters other than alphabets, numbers, and underscores, it preserves the tag name after the upgrade. You can still use this migrated alias, but you cannot update the alias until you change the name to meet the naming restrictions.
Application	Unique identifier for the Connections & Credentials alias, based on the format `scope_name.alias_name`. ▪ If the scope is Global, the ID is the alias name. For example, if you create a Workday alias in the global scope, it sets the ID to `workday`. ▪ If you create a workday alias in the HR app scope, it sets the ID to `x_hr_app.workday`.
Parent Alias	Option to select the alias under which you're creating this connection and credential alias. The connection and credential alias that you're creating is a child alias. A child alias is listed under the **Child Aliases** tab on the parent connection and credential alias page.
Type	Option to indicate the type of alias you're creating. Choose from the following options. ▪ Credential: Alias that contains a credential record. ▪ Connection and Credential: Alias that contains both connection and credential record. This option is selected by default. Confirm that Connection and Credential is selected.
Support Multiple Active Connections	Designator that indicates whether the alias supports multiple active connections. Add connections using the Connections table

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	and associated them to the alias using the Connections related list.
Default Retry Policy	Retry policy for the alias. For more information, see Retry policy.
Configuration Template	Option to select the configuration template based on which you're creating the connection and credential alias. Select the template of the type **HTTP Connection with OAuth Client Credentials grant type (External Storage)** that you had created.

h. Select **Submit**.
You have created the connection and credential alias record.

i. Navigate to **All** > **IntegrationHub** > **Connections Dashboard**.

j. In the Search all connections field, enter the name of the connection and credential alias record that you created.

k. On the connection and credential alias record, select **View Details**.

l. Select **Configure**.

m. Fill the form.

Configure Connection form

Field	Description
Connection Name	Name of the connection. You can't update the name.
Connection URL	URL to the third-party server.
Use MID	Option to enable MID Server. **Important:** Confirm that the option is selected.
MID Selection	Option to specify MID Configuration for Connection. ▪ **Specific MID Server**: Option to indicate a manual selection of a specific MID Server. ▪ **Auto-Select MID-Server**: Option to indicate that you want the MID Server automatically selected. ▪ **Specific MID Cluster**: Option to indicate a manual selection of a MID cluster of MID Servers.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Important: Confirm that the MID Server you select resides on the same machine as the CyberArk AIM Client that is configured to access the CyberArk vault. See Configure the CyberArk vault and install the AIM API.
MID Server	Option to manually specify a MID Server. This option appears if you select **Specific MID Server** in the **MID Selection** field.
MID Cluster	Option to manually specify a MID Cluster. This option appears if you select **Specific MID Cluster** in the **MID Selection** field.
External Credential Store	Option to use the CyberArk external credential storage. When you select the option, the MID Server gets the OAuth 2.0 credentials (Client ID and Client secret) from the external credential storage. **Important:** Confirm that the option is selected.
Credential ID	Identifier for the CyberArk account that holds the Client ID and Client Secret details. To view the procedure to get the credential identifier, see Configure OAuth 2.0 credentials on CyberArk. In the Credential ID field, enter an expression using one of these formats. ▪ If all your credentials are in the same safe, configure this safe name in the MID Server `config.xml` file using the ext.cred.safe_name parameter, and then specify the credential ID by name only, as **<credential ID>**. ▪ To name credentials for a given platform that reside is a specific safe, define the credential ID as **<safe>:<credential ID>:<platform ID>**. ▪ If your credentials are in multiple safes, specify the credential ID in this format: **<safe>:<credential ID>**.
OAuth Token URL	URL that specifies the endpoint to get the access token from the OAuth server.

n. Select **Configure Connection**.

2. Configure a connection manually.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

a. Navigate to **All** > **System OAuth** > **Application Registry**.

b. Select **New**.

c. Select **Connect to a third party OAuth Provider using an external vault**.

d. Fill the form.

New application registry details

Field	Description
Name	Name to identify the application registry record. For example, enter: OAuth 2.0 token request via MID app.
Application	Option to specify the names of applications that can access this application registry. The field is read only.
Default Grant type	Default method to obtain access token by the client application from the OAuth server. The default and read-only grant type is Client Credentials.
Accessible from	Option to specify which applications can access this application registry.
Token URL	URL that specifies the endpoint to get the access token from the OAuth server.
Send Credentials	Option to specify the method of sending the OAuth 2.0 in the request body.
Comments	Enter related comments.

e. Under the **OAuth scope** column, create one or more OAuth scopes by doing the following steps.

i. Under the Name column, double-click the field and enter a name of the OAuth scope.

ii. Under the OAuth scope column, double-click the field and enter the scope.

f. Select **Submit**.
You have created an OAuth entity profile and the application registry.

g. Navigate to **All** > **IntegrationHub** > **Connections & Credentials** > **Credentials**.

h. Select **New**.

i. Select **OAuth 2.0 Credentials**.

j. Select **External Storage View**.

Important:
Select **External Storage View** only if the view is different from that of an OAuth 2.0 credentials external storage form.

k. Fill the form.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

OAuth 2.0 Credentials

Field	Description
Name	Name of the credential record.
Applies to	Option to specify if the credential record is applicable for all MID Servers, or a specific MID Server. If specific, add the MID Servers. Choose from either of the following options. ▪ All MID Servers: The MID Server is automatically selected from a collection of MID Servers. ▪ Specific MID Servers: Option to specify one or more MID Servers.
MID Servers	Option to specify one or more MID Servers. **Note:** This field appears if you select **Specific MID Servers** in the Applies to field.
Active	Option to specify whether the credential record is available for use. By default, it's available.
OAuth Entity Profile	Option to specify an OAuth entity profile that the credential uses. Select the OAuth entity profile you had created above. See Configure an OAuth entity profile.
External credential store	Option to specify that the credentials are stored in an external storage and not in the ServiceNow instance. **Important:** Confirm that the option is selected.
Credential ID	Option to specify credential identifier for the CyberArk account which holds Client ID and Client Secret. To view the procedure to get the credential identifier, see Configure OAuth 2.0 credentials on CyberArk.
Credential storage vault	Option to specify the name of the external credential storage vault. Verify that you have selected CyberArk.

l. Select **Submit**.
You have created the credential record.

m. Create a connection and credential alias.
To know the steps, see Create a Connection & Credential alias.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

n. Navigate to **All** > **IntegrationHub** > **Connections**.

o. Select **New**.

p. Select **HTTP(s) Connection**.

q. Fill the form.

Connection form

Field	Description
Name	Unique name of this HTTP(s) connection.
Active	Option to set the connection that you're creating active. The option is selected by default.
Credential	Select the credential record used to authorize the connection. Select the credential that you had created above.
Connection alias	Select the alias record to associate with this connection. Using an alias enables you to update the connection record without having to reconfigure any actions or activities that use the alias.
URL builder	Either manually enter the connection URL or use system to build the URL based on the inputs. Default is unchecked. If checked, the connection URL is calculated from the following fields: ▪ Mutual authentication — Check box if mutual authentication is used. ▪ Protocol — If mutual authentication is not used, enter protocol. The default is HTTPs. ▪ Protocol profile — If mutual authentication is used, enter protocol profile from sys_protocol_profile. ▪ Host ▪ Port ▪ Base path — Path of the connection string. **Note:** If mutual authentication is checked, connection URL is built: Protocol + :// + host:port +URL. If mutual authentication is unchecked, connection URL is built: Protocol profile + :// + host:port +URL
Connection URL	If URL builder is unchecked, enter the connection URL into this field.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Note: If mutual authentication is checked, connection URL is built: Protocol + :// + host:port +URL. If mutual authentication is unchecked, connection URL is built: Protocol profile + :// + host:port +URL
Use MID server	Option to specify that you want to send OAuth token requests via a MID Server. **Important:** Confirm that the option is selected.
Connection timeout	Number of milliseconds the system waits for a successful host connection. If a successful connection does not occur during this time, the connection request times out. Leave this field empty to use the system default connection timeout value.
MID Selection	Option to specify one of the following options. ▪ Auto-Select MID Server: Selects from MID Servers based on MID Server criteria, regardless of whether they are members of a cluster. ▪ Specific MID Server: Manually select a MID Server. ▪ Specific MID Cluster: Automatic reassignment to another MID Server only selects from members of the specified cluster. **Important:** Confirm that the MID Server you select resides on the same machine as the CyberArk AIM Client that is configured to access the CyberArk vault. See Configure the CyberArk vault and install the AIM API.
Capabilities	Option to select one or more MID Server capabilities. Capabilities define the specific functions of a MID Server within an IP address range, allowing an application to select the most appropriate MID Server. Select the MID capabilities icon ( ) to select one or more capabilities.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	Note: ▪ Confirm that the MID Server you select resides on the same machine as the CyberArk AIM Client that is configured to access the CyberArk vault. See Configure the CyberArk vault and install the AIM API. ▪ This option appears if you select **Auto-Select MID Server** in the MID Selection field.
MID Server	Manually select a MID Server. This option appears if you select Specific MID Server from the MID Selection field.
MID Cluster	Manually select a MID cluster. This option appears if you select Specific MID Cluster from the MID Selection field.
MID Application	Option to specify a MID application or accept the default application choice. **Note:** This option appears if you select **Auto-Select MID Server** in the MID Selection field. By default, the **ALL** option is selected.

r. Select **Submit**.
You've created an HTTP(s) connection record.

s. Navigate to **All** > **Process Automation** > **IntegrationHub** > **Connections Dashboard**.

t. In the Search all connections field, enter the name of the connection record that you created.
The connection alias record appears.

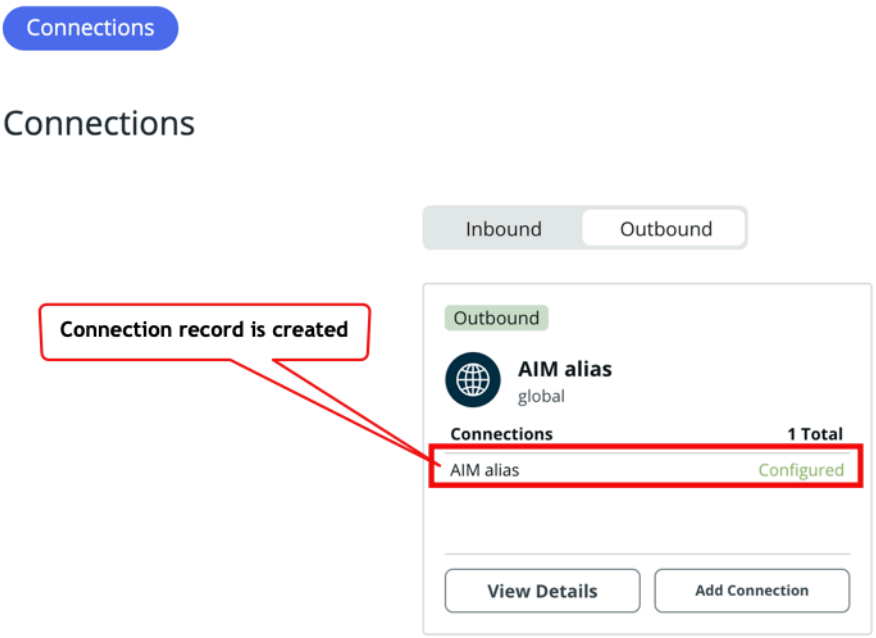
OAuth 2.0 connection record is created



Authentication Algorithms

Verify the identity of the sender using Authentication Algorithms

Allow integration steps to authenticate with web services that require complex or non-standard connection or credential mechanisms. Associate authentication algorithms to credential and connection aliases to reduce or eliminate the need to manually configure integration steps.

You can use an authentication algorithm to generate custom authentication data for your integration steps. Integration steps can use this dynamic data to create any custom artifacts necessary to authenticate with the target web service. For example, a REST step could create an authentication header, query parameters, or a token.

Authentication algorithms support the following steps:

- Get Connection Info Step
- REST Step
- SOAP Step

For more information, see Integration steps

Authentication algorithm types

- **Amazon Signature Version 4**: This is a pre-built authentication algorithm to connect to Amazon Web Services.
- **Custom Authentication**: This is a template that developers can use to create their own authentication algorithms.

To know more, on how to configure the authentication algorithm, see Configure an authentication algorithm.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Scripts

Instance Authentication Scripts are on instance scripts part of *sys_script_include* table.

Instance Authentication Scripts

RequestAuthInternal	Read only script on instance, which supports generating AWS V4 signature or custom authentication that is sent with outbound request.
RequestAuthAWSV4Signer	Script extending RequestAuthInternal to implement signer to generate AWS V4 signature.
RequestAuthTwitterSigner	Script extending RequestAuthInternal to implement signer to generate Twitter signature using OAuth 1.0a.
RequestAuthSampleCustomSigner	Sample script extending RequestAuthInternal to understand how to write custom signer on instance.

MID Authentication Scripts are on MID scripts part of *ecc_agent_script_include* table.

MID Authentication Scripts

RequestAuthInternal	Read only script on MID, which supports generating AWS V4 signature or custom authentication that is sent with outbound request.
RequestAuthAWSV4MIDSigner	Script extending RequestAuthInternal to implement signer to generate AWS V4 signature.
RequestAuthTwitterSigner	Script extending RequestAuthInternal to implement signer to generate Twitter signature using OAuth 1.0a.
RequestAuthSampleMidCustomSigner	Sample script extending RequestAuthInternal to understand how to write custom signer on MID.

JavaScript API's

Following are the JavaScript API's for authentication algorithm.

- AuthCredential
- HttpRequestAuthedData
- HttpRequestData
- RequestAuthAPI

Configure an authentication algorithm

Configure an authentication algorithm so that you can sign outbound HTTP requests.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin

You should have a script include configured before you configure an authentication algorithm.
Role required: admin

Procedure

1. Navigate to **All** > **Credentials & Connections** > **Authentication Algorithms**, and click **New**.
2. On the form, fill in the fields.
   The database selection in the **Format** field determines which fields are available.

Authentication form

Field	Description
Name	Unique name of this algorithm.
Algorithm	Outbound request type.
Description	Description of what your algorithm does.
Application	Scope that your application runs in.
Instance Authentication Script	Script that you select from the Script Includes table.
MID Authentication Script	Script that you select from the MID Server Script Includes [Discovery view] table.

3. Click **Submit**.

Configure an Amazon Signature based Custom Algorithm

Generate the Amazon Signature based data needed to authenticate to a web service by running script.

Before you begin

- JavaScript knowledge
- REST knowledge
- Target web service API knowledge
- Connection, credential, and alias knowledge
- Role required: Developer

About this task

Use a connection and credential alias and Amazon Signature Version 4 based algorithm for authentication.

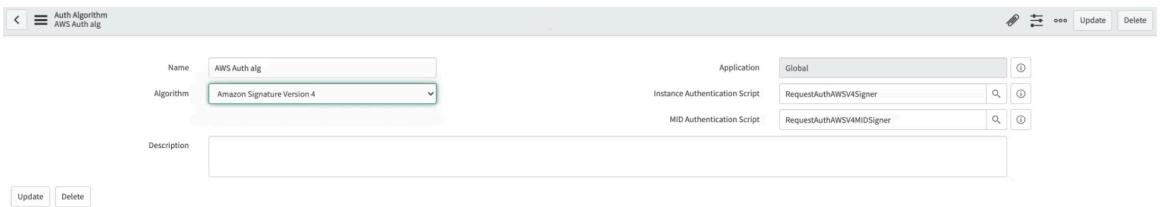
Procedure

1. Navigate to **All** > **Credentials & Connections** > **Authentication Algorithms**, and click **New**.
2. On the form, fill in the fields.
   The database selection in the **Format** field determines which fields are available.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Authentication form

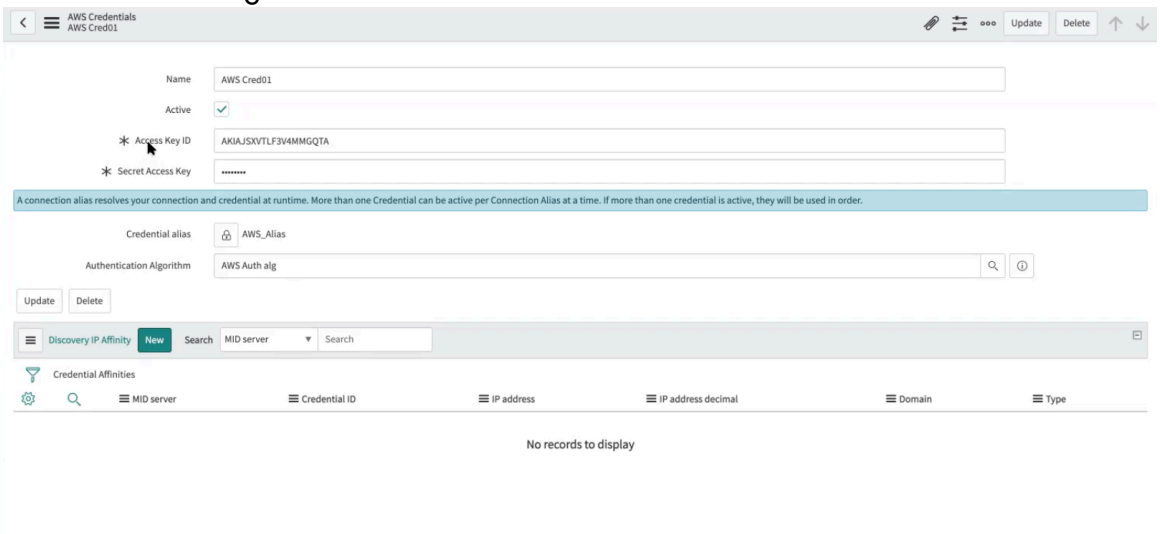
Field	Description
Name	Unique name of this algorithm.
Algorithm	Outbound request type. Select **Amazon Signature Version 4**.
Description	Description of what your algorithm does.
Application	Scope that your application runs in.
Instance Authentication Script	Script that you select from the Script Includes table. In case of **Amazon Signature Version 4** algorithm, choose **RequestAuthAWSV4Signer**. The scripts available are as follows: ○ RequestAuthAWSV4Signer ○ RequestAuthInternal ○ RequestAuthSampleCustomSigner ○ RequestAuthTwitterSigner **Note:** To know more about the script click the information icon next to the field. The details of the script such as Name, API Name, Application, Accessible from, Script, and so on is displayed.
MID Authentication Script	Script that you select from the MID Server Script Includes [Discovery view] table. The scripts available are as follows: ○ RequestAuthAWSV4Signer ○ RequestAuthInternal ○ RequestAuthSampleCustomSigner ○ RequestAuthTwitterSigner



3. Click **Update**.
4. Navigate to **All** > **Connections & Credentials** > **Credentials**.
5. Click **New**.
6. Create AWS Credentials with Authentication Algorithm.
   In this case **AWS Auth alg**.
7. Specify the following:
   - Name
   - Active
   - Access Key ID
   - Secret Access Key

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Credential alias
- Authentication Algorithm



8. Click **Update**.

Result

Based on the selected scripts and authentication algorithm, the configured credentials (**Access Key ID** and **Secret Access Key**) or user's credentials (**Access Key ID**, **Secret Access Key**, and **Session Token**) generates a Amazon V4 signature that is sent as outbound request from ServiceNow to the provider (in this case AWS).

Example: REST step with AWS

> **Note:**
> Amazon V4 signature based authentication can also be used from Script background.

Action: Get AWS Regions

Input REST step with AWS as follows:

- **Credentials Alias**: The alias that is created for AWS.
- **Base URL**: Base URL details from AWS.
- **HTTPS Method**: In this case it is GET method.
- **Query Parameters**: **Action** as **DescribeRegions**.

You can test the action, the associated regions are displayed. The response body is as follows:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Amazon V4 is defined with standard set of algorithm that supports authentication mechanism. This algorithm when used adds the signature as authorization header for authentication (HTTP request) using REST step.

Configure a custom authentication algorithm

Generate the custom data needed to authenticate to a web service by running script.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin

- JavaScript knowledge
- REST knowledge
- Target web service API knowledge
- Connection, credential, and alias knowledge
- Role required: Developer

About this task

Use a connection and credential alias and custom authentication based algorithm for authentication.

Procedure

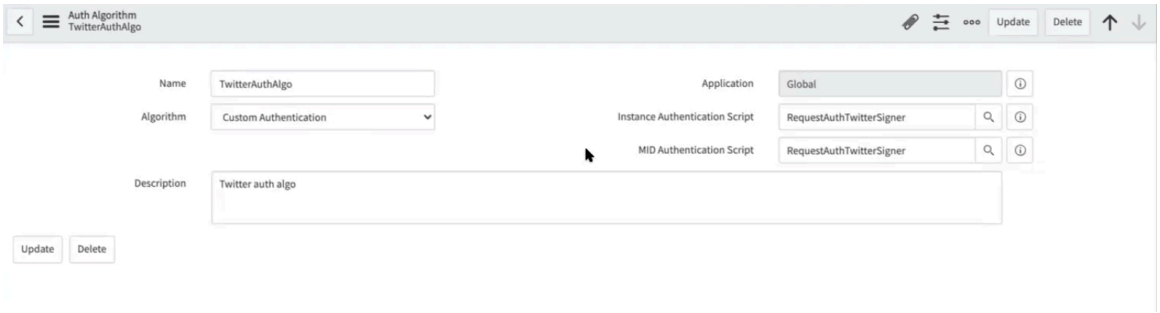
1. Navigate to **All** > **Credentials & Connections** > **Authentication Algorithms**, and click **New**.
2. On the form, fill in the fields.
   The database selection in the **Format** field determines which fields are available.

Authentication form

Field	Description
Name	Unique name of this algorithm.
Algorithm	Outbound request type. Select **Custom Authentication**.
Description	Description of what your algorithm does.
Application	Scope that your application runs in.
Instance Authentication Script	Script that you select from the Script Includes table. The scripts available are as follows: ○ RequestAuthAWSV4Signer ○ RequestAuthInternal ○ RequestAuthSampleCustomSigner ○ RequestAuthTwitterSigner **Note:** ○ To know more about the script click the information icon next to the field. The details of the script such as Name, API Name, Application, Accessible from, Script, and so on is displayed. ○ In case of custom authentication with Twitter, you can choose **RequestAuthTwitterSigner**, since it uses an OAuth 1.0a method of authentication. This requires informations such as **API key and secret** and **Access token and secret** that can be used to create signatures to pass in an authorization header. For more information, see Authentication in Twitter.
MID Authentication Script	Script that you select from the MID Server Script Includes [Discovery view] table. The scripts available are as follows: ○ RequestAuthAWSV4Signer ○ RequestAuthInternal

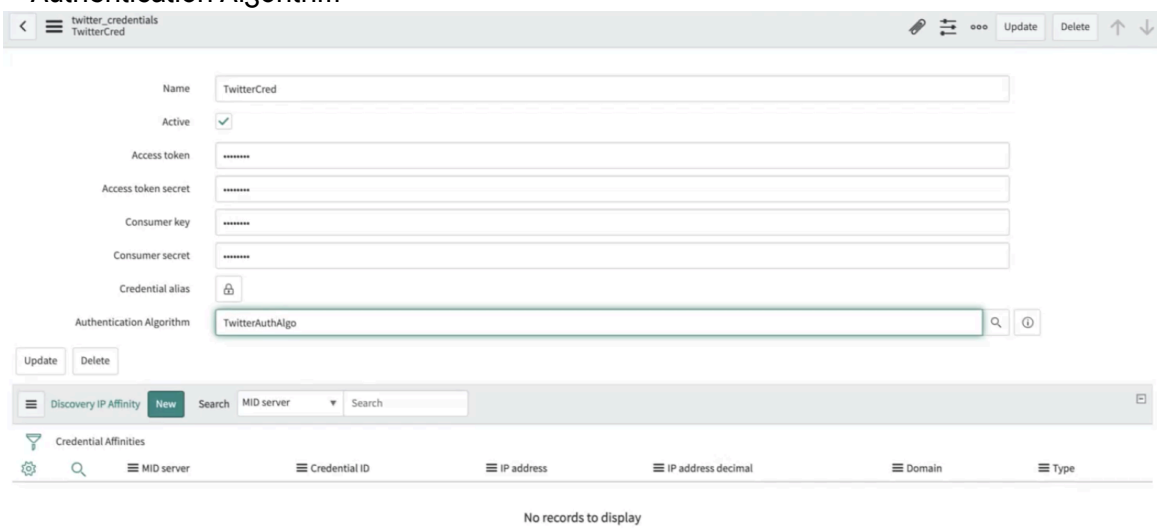
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	○ RequestAuthSampleCustomSigner ○ RequestAuthTwitterSigner



Based on the selected scripts and authentication algorithm, the configured credentials is sent as outbound request from ServiceNow to the provider.

3. Click **Update**.
4. Navigate to **All** > **Connections & Credentials** > **Credentials**.
5. Click **New**.
6. Create Twitter Credentials with Authentication Algorithm.
   In this case **TwitterAuthAlgo**.
7. Specify the fields:
   - Name
   - Active
   - Access token
   - Access token secret
   - Consumer key
   - Consumer secret
   - Credential alias
   - Authentication Algorithm



8. Click **Update**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Example: REST step with Twitter

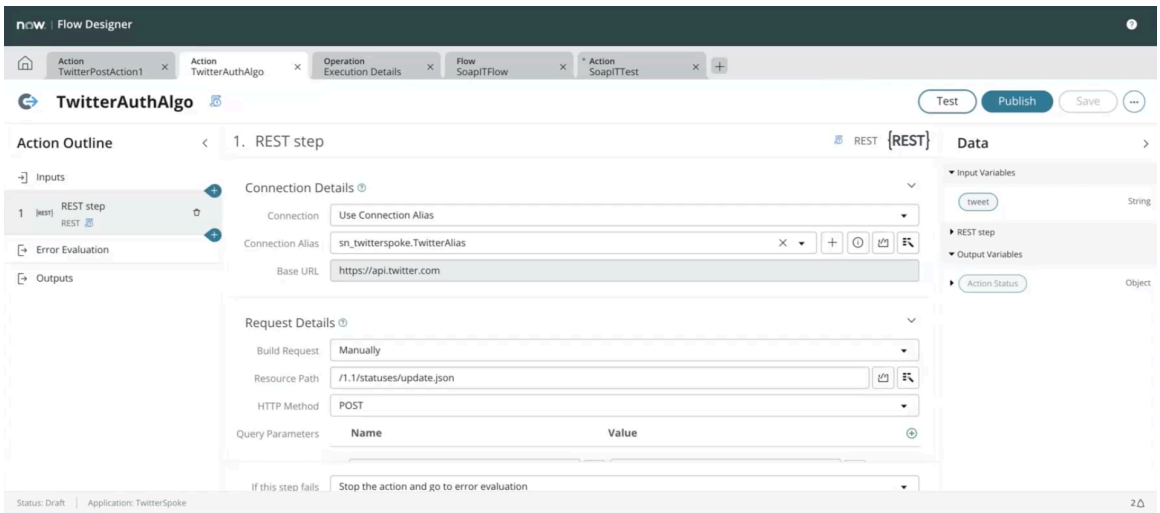
In case of Twitter, you must ensure the following spokes or credentials are available:

- Access token
- Access token secret
- Consumer key
- Consumer secret
- Authentication Algorithm

Action: TwitterAuthAlgo.

Input REST step with Twitter as follows:

- **Credentials Alias**: The alias that is created for Twitter.
- **Base URL**: Base URL details from Twitter.
- **HTTPS Method**: In this case it is POST method. Posting a tweet.
- **Query Parameters**: **Action** as **tweet**.



You can test the action. The tweet is posted on the Twitter page.

Check IP service affinity for Discovery and Orchestration

You can check the IP Services table for a list of IP addresses that are associated with a protocol.

Before you begin

Role required: admin

About this task

The IP Services table maps a port to a protocol. Several mappings are provided by default for commonly used port-protocol combinations, such as port 80 for HTTP, port 22 for SSH, and port 161 for SNMP.

A system property called *`glide.discovery.ip_service_affinity`* allows Discovery to remember the last port of the IP address that was discovered.

Important:
You should not modify IP services unless your organization uses custom ports.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Discovery Definition** > **IP Services**.
2. Filter the list to find the appropriate IP service.
3. Select the name of the service to go to that IP service page.
4. Select the **IP Service Affinities** tab for the list of IP addresses associated with that service.

ServiceNow® access control

The SNC Access Control plugin (com.snc.snc_access_control) enables you to control which Customer Service and Support employees can access your instance, and when.

Explore ServiceNow access control Learn about the features of ServiceNow® access control.	Activate ServiceNow access control Active ServiceNow® access control.
Configure ServiceNow access control Understand how to configure ServiceNow® access control.	Audit Logging Learn and review the ServiceNow® access control audit logging.

Explore ServiceNow® access control

The SNC Access Control plugin (com.snc.snc_access_control) enables you to control which Customer Service and Support employees can access your instance, and when.

When you first activate the plugin, Customer Service and Support employees cannot log into the instance. Any currently logged-in Customer Service and Support employees remain logged in. You create records in the SNC Access Control table that grant access to specific SNC employees or all employees.

The plugin prevents Customer Service and Support personnel from accessing the instances without your express permission. However, other authorized ServiceNow Operations personnel, in their capacity to support and manage the product, and verify usage are required to perform administrative actions on the underlying infrastructure. This infrastructure includes servers and

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

databases, among other infrastructure components that make up the SaaS solution. This access method is fully auditable and tracked.

This plugin enables you to restrict access to your instance without your express permission, so it may affect support service levels and the Availability SLA. Availability SLA is then measured from the time that Support staff personnel are granted access to your instance.

Login security

Security for authorized Customer Service and Support employee logins to instances employs encrypted tokens generated by a secure server. Only properly authenticated Customer Service and Support employees are granted access to an instance. Without the SNC Access Control plugin, the security server ensures that access rights are enforced on hi.service-now.com. When the plugin is enabled, the encrypted login tokens must match names in the plugin-provided access list, using the criteria defined in those records. This method of authentication enables you to determine precisely which Customer Service and Support employees may access their instances, and when these employees may do so.

The architecture chosen for this system has several features designed to enhance security for your instances:

Security server

The security server is a locked-down, Linux host that only ServiceNow security personnel can access. This server is the only system that has access to the critical private encryption key necessary to produce the login tokens. By using this compartmentalization (a standard security practice), the private key is protected, even in the unlikely event that an attacker compromises the HI instance.

Synthetic user

The facility on instances that enables authorized Customer Service and Support employees to log into their instance does not require an account to be provisioned on that instance. There is no user record provisioned, and no permanent or persisted credentials. Instead, a synthetic user is created for each Customer Service and Support employee logon. This user exists only in memory and provides no ongoing privileges. If the SNC Access Control plugin is enabled, you can deauthorize any Customer Service and Support employee at any time.

Tokens

The security tokens are specific to an instance and a particular Customer Service and Support employee. In addition, the mechanism that generates the tokens only works with actual Customer Service and Support employee logins to HI, not impersonated users. Once a security token is generated, only a specific Customer Service and Support employee can use it to log into an instance.

Time limit

Security tokens expire four hours after they are generated. This expiration limits the utility of hijacked tokens, which can only be used during this short window.

Logging

Logins by Customer Service and Support employees to instances are recorded as a login event.

- Every action taken by the logged-in Customer Service and Support employee is added to the transaction log in the database.
- It is also added to the instance log on the file system, which is inaccessible to most ServiceNow employees.
- Customer Service and Support employee logins and actions are readily identifiable, since the user names all end in @snc (like frodo.baggins@snc).

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

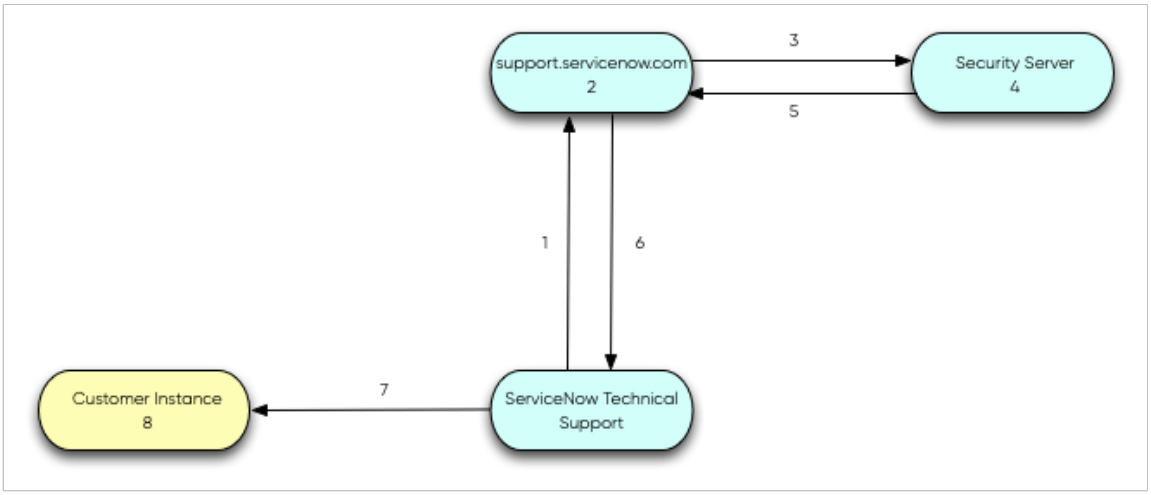
These actions provide you with easy-to-use, robust, and reliable security logging for non-employee access.

Security processing flow

When a Customer Service and Support employee wants to log into an instance, the security processing flow is as follows:

1. A Customer Service and Support technician requests a login for the instance through hi.service-now.com.
2. HI checks that the technician has the proper role authorizing access to instances.
3. If the user has the proper role, HI sends the request for access to the Security Server.
4. The Security Server verifies that the request came from the HI IP address, and evaluates the request (user, role, and IP address of the requester). If the request is valid, the Security Server approves it and constructs a token. This token contains the user name, roles, the instance ID, and the time (the start of the 4-hour token life span). Finally, the Security Server encrypts the token with the private encryption key.
5. The Security Server sends the encrypted token to HI.
6. Hi sends the token to the Support technician's browser.
7. The Support technician's browser initiates a login into the instance, using the special user name ending with `@snc`.
8. The instance uses the public key to decrypt the token. To verify the token, the instance matches it to the user name supplied in the previous step, the instance ID, and the authorized time window. If the SNC Access Control plugin is enabled, the instance verifies that the user is:
   - Listed
   - Active
   - Configured to access the instance in the current time window
9. If the user is authenticated, the instance creates a synthetic user in memory with the given roles. This user does not persist after the time limit expires, the user logs off, or the instance is restarted.

ServiceNow security access process flow



Audit logging

The following logging tracks logins and activity by Customer Service and Support employees:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Event logs: The event logs show all Customer Service and Support logins to an instance.
- Transaction logs: The transaction logs show all activity on the instance, including any efforts to delete logs.

Note:
To learn more about this plugin, see Enable SNC access control plugin [Updated in Security Center 1.3] in Instance Security Hardening Settings.

Activate ServiceNow® access control

You request activation of the SNC Access Control plugin (com.snc.snc_access_control).

Before you begin
Role required: admin

About this task
There are two ways to request a plugin:

- Access the Now Support Service Catalog directly by selecting **Automation Store** > **Service Catalog** > **Activate Plugin** on Now Support.
- Access the Now Support Service Catalog through the All Applications page on your instance by following these steps.

For additional details about requesting a plugin, see Requesting a Plugin from the Service Catalog [KB0751715] article in the Now Support Knowledge Base.

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Select **Request plugin** to open the **Activate Plugin** form on Now Support.
3. On the **Activate Plugin** form, provide the following information.

Activate Plugin form

Field	Description
What is your target instance	Select the instance that you want to activate the plugin on.
Which plugin would you like to activate	Select the name of the plugin to activate. **Note:** If the system doesn't list the plugin you want or if you're activating the plugin on an OEM or on-premise instance, select the **Plugin I'm looking for is not listed** check box and then enter the name of the plugin.
Select Maintenance Date and Time	Select the date and time to activate the plugin.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Example

For example, see the following form to activate the Event Management plugin on an instance named SNC Instance.

4. Select **Submit**.
   After the maintenance window, the system installs the plugin on your instance. To confirm the installation, go to the Installed tab in the Application Manager.

Configure ServiceNow® access control

Configure an access control record to specify one or more Customer Service and Support employees who have permission to log in your instance.

Before you begin

Role required: admin

About this task

Note:

The SNC Access Control (com.snc.snc_access_control) plugin prevents Customer Service and Support personnel from accessing the instances without your express permission. However, other authorized ServiceNow Operations personnel, in their capacity to support and manage the product, are required to perform administrative actions on the underlying infrastructure. This infrastructure includes servers and databases, among other infrastructure components that make up the SaaS solution. This access method is fully auditable and tracked.

This plugin enables you to restrict access to your instance without your express permission, so it may affect support service levels and the Availability SLA. Availability SLA is then measured from the time that Support staff personnel are granted access to your instance.

Procedure

1. Navigate to **All** > **System Security** > **SNC Access Control**.
2. Click **New**.
3. Fill in the form fields (see table).
4. Click **Submit**.

SNC Access Control

Form fields	Description
Name	Names each Customer Service and Support employee who has permission to log in this instance. ○ Express the names as firstname.lastname in lower case letters, separated by a period (for example, `john.smith`). Each name must have a corresponding user record in *`support.servicenow.com`*. ○ If more than one Customer Service and Support employee has permission to log in this instance, enter multiple names and separate them by commas.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Form fields	Description
	○ To enable all Customer Service and Support employees login rights to access the instance, enter an asterisk (*) in place of the name. ○ If you intend on restricting Customer Service and Support employee access to the instance, the values in the **Name** field must not have an asterisk (*) anywhere in the field.
Reason	Human-readable field that describes why you are granting access permission. This field is optional.
Start	Specifies the start date and time of the period during which the specified Customer Service and Support employees have login access. This field is mandatory.
End	Specifies the ending date and time of the period during which the specified Customer Service and Support employees have login access. This field is mandatory.
Active	Controls whether this permission record is active. The default is Active.

Audit logging

The following logging tracks logins and activity by ServiceNow employees.

Event Logs	The event logs show all ServiceNow logins to a customer instance.
Transaction logs	The transaction logs show all activity on the instance, including any efforts to delete logs.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Identity

Know more about the Identities in the instance.

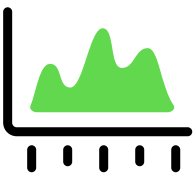
Identity Center

Identity Center allows you to monitor, manage, and minimize identity-based risk and security gaps.

Global Identity

Global Identity is a ServiceNow® store app enables to update user attributes from one instance to instance (multiple instances).

System for Cross-domain Identity Management (SCIM)



The System for Cross-domain Identity Management (SCIM) API provides endpoints to create, read, update, and delete operations on users and groups using the SCIM protocol.

Identity and Access Audit

Use the Identity and Access Audit to understand the changes made a user, group, role, and ACL.

Global Identity

Global Identity is a ServiceNow® product that enables to identify unique users across multiple instances.

Global Identity helps with multiple ServiceNow® instances to manage users, their attributes, and other foundational data across multiple ServiceNow® instances.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Explore Federated ID Learn the key features and business value of Federated ID.	Accessing Federated ID Access Federated ID.
Updating ID fields Update and set-up the Federated ID.	

Explore Federated ID

Determine the users across multiple instances based on user name and email and provide a unique ID (Federated ID) to the user across instances.

Federated ID is used to identity users across the multiple ServiceNow® instance. Based on the federated id the user can be identified and the accurate number of users across multiple instances can be determined. For more information, see Federated ID.

Note:
User name is required for generating Federated IDs.

Federated ID is a unique identifier for an identity using a hashing function across the ServiceNow® instances.

Federated ID for Users

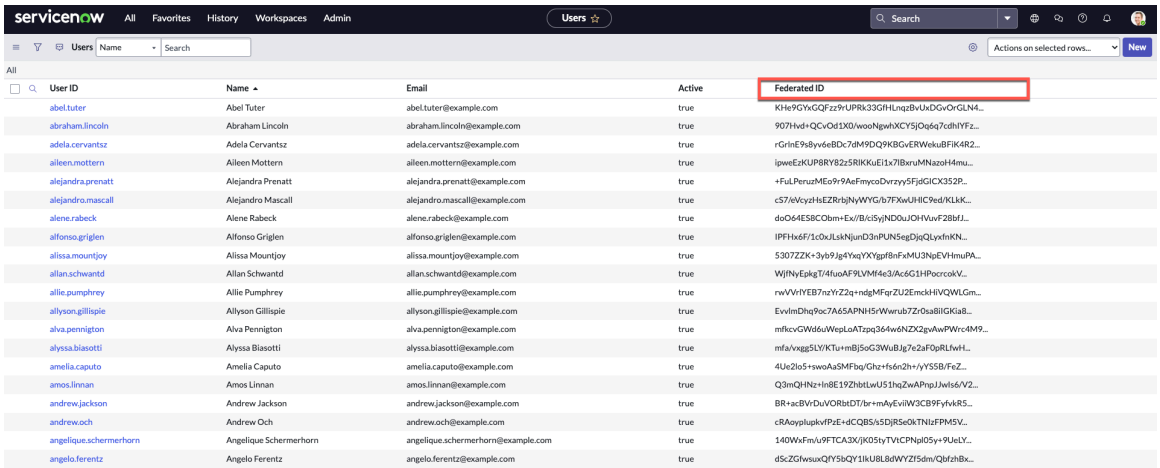
By using the **User ID** and **Email** of the user across the instances, the Federated ID is created and displayed in the **sys_user** table.

After upgrading to the Zurich release, the Federated ID Generation (`com.glide.identity.globalid`) plugin is auto-installed on all instances.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:

- User name is required for generating Federated IDs.
- User name and email are used to generate Federated IDs by default. To update the fields for generating Federated IDs based on your requirement, see Update ID fields.
- **iamsync_admin** role is required to update the configuration.
- If there are users with duplicate user names and email, then the Federated ID is generated only for one user. If the user name is null or empty, then the Federated ID is null.



Schema changes after the plugin installed are as follows:

- New column federated_id in the `sys_user` table is created.
- New table - `iamsync_type` is auto populated with the default configuration for the `sys_user` table.

Federated ID is only supported for the `sys_user` table and all the tables that extend the sys_user table.

After upgrading to the Zurich release, the Federated ID Generation (`com.glide.identity.globalid`) plugin is auto-installed on all instances.

Federated ID for Roles

By using the `roles` of the user across the instances, the Federated ID is created and displayed in the **sys_user_role** table.

Note:

- Role is required for generating Federated IDs in the **sys_user_role** table.
- The Federated IDs in the **sys_user_role** table can be used to the over usages of the roles.
- Updating ID fields and Regenerate Federated IDs options are not available for Role type. There's a scheduled job that runs periodically to generate ID for roles in case its empty.

Access Federated ID Criteria

Access Federated ID Criteria to know about the ID fields used to generated Federated ID.

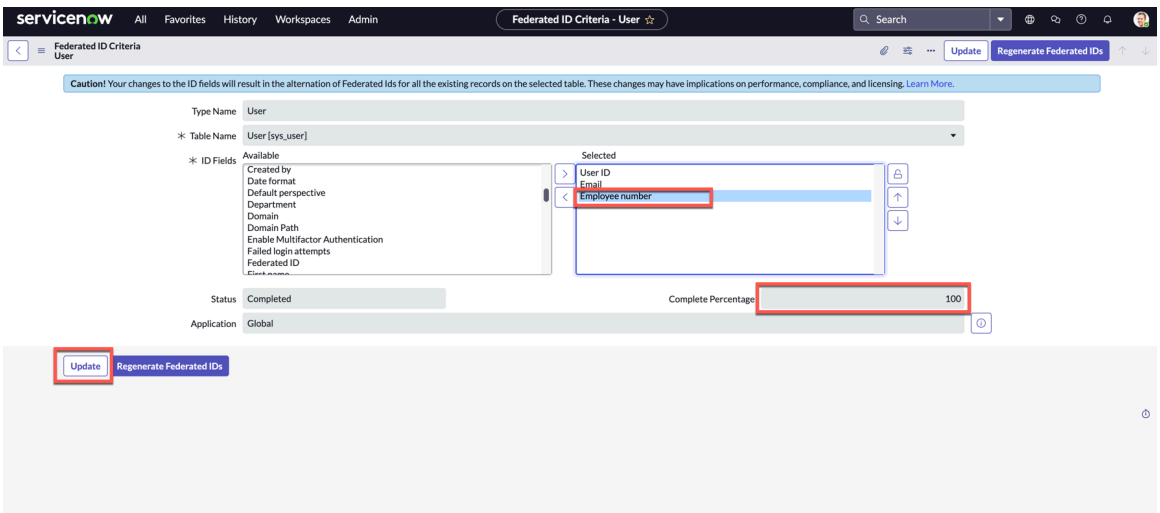
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin
Role required: iamsync_admin

Procedure

1. Navigate to **All** > **Manage Federated ID** > **Federated ID Criteria**.
2. The Federated ID Criterias page, displays the record with the following details:
   - Type Name: **User**
   - Table Name: **User [sys_user]**
   - ID Fields: **user_name (User ID), email** (default fields that are used for Federated ID generation).
   - Status: **Completed** (Federated ID generation status). Available Status: **Ready**, **Running**, **Completed**, **Error**.

Note:
- User name is required for generating Federated IDs.
- User name and email are used to generate Federated IDs by default.



Note:
Only the ID fields can be updated to generate a new Federated ID for the existing records. To know more, see Update ID fields.

Update ID fields

Update the ID fields to regenerate the Federated IDs based on the updated fields.

Before you begin
Role required: iamsync_admin

Note:
Any changes to the ID fields result in the change of Federated Ids for all the existing records on the selected table. These changes may have implications on performance, compliance, and licensing.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Procedure

1. Navigate to **All** > **Manage Federated ID** > **Federated ID Criteria**.
2. Select the Type Name (**User**).
3. Select the new ID fields in the Federated ID Criteria User page that you want to add from the Available to Selected using the arrow buttons.

   For example, **Employee number**.

   Note:
   - User name is required for generating Federated IDs.
   - User name and email are used to generate Federated IDs by default.
   - If there are users with duplicate user names and email, then the Federated ID is generated only for one user. If the user name is null or empty, then the Federated ID is null.

   Now, the **Employee number** selected becomes another attribute for generating the Federated ID.

4. Select **Update** to generate Federated IDs.

   Note:
   Select **Update** first and then check for the completion percentage (100) before initiating another update.

   The status percentage indicates the Federated ID generation for all the identities across instances.

   Note:
   - Until the previous update job is complete, don't change the field.
   - Fields that are updated should be a string type.
   - Fields that cannot be select as ID fields are as follows:
     - System level fields
     - Edge encryption fields
     - Password fields.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

5. Navigate to the sys_user table to view the new Federated IDs that are generated due to updating the ID fields.

Note:
Select **Regenerate Federated IDs** if a user is created or updated via XML imports, low-level database updates, the instance not working correctly. Selecting **Regenerate Federated IDs**, regenerates the IDs for all the users, using the current id field criteria.

Identity and Access Audit

Use the Identity and Access Audit to understand changes made for users, groups, roles, and ACLs.

Explore Learn about the features and business value of Identity and Access Audit.	Configure Understand how to configure Identity and Access Audit.
Audit Results View results from Identity and Access Audit.	

Explore Identity and Access Audit

Use the Identity and Access Audit to understand changes made for users, groups, roles, and ACLs.

Identity and Access Audit helps to understand the critical information about who has modified what, where and when in user accounts, groups and roles.

Helps to detect malicious users and track unusual activity in the ServiceNow® instance and adhere with compliance standards of being able to track access changes.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Identity and Access Audit (Identity Security Audit) is a plugin (`com.glide.security.audit`), which is auto-installed.

Auditing feature can be turned on or off by toggling the`glide.identity.security.audit.enabled` system property. By default, the property is set `true`.

Identity and Access Audit enables you to:

- View the changes made in the last 30 days to users, groups, role ACL attributes, role memberships, group memberships, and ACL roles.
- Track the changes in your ServiceNow instance.
- Help mitigate potential security and regulatory risks.
- Demonstrate compliance with auditors for different groups within the organization.
- Demonstrate that the organization isn't vulnerable to threats related to a lack of visibility in the user group and role changes.

User personas in Identity Access and Audit

Following are the different user personas in Identity and Access Audit:

- **Admin**: View the audit records and the configuration.
- **Security Admin**: View these audit trails. Modify the configuration to enable or disable auditing for a certain table or modify the fields that are being audited.

Audit Tables

The following tables can be audited using Identity and Access Audit:

- Group [sys_user_group]
- Role [sys_user_role]
- Access Control [sys_security_acl]
- User [sys_user]
- Group Role [sys_group_has_role]
- User Role [sys_user_has_role]
- Access Roles [sys_security_acl_role]
- Contained Role [sys_user_role_contains]
- Group Member [sys_user_grmember]

Modules in Identity and Access Audit

Identity and Access Audit has the following modules on the ServiceNow instance:

Module	Description
Audit Results	Displays the audits that occurred in the ServiceNow instance.
Configure Table & Fields	Configure the system tables and fields with the available fields from the Identity and Access Audit.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Module	Description
Configure Retention Period	Configure the retention period of the audited data. The maximum period that can be set is 30 days.
User Trails	Displays audits of users.
Group Trails	Displays audits of groups.
Role Trails	Displays audits of roles.
ACL Trails	Displays audits of ACLs.

Identity Audit Results

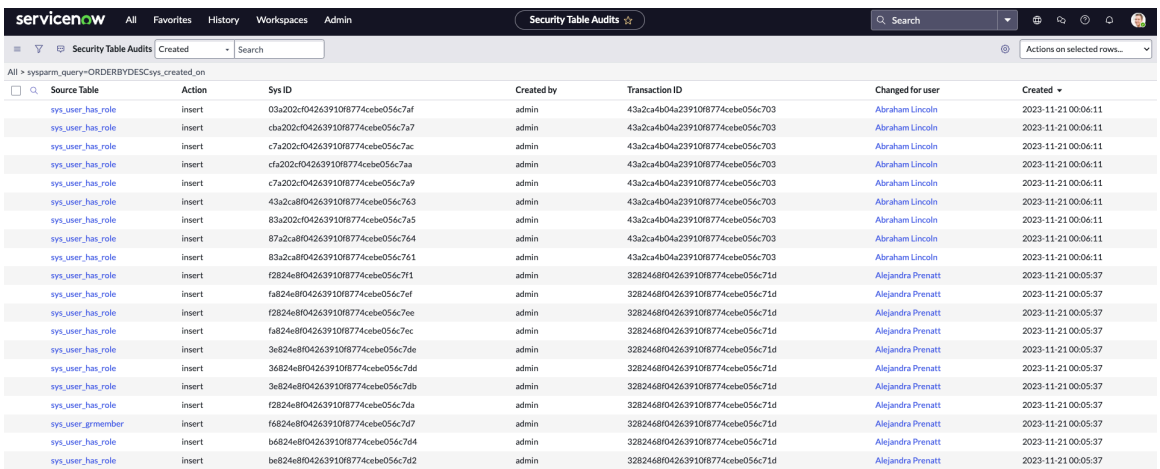
Displays audits that occurred in the ServiceNow® instance.

Audit Results displays changes made for users, groups, roles, and ACLs in the ServiceNow instance.

To access the Audit Results, navigate **All** > **System Security** > **Identity and Access Audit** > **Audit Results**. The Security Table Audits page is displayed with the following information.

Security Table Audits

Column Name	Description
Source Table	Details of the source table where the audit occurred.
Action	Describes the audit action.
Sys_id	Details about the sys_id for the audited record.
Created by	Details of the audit that was created by.
Transaction ID	A unique ID that represents every action on the particular audit performed.
Changed for user	Name of the user when the audit was performed.
Created	The time and date the audit was performed.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

User Trails

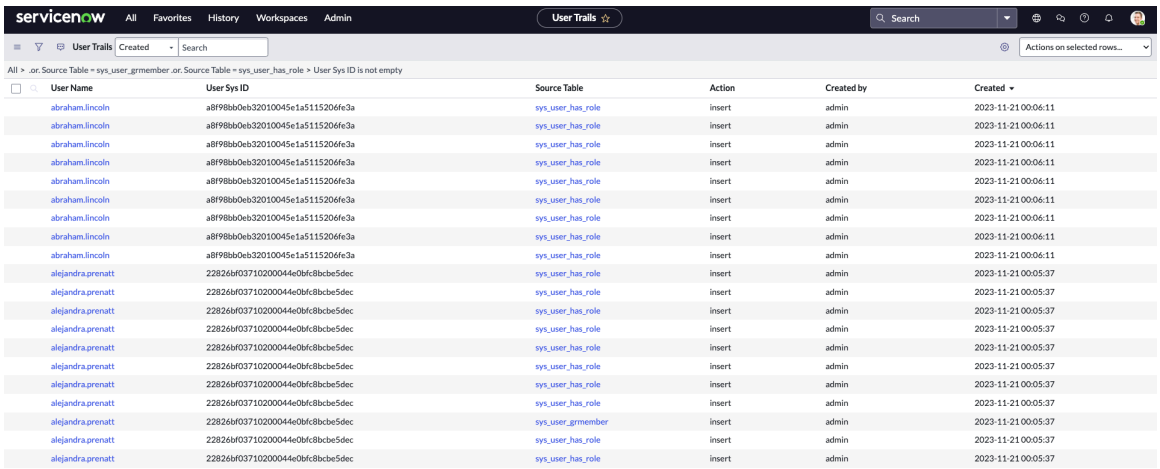
Displays audits of users in the ServiceNow® instance.

User Trails display identity attribute changes, role membership changes, and group membership changes for a user.

To access User Trails, navigate to **All** > **System Security** > **Identity and Access Audit** > **User Trails**. The User Trails page is displayed with the following information.

User Trails

User Name	Name of the user.
User Sys id	Details about the User sys_id for the audited record.
Source Table	Details about the Source Table where the audit was performed.
Action	Describes the audit action.
Created By	The user who made the change.
Created	The time and date the audit was performed.



Group Trails

Displays audits of groups in the ServiceNow® instance.

Group Trails display attribute changes, membership changes, and roles changes for a group.

To access Group Trails, navigate to **All** > **System Security** > **Identity and Access Audit** > **Group Trails**. The Group Trails page is displayed with the following information.

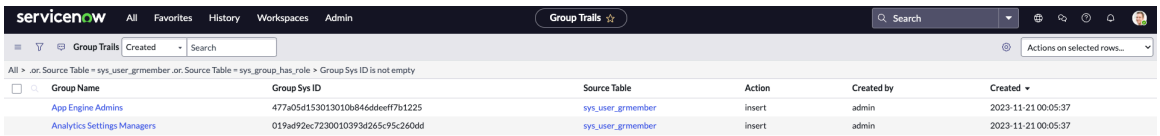
Group Trails

Group Name	Name of the group.
Group Sys id	Details about the Group sys_id for the audited record.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Group Trails (continued)

Source Table	Details about the Source Table where the audit performed.
Action	Describes the audit action.
Created By	The user who made the change.
Created	The time and date the audit was performed.



Role Trails

Displays audits of roles in the ServiceNow® instance.

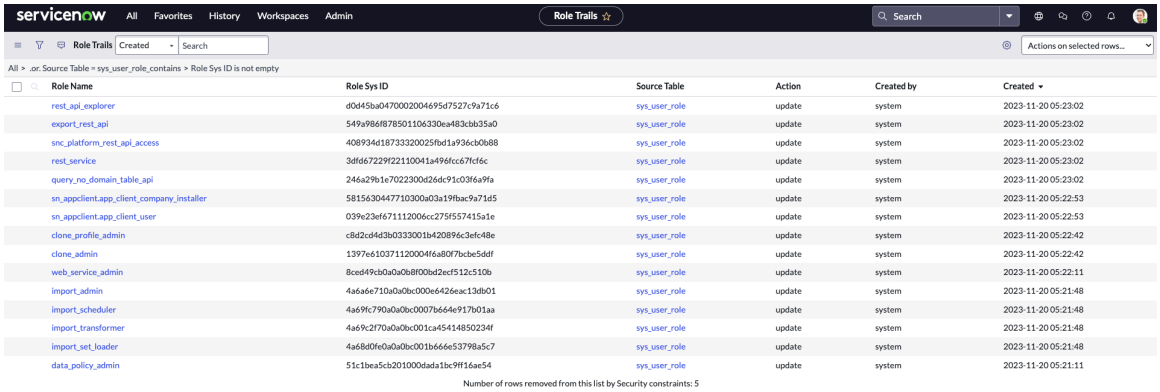
Role Trails display attribute changes and parent-child relation changes for a role.

To access Role Trails, navigate to **All** > **System Security** > **Identity and Access Audit** > **Role Trails**. The Role Trails page is displayed with the following information.

Role Trails

Role Name	Name of the role.
Role Sys id	Details about the Role sys_id for the audited record.
Source Table	Details about the Source Table where the audit performed.
Action	Describes the audit action.
Created By	The user who made the change.
Created	The time and date the audit was performed.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



ACL Trails

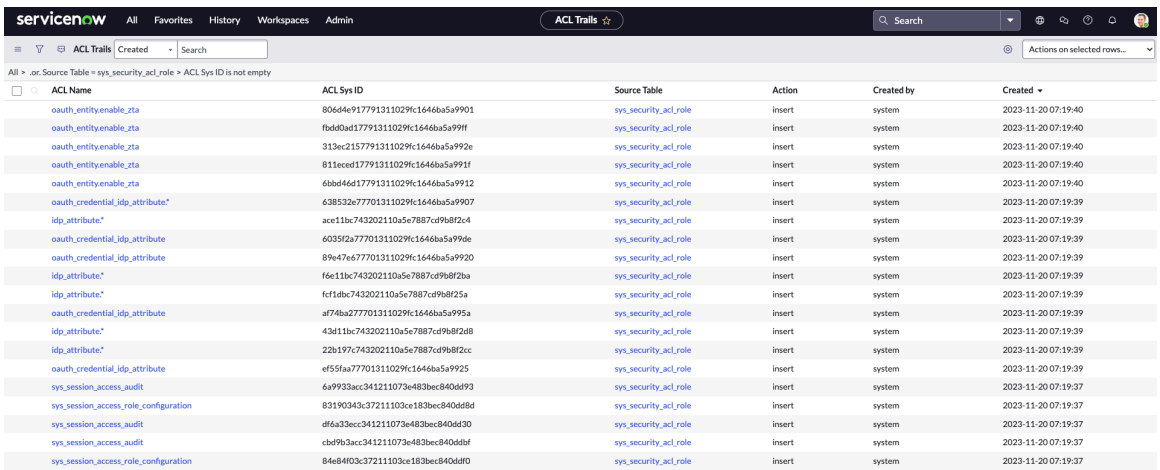
Displays audits of ACLs in the ServiceNow® instance.

ACL Trails display attribute changes and required role relation changes for an ACL.

To access the ACL Trails, navigate to **All** > **System Security** > **Identity and Access Audit** > **ACL Trails**. The ACL Trails page is displayed with the following information.

ACL Trails

ACL Name	Name of the ACL.
ACL Sys id	Details about the ACL sys_id for the audited record.
Source Table	Details about the Source Table where the audit was performed.
Action	Describes the audit action.
Created By	The user who made the change.
Created	The time and date the audit was performed.



© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Security Auditable Fields

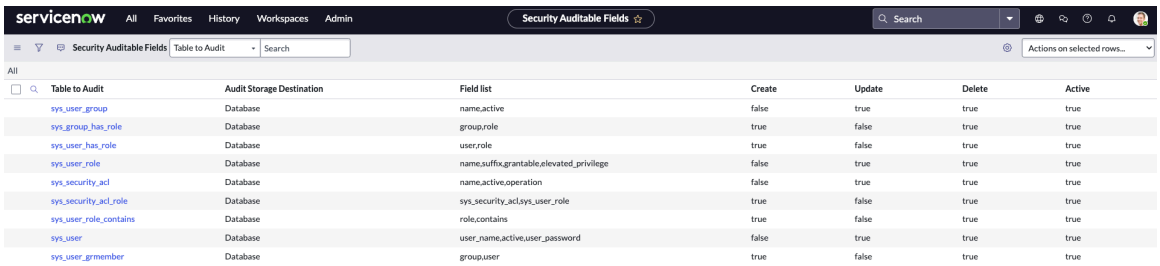
Displays table and field level details that will be audited in the ServiceNow® instance.

Security Auditable Fields displays the details of tables and fields that will be audited in the ServiceNow instance.

To access the Security Auditable Fields page, navigate to **All** > **System Security** > **Identity and Access Audit** > **Configure Tables & Fields**. The Security Auditable Fields page is displayed with the following information.

Security Auditable Fields

Column Name	Description
Table to Audit	Details of the table that is audited.
Audit Storage Destination	Details of the destination where the audit details are stored.
Field List	Auditing will be done for fields specified in the list.
Create	Audit the changes that are related to Create operation.
Update	Audit the changes that are related to Update operation.
Delete	Audit the changes that are related to Delete operation.
Active	Audit only if the configuration for the table is active.



The following tables can be audited using the Identity and Access Audit:

- Group [sys_user_group]
- Role [sys_user_role]
- Access Control [sys_security_acl]
- User [sys_user]
- Group Role [sys_group_has_role]
- User Role [sys_user_has_role]
- Access Roles [sys_security_acl_role]

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Contained Role [sys_user_role_contains]
- Group Member [sys_user_grmember]

Configure Tables and Fields

Identity and Access Audit to understand the changes made for a user, group, role, and ACL.

Before you begin

Role required: security_admin

You must elevate your role to Security Admin to configure tables and fields for Identity and Access Audit.

The following tables can be configured for auditing:

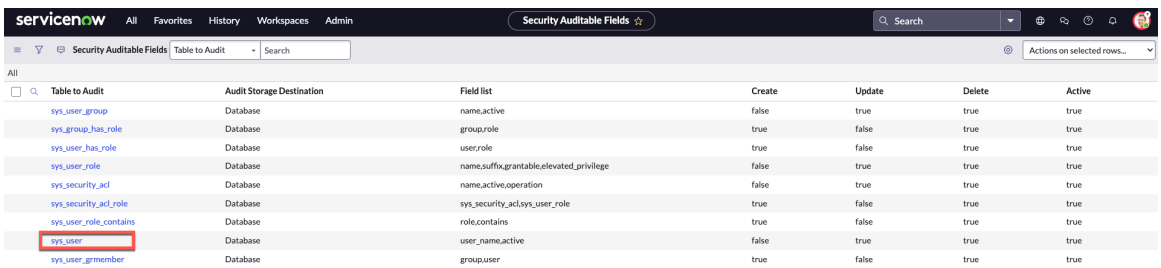
- Group [sys_user_group]
- Role [sys_user_role]
- Access Control [sys_security_acl]
- User [sys_user]
- Group Role [sys_group_has_role]
- User Role [sys_user_has_role]
- Access Roles [sys_security_acl_role]
- Contained Role [sys_user_role_contains]
- Group Member [sys_user_grmember]

Note:
To understand which fields can be configured for the tables, see Supported and unsupported fields in Identity Access and Audit.

Procedure

1. Navigate to **All** > **System Security** > **Identity and Access Audit** > **Configure Tables & Fields**.
2. Select the table that you want to audit a field from.

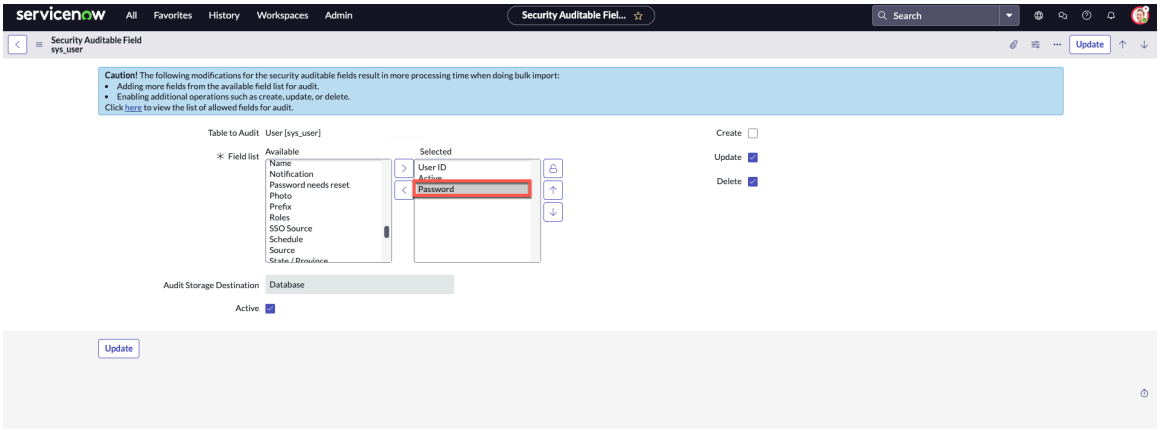
   For example, **sys_user**.



3. Add the field to be audited.

   For example, **Password**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



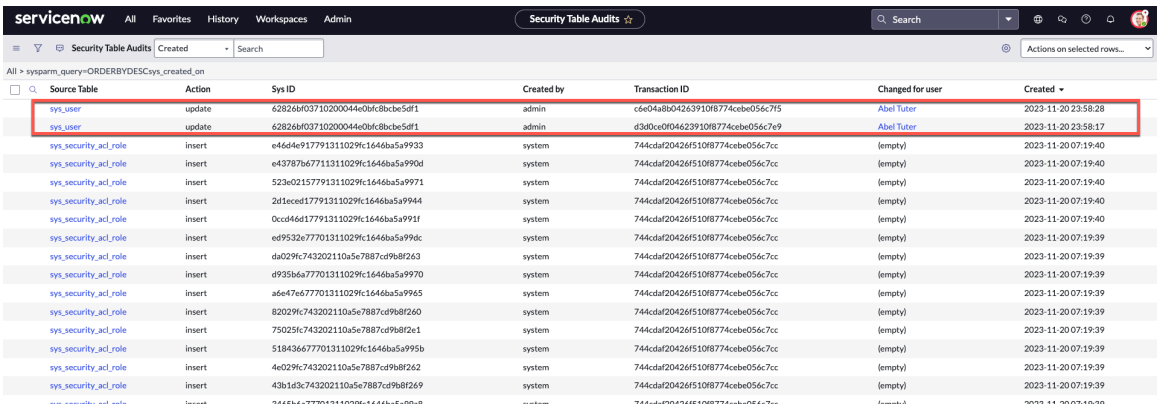
Note:

The following modifications for the security auditable fields result in more processing time when doing bulk import:

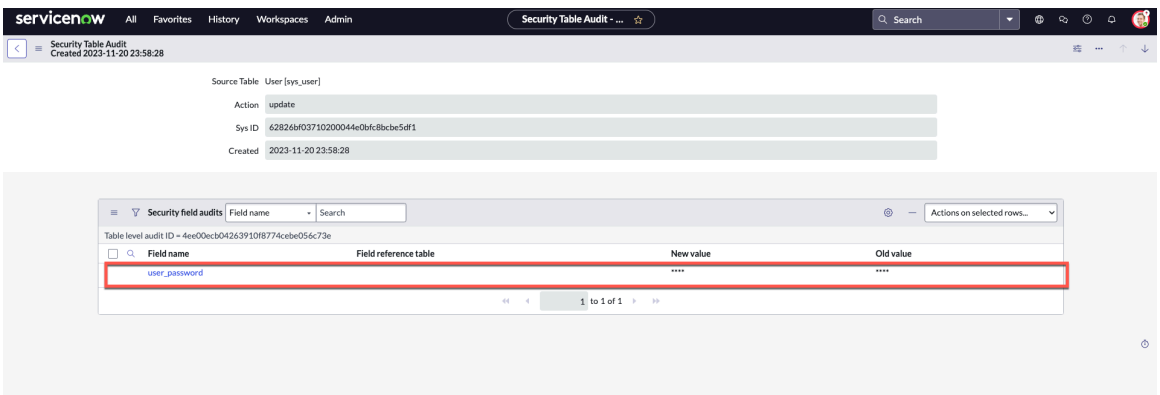
- Adding more fields from the available field list for audit.
- Enabling additional operations such as create, update, or delete.

4. Update the record.

Any changes to the password field add a new record to the Security Table Audits. In this example, the audit shows a changed password field for the user **Abel Tuter**.



Selecting the created record displays the details of the changes.



Configure Retention Period

Configure the retention period for Identity and Access Audit.

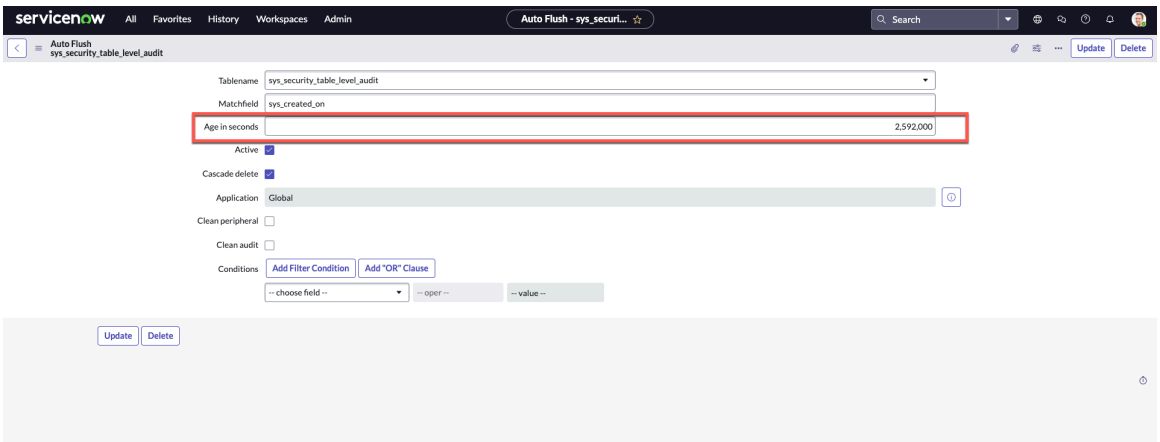
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Before you begin
Role required: admin

Procedure

1. Navigate to **All** > **System Security** > **Identity and Access Audit** > **Configure Retention Period**.
2. On the form, you can change the Age in seconds.

> **Note:**
> The maximum number of days for Identity and Access Audit is 30 days (2,592,000 seconds).



3. Save or Update the record.

Supported and unsupported fields in Identity Access and Audit

List of fields that are supported and not supported for audit.

Audit Fields Validation prevents some fields from being chosen in the field_list in the Security Field Audit Config (sys_sec_field_audit_config) table.

Field supported or not supported for Audit

Table	Fields supported or not supported
All tables	Fields that aren't supported: • Created On (sys_created_on) • Created By (sys_created_by) • Updated By (sys_updated_by) • Updated On (sys_updated_on)
User has role (sys_user_has_role)	Fields that are supported: • User • Role • Inherited • Count

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field supported or not supported for Audit (continued)

Table	Fields supported or not supported
User (sys_user)	Fields that aren't supported: • Last Login (last_login) • Last Login Time (last_login_time) • Last Login Device (last_login_device) • Enable Multi-factor Authentication (enable_multifactor_authn) • Default Perspective (default_perspective) • Calendar Integration (calendar_integration) • Federated ID (federated_id) • Password Needs Reset (password_needs_reset) • Failed Attempts (failed_attempts) • Last Password (last_password) • LDAP Server (ldap_server) • Locked Out (locked_out) • Notification (notification) • Roles (roles) • Domain (sys_domain) • Domain Path (sys_domain_path) • Time Format (time_format) • Hashed User ID (hashed_user_id) • Class Name (sys_class_name) • Mod Count (sys_mod_count)

Identity Center

Allows you to monitor, manage, and minimize identity-based risk and security gaps.

Explore

Learn the features and business value of Identity Center.

Activate

Understand how to activate Identity Center.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Identity Metrics for administrators

Know how the permissions are evaluated.

Identity Center for users

Get details about the commonly asked questions about the Access Analyzer.

Explore Identity Center

Identity Center is a collection of user attributes, access, devices, login history, security activity, and much more.

Identity Center offers capabilities to monitor, manage, and minimize identity-based risk and security gaps.

Identity Center is one stop to monitor, manage, and minimize identity-based risk and security gaps on ServiceNow.

To activate the Identity Center, install the Identity Center (`com.snc.identity_center`) plugin. Identity Center is available for the end user - to view the details about the active sessions, login history, and trusted devices with the Identity Center. For more information see, Identity Center for users.

Activate the Identity Center

For Identity Center, install the Identity Center (`com.snc.identity_center`) plugin.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the Identity Center (`com.snc.identity_center`) plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:
When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Identity Center for users

View the details about your active sessions, login history, and trusted devices with the Identity Center.

Identity Center is a collection of user attributes, devices, login history, security activity and much more. It provides a single pane view of all the data with additional security controls and notification capabilities.

With the Identity Center you can view the details about your active sessions, login history, and trusted devices.

To access the Identity Center for users, navigate to one of the following:

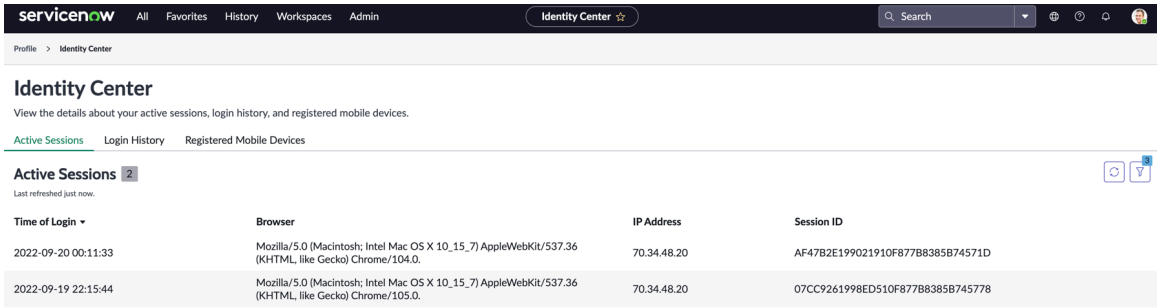
- On ServiceNow AI Platform, navigate to **All** > **Self-Service** > **My Profile** and select **View Identity Center** under the Related Links section.

  Note:
  You can also access your profile by selecting your user name in the instance header.

- On Now Support, select the profile, select **View Identity Center** at the bottom of the page.

The Identity Center page is displayed as follows:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Identity Center has the following tabs:

- Active Sessions
- Login History
- Registered Mobile Devices

You can select these tabs to view the details such browser, IP Addressees, session relation information, login information, your registered mobile devices.

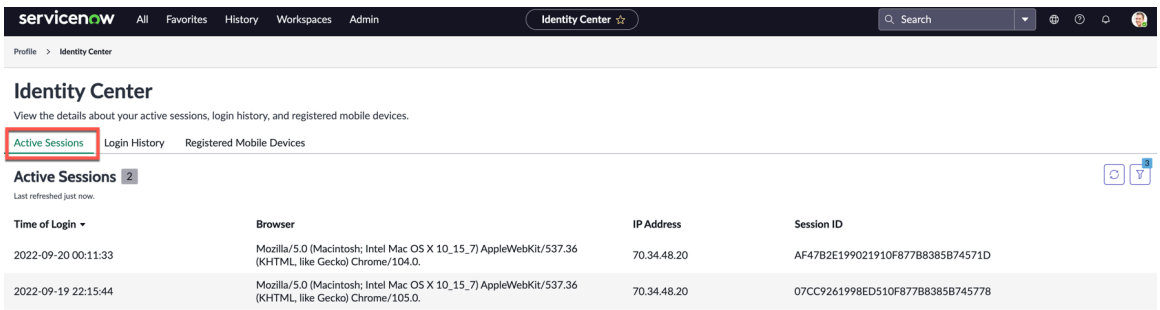
View Active Sessions in Identity Center

Displays the information about the user sessions.

Active sessions are the sessions that are open on the current#ServiceNow®#nstance with different browsers or devices.

The Active Sessions tab in the Identity Center helps you to identity your sessions based on the Browser, IP Address, and Sessions ID. Using this information you can take required actions such as extending or terminating the session.

Using this information can help determine if the sessions are real and not a security concern.



View Login History in Identity Center

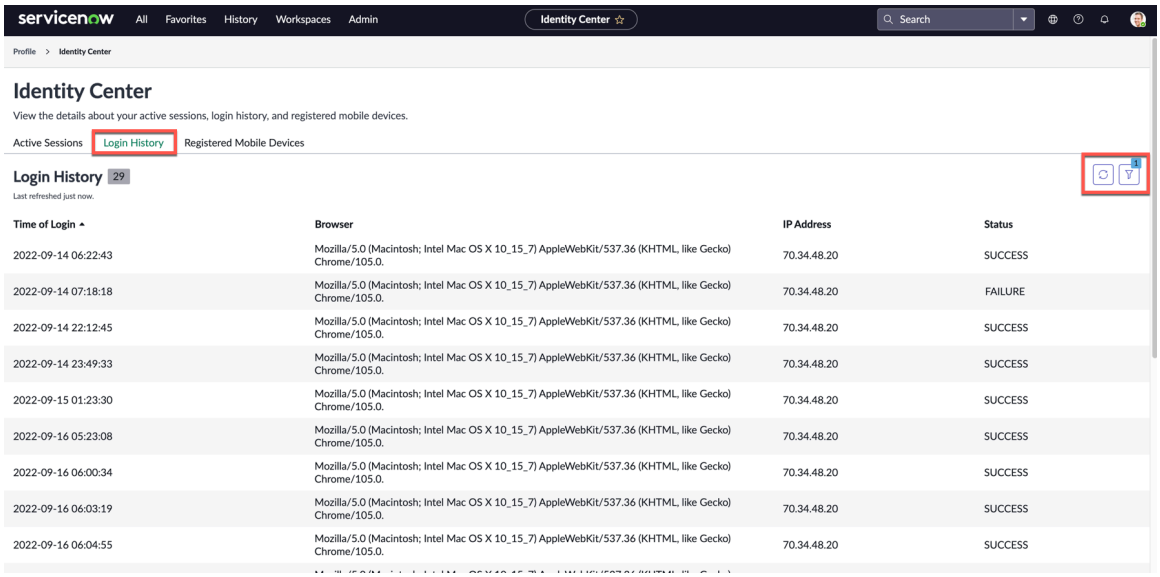
Provides details about your login history.

The Login History tab in the Identity Center helps you with your login information and the status of your login.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

You can use the filters to specify login actions to help security investigations. Filter can help determine if the activity was real or suspicious and report the information to your administrator.

Pagination in the login history is 20 by default and can be set to a maximum of 100.



Following are some of the other details from the Login History:

- The Time of Login is the updated time when the mobile devices are used to access the instance.
- The records are stored in Identity Center for 30 days.

View Registered Mobile Devices in Identity Center

Provide details about your registered mobile on the ServiceNow instance.

The Registered Mobile Devices tab in the Identity Center displays the details about your registered devices that were used to access the ServiceNow instance.

If the Adaptive Authentication module is enabled and a registered mobile device is enrolled the Identity Center displays the details about your registered devices.

Further, it also displays details of the devices such as Operating System, Device Id, and Status of the device along with the Registration Time of the device.

To register your mobile device, you must make sure the Adaptive Authentication (*com.snc.adaptive_authentication*) plugin is installed and you've activated your Trusted Mobile App feature. For more information, see Activate Trusted Mobile App.

Explore Machine Identity Console

Manage your service accounts, which are used for integrations with ServiceNow.

Machine Identity Console enables you to manage your non-human identities (NHIs) that are used to identify, authenticate, and authorize different software entities to access secured resources of ServiceNow. The entities that gain access include applications, workloads, APIs, bots, and automated systems. Unlike human identities, non-human identities (NHIs) aren't governed in the same manner and aren't directly associated with a human. Their identity and verification methods are distinct from the human users, and standard human security measures are not applicable to them.

https://player.vimeo.com/video/1101308622?h=b01d69f65a&badge=0&autopause=0&player_id=0&app_id=58479

Here's what is available on the Machine Identity Console Overview page:

- Total Machine identity (integration) accounts and the Accounts with high privilege roles.
- Unique API calls - Last 7 days
- Authentication method used - Last 7 days
- Machine Identity Security score and findings related to the identity.

Note:
Accounts that have the **Internal Integration User** field set to `true` in their `sys_user` record will not populate data in the Machine Identity Console.

Machine Identity Console Settings

Inbound integrations

Inbound integrations

Inbound Integrations in the machine identity console allows you to configure and manage external applications to access ServiceNow APIs.

The Inbound integrations within the ServiceNow's Machine Identity Console helps you manage and configure integrations and applications that connect with the ServiceNow platform. It acts as a central hub for storing application settings and API credentials, ensuring secure communication between ServiceNow and external systems. To know more, see New Inbound integrations experience.

Connections types:

- OAuth - Authorization code grant: Access a resource by authenticating directly with an OAuth server that trusts the resource. For more information, see Configure an OAuth authorization code grant.
- OAuth - Client credential grant: Used for Inbound Integrations from a third party OAuth client to the ServiceNow platform. For more information, see Configure an OAuth Client credential grant.
- OAuth - JWT bearer grant: Use a JSON Web Token (JWT) grant to authenticate with your instance. For more information, see Configure an OAuth JSON web token bearer grant.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Third party ID token issued by OIDC supporting identity provider: Configure an OAuth OIDC provider to accept identity tokens generated by a third-party OIDC provider using inbound API calls. For more information, see Configure a third party ID token.
- OAuth - Resource owner password credential grant: Authorize Access to an OAuth Endpoint using auth code flow. For more information, see Configure an OAuth resource owner password credential grant.

> **Note:**
> For authorization code flow, user must complete the Authentication by local login, SSO or MFA and then provide consent.

To learn more, see New Inbound integrations experience.

Security findings

Provides Machine Identity security score and findings.

Machine identity security score and findings

The security score is displayed for following security findings. You can select each findings for learn more.

Security findings

Findings	Description
Accounts with no login for 100 days	Findings about the accounts that have not accessed any API in 100 days.
Accounts using Basic Authentication	Findings about the accounts that are using username and password for authentication.
Integration accounts with Web Service Access disabled	Findings about all the accounts that have WSA disabled.
Accounts performing both UI and API logins	Findings about the accounts that are used for both interactive (UI) and machine (API) logins.

Machine identity Security score and findings

The security score is based on the usage and method of machine identities. A lower score indicates a higher risk. You can view the recommendations to take preventive actions for these identities.

© 2026 ServiceNow, Inc. All rights reserved.

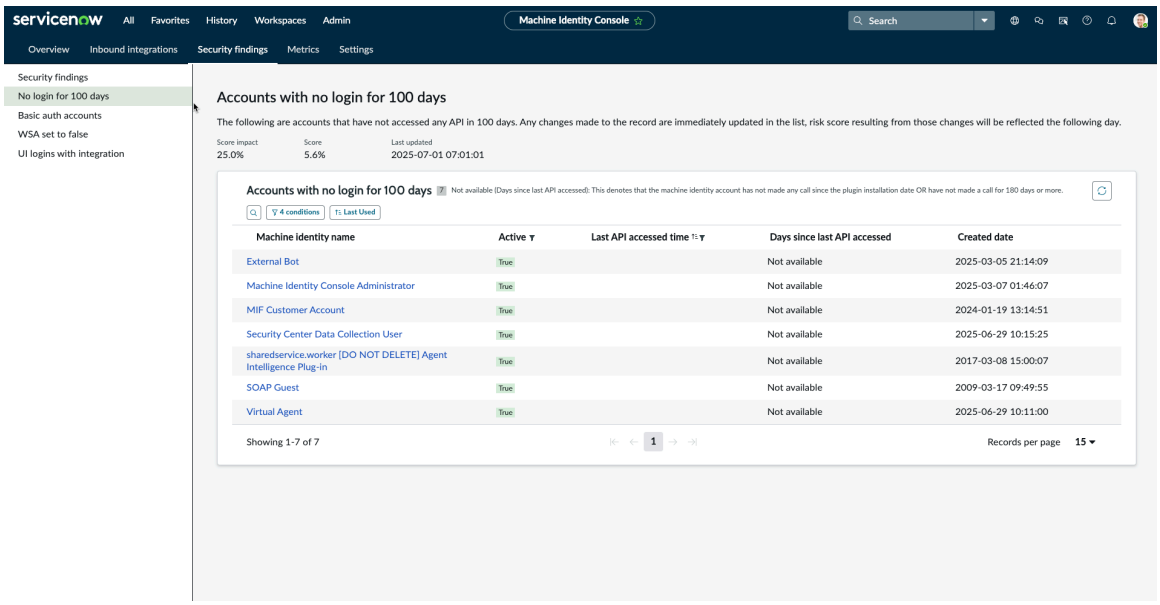
Accounts with no login for 100 days

Display the findings about the accounts that have not accessed any API in 100 days under the Security findings in the Machine Identity Console.

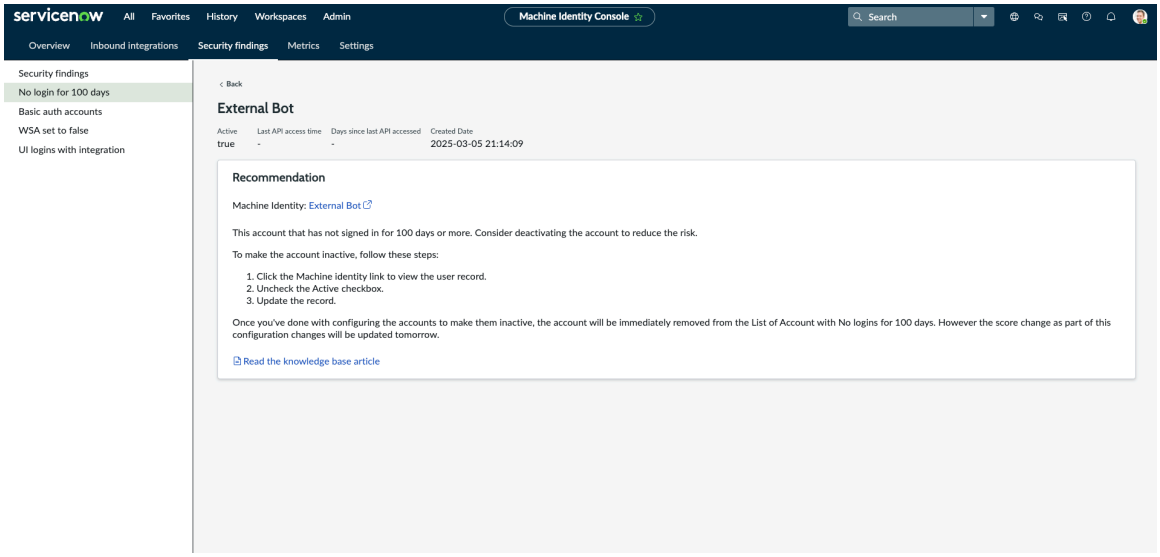
Accounts with no login for 100 days displays the non human identity accounts that have not accessed any API in 100 days.

Note:
Any changes made to the record displayed on this page are immediately updated in the list, risk score resulting from those changes will be reflected the following day.



You can select the machine identity name to know more about the account and the recommendation to maintain a good security posture for the account.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

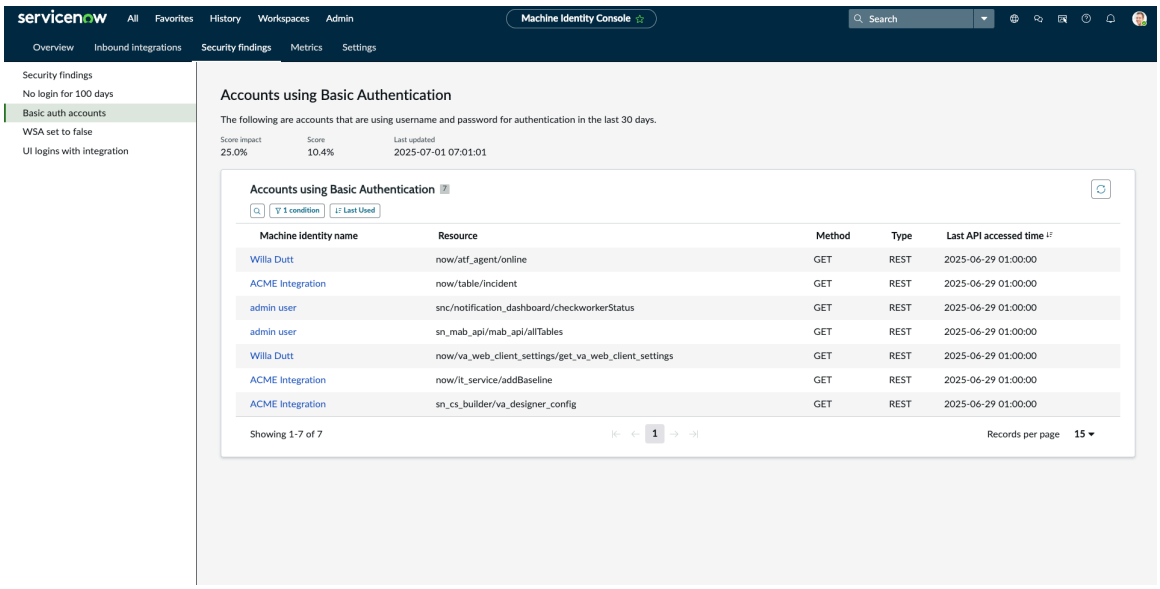


Accounts using Basic Authentication

Display the findings about the accounts that are using only basic authentication to authenticate the APIs under the Security findings in the Machine Identity Console.

Accounts using basic authentication displays the non human identity accounts that using basic authentication for the APIs to login to ServiceNow.

Note:
The accounts displayed on the page are the accounts that are using username and password for authentication in the last 30 days.



You can select the machine identity name to know more about the account and the recommendation to maintain a good security posture for the account.

Metrics

Metrics of the machine identities.

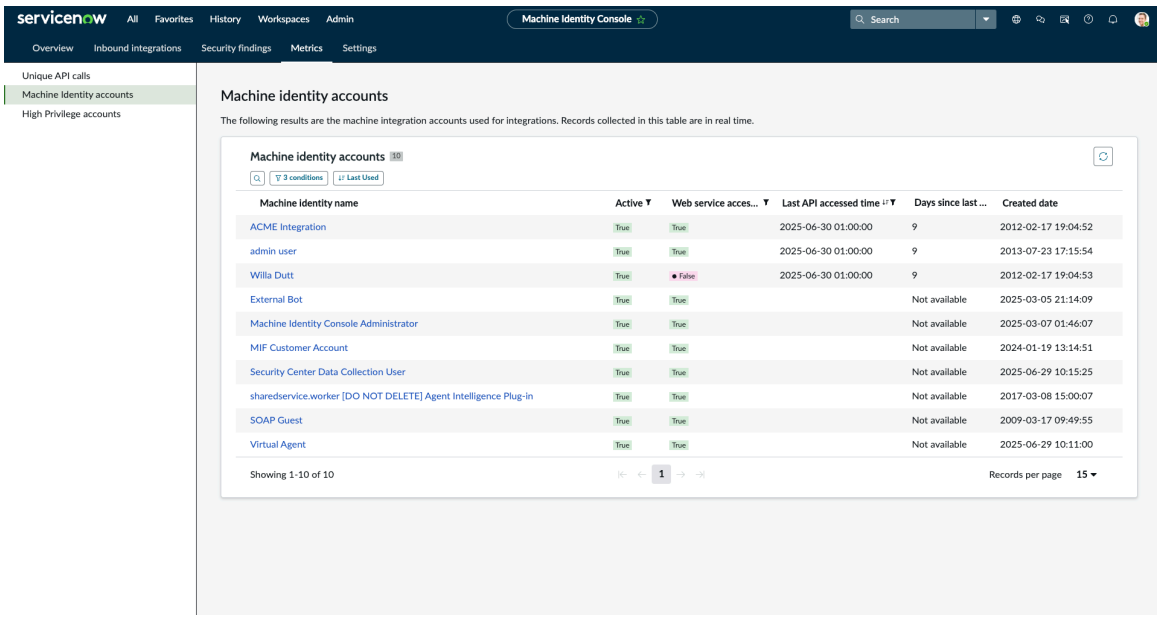
Unique API calls in last 7 days

The following results are unique API calls in the last 7 days. Records collected in this table are in real time.

> **Note:**
> Accounts that have the **Internal Integration User** field set to `true` in their `sys_user` record will not populate data in the Machine Identity Console.

Machine identity accounts

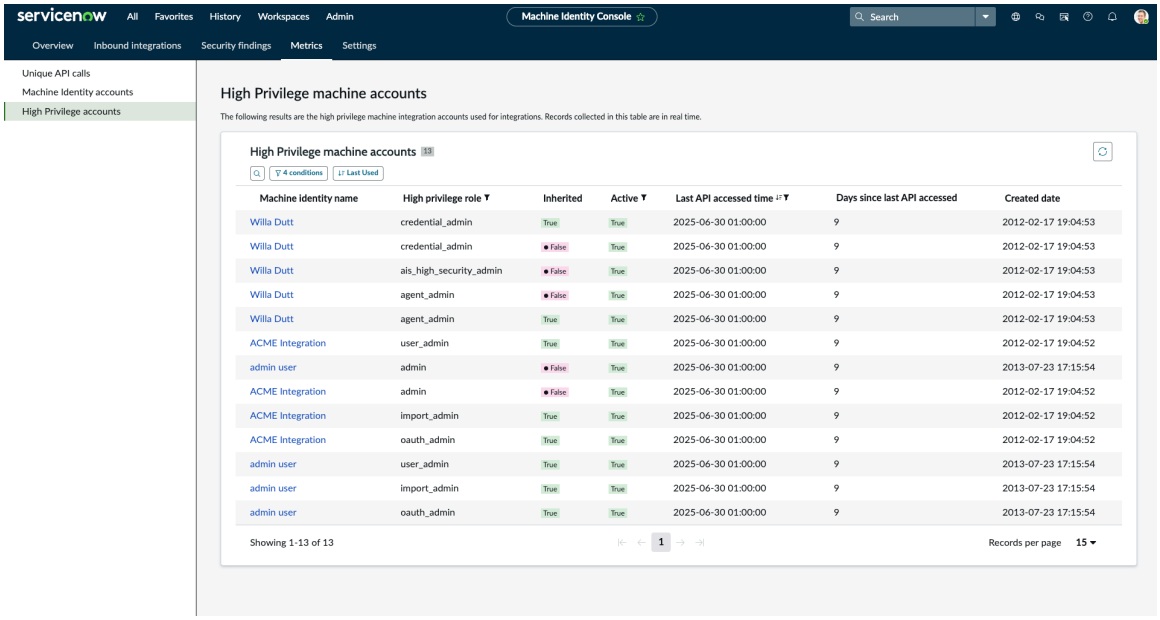
The following results are the machine integration accounts used for integrations. Records collected in this table are in real time.



High Privilege machine accounts

The following results are the high privilege machine integration accounts used for integrations. Records collected in this table are in real time.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Machine Identity Console Settings

Configure the Machine Identity security score settings.

Before you begin

Role required: mi_admin

The following task is specific to your organization on how to handle the inactive accounts.

> **Note:**
> If your organization does not want to report on accounts inactive for 100 days, you can deactivate this report below. This is the only report that can be set to inactive.

Procedure

1. Navigate to **All** > **Machine Identity Console** > **Settings**.
2. Select the settings based on your requirements:
   - **Accounts with no login for 100 days**
   - **Accounts using Basic Authentication**
   - **Integration accounts with Web Service Access disabled**
   - **Accounts logging into the UI despite being integration only**

Activate Machine Identity Console

Activate the **Machine Identity Management** `com.glide.identity.machine_identity_management` to manage your service accounts which are used for integrations with ServiceNow.

Before you begin

Role required: mi_admin

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the **Machine Identity Management** (`com.glide.identity.machine_identity_management`) plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

   Note:
   When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

   You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Use Machine Identity Console

Manage your service accounts which are used for integrations with ServiceNow using the Machine Identity Console.

Before you begin

Role required: mi_admin

Activate the **Machine Identity Management** `com.glide.identity.machine_identity_management` plugin. For more information, see Activate Machine Identity Console.

Procedure

1. Navigate to **All** > **Machine Identity Console** > **Machine Identity Console**.
   The Machine Identity Console has the following tabs:
   - Overview: Displays the overall machine identity accounts and their metrics
   - Inbound integrations: Configure Inbound integrations for the APIs.
   - Security findings: Displays the security score is based on different security findings.
   - Metrics: Displays the different metrics for the machine identity accounts
   - Settings: Configure the machine identity console.
2. Select the appropriate tabs based on your security requirements.

System for Cross-domain Identity Management (SCIM)

The System for Cross-domain Identity Management (SCIM) API provides endpoints to create, read, update, and delete operations on users and groups using the SCIM protocol.

SCIM Provider

The SCIM provider synchronizes the changes made to identities in the IdP, including creating, updating, or deleting records.

SCIM Client

The SCIM Client is used for creating, updating, and deleting identity resources in a system that supports SCIM compliant REST requests.

The SCIM protocol is an application-level HTTP-based protocol based on the HTTP (RFC7230) standard. Use this API for provisioning and managing identity data, such as users and groups. Use the API on the web and in cross-domain environments, such as enterprise-to-cloud service providers or inter-cloud scenarios.

To access this API, you must activate the SCIM v2 - ServiceNow® Cross-domain Identity Management (com.snc.integration.scim2) plugin. To know more about the SCIM API, see System for Cross-domain Identity Management (SCIM) API.

SCIM Provider

The Service Provider provisions users and groups using the SCIM API.

Explore

Learn more about source definition for SCIM.

Explore SCIM Provider

The Service Provider provisions users and groups using the SCIM API.

As a SCIM provider, the ServiceNow schemas support SCIM APIs to provision users and groups.

The SCIM provider synchronizes the changes made to identities in the IdP, including creating, updating, or deleting records. These changes are automatically synchronized to the provider according to the SCIM protocol. Also, the IdP can read identities from the provider to add to the IdP directory. The IdP can then detect incorrect values in the provider that could create security vulnerabilities. The synchronization enables end users to have seamless access to applications for which they're assigned, with up-to-date profiles and permissions.

Configurations for SCIM Provider

To configure the SCIM Provider, perform the following tasks:

- Activate the **SCIM v2 - ServiceNow Cross-domain Identity Management** plugin. To learn more, see Activate the SCIM plugin.
- Activate the other plugins that other plugins that are required for SCIM:
  - OAuth 2.0
  - REST API Provider
  - REST API Access Policy
- Add the scim_admin role as part of the SCIM service.

Warning:
Grant this role carefully. The scim_admin role is equivalent to giving the user the admin role, where the scmin_admin can add or update Personally Identifiable Information (PII).

Tables

Two tables, sys_user and sys_group, contain the SCIM attributes that do not map to existing ServiceNow tables. To know more about the tables, see the SCIM-specific tables.

Activate the SCIM plugin

For SCIM activation, install the SCIM v2 - ServiceNow Cross-domain Identity Management (com.snc.integration.scim2) plugin.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the SCIM v2 - ServiceNow Cross-domain Identity Management (com.snc.integration.scim2) plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.

3. Select **Install** to start the installation process.

> **Note:**
> When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

Tutorial: Configure SCIM for user provisioning with a Provider

Configuring SCIM automatically provisions and de-provisions users and groups to ServiceNow by using the providers provisioning service.

Before you begin

Install SCIM plugin.

Role required: scim_admin

> **Warning:**
> Grant this role carefully. The scim_admin role is equivalent to giving the user the admin role, where the scmin_admin can add or update Personally Identifiable Information (PII).

About this task

You can provision users using SCIM by the following authentication methods:

- Provision user using Basic Authentication
- Provision user using OAuth

Provision user using Basic Authentication

Configuring SCIM automatically provisions and de-provisions users and groups to ServiceNow by using the providers' provisioning service with Basic Authentication.

Before you begin

Role required: scim_admin

> **Warning:**
> Grant this role carefully. The scim_admin role is equivalent to giving the user the admin role, where the scmin_admin can add or update Personally Identifiable Information (PII).

You must activate the SCIM plugin.

Procedure

1. Navigate to **All** > **System Web Services** > **REST API Access Policies** to check the details on the REST API Access Policies.
2. In the API Access Policy page, click the **SCIM API Policy** record.
3. Verify the **SCIM API Basic Auth** record is available in the Authentication Profiles sections.
4. Select **Basic Auth** as the Type.
5. Create the required configurations at the provider's end.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

6. Test the connection to ensure that the provider can connect to ServiceNow.

> **Note:**
> If the connection fails, ensure that your ServiceNow account has admin permissions and try again.

Provision user using OAuth

Configure the provider for SCIM automatically provisions and de-provisioning of users and groups to ServiceNow by using the providers provisioning service with OAuth.

Before you begin
Role required: scim_admin

> **Warning:**
> Grant this role carefully. The scim_admin role is equivalent to giving the user the admin role, where the scmin_admin can add or update Personally Identifiable Information (PII).

You must activate the SCIM plugin.

Procedure

1. Navigate to **All** > **System OAuth** > **Application Registry**.
2. In the Application Registries page, click the **SCIM API** record.
3. Verify the **SCIM API** record details.

   These details should be provided while configuring the ServiceNow application on Azure AD.
4. Navigate to **All** > **System Web Services** > **REST API Access Policies** to check the details on the REST API Access Policies.
5. In the API Access Policy page, click the **SCIM API Policy** record.
6. Verify the **SCIMAPIOAuthOnly** record is available in the Authentication Profiles sections.
7. Check if the **OAuth Entity** field is specified with **SCIM API** record that was earlier configured or verified as application registry.
8. Create the required configurations at the provider's end.
9. Test the connection to ensure that the provider can connect to ServiceNow.

> **Note:**
> If the connection fails, ensure that your ServiceNow account has admin permissions and try again.

SCIM Troubleshooting

Common error scenarios integrating with SCIM.

Invalid Rest API URL

Action: Enter valid API URL. Would be able to cross check the REST API URL in the **REST API Explorer**.

No Redirect URL is set in ServiceNow instance

Action: Enter valid Redirect URL for SCIM OAuth entity in ServiceNow. Enter redirect URL while configure OAuth entity in ServiceNow.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

When Redirect URL is different than the request

Action: '**redirect_url**' provided in '**Authorization Endpoint'** should be same as the OAuth entity configured in ServiceNow.

Note:

This error occurs when there is a mismatch between Azure 'Authorization Endpoint' and ServiceNow 'Redirect URL'

When an invalid client secret is passed

Action: Value entered in 'Client Secret' should be same as the OAuth entity configured in ServiceNow.

When an invalid 'ClientId' passed in Azure 'Authorization EndPoint'

Action: Value entered for 'client_id' parameter in 'Authorization Endpoint' has to be same as OAuth entity configured in ServiceNow.

SCIM customization

Customize SCIM protocols for your identity management.

SCIM customization enables you to do the following:

- Support custom fields on the sys_user and sys_user_group tables through dynamic extension schema generation.
- Provide an ability to override the default SCIM mappings.

A SCIM admin can define custom extension schemas for user and group resources. The attributes defined in the custom extension schema can be mapped to fields in the sys_user or sys_user_group tables.

Configurations for SCIM customization

For SCIM customization, you should perform the following tasks:

- Define a custom extension schema for users and groups in the SCIM Extension schema table. #For more information see, Create a SCIM Extension schema.
- Create entities in an ETL definition for custom schema attributes. The entities are created for the target table that is mapped with either the sys_user or sys_user_group attributes. For more information see, Create a SCIM ETL definition.
- Create an RTE mapping between these two entities.#For more information see, step 5 in the Create a SCIM ETL definition.
- Send custom schema attributes with data in the SCIM API request payload.

The SCIM API calls the RTE engine with the defined mapping. The data is stored in the respective fields in the target table as defined in the mapping.

SCIM customization properties and schemas

The SCIM customization includes the following properties, supported schemas, and unsupported schemas.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Properties

SCIM customization adds the following system properties.

Properties

Name	Description
com.snc.integration.scim2.max.member	The SCIM maximum member count.
com.snc.integration.scim2.resolve	Resolve SCIM resources based on the source definition of the requesting client if multiple resources are found with an external ID SCIM filter. **Note:** As a prerequisite, if provisioning is done from multiple sources, then the sources must be defined in the SCIM Source Definition table. If sources are not defined or if this property is inactive, then all matching resources are returned with an external Id filter response.
com.snc.integration.scim2.user.etl	The SCIM User ETL definition ID.
com.snc.integration.scim2.group.etl	The SCIM Group ETL definition ID.
com.snc.integration.scim2.rte.verbose	Enables verbose logging for SCIM User and Group RTE definitions.
com.snc.integration.scim2.string.validation	The length validation of fields. This property enables validation instead of truncating and saving the field.
com.snc.integration.scim2.provider	The ID of the script include for customizing the SCIM responses.

Supported schemas

SCIM customization adds the following supported schemas.

Supported Schemas

Schemas	Description	Prefix	Example
urn:ietf:params:scim:schemas:core:2.0:User	Includes core attributes for the resources.	none	name.middleName
urn:ietf:params:scim:schemas:extension:servicenow:2.0:User	Includes attributes that are related to ServiceNow.	*servicenow*	servicenow.manager.value
urn:ietf:params:scim:schemas:extension:custom:2.0:User	Includes custom attributes that are not mapped as part of the core extension or the	*custom*	custom.c2

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Supported Schemas (continued)

Schemas	Description	Prefix	Example
	ServiceNow extension schema.		

Unsupported schema

urn:ietf:params:scim:schemas:extension:enterprise:2.0:User: Includes attributes commonly used in representing users that belong to or act on behalf of a business or an enterprise.

Note:
Enterprise schema is a valid schema but its attributes are mapped to any table. Because database persistence is not supported, there will be no error displayed if an enterprise schema is included in the request body.

Create a SCIM Extension schema

Create custom attributes to map to fields that are not mapped as part of either the core schema or the ServiceNow extension schema.

Before you begin
Role required: scim_admin

Warning:
Grant this role carefully. The scim_admin role is equivalent to giving the user the admin role, where the scmin_admin role can insert new records into the tables that can bypass business logic or ACL protection.

Procedure

1. Navigate to **All** > **SCIM** > **SCIM Extension schemas**.
2. Click **New**.
3. On the form, fill in the fields.

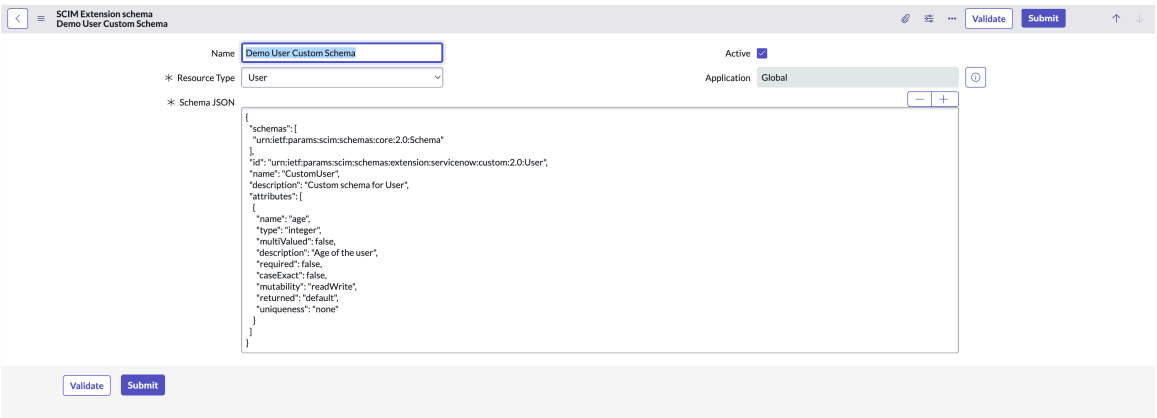
Note:
Only one extension schema can be mapped to the **Resource Type** field. For example, User as a resource type can be mapped to a user extension schema.

SCIM Extension schema

Field	Description
Name	Name of the extension schema.
Active	Option to activate the schema. Select this field if the record must be considered as custom extension schema. Only one custom extension schema record can be active at a time for a specific resource type, whether for the User or Group type.
Resource Type	Resource type that has to be mapped to the extension schema. The following are the options:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
	○ **User** ○ **Group**
Application	Application scope for this record.
Schema JSON	Details within the JSON schemas. For more information about defining the extension schema with attributes, see Datatracker.



4. Validate the attributes by clicking **Validate**.
5. Click **Submit**.

Result

The extension schema with custom attributes related to User or Group resource type is created. Use the SCIM ETL Definitions to map the resources based on the extension schema on the sys_user and sys_user_group table. For more information, see Create a SCIM ETL definition.

Create a SCIM ETL definition

Use the SCIM ETL definitions to map the custom attributes with the sys_user or sys_user_group tables.

Before you begin

Role required: scim_admin

Warning:
Grant this role carefully. The scim_admin role is equivalent to giving the user the admin role, where the scmin_admin role can insert new records into the tables that can bypass business logic or ACL protection.

Note:

- SCIM Group and SCIM User ETL definitions are part of the base system for resource mapping. You can use the same resource mappings and change the criteria as required, or you can create new resource mappings.
- There is no support for [*] fields through RTE in SCIM mapping.

Procedure

1. Follow the instructions in Create Extract Transform Load (ETL) definitions.
2. Open the newly created record and view the details.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

3. In the ETL Entities section, create an entity by clicking **New**.
   You have to create entities for the following users:
   - scim-user: For the fields that are from SCIM.
   - user (sys_user) or group (sys_user_group) table: For the fields that you want to map from the database table with SCIM. For example, for customization of user details through SCIM, you can use the sys_user table.

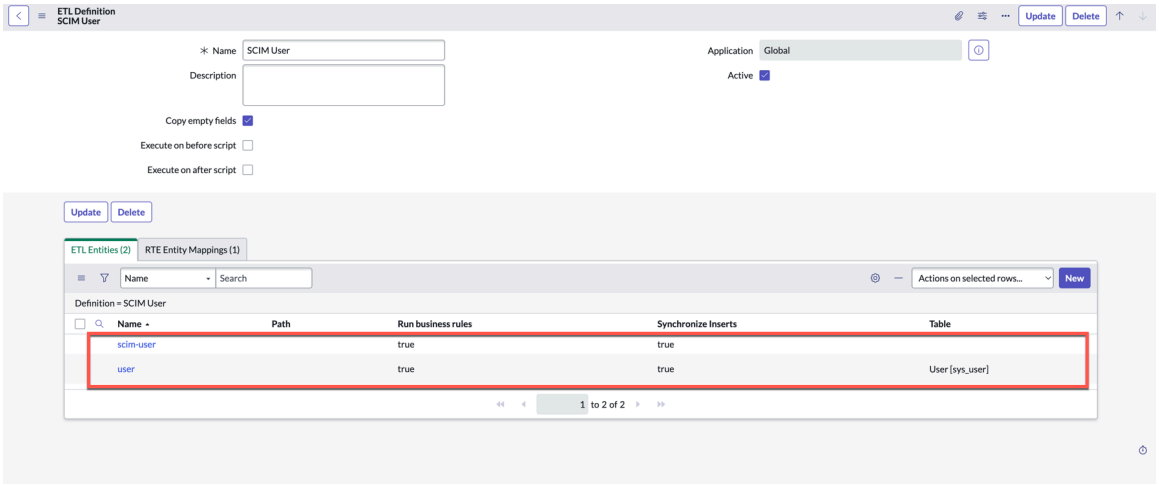
   a. On the form, fill in the fields.

   ETL Entity form

Field	Description
Name	Name of the ETL entity.
Application	Application scope for this record.
Table	Target table for the ETL entity.
Definition	Selected ETL entity.
Path	Unique path for this entity. Do not specify any path for the entity representing the import set table. When an entity represents a collection, the path must end with an asterisk [*]. This requirement applies to intermediate entries and the target table entity.
Synchronize Inserts	Option to guarantee only one record with unique coalesced field values by synchronizing record inserts.
Run business rules	Option to run business rules.

   b. Click **Submit**.

   The ETL entities are created for scim-user and user tables. You have to create ETL entity fields within these ETL entities, and map both entities by creating an RTE Entity Mapping.



4. Create the entities and map them.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

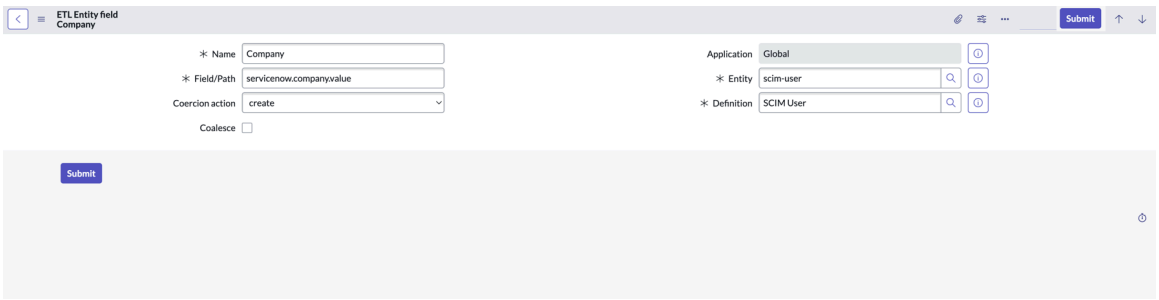
a. Open the submitted record (scim-user and user).

b. In the ETL Entity fields, add the fields by clicking **New**.

c. On the form, fill in the fields.

ETL Entity form

Field	Description
Name	Name of the ETL Entity field definition.
Application	Selected ETL entity that this field definition belongs to.
Field/Path	This field is either a column or path. ▪ The field is a column name when the entity is the Import or Target table. ▪ The field is a path when the field has nested structures.
Entity	Entity that this operation applies to. Choose the entity using the look-up icon.
Coercion action	What the system should do if a reference or choice could not be found. Options are as follows: ▪ **Create**: Create a new reference or choice. Assign the reference or choice to the current record. ▪ **Reject**: Do not save the whole record to the database. ▪ **Ignore**: Set the current value as empty.
Definition	Selected ETL entity that this field definition belongs to.
Coalesce	Option to query the existing records.

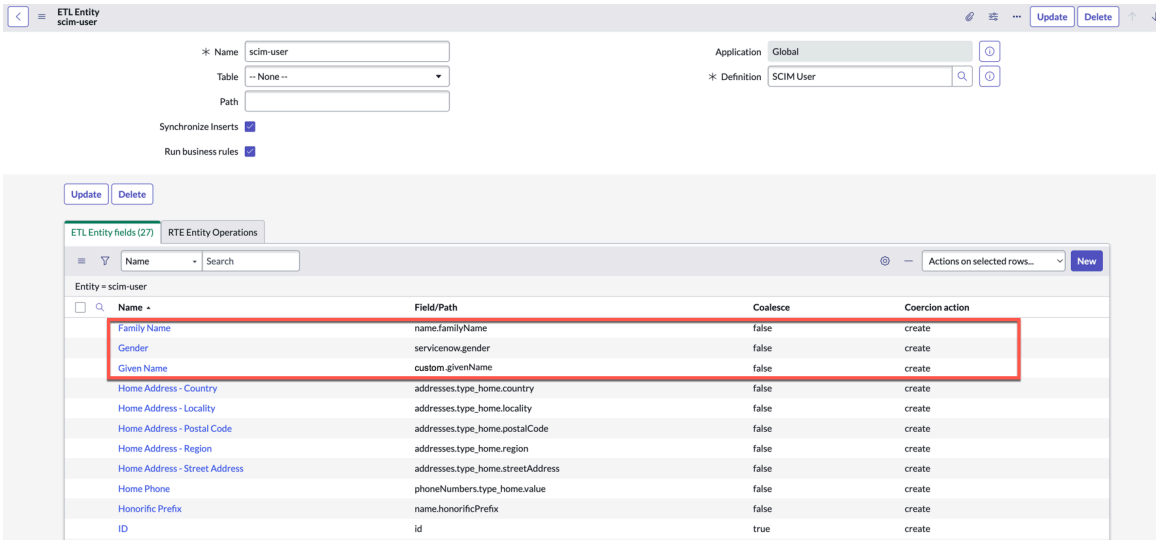


d. Submit the entries by clicking **Submit**.

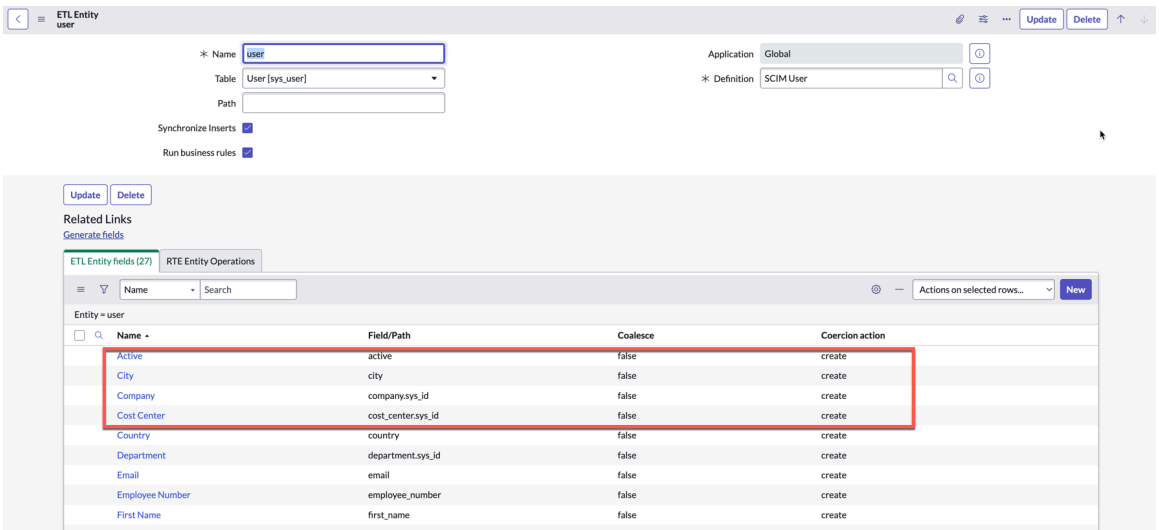
You can add multiple entries as your ETL Entity field based on your requirement.

The scim-user ETL entity can have entities with the core extension (user), the ServiceNow extension, or custom extension.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



The user ETL entity can have entities from the database table. For example, sys_user table.



Note:
To add a filter in the incoming SCIM fields, use an underscore (_). This underscore translates to an EQ filter. For example, the attribute *email.type_work.value* applies the SCIM filter of email *[type eq "work"].value*.

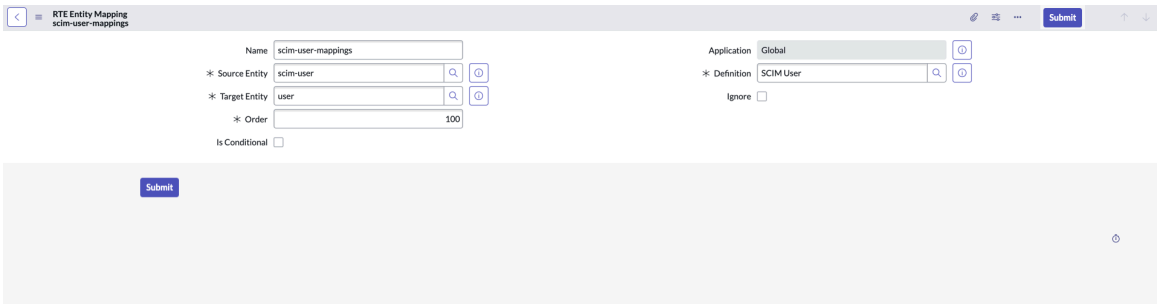
After the fields are created in both the scim-user and user ETL Entity records, you have to create an RTE Entity mapping record. You must then specify the source and target definition to map both the fields.

5. In the RTE Entity Mappings section, create an entity mapping by clicking **New**
6. On the form, fill the fields.

Field	Description
Name	Name of the mapping.
Source Entity	Source entity for the mapping.

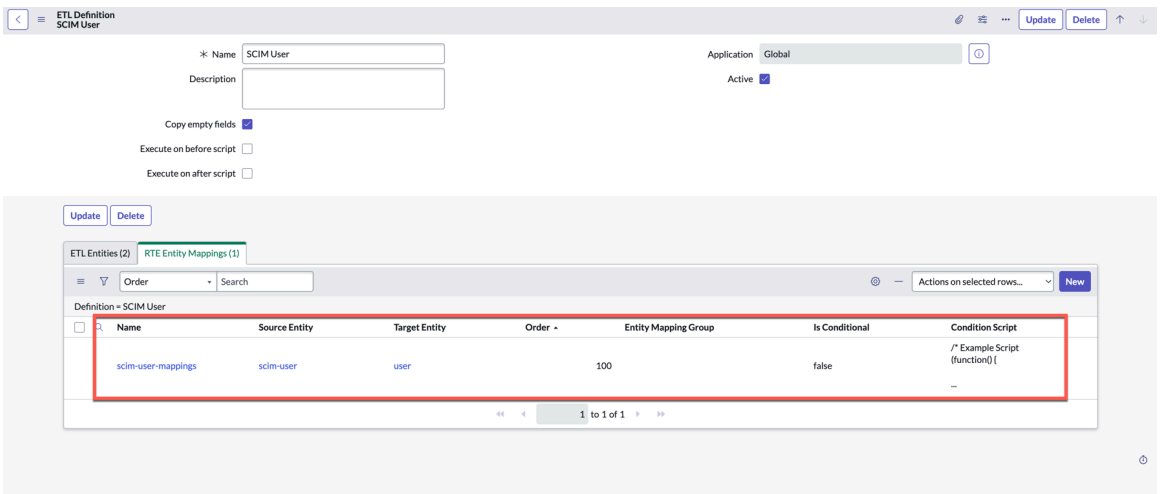
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Target Entity	Target entity for the mapping.
Order	Order in which the mapping should be processed.
Is Conditional	Option to designate the mapping as conditional.
Condition Script	Script that defines the conditions that must be met for the mapping.
Application	Application scope for this record.
Definition	Selected ETL entity that this mapping belongs to.
Ignore	Option to designate if this ETL entity mapping should be ignored when performing data integrations using Robust Import Set Transformation (RTE).



7. Click **Submit**.

   The following example shows a record created for mapping both the scim-user and user ETL Entity records.



8. Open the submitted record (scim-user-mappings) and create a mapping between the scim-user and user ETL Entity records.

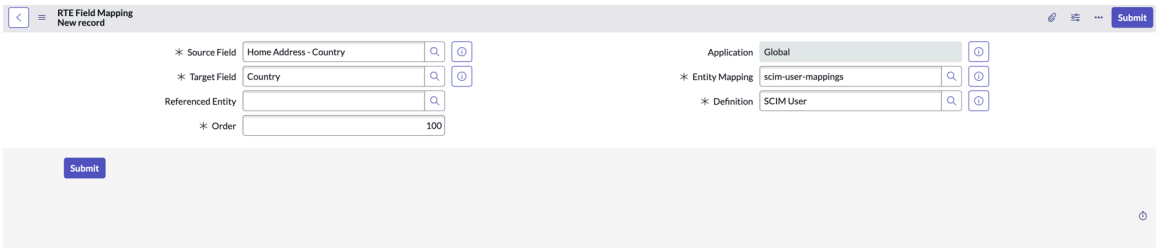
   a. In the RTE Field Mappings section, click **New**.

   b. On the form, fill in the fields.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

ETL Entity fields

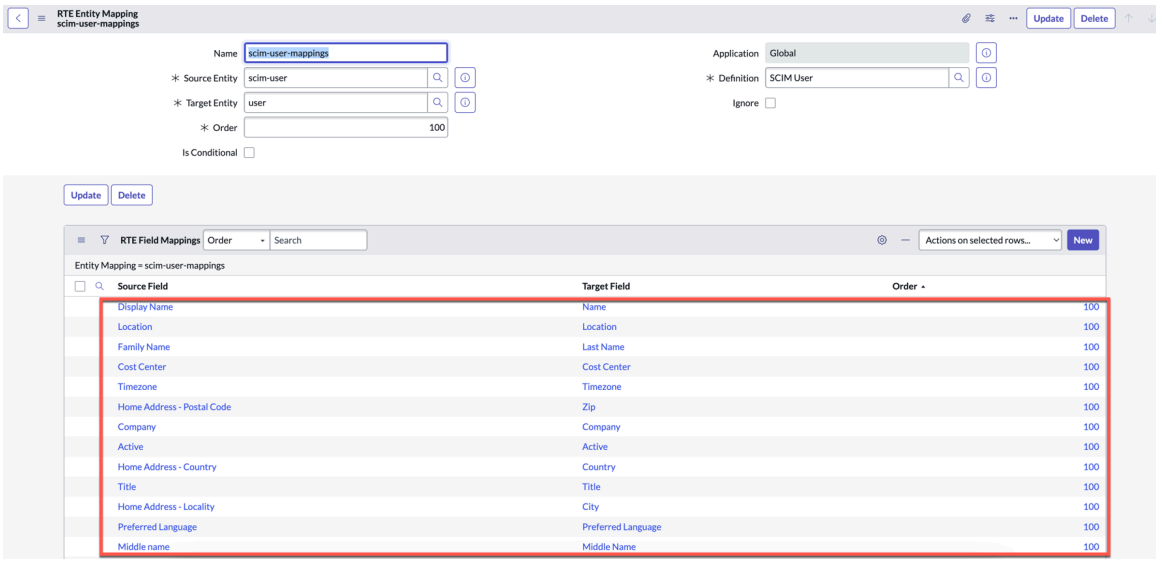
Field	Description
Source Field	Application scope for this record.
Application	Selected ETL entity that this field definition belongs to.
Target Field	Output ETL field for the operation if the operation takes a single output.
Entity Mapping	Entity mapping that this operation applies to.
Referenced Entity	Entity that is referenced and the operation that it applies to.
Definition	Selected ETL entity that this field definition belongs to.
Order	Order in which the operation runs on the entity.



The source field **Home Address - Country** (scim-user ETL Entity) maps the target field as **Country** (user ETL Entity).

c. Submit the entries by clicking **Submit**.

You can add multiple entries as your RTE Entity mappings based on your requirement.



The source fields and targets fields are mapped as configured. When you perform CRUD operations using SCIM, the customized values are updated in the respective table.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Result

These ETL definitions and mappings enable you to extract data from a source table, transform the data as desired, and load the data into a target table.

Related topics

Create Extract Transform Load (ETL) definitions

Handle unmapped fields

You can handle unmapped fields in SCIM customization in different ways.

During SCIM customization, the fields that are not part of the sys_user and sys_user_group tables can be mapped by performing the following functions.

Customize SCIM (Create or Update)

You can create or update the SCIM Client.

- The SCIM admin can add custom scripts in the *onBefore* and *onAfter* scripts for fields that are not mapped in ETL Definition or RTE.
- The SCIM admin can override RTE Mappings by adding custom scripts in the *onBefore* and *onAfter* scripts.
- You can invoke a scriptable API in the RTE *onBefore* or *onAfter* scripts to access incoming request and perform transformations on other tables, lists, and unmapped attributes.
- You can use the *sn_auth.SCIM2Util.getScimProviderCustomizationContext()* method to provide the SCIM request context that contains the *scimResource* object. The *scimResource* in context represents the following in each operation:
  - **POST**: The SCIM resource sent in the request payload.
  - **PUT**: The current SCIM resource from database replaced with the SCIM resource sent in thee request payload.
  - **PATCH**: The current SCIM resource from the database after performing the patch operations.

The following is an example of an *onAfter* script.

```
(function onAfter(source, target, importLog) {

    var ctx =
sn_auth.SCIM2Util.getScimProviderCustomizationContext();
    gs.info("scim context ee: " +
JSON.stringify(ctx.scimResource));

    var roles = ctx.scimResource.roles;
    if(roles) {
        var removingRolesGR = new
GlideRecord("sys_user_has_role");
        removingRolesGR.addQuery("user",
target.sys_user[0].sys_id);
        removingRolesGR.query();
        removingRolesGR.deleteMultiple();

    for (var i = 0; i < roles.length; i++) {
        var addingRolesGR = new
GlideRecord("sys_user_has_role");
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
        addingRolesGR.setValue("user",
 target.sys_user[0].sys_id);
        addingRolesGR.setValue("role", roles[i].value);
        addingRolesGR.setValue("state", "active");
        addingRolesGR.insert();
        }
        }
        var customUserExtn = new
 global.SCIMProviderCustomization().getCustomExtensionUrn('User
');
        var salary = ctx.scimResource[customUserExtn].salary;
        if (salary) {
            var gr = new GlideRecord("u_user_salary");
            gr.addQuery("user", target.sys_user[0].sys_id);
            gr.query();
            if (gr.next()) {
                gr.setValue("salary", salary);
                gs.info("scim update: " + gr.update());
            } else {
            gr.setValue("salary", salary);
            gr.setValue("user", target.sys_user[0].sys_id);
            gr.insert();
            }
           }

})(source, target, importLog);
```

Customize SCIM response

For the GET API calls, any response back to the SCIM client can be customized using the script by extending the *SCIMProviderCustomization* script.

While extending the script, the author can override the *customizeUserResponse* and *customizeGroupResponse* methods to modify the responses for User and Group resources.

The *com.snc.integration.scim2.provider.customization.script.id* property enables the SCIM plugin to use the script that should be used for response customization.

The following is an example of extending the base script.

```
var SCIMCustomizationScript = Class.create();
SCIMCustomizationScript.prototype =
 Object.extendsObject(SCIMProviderCustomization, {
    initialize: function() {

 SCIMProviderCustomization.prototype.initialize.call(this);
    },
    customizeUserResponse: function(context) {
        try {
            var rolesGR = new GlideRecord("sys_user_has_role");
            rolesGR.addQuery("user", context.scimResource.id);
            rolesGR.query();
            var i = 0;
            context.scimResource.roles = [];
            while (rolesGR.next()) {
                context.scimResource.roles[i] = {
```

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

```
                    display:
 rolesGR.getElement('role.name').getValue(),
                    value:
 rolesGR.getElement('role.sys_id').getValue()
                };
                i++;
            }
            var userGR = new GlideRecord("u_user_salary");
            userGR.addQuery("user", context.scimResource.id);
            userGR.query();
            if (userGR.next()) {
                var salary = userGR.getValue("salary");
                if (salary) {
                    var customExtensionValue =
 SCIMProviderCustomization.prototype.getCustomExtensionNodeValue
.call(this, "User", context);
                    customExtensionValue.salary = salary;

 SCIMProviderCustomization.prototype.setCustomExtensionNodeValue
.call(this, "User", context, customExtensionValue);
                }
            }
        } catch (ex) {
            gs.error("err: " + ex);
        }
        return context;
    },
    customizeGroupResponse: function(context) {
        return context;
    },
    type: 'SCIMCustomizationScript'
});
```

Note:

- The parameter that the *customizeUserResponse* and *customizeGroupResponse* methods contain is a context object with one attribute called *scimResource*. This attribute has all the attributes of a user or group resource object.
- A customized script include can only be created and viewed by the admin.
- If a user or group resource is modified, then you must return the context back.
- If there are no modification of any attribute in the resource object, then set the *com.snc.integration.scim2.provider.customization.script.id* to empty or return as null.
- If certain attributes are persisted through the *onAfter* script, they must be populated with database values in the *scimResource* object inside the customized script. This action is required so that the system can do the following:
  - To get the correct *scimResource* object in *onAfter* scripts during the PUT and PATCH operation.
  - To include the attributes that persisted through the *onAfter* script in the response back to the client.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Helper functions

The following are some of the helper functions for SCIM customization. These functions enable you to fetch or set different types of information.

Helper functions

Function	Purpose
`SCIMProviderCustomization.prototype.getCustomExtensionUrn.call(this, "User");`	Fetch the value of the custom extension schema.
`SCIMProviderCustomization.prototype.getServiceNowExtensionUrn.call(this, "User");`	Fetch the value of the ServiceNow extension schema.
`SCIMProviderCustomization.prototype.getCustomExtensionNodeValue.call(this, "User", context);`	Fetch the custom extension node value from the response.
`SCIMProviderCustomization.prototype.getServiceNowExtensionNodeValue.call(this, "User", context);`	Fetch the ServiceNow extension node value from the response.
`SCIMProviderCustomization.prototype.setCustomExtensionNodeValue.call(this, "User", context, customExtensionValue);`	Set the custom extension node value in the response.

The following is an example of using the helper function:

```
var customExtensionUrn =
SCIMProviderCustomization.prototype.getCustomExtensionUrn.call(t
his, "User");
var customExtensionValue =
SCIMProviderCustomization.prototype.getCustomExtensionNodeValue.
call(this, "User", context);
customExtensionValue.age = "18";
SCIMProviderCustomization.prototype.setCustomExtensionNodeValue
 call(this, "User", context, customExtensionValue);
```

Note:
RTE supports setting data in tables other than the sys_user and sys_user_group tables.

Creating a source definition

Create a source definition to capture information about which identity source a resource is provisioned from.

Before you begin

Role required: scim_admin

Warning:
Grant this role carefully. The scim_admin role is equivalent to giving the user the admin role, where the scmin_admin can add or update Personally Identifiable Information (PII).

About this task

Using a source definition, the provisioning identity source can be mapped to an OAuth entity using which it authenticates while provisioning.

After a source definition is created, all resources getting provisioned from that identity source is mapped to its corresponding source definition ID.

The source definition captures the required source information, such as by doing the following:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- Identifies the SCIM Client from which the resource is provisioned.
- Resolves duplicate information provided by the external ID:
  - If multiple identity sources are provisioning resources, there can be two or more resources have the same external ID value because the external Id is only unique to the identity source.
  - If multiple resources are returned with an external ID SCIM filter then the resources can be resolved based on the source definition of the requesting identity source.

Note:
A source definition can be created only for the identity source, which, uses an OAuth authentication method.

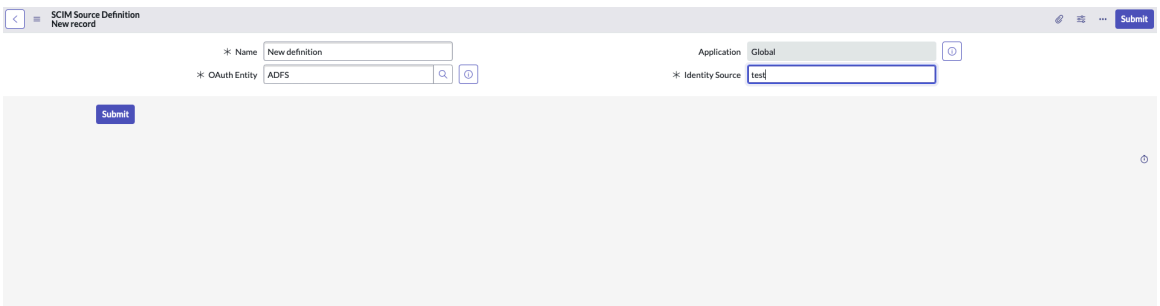
Procedure

1. Navigate to **All** > **SCIM** > **Source Definition**.
2. On the SCIM Source Definitions page, click **New**.
3. On the form, fill in the fields.

SCIM Source Definition

Field	Description
Name	Name of the source definition.
Application	Application scope for this record.
OAuth Entity	The OAuth entity of the integration user. The entity is used for provisioning the user by the identity source provider.
Identity Source	The name of the identity source provider. For example, Azure AD, Okta, and so on

Note:
Enable the *com.snc.integration.scim2.resolve.externalid.conflict* property to return only SCIM resources created by the requesting identity source. By default, all the matching resources with an external ID filter are returned.



4. Click **Submit**.

Result

The SCIM source definition is created. Use the SCIM ETL Definitions to map the resources based on the extension schema on the sys_user and sys_user_group table. For more information, see Create a SCIM ETL definition.

Learn about SCIM Client.

Activate

Activate SCIM Client.

SCIM Client Properties

Get details about how to customize SCIM.

Troubleshoot

Learn more about source definition for SCIM.

Explore SCIM Client

The SCIM Client facilitates provisioning and updates on identity resources through CRUD operations exposed by SCIM endpoint on an external system.

The SCIM Client is used for creating, updating, and deleting identity resources in a system that supports SCIM compliant REST requests. The client is used for identity life-cycle management and for identity attribute synchronization across ServiceNow instances or between ServiceNow and other SCIM providers.

Because the APIs are exposed by the client, you can automate the process of creating, updating, or deleting any resources on a single or multiple SCIM providers. For example, if a developer joins the organization, you have to provide access to Git, workplace, and so on.

The SCIM client enables you to perform the following actions:

- Provision identities and access for user or group membership.
- Synchronize identity and related resources with SCIM compliant systems.
- Integrate any SCIM Provider on ServiceNow®.
- De-provision identities and access.

The SCIM client provides scriptable APIs that the integration developer can use to build workflows or automations to do specified jobs. To know more about the scriptable API, see SCIM2Client API.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Configurations for SCIM Client

To configure the SCIM Client, perform the following tasks:

- Create a REST message for all outbound calls for a particular SCIM Provider. For more information, see Create a REST message.
- Create a SCIM Provider to fetch resource types and schemas information from the SCIM Provider with the REST message. Enable the configuration of the HTTP Method (PUT or PATCH) to update a resource in the SCIM Provider. For more information, see Create a SCIM Provider.
- Create the mappings of SCIM attributes to ServiceNow attributes for a particular resource type and SCIM Provider. To know more, see Create a SCIM Provider Resource Mapping.
- Perform the mapping of SCIM field with the database table and field name. Pass the default value or write a script to fetch the value. For more information know, see Create a SCIM attribute mapping.

Activate the SCIM Client plugin

For SCIM Client activation, install the SCIM v2 - ServiceNow Cross-domain Identity Management Client (com.snc.integration.scim2.client) plugin.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Applications** > **All Available Applications** > **All**.
2. Find the SCIM v2 - ServiceNow Cross-domain Identity Management Client (com.snc.integration.scim2.client) plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel.
3. Select **Install** to start the installation process.

   Note:
   When domain separation and delegated Admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: `Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.`

   You will see a message after installation is completed. For information about the components installed with a plugin, see Find components installed with an application.

SCIM Client properties, tables, scriptable APIs, and logs

The SCIM v2 - ServiceNow Cross-domain Identity Management Client (com.snc.integration.scim2.client) plugin includes the following system properties, tables, scriptable APIs, and logs.

Properties

SCIM Client adds the following system properties.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Properties

Name	Description
com.snc.integration.scim2.client.log.property	This property determines whether to write all the log records or just the error log records. The possible values are **FAILURE** or **ALL**. Default value: **ALL**
com.snc.integration.scim2.client.log.cleanup.duration	This property determines the number of days for clearing the logs. Default value: **180**

To set the properties, navigate to **All** > **SCIM** > **SCIM Client Properties**.

Tables

The SCIM Client adds the following tables.

Tables

Name	Description
SCIM Provider (sys_scim_provider)	Stores data for each SCIM provider, such as the name, REST message resource definitions, and so on.
SCIM Provider Resource Mapping (sys_scim_provider_resource_mapping)	Stores the primary table information for each provider and resource name.
SCIM Attribute Mapping (sys_scim_attribute_mapping)	Stores the source details where each SCIM attribute value should come from, such as the table field, script, and so on.
SCIM Client Log (sys_scim_client_logs)	Stores the statuses of each call triggered to SCIM Provider.

Scriptable API

The SCIM2Client API calls the System for Cross-domain Identity Management (SCIM) Provider (server role) to create, update, or delete data in a service provider (SP). The scriptable API of the SCIM Client should be used in the scripts that are running in the system context or by a system admin user.

For example, you can use the script while running the integration hub workflow as a system user, while running the scheduled jobs, and so on.

The following are some of the use cases for using the scriptable APIs:

- As an admin, provision identity information from background scripts, business rules, script include calls, workflows, and so on.
- As an admin, run a scheduled job or an on-demand job for identity provisioning.
- Run a workflow or sub-workflow with the Script step using the provision scriptable API call.
- Add the provision script directly in a business rule or script include. The script can be triggered by non-admin users. This use-case works in the following situations:

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

- The user has access to the token, meaning that the user has the role to generate the token from the REST template.
- The user has access to retrieve the SCIM attribute values from the mapped tables.

To know more about the scriptable API, see SCIM2Client API.

SCIM Client Logs

The SCIM Client Logs display the provisioning status about the SCIM APIs. To view the provisioning status, navigate to **All** > **SCIM** > **SCIM Client Logs**.

Create a REST message

Configure a REST message for all outbound calls for a particular SCIM Provider.

Before you begin

Role required: admin

Procedure

1. Navigate to **All** > **System Web Services** > **Outbound** > **REST Message**.
2. Click **New**.
3. On the form, fill in the fields.

SCIM Provider

Field	Description
Name	Descriptive name for this message.
Endpoint	Base URL of SCIM Provider. For example, `https://example.service-now.com/api/now/scim`.
Authentication Type	Type of authentication to be used to connect to the external SCIM Provider. For more information see, Outbound REST authentication.
HTTP Headers	The content type that is expected from the external SCIM Provider. For example, Header Name is the content type in the following API request body: `Content-type: application/scim+json`

4. In the#HTTP Methods#elated list, click#**New**.
5. Configure the following HTTP Methods.

Note:
The URLs have variables that you must replace.

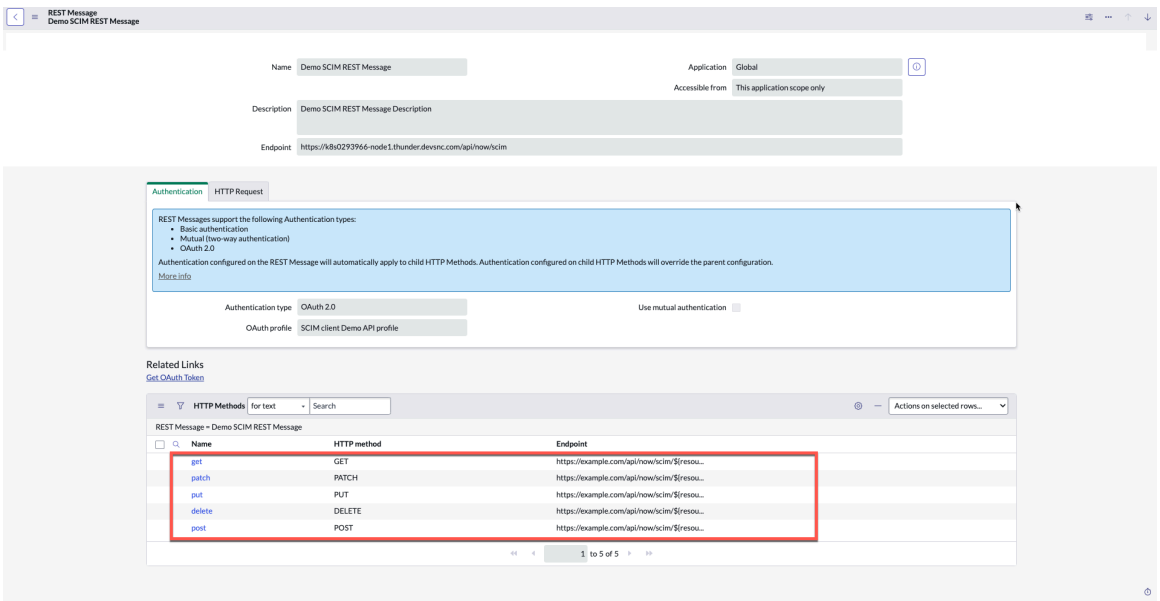
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

HTTP Methods

Methods	Sample URL
GET	`https://example.com/api/now/scim/${resourceName}`
PATCH	`https://example.com/api/now/scim/${resourceName}/${resourceId}`
PUT	`https://example.com/api/now/scim/${resourceName}/${resourceId}`
DELETE	`https://example.com/api/now/scim/${resourceName}/${resourceId}`
POST	`https://example.com/api/now/scim/${resourceName}/${resourceId}`

Note:

- You must create all the HTTP methods for the operation of the SCIM Client.
- A sample REST message is shipped from the base system.



6. Click **Submit**.

Result
The REST message record is created.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

What to do next

Use the REST message to create a SCIM Provider. For more information, see Create a SCIM Provider.

To learn more about how to create a REST message, see Create a REST message.

Create a SCIM Provider

Create a SCIM Provider to fetch resource types and schemas information from the SCIM Provider with the REST message. Enable the configuration of the HTTP Method (PUT or PATCH) to update a resource in the SCIM Provider.

Before you begin

Note:
A sample SCIM Provider is part of the base system. You can use and configure based on your requirement, or create a new record.

Roles required: admin

Procedure

1. Navigate to **All** > **SCIM Client** > **SCIM Provider**.
2. In the SCIM Providers page, click **New**.
3. On the form, fill in the fields.

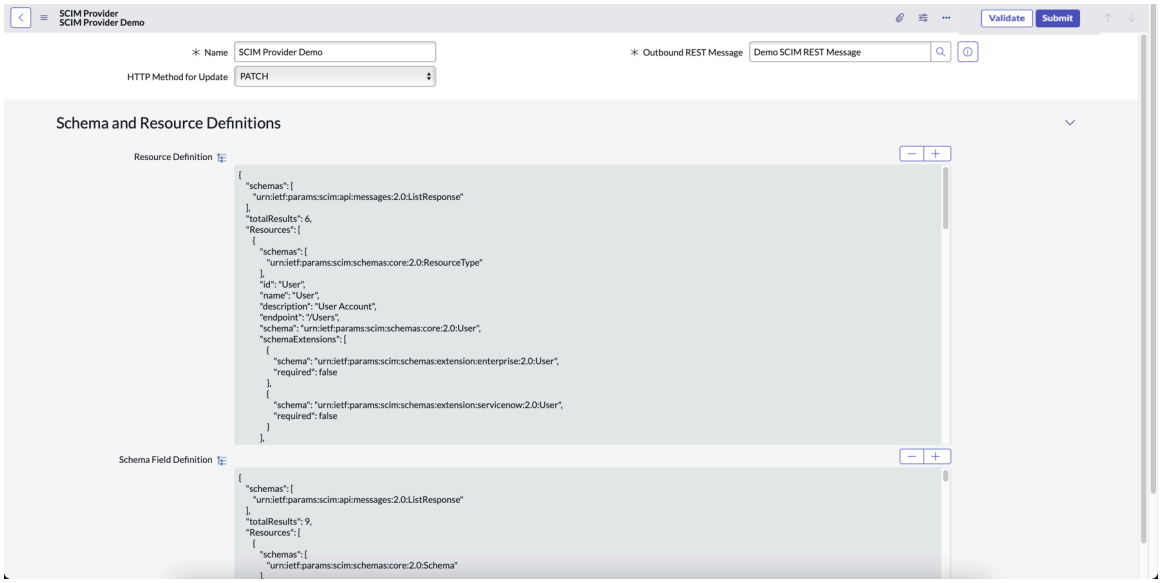
SCIM Provider form

Field	Description
Name	Name of the SCIM Provider
Outbound REST Message	Message that is used to call the API of the SCIM Provider. For more information, see Create a REST message.
HTTP Method for Update	Type of HTTPS method that is used for updating the resource mapping. The PATCH or PUT method can be used by the Client while updating the identity resource during the provision of an already existing resource.

Note:

- The **Resource Definition** and **Schema Field Definition** fields are fetched from the */ResourceTypes* and */Schemas* public endpoints of the SCIM Provider. These fields are auto-populated after the rest message is selected.
- If the REST message, Schemas, or the Resource Types are updated on the SCIM Provider, then click **Refresh** and then **Update** to update the **Resource Definition** and **Schema Field Definition** fields.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



4. Click **Submit**.

Result

The SCIM Provider details are created successfully. Use the SCIM Provider Resource Mapping to map the SCIM Provider details to the resources such as users or groups. For more information, see Create a SCIM Provider Resource Mapping.

Create a SCIM Provider Resource Mapping

Define the mappings of SCIM attributes to ServiceNow attributes for a particular resource type and SCIM Provider.

Before you begin

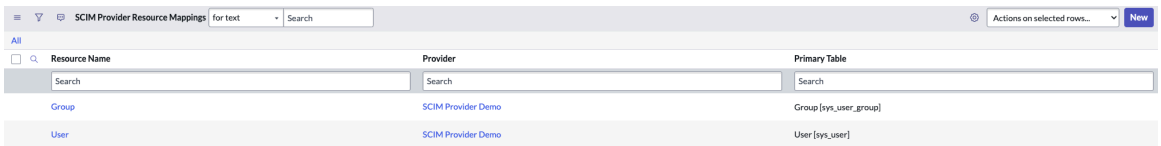
Roles required: admin

Procedure

1. Navigate to **All** > **SCIM Client** > **SCIM Provider Resource Mapping**.

   The SCIM Provider Resource Mapping is shipped with the User and Group mapping by default.

   Note:
   The User or Group mappings contains sample mappings, which you can use as a reference. You can also create mapping based on the user or group resources.

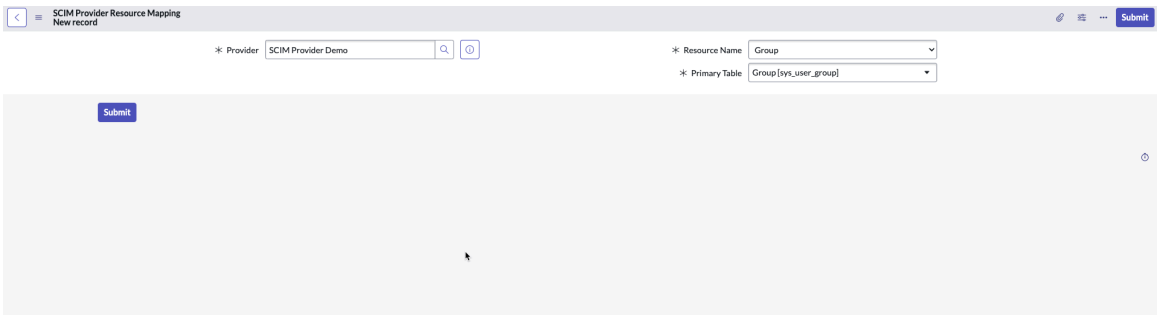


2. Create a resource mapping by clicking **New**.
3. On the form, fill in the fields.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Resource Mapping

Fields	Description
Provider	Name of the SCIM Provider. Refer to the configured Provider name when creating a SCIM Provider.
Resource Name	Resource for which the mapping must be defined.
Primary Table	The table that contains the sys_id of the resource being mapped.



4. Click **Submit**.

Result
The record is created and displayed in the SCIM Provider Resource Mapping page. Use the SCIM Attribute Mappings to further map the attributes from schemas. For more information, see Create a SCIM attribute mapping.

Create a SCIM attribute mapping

Create a SCIM attribute mapping and use it as a single source of resource to the ServiceNow table fields.

Before you begin
Roles required: admin

About this task
The following are the attribute mapping types and their descriptions.

Attribute mapping types

Attribute mapping type	Description
Direct	The SCIM attribute is populated with the help of the **Database Table Name** and **Database Field Name** fields.
Constant	The SCIM attribute is populated with the help of a specified default value.
Script/Custom	The SCIM attribute is populated with the help of the return value of a script. This attribute requires enabling the run script option.

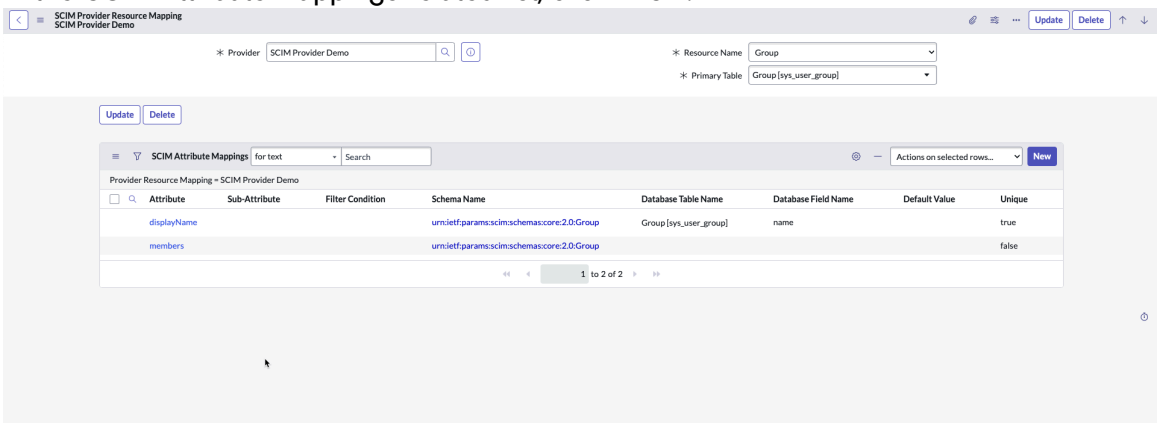
© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Note:

- The password attribute is not supported
- A sample attribute mapping for the User and Group resources is part of the base system. You can use and configure the mappings based on your requirements, or you can create a new record.

Procedure

1. Navigate to **All** > **SCIM Client** > **SCIM Provider Resource Mapping**.
2. Selected the SCIM Resource Mapping that is created for the configuration.
3. In the#SCIM Attribute Mappings#elated list, click#**New**.



4. On the form, fill in the fields.

SCIM Attribute Mappings form

Fields	Description
Provider Resource Mapping	Attribute mapping for a Provider-resource combination. If this field is not populated automatically, then use the search option. Select the Provider Resource Mapping record.
Schema Name	Schema name of the SCIM attribute for which the mapping must be defined. For example, *urn:ietf:params:scim:schemas:core:2.0:User*.
Attribute	Attribute for which the mapping must be defined. For example, *userName*.
Sub-Attribute	Sub-Attribute (if any) for which the mapping must be defined. For example, if there is a complex type attribute like *name.familyName*, then the

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Fields	Description
	attribute is **name** and the sub-attribute is **familyName**.
Field Type	The SCIM Attribute data type. This field is auto-populated from the schemas defined by the SCIM Provider. For example, **boolean**.
Multi-Value	Multiple values that are assigned to the attribute. An attribute can have multiple values like work email, home email, or another email. For example, *`emails`*. This field is populated using the schemas defined by SCIM Provider.
Filter Condition	Some multi-valued attributes can have additional information that can be specified by using a Filter Condition. The choices of filter condition are populated using the schemas defined by the SCIM Provider. For example, the *`phoneNumbers`* attribute has multiple types like work, mobile, home, and so on
Unique	Option to uniquely identify a resource between the SCIM Client and SCIM Provider systems. Multi-valued attributes cannot be marked as unique. For example, for a User Resource, the *`username`* attribute can be made unique.
Database Table Name	Use this field to map the attribute table name to the ServiceNow table name. If you choose direct attribute mapping, you must define this field. For example, the *`username`* SCIM Attribute can be mapped to the **User** field in the **Database Table Name** field.
Database Field Name	TheDatabase Field Name field maps the SCIM attribute to the ServiceNow field name to be mapped with the SCIM Attribute. If you choose direct attribute mapping, you must define this field.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Fields	Description
	For example, the *username* SCIM Attribute can be mapped to the **User ID** field in the **Database Field Name** field.
Default Value	Details about the default value that is passed to the SCIM Provider. Can be used if the direct attribute mapping of the field returns null, or if the default can be used to return a hard-coded value. In the case of a hard-coded value, the database table name and field name should be **None**. For example, the primary sub-attribute value of work email can be hard-coded as **true**.
Run Script	Option to fetch the value of the attribute via script. This option is required for the multi-valued attributes that don't contain a filter condition. For a complex type of attribute, a script can supply the value at an attribute or sub-attribute level. For example, the **Members** attribute of group resource has no filter condition. So, the script option should be defined on the parent attribute level of the **Members** attribute.
Script	Script that is used to fetch the attribute value. The return type of script should be a string, or a JSON converted as a string. The output of the script should be in the proper format as expected by the provider for that attribute.

5. Click **Submit**.

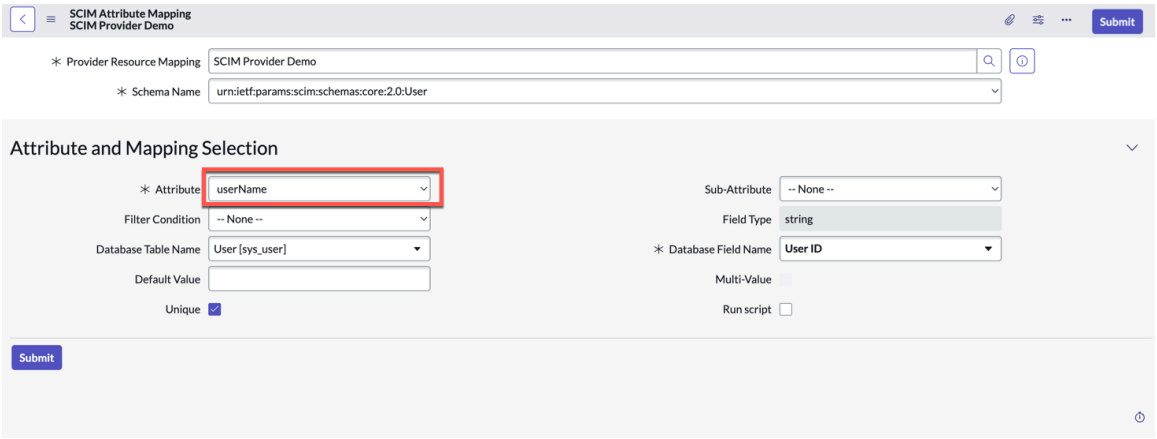
Attribute Mapping references

The attribute mappings enables you to use the attributes as a single source of resource to the ServiceNow table fields.

Attribute

The attribute for which mapping needs to be defined. For example, *userName*.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

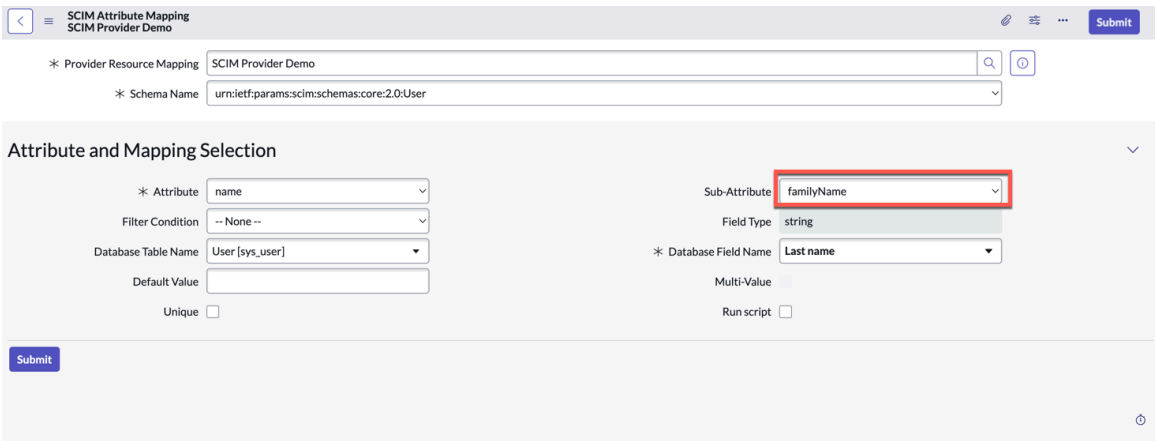


Sub-Attribute

Select the sub-attribute, if any, for which a mapping needs to be defined.

For example, if there is a complex type attribute like *`name.familyName`*, then the attribute is *`name`* and the sub-attribute is *`familyName`*.

For simple attributes like user name, the **Sub-Attribute** value would be **None**.



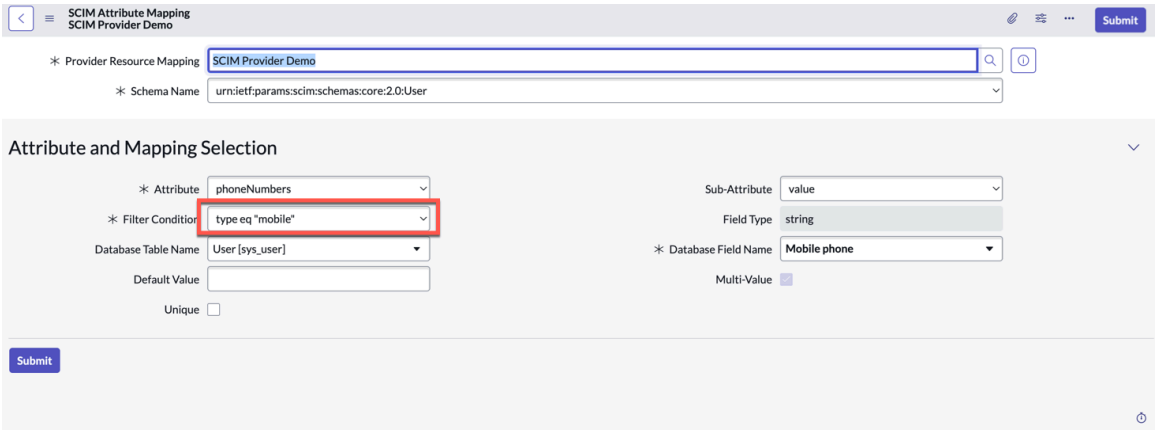
Filter Condition

A multi-valued attribute can have additional information that can be specified by using a Filter Condition. The choices for the filter condition are populated using the schemas defined by the SCIM Provider.

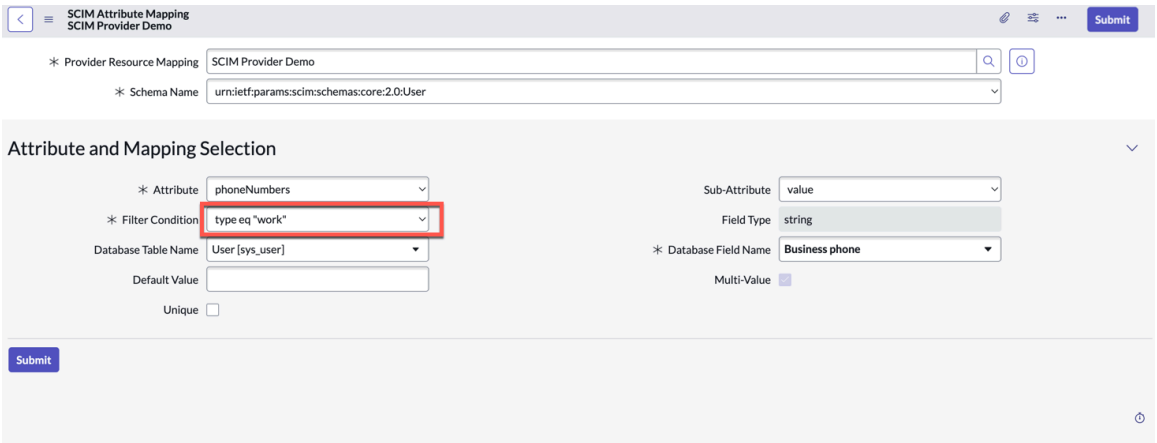
For example, the *`phoneNumbers`* attribute has multiple types like work, mobile, home, and so on.

You can specify a Filter Condition from a set of possible values. For example, the *`phoneNumber`* attribute can have the Filter Condition as **type eq "mobile"**.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



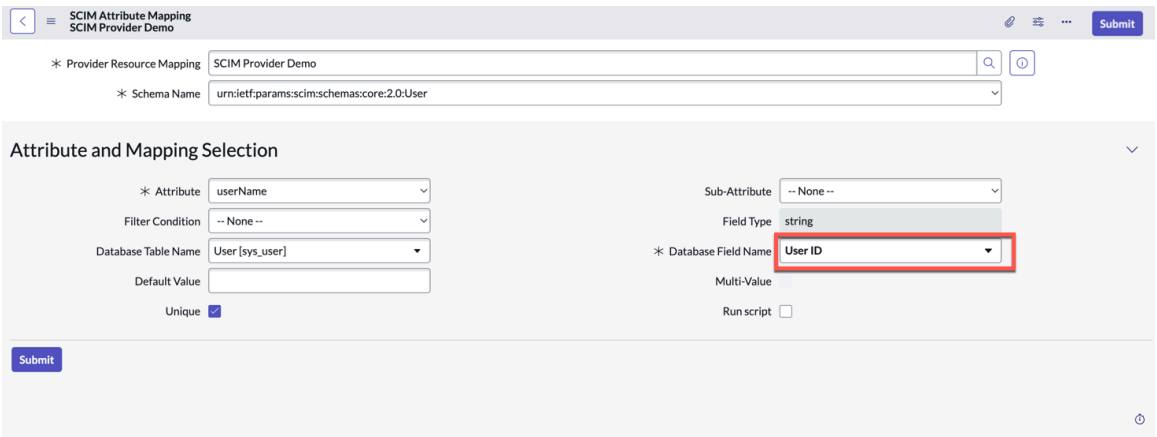
The *phoneNumber* attribute can instead have a Filter Condition as **type eq "work"**.



Database Field Name

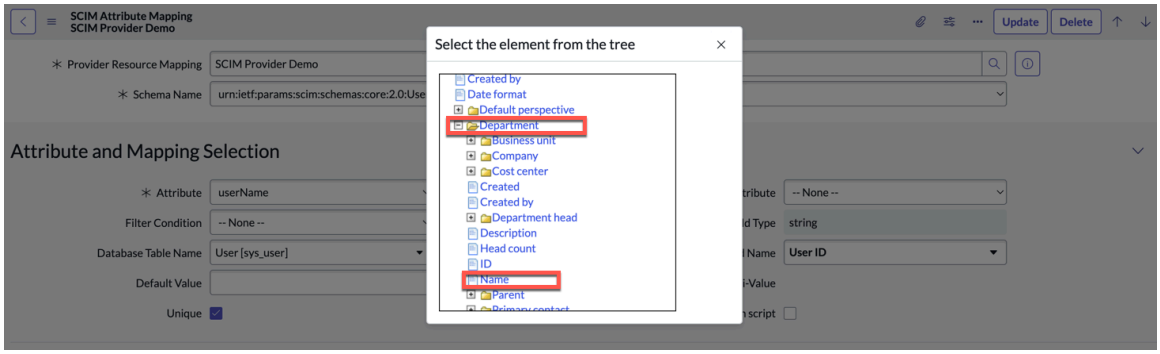
If the direct attribute mapping option is chosen, then this attribute needs to be defined. The **Database Field Name** field represents the ServiceNow field name that is mapped with the SCIM Attribute.

For example, the *username* SCIM Attribute can be mapped to a user as the **Database Table Name** field, and to the user ID field as the **Database Field Name** field.

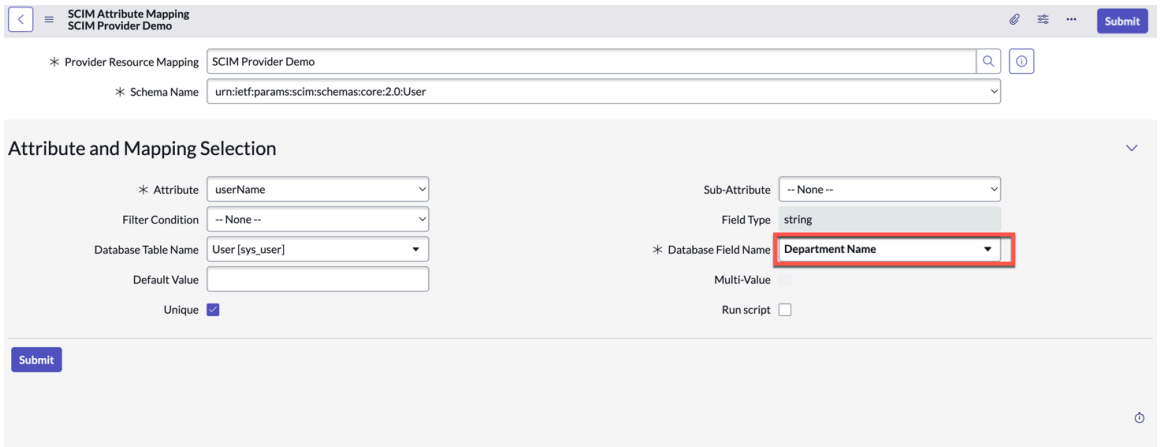


You can also dot-walk using the **Database Field Name**. For example, the **department** SCIM Attribute can be mapped to the **Department Name** field.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



Here the Database Table is **User** and the Database field Name is **Department Name**.

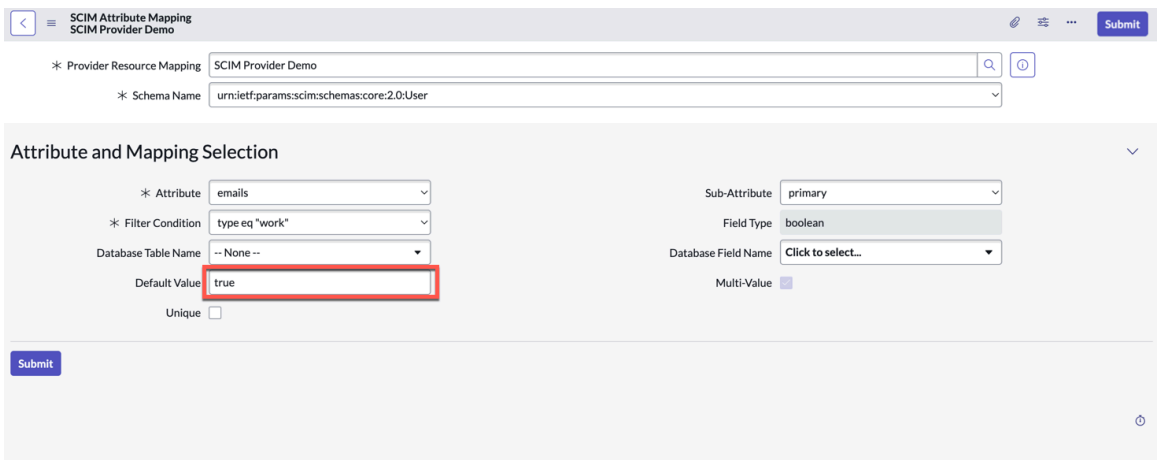


Default Value

The default value is passed to the SCIM Provider if direct attribute mapping of that field returns null. The default value can also be used to return a hard-coded value.

In the case of a hard-coded value, the database table name and field name should be **None**.

For example, the primary sub-attribute value of work email can be hard coded as **true**.

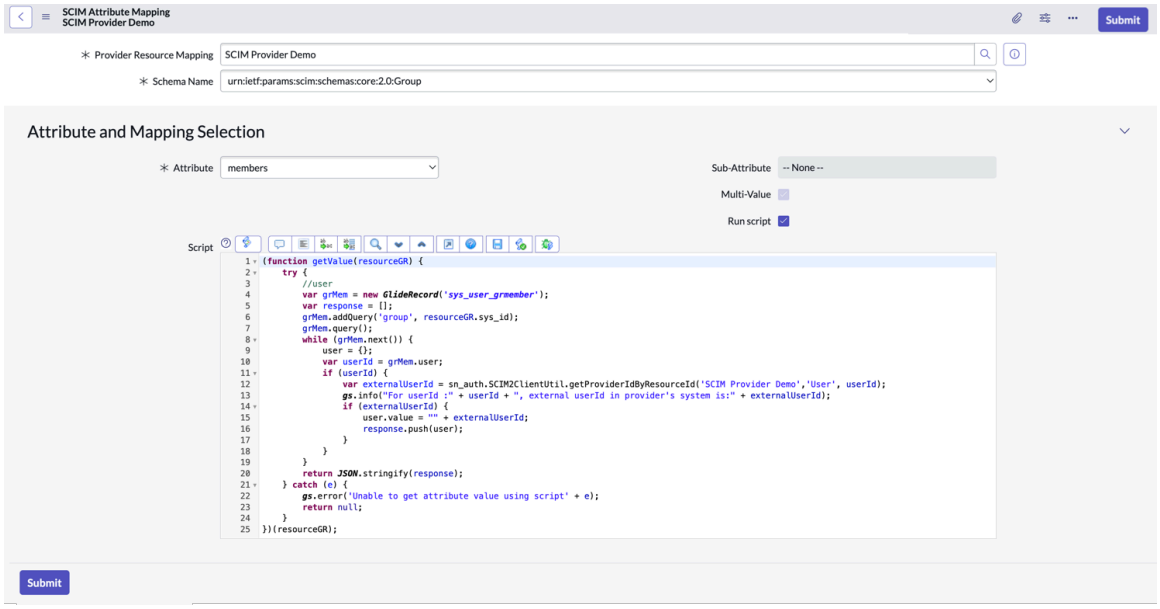


Script

The script is used to fetch the attribute value. The return type of the script should be always a string, or a JSON converted as a string. The output of the script should be in the proper format as expected by the provider for that attribute.

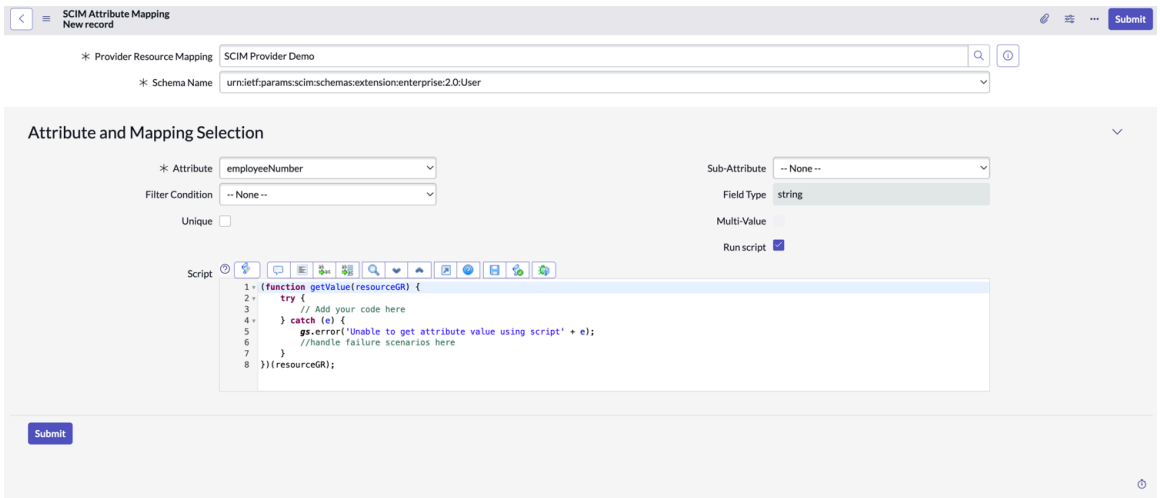
The following is a sample script for a multi-valued attribute.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.



The output of the script should have a stringified JSON Array.

The following is a sample Script of a simple-valued Attribute.



The output of the script should be a string.

Troubleshoot SCIM Client

Troubleshooting actions can help resolve common issues when setting up or running the SCIM Client.

Troubleshooting

Issue	Action
Response contains the following message: `“message":"Unable to access the table core_company with id: 0c441abbc6112275000025157c651c89,`	The message is displayed if the API is called in a user context and the user does not have access to the table. You must make sure that the scriptable API is called in the system context.

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Troubleshooting (continued)

Issue	Action
`Please cross check the Access control rules"`	
Response contains the following message: `{"message":"User Not Authenticated","detail":"Required to provide Auth information”}`	• Make sure that the token is generated through the corresponding REST message and it is valid. • Make sure that the scriptable API is called in the system context.
Response contains the following message: `Script execution failed, the reason is: Cannot cast java.lang.Integer to java.lang.String`	In the SCIM attribute mapping, if the field is defined to fetch from a script with this issue, then make sure that the return type should always be a string.
Response contains the following message: `"status": "400", "scimType": "invalidValue", "detail": "Manager id : 02826bf03710200044e0bfc8bcbe5ds8 doesn't exist"`	For any SCIM attribute that expects the ID, then that ID is always of the provider system. Make sure the ID that is passed in the payload is valid in the provider system.

Areas to check for troubleshooting

The following are some of the areas that can be checked for troubleshooting errors when using the SCIM Client:

- If any issue is found while running any of the scriptable APIs, see the SCIM Client logs section.

Logs Fields

Field	Description
Request ID	Unique ID that represents a scriptable API called.
SCIM Provider	Provider name for which the API is called.
Resource	Name of the resource for which the API is called.
Resource ID	The ID for which the API is called. For deletion, the ID represents the resource ID in the provider system and the ID is in the client system.
Action	API that is called
Status	Status of the log as a success or failure

© 2026 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.

Field	Description
Message	Success or error message. The error message can be from the SCIM provider or because of configuration issues in the SCIM Client.

- Check the request body by configuring and viewing outbound calls. To learn more, see Outbound web services logging.
- Update log levels by adding the content-type, testing the sample, and navigating to corresponding the HTTP Method form in the REST message of the corresponding provider.
- If the request body is truncated, then increase the limit by using system property *glide.outbound_http.content.max_limit*.

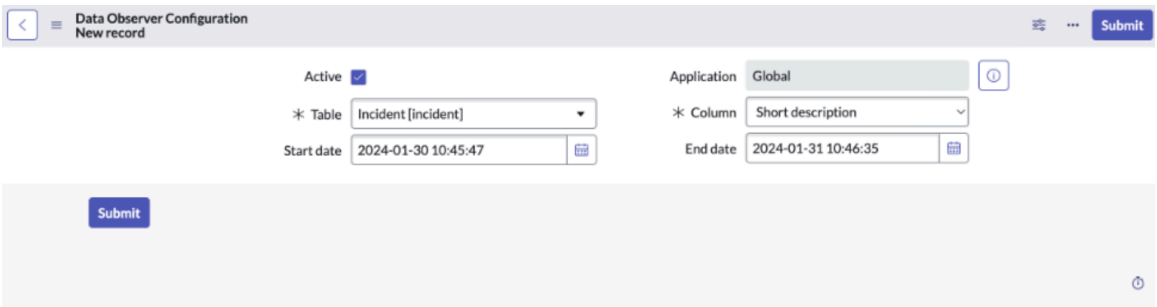
Access observer

Use Access Observer to understand people and processes access data on your instance.

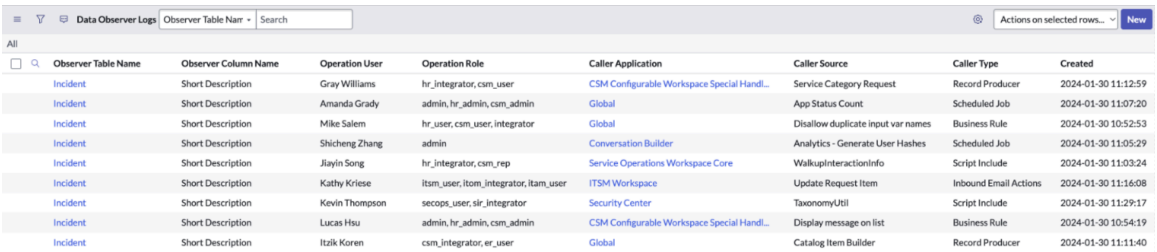
With Access Observer security administrators can:

- Understand which entities like users, roles, scoped apps, and scripts that access your data.
- Use this foreknowledge to know how best to apply security to limit unnecessary access to your data, while confirming those requiring access and still operate normally.
- Avoid broken automation by seeing a clear view of how your data is accessed before making security changes.
- Address the need to provide information regarding how encryption is applied on your instance.

Configure Access Observer by creating Access Observer configuration records. Within these records, you define a specific table and column to be observed and the time in which the column is observed.



Find the results of your observations on the Access Observer log record table. On this table you can see a record detailing each time the specified column is accessed.



Observer Table Name	Observer Column Name	Operation User	Operation Role	Caller Application	Caller Source	Caller Type	Created
Incident	Short Description	Gray Williams	hr_integrator, csm_user	CSM Configurable Workspace Special Handl...	Service Category Request	Record Producer	2024-01-30 11:12:59
Incident	Short Description	Amanda Grady	admin, hr_admin, csm_admin	Global	App Status Count	Scheduled Job	2024-01-30 11:07:20
Incident	Short Description	Mike Salem	hr_user, csm_user, integrator	Global	Disallow duplicate input var names	Business Rule	2024-01-30 10:52:53
Incident	Short Description	Shicheng Zhang	admin	Conversation Builder	Analytics - Generate User Hashes	Scheduled Job	2024-01-30 11:05:29
Incident	Short Description	Jiayin Song	hr_integrator, csm_rep	Service Operations Workspace Core	WalkupInteractionInfo	Script Include	2024-01-30 11:03:24
Incident	Short Description	Kathy Kriese	itsm_user, itom_integrator, itam_user	ITSM Workspace	Update Request Item	Inbound Email Actions	2024-01-30 11:16:08
Incident	Short Description	Kevin Thompson	secops_user, sir_integrator	Security Center	TaxonomyUtil	Script Include	2024-01-30 11:29:17
Incident	Short Description	Lucas Hsu	admin, hr_admin, csm_admin	CSM Configurable Workspace Special Handl...	Display message on list	Business Rule	2024-01-30 10:54:19
Incident	Short Description	Itzik Koren	csm_integrator, er_user	Global	Catalog Item Builder	Record Producer	2024-01-30 11:11:40

Configure access observation

Create an access observation record to review access to a data column during a specified time window.

Before you begin

Role required: security_admin

Procedure

1. Navigate to **All** > **Access Observer** > **Access Observer Configuration**.
2. Select **New** to create a record.
3. On the form, fill in the fields.

Access observer configuration fields

Field	Description
Active	Whether the record is active. Your record is automatically marked active during the observation period and is inactive otherwise.
Application	The scoped application for the record. This field is read only.
Table	Table that contains the column to be observed
Column	The column within the selected table to be observed. The following field types are supported: ○ Email ○ Date ○ Date/Time ○ Journal ○ Journal Input ○ Phone number (E164) ○ String ○ String (UTF-8) ○ Translated ○ Translated Field ○ Translated HTML ○ Translated Text ○ URL
Start job immediately	If selected, observation begins as soon as the record is created.
End date and time	The time at which observation ends.
Start date and time	The time at which observation begins. This field is only visible if **Start job immediately** isn't selected.

4. Select **Submit** to save the record.

What to do next

Once the observation window your defined has started, you can see each instance where the column was access detailed in the records on the Access Observer log [sys_data_ob_log] table.

Review Access Observer logs

Use information in the Access Observer log records for insights on how your data is accessed.

Once you've configured one or more access observation records, your instance begins creating Access Observer log records with details about access to the columns you have chosen. You can find these records on your instance at **All** > **Access Observer** > **Access Observer Log**.

Access observer log results

Use the following table to understand the information presented in the logs.

Access observer log fields

Field	Description
Observer Table Name	The table selected in the access observation record that generated this record.
Observer Column Name	The column selected in the access observation record that generated this record.
Operation User	User that accessed the column
Operation Role	Roles for the user that accessed the column
Caller Application	The scoped application from which the data was accessed.
Caller Type	The type of element which has accessed the column, such as record producer, scheduled job, or business rule.
Caller Source Document ID	
Caller Source	Element which accessed the column. Used along the **Caller Type** field to see what specifically has accessed the column. For example if the caller type is `Business Rule`, the caller source is the name of the business rule which accessed the column.
Primary Hash	
Repeat Count	
Java Stack	
JavaScript Stack	
Session ID	ID of the session in which the column was accessed.

Granular admin roles required to secure your instance

Verify proper access management by assigning roles that define user permissions and responsibilities. By doing so, organizations can maintain security, enforce conformance, and optimize their operations effectively.

Roles are a fundamental part of managing access and maintaining security within your instance. They define what you can see and do, verifying that you have the appropriate level of access based on your responsibilities. By assigning the correct roles to the users, organizations can safeguard sensitive data, enforce compliance, and streamline operations.

To optimize access management within the ServiceNow AI Platform, consider adopting granular admin roles. This approach enables you to assign specific permissions to developers or users who perform minor administrative tasks, without granting them unrestricted access to the full admin role.

By adopting granular admin roles, you can create a more secure and efficient access management system that aligns with your organization's needs.

Note:

- Each product within the ServiceNow AI Platform has its own set of granular admin roles. To determine the appropriate roles for your developers, refer to the specific product documentation.
- Granular admin roles are separate from the existing admin role and must be assigned independently.
